**TOperatingSystem = ( osUnknown, osWindows, osLinux, osOSX, osBSD, osPOSIX, osArch, osAurox, osDebian, osFedora, osGentoo, osKnoppix, osMint, osMandrake, osMandriva, osNovell, osUbuntu, osSlackware, osSolaris, osSuse, osSynology, osTrustix, osClear, osUnited, osRedHat, osLFS, osOracle, osMageia, osCentOS, osCloud, osXen, osAmazon, osCoreOS, osAlpine, osAndroid );**

*The recognized operating systems*

- it will also recognize some Linux distributions

**TOrdType = ( otSByte, otUByte, otSWord, otUWord, otSLong, otULong );**

*Specify ordinal (tkInteger and tkEnumeration) storage size and sign*

- note: Int64 is stored as its own TTypeKind, not as tkInteger

**TPatchCode = array[0..4] of byte;**

*Small memory buffer used to backup a RedirectCode() redirection hook*

**TPersistentWithCustomCreateClass = class of TPersistentWithCustomCreate;**

*Used to determine the exact class type of a TPersistentWithCustomCreateClass*

- could be used to create instances using its virtual constructor

**TPublishedMethodInfoDynArray = array of TPublishedMethodInfo;**

*Information about all methods, as returned by GetPublishedMethods*

**TPUTF8CharArray = array[0..MaxInt div SizeOf(PUTF8Char)-1] of PUTF8Char;**

*A Row/Col array of PUTF8Char, for containing sqlite3\_get\_table() result*

**TPUTF8CharDynArray = array of PUTF8Char;**

*A dynamic array of PUTF8Char pointers*

**TRawUTF8DynArray = array of RawUTF8;**

*A dynamic array of UTF-8 encoded strings*

**TRawUTF8ListFlags = set of ( fObjectsOwned, fCaseSensitive, fNoDuplicate, fOnChangeTriggerred);**

*Possible values used by TRawUTF8List.Flags*

**TRawUTF8ListLocked = type TRawUTF8List;**

*Some declarations used for backward compatibility only*

**TShort16 = string[16];**

*Used e.g. by PointerToHexShort/CardinalToHexShort/Int64ToHexShort/FormatShort16*

- such result type would avoid a string allocation on heap, so are highly recommended e.g. when logging small pieces of information

**TShort4 = string[4];**

*Used e.g. by UInt4DigitsToShort/UInt3DigitsToShort/UInt2DigitsToShort*

- such result type would avoid a string allocation on heap

**TStrCnt = longint ;**

*Cross-compiler type used for string reference counter*

- FPC and Delphi don't always use the same type

**TStreamClass = class of TStream;**

*Class-reference type (metaclass) of a TStream*

**TStrLen = longint;**

*Internal integer type used for string header length field*

**TSynAnsicharSet = set of AnsiChar;**

*Used to store a set of 8-bit encoded characters*

**TSynByteSet = set of Byte;**

*Used to store a set of 8-bit unsigned integers*

**TSynDateDynArray = array of TSynDate;**

*Store several dates as Year/Month/Day*

**TSynDictionaryCanDeleteEvent = function(const aKey, aValue; aIndex: integer): boolean of object;**

*Event called by TSynDictionary.DeleteDeprecated*

- called just before deletion: return false to by-pass this item

**TSynDictionaryEvent = function(const aKey; var aValue; aIndex,aCount: integer; aOpaque: pointer): boolean of object;**

*Event called by TSynDictionary.ForEach methods to iterate over stored items*

- if the implementation method returns TRUE, will continue the loop

- if the implementation method returns FALSE, will stop values browsing

- aOpaque is a custom value specified at ForEach() method call

**TSynDictionaryInArray = ( iaFind, iaFindAndDelete, iaFindAndUpdate,**

```
iaFindAndAddIfNotExisting, iaAdd);
```

*Internal flag, used only by TSynDictionary.InArray protected method*

```
TSynExtended = extended;
```

*The floating-point type to be used for best precision and speed*

- will allow to fallback to double e.g. on x64 and ARM CPUs

```
TSynInvokeableVariantTypeClass = class of TSynInvokeableVariantType;
```

*Class-reference type (metaclass) of custom variant type definition*

- used by SynRegisterCustomVariantType() function

```
TSynLogExceptionToStr = function(WR: TTextWriter; const Context:
TSynLogExceptionContext): boolean;
```

*Global hook callback to customize exceptions logged by TSynLog*

- should return TRUE if all needed information has been logged by the event handler

- should return FALSE if Context.EAddr and Stack trace is to be appended

```
TSynLogInfo = (sllNone, sllInfo, sllDebug, sllTrace, sllWarning, sllError, sllEnter,
sllLeave, sllLastError, sllException, sllExceptionOS, sllMemory, sllStackTrace,
sllFail, sllSQL, sllCache, sllResult, sllDB, sllHTTP, sllClient, sllServer,
sllServiceCall, sllServiceReturn, sllUserAuth, sllCustom1, sllCustom2, sllCustom3,
sllCustom4, sllNewRun, sllDDDError, sllDDDInfo, sllMonitoring);
```

*The available logging events, as handled by TSynLog*

- defined in SynCommons so that it may be used with TTextWriter.AddEndOfLine

- sllInfo will log general information events

- sllDebug will log detailed debugging information

- sllTrace will log low-level step by step debugging information

- sllWarning will log unexpected values (not an error)

- sllError will log errors

- sllEnter will log every method start

- sllLeave will log every method exit

- sllLastError will log the GetLastError OS message

- sllException will log all exception raised - available since Windows XP

- sllExceptionOS will log all OS low-level exceptions (EDivByZero, ERangeError, EAccessViolation...)

- sllMemory will log memory statistics

- sllStackTrace will log caller's stack trace (it's by default part of TSynLogFamily.LevelStackTrace like sllError, sllException, sllExceptionOS, sllLastError and sllFail)

- sllFail was defined for TSynTestsLogged.Failed method, and can be used to log some customer-side assertions (may be notifications, not errors)

- sllSQL is dedicated to trace the SQL statements

- sllCache should be used to trace the internal caching mechanism

- sllResult could trace the SQL results, JSON encoded

- sllDB is dedicated to trace low-level database engine features

- sllHTTP could be used to trace HTTP process

- sllClient/sllServer could be used to trace some Client or Server process

- sllServiceCall/sllServiceReturn to trace some remote service or library

- sllUserAuth to trace user authentication (e.g. for individual requests)

- sllCustom\* items can be used for any purpose

- sllNewRun will be written when a process opens a rotated log

- sllDDDError will log any DDD-related low-level error information

- sllDDDInfo will log any DDD-related low-level debugging information

- sllMonitoring will log the statistics information (if available), or may be used for real-time chat

among connected people to ToolsAdmin

**TSynLogInfoDynArray = array of TSynLogInfo;**

*A dynamic array of logging event levels*

**TSynLogInfos = set of TSynLogInfo;**

*Used to define a set of logging level abilities*

- i.e. a combination of none or several logging event
- e.g. use LOG\_VERBOSE constant to log all events, or LOG\_STACKTRACE to log all errors and exceptions

**TSynMonitorBytesPerSec = type QWord;**

*Would identify the process throughput, during monitoring*

- it indicates e.g. "immediate" bandwidth usage
- any property defined with this type would be identified by TSynMonitorUsage

**TSynMonitorClass = class of TSynMonitor;**

*Class-reference type (metaclass) of a process statistic information*

**TSynMonitorCount = type cardinal;**

*Would identify a cumulative number of processes, during monitoring*

- any property defined with this type would be identified by TSynMonitorUsage

**TSynMonitorCount64 = type QWord;**

*Would identify a cumulative number of processes, during monitoring*

- any property defined with this type would be identified by TSynMonitorUsage

**TSynMonitorInputOutputObjArray = array of TSynMonitorInputOutput;**

*A list of incoming/outgoing data process statistics*

**TSynMonitorObjArray = array of TSynMonitor;**

*A list of simple process statistics*

**TSynMonitorOneBytes = type QWord;**

*Would identify an immediate process information as bytes count, during monitoring*

- "immediate" size won't accumulate, i.e. may be e.g. computer free memory at a given time
- any property defined with this type would be identified by TSynMonitorUsage

**TSynMonitorOneCount = type cardinal;**

*Would identify an immediate time count information, during monitoring*

- "immediate" counts won't accumulate, e.g. may store the current number of thread used by a process
- any property defined with this type would be identified by TSynMonitorUsage

**TSynMonitorOneMicroSec = type QWord;**

*Would identify an immediate time process information in micro seconds, during monitoring*

- "immediate" time won't accumulate, i.e. may store the duration of the latest execution of a SOA computation
- any property defined with this type would be identified by TSynMonitorUsage

**TSynMonitorTotalBytes = type QWord;**

*Would identify a process information as cumulative bytes count, during monitoring*

- "cumulative" size would add some byte for each process, e.g. input/output
- any property defined with this type would be identified by TSynMonitorUsage

**TSynMonitorTotalMicroSec = type QWord;**

*Would identify a cumulative time process information in micro seconds, during monitoring*

- "cumulative" time would add each process timing, e.g. for statistics about SOA computation of a given service
- any property defined with this type would be identified by TSynMonitorUsage

**TSynMonitorType = ( smvUndefined, smvOneMicroSec, smvOneBytes, smvOneCount, smvBytesPerSec, smvMicroSec, smvBytes, smvCount, smvCount64 );**

*The kind of value stored in a TSynMonitor / TSynMonitorUsage property*

- i.e. match TSynMonitorTotalMicroSec, TSynMonitorOneMicroSec, TSynMonitorOneCount, TSynMonitorOneBytes, TSynMonitorBytesPerSec, TSynMonitorTotalBytes, TSynMonitorCount and TSynMonitorCount64 types as used to store statistic information
- "cumulative" values would sum each process values, e.g. total elapsed time for SOA execution, task count or total I/O bytes
- "immediate" (e.g. smvOneBytes or smvBytesPerSec) values would be an evolving single value, e.g. an average value or current disk free size
- use SYNMONITORVALUE\_CUMULATIVE = [smvMicroSec,smvBytes,smvCount,smvCount64] constant to identify the kind of value
- TSynMonitorUsage.Track() would use MonitorPropUsageValue() to guess the tracked properties type from class RTTI

**TSynMonitorTypes = set of TSynMonitorType;**

*Value types as stored in TSynMonitor / TSynMonitorUsage*

**TSynMonitorWithSizeObjArray = array of TSynMonitorWithSize;**

*A list of data process statistics*

**TSynNameValueItemDynArray = array of TSynNameValueItem;**

*Name/Value pairs storage, as used by TSynNameValue class*

**TSynPersistentClass = class of TSynPersistent;**

*Used to determine the exact class type of a TSynPersistent*

- could be used to create instances using its virtual constructor

**TSynPersistentLockClass = class of TSynPersistentLock;**

*Class-reference type (metaclass) of an TSynPersistentLock class*

**TSynPersistentLockDynArray = array of TSynPersistentLock;**

*Abstract dynamic array of TSynPersistentLock instance*

- note defined as T\*ObjArray, since it won't

**TSystemPath = ( spCommonData, spUserData, spCommonDocuments, spUserDocuments, spTempFolder, spLog );**

*Identify an operating system folder*

**TTextChar = set of (tcNot01013, tc1013, tcCtrlNotLF, tcCtrlNot0Comma, tcWord, tcIdentifierFirstChar, tcIdentifier, tcURIUnreserved);**

*Char categories for text line/word/identifiers/uri parsing*

**TTextWriterClass = class of TTextWriterWithEcho;**

*Class of our simple TEXT format writer to a Stream, with echoing*

- as used by TSynLog for writing its content
- see TTextWriterWithEcho.SetAsDefaultJSONClass

**TTextWriterHTMLFormat = ( hfNone, hfAnywhere, hfOutsideAttributes, hfWithinAttributes**

);

*The potential places where TTextWriter.AddHtmlEscape should process proper HTML string escaping, unless hfNone is used*

< > & " -> &lt; &gt; &amp; &quot;

by default (hfAnywhere)

< > & -> &lt; &gt; &amp;

outside HTML attributes (hfOutsideAttributes)

& " -> &amp; &quot;

within HTML attributes (hfWithinAttributes)

TTextWriterJSONFormat = ( jsonCompact, jsonHumanReadable, jsonUnquotedPropName, jsonUnquotedPropNameCompact );

*The available JSON format, for TTextWriter.AddJSONReformat() and its JSONBufferReformat() and JSONReformat() wrappers*

- jsonCompact is the default machine-friendly single-line layout
- jsonHumanReadable will add line feeds and indentation, for a more human-friendly result
- jsonUnquotedPropName will emit the jsonHumanReadable layout, but with all property names being quoted only if necessary: this format could be used e.g. for configuration files - this format, similar to the one used in the MongoDB extended syntax, is not JSON compatible: do not use it e.g. with AJAX clients, but it would be handled as expected by all our units as valid JSON input, without previous correction
- jsonUnquotedPropNameCompact will emit single-line layout with unquoted property names

TTextWriterKind = ( twNone, twJSONEscape, twOnSameLine );

*Kind of adding in a TTextWriter*

TTextWriterOption = ( twoStreamIsOwned, twoFlushToStreamNoAutoResize, twoEnumSetsAsTextInRecord, twoEnumSetsAsBooleanInRecord, twoFullSetsAsStar, twoTrimLeftEnumSets, twoForceJSONExtended, twoForceJSONStandard, twoEndOfLineCRLF, twoBufferIsExternal, twoIgnoreDefaultInRecord, twoDateTimeWithZ );

*Available global options for a TTextWriter instance*

- TTextWriter.WriteObject() method behavior would be set via their own TTextWriterWriteObjectOptions, and work in conjunction with those settings
- twoStreamIsOwned would be set if the associated TStream is owned by the TTextWriter instance
- twoFlushToStreamNoAutoResize would forbid FlushToStream to resize the internal memory buffer when it appears undersized - FlushFinal will set it before calling a last FlushToStream
- by default, custom serializers defined via RegisterCustomJSONSerializer() would let AddRecordJSON() and AddDynArrayJSON() write enumerates and sets as integer numbers, unless twoEnumSetsAsTextInRecord or twoEnumSetsAsBooleanInRecord (exclusively) are set - for Mustache data context, twoEnumSetsAsBooleanInRecord will return a JSON object with "setname":true/false fields
- variants and nested objects would be serialized with their default JSON serialization options, unless twoForceJSONExtended or twoForceJSONStandard is defined
- when enumerates and sets are serialized as text into JSON, you may force the identifiers to be left-trimmed for all their lowercase characters (e.g. sllError -> 'Error') by setting twoTrimLeftEnumSets: this option would default to the global TTextWriter.SetDefaultEnumTrim setting
- twoEndOfLineCRLF would reflect the TTextWriter.EndOfLineCRLF property
- twoBufferIsExternal would be set if the temporary buffer is not handled by the instance, but specified at constructor, maybe from the stack
- twoIgnoreDefaultInRecord will force custom record serialization to avoid writing the fields with default values, i.e. enable soWriteIgnoreDefault when TJSONCustomParserRTTI.WriteOneLevel is

called

- twoDateTimeWithZ appends an ending 'Z' to TDateTime/TDateTimeMS values

**TTextWriterOptions = set of TTextWriterOption;**

*Options set for a TTextWriter instance*

- allows to override e.g. AddRecordJSON() and AddDynArrayJSON() behavior; or set global process customization for a TTextWriter

**TTextWriterStackBuffer = array[0..8191] of AnsiChar;**

*May be used to allocate on stack a 8KB work buffer for a TTextWriter*

- via the TTextWriter.CreateOwnedStream overloaded constructor

**TTextWriterWriteObjectOption = ( woHumanReadable, woDontStoreDefault, woFullExpand, woStoreClassName, woStorePointer, woStoreStoredFalse, woHumanReadableFullSetsAsStar, woHumanReadableEnumSetAsComment, woEnumSetsAsText, woDateTimeWithMagic, woDateTimeWithZSuffix, woTimeLogAsText, woIDAsIDstr, woSQLRawBlobAsBase64, woHideSynPersistentPassword, woObjectListWontStoreClassName, woDontStoreEmptyString, woDontStoreInherited, woInt64AsHex, woDontStore0 );**

*Available options for TTextWriter.WriteObject() method*

- woHumanReadable will add some line feeds and indentation to the content, to make it more friendly to the human eye
- woDontStoreDefault (which is set by default for WriteObject method) will avoid serializing properties including a default value (JSONToObject function will set the default values, so it may help saving some bandwidth or storage)
- woFullExpand will generate a debugger-friendly layout, including instance class name, sets/enumerates as text, and reference pointer - as used by TSynLog and ObjectToJSONFull()
- woStoreClassName will add a "ClassName":"TMyClass" field
- woStorePointer will add a "Address":"0431298A" field, and .map/.mab source code line number corresponding to ESynException.RaisedAt
- woStoreStoredFalse will write the 'stored false' properties, even if they are marked as such (used e.g. to persist all settings on file, but disallow the sensitive - password - fields be logged)
- woHumanReadableFullSetsAsStar will store an human-readable set with all its enumerates items set to be stored as ["\*"]
- woHumanReadableEnumSetAsComment will add a comment at the end of the line, containing all available values of the enumeration or set, e.g:  

```
"Enum": "Destroying", // Idle,Started,Finished,Destroying
```
- woEnumSetsAsText will store sets and enumerables as text (is also included in woFullExpand or woHumanReadable)
- woDateTimeWithMagic will append the JSON\_SQLDATE\_MAGIC (i.e. U+FFF1) before the ISO-8601 encoded TDateTime value
- woDateTimeWithZSuffix will append the Z suffix to the ISO-8601 encoded TDateTime value, to identify the content as strict UTC value
- TTimeLog would be serialized as Int64, unless woTimeLogAsText is defined
- since TSQLRecord.ID could be huge Int64 numbers, they may be truncated on client side, e.g. to 53-bit range in JavaScript: you could define woIDAsIDstr to append an additional "ID\_str":"#####" field
- by default, TSQLRawBlob properties are serialized as null, unless woSQLRawBlobAsBase64 is defined
- if woHideSynPersistentPassword is set, TSynPersistentWithPassword.Password field will be serialized as "\*\*\*\*" to prevent security issues (e.g. in log)
- by default, TObjectList will set the woStoreClassName for its nested objects, unless woObjectListWontStoreClassName is defined

- void strings would be serialized as "", unless woDontStoreEmptyString is defined so that such properties would not be written
- all inherited properties would be serialized, unless woDontStoreInherited is defined, and only the topmost class level properties would be serialized
- woInt64AsHex will force Int64/QWord to be written as hexadecimal string - see j2oAllowInt64Hex reverse option for Json2Object
- woDontStore0 will avoid serializing number properties equal to 0

**TTextWriterWriteObjectOptions = set of TTextWriterWriteObjectOption;**  
*Options set for TTextWriter.WriteObject() method*

**TThreadID = cardinal;**  
*Used to store the handle of a system Thread*

**TTimeLog = type Int64;**  
*Fast bit-encoded date and time value*

- faster than Iso-8601 text and TDateTime, e.g. can be used as published property field in mORMot's TSQLRecord (see also TModTime and TCreateTime)
- use internally for computation an abstract "year" of 16 months of 32 days of 32 hours of 64 minutes of 64 seconds - same as Iso8601ToTimeLog()
- use TimeLogFromDate/TimeLogToDate/TimeLogNow functions, or type-cast any TTimeLog value with the TTimeLogBits memory structure for direct access to its bit-oriented content (or via PTimeLogBits pointer)
- since TTimeLog type is bit-oriented, you can't just add or subtract two TTimeLog values when doing date/time computation: use a TDateTime temporary conversion in such case:  
 aTimestamp := TimeLogFromDate(IncDay(TimeLogToDate(aTimestamp)));

**TTimeLogDynArray = array of TTimeLog;**  
*Dynamic array of TTimeLog*

- used by TDynArray JSON serialization to handle textual serialization

**TTVarRecDynArray = array of TVarRec;**  
*A dynamic array of TVarRec, i.e. could match an "array of const" parameter*

**TTypeKind = ( tkUnknown, tkInteger, tkChar, tkEnumeration, tkFloat, tkString, tkSet, tkClass, tkMethod, tkWChar, tkLString, tkWString, tkVariant, tkArray, tkRecord, tkInterface, tkInt64, tkDynArray );**  
*Available type families for Delphi 6 and up, similar to typinfo.pas*

- redefined here to be shared between SynCommons.pas and mORMot.pas, also leveraging FPC compatibility as much as possible (FPC's typinfo.pp is not convenient to share code with Delphi - see e.g. its tkLString)

**TUnixMSTime = type Int64;**  
*Timestamp stored as millisecond-based Unix Time*

- i.e. the number of milliseconds since 1970-01-01 00:00:00 UTC
- see TUnixTime for a second resolution Unix Timestamp
- use UnixMSTimeToDate/DateTimeToUnixMSTime functions to convert it to/from a regular TDateTime
- also one of the JavaScript date encodings

**TUnixMSTimeDynArray = array of TUnixMSTime;**  
*Dynamic array of timestamps stored as millisecond-based Unix Time*

**TUnixTime = type Int64;**

*Timestamp stored as second-based Unix Time*

- i.e. the number of seconds since 1970-01-01 00:00:00 UTC
- is stored as 64-bit value, so that it won't be affected by the "Year 2038" overflow issue
- see TUnixMSTime for a millisecond resolution Unix Timestamp
- use UnixTimeToDateTime/DateTimeToUnixTime functions to convert it to/from a regular TDateTime
- use UnixTimeUTC to return the current timestamp, using fast OS API call
- also one of the encodings supported by SQLite3 date/time functions

**TUnixTimeDynArray = array of TUnixTime;**

*Dynamic array of timestamps stored as second-based Unix Time*

**TUTF8Compare = function(P1,P2: PUTF8Char): PtrInt;**

*Function prototype used internally for UTF-8 buffer comparison*

- used in mORMot.pas unit during TSQLTable rows sort and by TSQLQuery

**TValuePUTF8CharArray = array[0..maxInt div SizeOf(TValuePUTF8Char)-1] of TValuePUTF8Char;**

*Used e.g. by JSONDecode() overloaded function to returns values*

**TVarDataStaticArray = array[0..MaxInt div SizeOf(TVarData)-1] of TVarData;**

*A TVarData values array*

- is not called TVarDataArray to avoid confusion with the corresponding type already defined in Variants.pas, and used for custom late-binding

**TVariantCompare = function(const V1,V2: variant): PtrInt;**

*Function prototype used internally for variant comparison*

- used in mORMot.pas unit e.g. by TDocVariantData.SortByValue

**TWindowsVersion = ( wUnknown, w2000, wXP, wXP\_64, wServer2003, wServer2003\_R2, wVista, wVista\_64, wServer2008, wServer2008\_64, wSeven, wSeven\_64, wServer2008\_R2, wServer2008\_R2\_64, wEight, wEight\_64, wServer2012, wServer2012\_64, wEightOne, wEightOne\_64, wServer2012R2, wServer2012R2\_64, wTen, wTen\_64, wServer2016, wServer2016\_64, wEleven, wEleven\_64, wServer2019\_64 );**

*The recognized Windows versions*

- defined even outside MSWINDOWS to allow process e.g. from monitoring tools

**unaligned = Double;**

*Will actually change anything only on FPC ARM/Aarch64 plaforms*

**WinAnsiString = type AnsiString;**

*WinAnsiString is a WinAnsi-encoded AnsiString (code page 1252)*

- use this type instead of System.String, which behavior changed between Delphi 2009 compiler and previous versions: our implementation is consistent and compatible with all versions of Delphi compiler
- all conversion to/from RawUTF8 or RawUnicode must be explicit

### Constants implemented in the SynCommons unit

**ALGO\_SAFE: array[boolean] of TAlgoCompressLoad = (aclNormal, aclSafeSlow);**

*Used e.g. as when ALGO\_SAFE[SafeDecompression] for TAlgoCompress.Decompress*

**ALLBITS\_CARDINAL: array[1..32] of Cardinal = ( 1 shl 1-1, 1 shl 2-1, 1 shl 3-1, 1 shl 4-1, 1 shl 5-1, 1 shl 6-1, 1 shl 7-1, 1 shl 8-1, 1 shl 9-1, 1 shl 10-1, 1 shl 11-1, 1**

```
shl 12-1, 1 shl 13-1, 1 shl 14-1, 1 shl 15-1, 1 shl 16-1, 1 shl 17-1, 1 shl 18-1, 1 shl 19-1, 1 shl 20-1, 1 shl 21-1, 1 shl 22-1, 1 shl 23-1, 1 shl 24-1, 1 shl 25-1, 1 shl 26-1, 1 shl 27-1, 1 shl 28-1, 1 shl 29-1, 1 shl 30-1, $7fffffff, $ffffffff);
```

*Constant array used by GetAllBits() function (when inlined)*

```
BINARY_CONTENT_TYPE = 'application/octet-stream';
```

*MIME content type used for raw binary data*

```
BINARY_CONTENT_TYPE_HEADER = HEADER_CONTENT_TYPE+BINARY_CONTENT_TYPE;
```

*HTTP header for MIME content type used for raw binary data*

```
BINARY_CONTENT_TYPE_UPPER = 'APPLICATION/OCTET-STREAM';
```

*MIME content type used for raw binary data, in upper case*

```
BOOL_STR: array[boolean] of string[7] = ('false', 'true');
```

*JSON compatible representation of a boolean value, i.e. 'false' and 'true'*

- can be used e.g. in logs, or anything accepting a shortstring

```
CODEPAGE_LATIN1 = 819;
```

*Latin-1 ISO/IEC 8859-1 Code Page*

```
CODEPAGE_US = 1252;
```

*US English Windows Code Page, i.e. WinAnsi standard character encoding*

```
COMP_TEXT = 'Delphi';
```

*The compiler family used*

```
CPU_ARCH_TEXT = 'x86';
```

*The CPU architecture used for compilation*

```
CP_RAWBYTESTRING = 65535;
```

*Internal Code Page for RawByteString undefined string*

```
CP_SQLRAWBLOB = 65534;
```

*Fake code page used to recognize TSQLRawBlob*

- as returned e.g. by TTypeInfo.AnsiStringCodePage from mORMot.pas

```
CP_UTF16 = 1200;
```

*Internal Code Page for UTF-16 Unicode encoding*

- used e.g. for Delphi 2009+ UnicodeString=String type

```
djObject = djPointer;
```

*TDynArrayKind alias for a TObject field hashing / comparison*

```
djPointer = djCardinal;
```

*TDynArrayKind alias for a pointer field hashing / comparison*

```
DocVariantDataFake: TDocVariantData = (VType:1;
VOptions:[dvoReturnNullForUnknownProperty]);
```

*Constant used e.g. by \_Safe() overloaded functions*

- will be in code section of the exe, so will be read-only by design

- would have Kind=dvUndefined and Count=0, so \_Safe() would return a valid, but void document

- its VType is varNull, so would be viewed as a null variant

- dvoReturnNullForUnknownProperty is defined, so that U[]/I[]... methods won't raise any exception about unexpected field name

```
DOUBLE_SAME = 1E-11;
```

*A typical error allowed when working with double floating-point values*

- 1E-12 is too small, and triggers sometimes some unexpected errors; FPC RTL uses 1E-4 so we are paranoid enough

```
FILES_ALL = '*.*';
```

*Operating-system dependent wildchar to match all files in a folder*

```
GUID_NULL: TGUID = ();
```

*A TGUID containing '{00000000-0000-0000-0000-000000000000}'*

```
HASH_PO2 = 1 shl 18;
```

*Defined for inlining bitwise division in TDynArrayHasher.HashTableIndex*

- HashTableSize<=HASH\_PO2 is expected to be a power of two (fast binary op); limit is set to 262,144 hash table slots (=1MB), for Capacity=131,072 items
- above this limit, a set of increasing primes is used; using a prime as hashtable modulo enhances its distribution, especially for a weak hash function
- 64-bit CPU and FPC can efficiently compute a prime reduction using Lemire algorithm, so no power of two is defined on those targets

```
HEADER_BEARER_UPPER = 'AUTHORIZATION: BEARER ';
```

*HTTP header name for the authorization token, in upper case*

- could be used e.g. with IdempChar() to retrieve a JWT value
- will detect header computed e.g. by SynCrtSock.AuthorizationBearer()

```
HEADER_CONTENT_TYPE = 'Content-Type: ';
```

*HTTP header name for the content type, as defined in the corresponding RFC*

```
HEADER_CONTENT_TYPE_UPPER = 'CONTENT-TYPE: ';
```

*HTTP header name for the content type, in upper case*

- as defined in the corresponding RFC
- could be used e.g. with IdempChar() to retrieve the Content-Type value

```
HEADER_REMOTEIP_UPPER = 'REMOTEIP: ';
```

*HTTP header name for the client IP, in upper case*

- as defined in our HTTP server classes
- could be used e.g. with IdempChar() to retrieve the remote IP address

```
HTML_CONTENT_TYPE = 'text/html; charset=UTF-8';
```

*MIME content type used for UTF-8 encoded HTML*

```
HTML_CONTENT_TYPE_HEADER = HEADER_CONTENT_TYPE+HTML_CONTENT_TYPE;
```

*HTTP header for MIME content type used for UTF-8 encoded HTML*

```
JPEG_CONTENT_TYPE = 'image/jpeg';
```

*MIME content type used for a JPEG picture*

```
JSON_BASE64_MAGIC = $b0bfeF;
```

*UTF-8 encoded \uFFF0 special code to mark Base64 binary content in JSON*

- Unicode special char U+FFF0 is UTF-8 encoded as EF BF B0 bytes
- as generated by BinToBase64WithMagic() functions, and expected by SQLParamContent() and ExtractInlineParameters() functions
- used e.g. when transmitting TDynArray.SaveTo() content

```
JSON_BASE64_MAGIC_QUOTE = ord('')+cardinal(JSON_BASE64_MAGIC) shl 8;
```

*''' + UTF-8 encoded \uFFFF0 special code to mark Base64 binary in JSON*

```
JSON_BASE64_MAGIC_QUOTE_VAR: cardinal = JSON_BASE64_MAGIC_QUOTE;
```

*''' + UTF-8 encoded \uFFFF0 special code to mark Base64 binary in JSON*

- defined as a cardinal variable to be used as:

```
AddNoJSONEscape(@JSON_BASE64_MAGIC_QUOTE_VAR,4);
```

```
JSON_CONTENT_TYPE = 'application/json; charset=UTF-8';
```

*MIME content type used for JSON communication (as used by the Microsoft WCF framework and the YUI framework)*

*Used for DI-2.1.2 (page 2555).*

```
JSON_CONTENT_TYPE_HEADER = HEADER_CONTENT_TYPE+JSON_CONTENT_TYPE;
```

*HTTP header for MIME content type used for plain JSON*

```
JSON_CONTENT_TYPE_HEADER_UPPER = HEADER_CONTENT_TYPE_UPPER+JSON_CONTENT_TYPE_UPPER;
```

*HTTP header for MIME content type used for plain JSON, in upper case*

- could be used e.g. with IdempChar() to retrieve the Content-Type value

```
JSON_CONTENT_TYPE_UPPER = 'APPLICATION/JSON';
```

*MIME content type used for plain JSON, in upper case*

- could be used e.g. with IdempChar() to retrieve the Content-Type value

```
JSON_NAN: array[TFloatNan] of string[11] = ('0', 'NaN', 'Infinity', '-Infinity');
```

*The JavaScript-like values of non-number IEEE constants*

- as recognized by FloatToShortNan, and used by TTextWriter.Add() when serializing such single/double/extended floating-point values

```
JSON_OPTIONS: array[Boolean] of TDocVariantOptions = (
[dvoReturnNullForUnknownProperty],
[dvoReturnNullForUnknownProperty,dvoValueCopiedByReference]);
```

*Some convenient TDocVariant options, as JSON\_OPTIONS[CopiedByReference]*

- JSON\_OPTIONS[false] is e.g. \_Json() and \_JsonFmt() functions default

- JSON\_OPTIONS[true] are used e.g. by \_JsonFast() and \_JsonFastFmt() functions

- warning: exclude dvoAllowDoubleValue so won't parse any float, just currency

```
JSON_OPTIONS_FAST = [dvoReturnNullForUnknownProperty,dvoValueCopiedByReference];
```

*Same as JSON\_OPTIONS[true], but can not be used as PDocVariantOptions*

- warning: exclude dvoAllowDoubleValue so won't parse any float, just currency

- as used by \_JsonFast()

```
JSON_OPTIONS_FAST_EXTENDED: TDocVariantOptions =
[dvoReturnNullForUnknownProperty,dvoValueCopiedByReference,
dvoSerializeAsExtendedJson];
```

*TDocVariant options to be used so that JSON serialization would use the unquoted JSON syntax for field names*

- you could use it e.g. on a TSQLRecord variant published field to reduce the JSON escape process during storage in the database, by customizing your TSQLModel instance:

```
(aModel.Props[TSQLMyRecord]['VariantProp'] as TSQLPropInfoRTTIVariant).
DocVariantOptions := JSON_OPTIONS_FAST_EXTENDED;
```

or - in a cleaner way - by overriding TSQLRecord.InternalDefineModel():

```
class procedure TSQLMyRecord.InternalDefineModel(Props: TSQLRecordProperties);
begin
```

```
(Props.Fields.ByName('VariantProp') as TSQLPropInfoRTTIVariant).
 DocVariantOptions := JSON_OPTIONS_FAST_EXTENDED;
end;
```

or to set all variant fields at once:

```
class procedure TSQLMyRecord.InternalDefineModel(Props: TSQLRecordProperties);
begin
 Props.SetVariantFieldsDocVariantOptions(JSON_OPTIONS_FAST_EXTENDED);
end;
```

- consider using JSON\_OPTIONS\_NAMEVALUE[true] for case-sensitive TSynNameValue-like storage, or JSON\_OPTIONS\_FAST\_EXTENDEDINTERN if you expect RawUTF8 names and values interning

```
JSON_OPTIONS_FAST_EXTENDEDINTERN: TDocVariantOptions =
[dvoReturnNullForUnknownProperty, dvoValueCopiedByReference,
dvoSerializeAsExtendedJson, dvoJSONParseDoNotTryCustomVariants,
dvoInternNames, dvoInternValues];
```

*TDocVariant options for JSON serialization with efficient storage*

- i.e. unquoted JSON syntax for field names and RawUTF8 interning
- may be used e.g. for efficient persistence of similar data
- consider using JSON\_OPTIONS\_FAST\_EXTENDED if you don't expect RawUTF8 names and values interning, or need BSON variants parsing

```
JSON_OPTIONS_FAST_FLOAT =
[dvoReturnNullForUnknownProperty, dvoValueCopiedByReference, dvoAllowDoubleValue];
```

*Same as JSON\_OPTIONS\_FAST, but including dvoAllowDoubleValue to parse any float*

- as used by \_JsonFastFloat()

```
JSON_OPTIONS_FAST_STRICTJSON: TDocVariantOptions =
[dvoReturnNullForUnknownProperty, dvoValueCopiedByReference,
dvoJSONParseDoNotTryCustomVariants];
```

*TDocVariant options which may be used for plain JSON parsing*

- this won't recognize any extended syntax

```
JSON_OPTIONS_NAMEVALUE: array[boolean] of TDocVariantOptions = (
[dvoReturnNullForUnknownProperty, dvoValueCopiedByReference, dvoNameCaseSensitive],
[dvoReturnNullForUnknownProperty, dvoValueCopiedByReference,
dvoNameCaseSensitive, dvoSerializeAsExtendedJson]);
```

*TDocVariant options to be used for case-sensitive TSynNameValue-like storage, with optional extended JSON syntax serialization*

- consider using JSON\_OPTIONS\_FAST\_EXTENDED for case-insensitive objects

```
JSON_OPTIONS_NAMEVALUEINTERN: array[boolean] of TDocVariantOptions = (
[dvoReturnNullForUnknownProperty, dvoValueCopiedByReference,
dvoNameCaseSensitive, dvoInternNames, dvoInternValues],
[dvoReturnNullForUnknownProperty, dvoValueCopiedByReference,
dvoNameCaseSensitive, dvoInternNames, dvoInternValues, dvoSerializeAsExtendedJson]);
```

*TDocVariant options to be used for case-sensitive TSynNameValue-like storage, RawUTF8 interning and optional extended JSON syntax serialization*

- consider using JSON\_OPTIONS\_FAST\_EXTENDED for case-insensitive objects, or JSON\_OPTIONS\_NAMEVALUE[] if you don't expect names and values interning

```
JSON_SQLDATE_MAGIC = $b1bfef;
```

*UTF-8 encoded \uFFF1 special code to mark ISO-8601 SQLDATE in JSON*

- e.g. ""\uFFF12012-05-04"" pattern
- Unicode special char U+FFF1 is UTF-8 encoded as EF BF B1 bytes
- as generated by DateToSQL/DateTimeToSQL/TimeLogToSQL functions, and expected by

SQLParamContent() and ExtractInlineParameters() functions

```
JSON_SQLDATE_MAGIC_QUOTE = ord('')+cardinal(JSON_SQLDATE_MAGIC) shl 8;
```

*''' + UTF-8 encoded \uFFF1 special code to mark ISO-8601 SQLDATE in JSON*

```
JSON_SQLDATE_MAGIC_QUOTE_VAR: cardinal = JSON_SQLDATE_MAGIC_QUOTE;
```

*''' + UTF-8 encoded \uFFF1 special code to mark ISO-8601 SQLDATE in JSON*

- defined as a cardinal variable to be used as:

```
AddNoJSONEscape(@JSON_SQLDATE_MAGIC_QUOTE_VAR,4);
```

```
LOGESCAPELEN = 200;
```

*Maximum size, in bytes, of a TLogEscape / LogEscape() buffer*

```
MAXLOGSIZE = 1024*1024;
```

*Rotate local log file if reached this size (1MB by default)*

- .log file will be save as .log.bak file
- a new .log file is created
- used by AppendToTextFile() and LogToTextFile() functions (not TSynLog)

```
MAX_SQLFIELDS = 64;
```

*Maximum number of fields in a database Table*

- is included in SynCommons so that all DB-related work will be able to share the same low-level types and functions (e.g. TSQLFieldBits, TJSONWriter, TSynTableStatement, TSynTable, TSQLRecordProperties)
- default is 64, but can be set to any value (64, 128, 192 and 256 optimized) changing the source below or using MAX\_SQLFIELDS\_128, MAX\_SQLFIELDS\_192 or MAX\_SQLFIELDS\_256 conditional directives for your project
- this constant is used internally to optimize memory usage in the generated asm code, and statically allocate some arrays for better speed
- note that due to compiler restriction, 256 is the maximum value (this is the maximum number of items in a Delphi/FPC set)

```
MAX_SQLFIELDS_INCLUDINGID = MAX_SQLFIELDS+1;
```

*Sometimes, the ID field is included in a bits set*

```
ORDTYPE_SIZE: array[TOrdType] of byte = (1,1,2,2,4,4);
```

*Quick retrieve how many bytes an ordinal consist in*

```
OS_INITIAL: array[TOperatingSystem] of AnsiChar = ('?', 'W', 'L', 'X', 'B', 'P', 'A',
'a', 'D', 'F', 'G', 'K', 'M', 'm', 'n', 'N', 'U', 'S', 's', 'u', 'Y', 'T', 'C', 't',
'R', 'l', 'O', 'G', 'c', 'd', 'x', 'Z', 'r', 'p', 'J');
```

*Translate one operating system (and distribution) into a single character*

- may be used internally e.g. for a HTTP User-Agent header, as with TFileVersion.UserAgent

```
OS_LINUX = [osLinux, osArch .. osAndroid];
```

*For Android ... J = Java VM the operating systems items which actually are Linux distributions*

```
OS_TEXT = 'Win';
```

*The target Operating System used for compilation, as text*

```
PLURAL_FORM: array[boolean] of RawUTF8 = ('','s');
```

*Can be used to append to most English nouns to form a plural*

- see also the Plural function

**POINTERAND = 3;**

*Could be used to compute the bitmask of a pointer integer*

**POINTERBITS = 32;**

*Could be used to check all bits on a pointer*

**POINTERSHR = 2;**

*Could be used to compute the index in a pointer list from its position*

**ptPtrInt = ptInteger;**

*Map a PtrInt type to the TJSONCustomParserRTTIType set*

**ptPtrUInt = ptCardinal;**

*Map a PtrUInt type to the TJSONCustomParserRTTIType set*

**PT\_COMPLEXTYPES = [ptArray, ptRecord, ptCustom, ptTimeLog];**

*Which TJSONCustomParserRTTIType types are not simple types*  
- ptTimeLog is complex, since could be also TCreateTime or TModTime

**SYNLZTRIG: array[boolean] of integer = (100, maxInt);**

*CompressionSizeTrigger parameter SYNLZTRIG[true] will disable then SynLZCompress() compression*

**SYNOPSE\_FRAMEWORK\_FULLVERSION = SYNOPSE\_FRAMEWORK\_VERSION ;**

*A text including the version and the main active conditional options*  
- usefull for low-level debugging purpose

**SYNOPSE\_FRAMEWORK\_VERSION = '1.18.6420' ;**

*For TEvent and TCriticalSection for TObjectList needed for TSynMapFile .mab format the corresponding version of the freeware Synopse framework*  
- includes a commit increasing number (generated by SourceCodeRep tool)  
- a similar constant shall be defined in SynCrtSock.pas

**TEXT\_CONTENT\_TYPE = 'text/plain; charset=UTF-8';**

*MIME content type used for plain UTF-8 text*

**TEXT\_CONTENT\_TYPE\_HEADER = HEADER\_CONTENT\_TYPE+TEXT\_CONTENT\_TYPE;**

*HTTP header for MIME content type used for plain UTF-8 text*

**tkOrdinalTypes = [tkInteger, tkChar, tkWChar, tkEnumeration, tkSet, tkInt64 ];**

*Maps 1, 8, 16, 32 and 64-bit ordinal in TTypeKind RTTI enumerate*

**tkRecordKinds = tkRecord;**

*Maps record or object in TTypeKind RTTI enumerate*

**tkRecordTypes = [tkRecord];**

*Maps record or object in TTypeKind RTTI enumerate*

**tkStringTypes = [tkLString, tkWString ];**

*Maps long string in TTypeKind RTTI enumerate*

**TwoDigitLookup: packed array[0..99] of array[1..2] of AnsiChar =**  
( '00', '01', '02', '03', '04', '05', '06', '07', '08', '09',  
'10', '11', '12', '13', '14', '15', '16', '17', '18', '19',  
'20', '21', '22', '23', '24', '25', '26', '27', '28', '29',  
'30', '31', '32', '33', '34', '35', '36', '37', '38', '39',  
'40', '41', '42', '43', '44', '45', '46', '47', '48', '49',  
'50', '51', '52', '53', '54', '55', '56', '57', '58', '59',

```
'60','61','62','63','64','65','66','67','68','69',
'70','71','72','73','74','75','76','77','78','79',
'80','81','82','83','84','85','86','87','88','89',
'90','91','92','93','94','95','96','97','98','99');
```

*Fast lookup table for converting any decimal number from 0 to 99 into their ASCII equivalence*  
 - our enhanced SysUtils.pas (normal and LVCL) contains the same array

```
UNIXTIME_MINIMAL = 1481187020;
```

*A contemporary, but elapsed, TUnixTime second-based value*  
 - corresponds to Thu, 08 Dec 2016 08:50:20 GMT  
 - may be used to check for a valid just-generated Unix timestamp value

```
varNativeString = varString;
```

*This variant type will map the current string type*  
 - depending on the compiler version

```
varSynUnicode = varOleStr;
```

*This variant type will map the current SynUnicode type*  
 - depending on the compiler version

```
varWord64 = 21;
```

*Unsigned 64bit integer variant type*  
 - currently called varUInt64 in Delphi (not defined in older versions), and varQWord in FPC

```
WINDOWS_32 = [w2000, wXP, wServer2003, wServer2003_R2, wVista, wServer2008, wSeven,
wServer2008_R2, wEight, wServer2012, wEightOne, wServer2012R2, wTen, wServer2016,
wEleven];
```

*The recognized Windows versions which are 32-bit*

```
WINDOWS_NAME: array[TWindowsVersion] of RawUTF8 = ('', '2000', 'XP', 'XP 64bit', 'Server
2003', 'Server 2003 R2', 'Vista', 'Vista 64bit', 'Server 2008', 'Server 2008 64bit',
'7', '7 64bit', 'Server 2008 R2', 'Server 2008 R2 64bit', '8', '8 64bit', 'Server 2012',
'Server 2012 64bit', '8.1', '8.1 64bit', 'Server 2012 R2', 'Server 2012 R2 64bit', '10',
'10 64bit', 'Server 2016', 'Server 2016 64bit', '11', '11 64bit', 'Server 2019 64bit');
```

*The recognized Windows versions, as plain text*  
 - defined even outside MSWINDOWS to allow process e.g. from monitoring tools

```
XMLUTF8_HEADER = '<?xml version="1.0" encoding="UTF-8"?>#13#10';
```

*Standard header for an UTF-8 encoded XML file*

```
XMLUTF8_NAMESPACE = '<contents xmlns="http://www.w3.org/2001/XMLSchema-instance">';
```

*Standard namespace for a generic XML File*

```
XML_CONTENT_TYPE = 'text/xml; charset=UTF-8';
```

*MIME content type used for UTF-8 encoded XML*

```
XML_CONTENT_TYPE_HEADER = HEADER_CONTENT_TYPE+XML_CONTENT_TYPE;
```

*HTTP header for MIME content type used for UTF-8 encoded XML*

```
_DALEN = SizeOf(PtrInt);
```

*Cross-compiler negative offset to TDynArrayRec.high/length field*  
 - to be used inlined e.g. as PDALen(PtrUInt(Values)-\_DALEN)^({\$ifdef FPC}+1{\$endif})

```
_DAREFCNT = Sizeof(TDACnt)+_DALEN;
```

*Cross-compiler negative offset to TDynArrayRec.refCnt field*  
 - to be used inlined e.g. as PDACnt(PtrUInt(Values)-\_DAREFCNT)^

```
_STRLEN = SizeOf(TStrLen);
```

*Cross-compiler negative offset to TStrRec.length field*  
- to be used inlined e.g. as PStrLen(p-\_STRLEN)^

```
_STRREFCNT = Sizeof(TStrCnt)+_STRLEN;
```

*Cross-compiler negative offset to TStrRec.refCnt field*  
- to be used inlined e.g. as PStrCnt(p-\_STRREFCNT)^

## Functions or procedures implemented in the *SynCommons* unit

| Functions or procedures | Description                                                                   | Page |
|-------------------------|-------------------------------------------------------------------------------|------|
| AddArrayOfConst         | Append one or several values to a local "array of const" variable             | 941  |
| AddGUID                 | Append one TGUID item to a TGUID dynamic array                                | 942  |
| AddInt64                | Add a 64-bit integer array at the end of a dynamic array                      | 942  |
| AddInt64                | Add a 64-bit integer value at the end of a dynamic array of integers          | 942  |
| AddInt64                | Add a 64-bit integer value at the end of a dynamic array                      | 942  |
| AddInt64Once            | If not already existing, add a 64-bit integer value to a dynamic array        | 942  |
| AddInt64Sorted          | If not already existing, add a 64-bit integer value to a sorted dynamic array | 942  |
| AddInteger              | Add an integer value at the end of a dynamic array of integers                | 942  |
| AddInteger              | Add an integer array at the end of a dynamic array of integer                 | 942  |
| AddInteger              | Add an integer value at the end of a dynamic array of integers                | 942  |
| AddInteger              | Add an integer value at the end of a dynamic array of integers                | 942  |
| AddPrefixToCSV          | Append some prefix to all CSV values                                          | 942  |
| AddRawUTF8              | Add the Value to Values[], with an external count variable, for performance   | 943  |
| AddRawUTF8              | True if Value was added successfully in Values[]                              | 943  |
| AddSortedInteger        | Add an integer value in a sorted dynamic array of integers                    | 943  |
| AddSortedInteger        | Add an integer value in a sorted dynamic array of integers                    | 943  |
| AddSortedRawUTF8        | Add a RawUTF8 value in an alphatically sorted dynamic array of RawUTF8        | 943  |
| AddToCSV                | Append a Value to a CSV string                                                | 943  |
| AddWord                 | Add a 16-bit integer value at the end of a dynamic array of integers          | 943  |
| AndMemory               | Logical AND of two memory buffers                                             | 943  |
| Ansi7ToString           | Convert any Ansi 7 bit encoded String into a generic VCL Text                 | 944  |

| Functions or procedures | Description                                                                                                                                                                                                            | Page |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| Ansi7ToString           | Convert any Ansi 7 bit encoded String into a generic VCL Text                                                                                                                                                          | 944  |
| Ansi7ToString           | Convert any Ansi 7 bit encoded String into a generic VCL Text                                                                                                                                                          | 944  |
| AnsiCharToUTF8          | Convert an AnsiChar buffer (of a given code page) into a UTF-8 string                                                                                                                                                  | 944  |
| AnsiIComp               | Fast WinAnsi comparison using the NormToUpper[] array for all 8 bits values                                                                                                                                            | 944  |
| AnsiICompW              | Fast case-insensitive Unicode comparison                                                                                                                                                                               | 944  |
| AnyAnsiToUTF8           | Direct conversion of an AnsiString with an unknown code page into an UTF-8 encoded String                                                                                                                              | 944  |
| AnyAnsiToUTF8           | Direct conversion of an AnsiString with an unknown code page into an UTF-8 encoded String                                                                                                                              | 944  |
| AnyScanExists           | Fast search of a binary value position in a fixed-size array                                                                                                                                                           | 944  |
| AnyScanIndex            | Fast search of a binary value position in a fixed-size array                                                                                                                                                           | 944  |
| AnyTextFileToRawUTF8    | Get text file contents (even Unicode or UTF8) and convert it into an UTF-8 string according to any BOM marker at the beginning of the file                                                                             | 944  |
| AnyTextFileToString     | Get text File contents (even Unicode or UTF8) and convert it into a Charset-compatible AnsiString (for Delphi 7) or an UnicodeString (for Delphi 2009 and up) according to any BOM marker at the beginning of the file | 944  |
| AnyTextFileToSynUnicode | Get text file contents (even Unicode or UTF8) and convert it into an Unicode string according to any BOM marker at the beginning of the file                                                                           | 945  |
| Append999ToBuffer       | Fast add text conversion of 0-999 integer value into a given buffer                                                                                                                                                    | 945  |
| AppendBuffersToRawUTF8  | Fast add some characters to a RawUTF8 string                                                                                                                                                                           | 945  |
| AppendBufferToRawUTF8   | Fast add some characters to a RawUTF8 string                                                                                                                                                                           | 945  |
| AppendCharToRawUTF8     | Fast add one character to a RawUTF8 string                                                                                                                                                                             | 945  |
| AppendCSVValues         | Append some text lines with the supplied Values[]                                                                                                                                                                      | 945  |
| AppendRawUTF8ToBuffer   | Fast add some characters from a RawUTF8 string into a given buffer                                                                                                                                                     | 945  |
| AppendShortComma        | Fast append some UTF-8 text into a shortstring, with an ending ','                                                                                                                                                     | 945  |
| AppendToTextFile        | Log a message to a local text file                                                                                                                                                                                     | 945  |
| AppendUInt32ToBuffer    | Fast add text conversion of a 32-bit unsigned integer value into a given buffer                                                                                                                                        | 945  |
| AreUrlValid             | Checks if the supplied UTF-8 text values don't need URI encoding                                                                                                                                                       | 946  |

| Functions or procedures   | Description                                                                                                                   | Page |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------|------|
| ArrayOfConstValueAsText   | Find a given name in name/value pairs, and returns the value as RawUTF8                                                       | 946  |
| AsciiToBaudot             | Convert some ASCII-7 text into binary, using Emile Baudot code                                                                | 946  |
| AsciiToBaudot             | Convert some ASCII-7 text into binary, using Emile Baudot code                                                                | 946  |
| Base64Decode              | Direct low-level decoding of a Base64 encoded buffer                                                                          | 946  |
| Base64MagicCheckAndDecode | Check and decode '\uFFFF0base64encodedbinary' content into binary                                                             | 946  |
| Base64MagicCheckAndDecode | Check and decode '\uFFFF0base64encodedbinary' content into binary                                                             | 946  |
| Base64MagicCheckAndDecode | Check and decode '\uFFFF0base64encodedbinary' content into binary                                                             | 946  |
| Base64MagicDecode         | Just a wrapper around Base64ToBin() for in-place decode of JSON_BASE64_MAGIC '\uFFFF0base64encodedbinary' content into binary | 947  |
| Base64ToBin               | Fast conversion from Base64 encoded text into binary data                                                                     | 947  |
| Base64ToBin               | Fast conversion from Base64 encoded text into binary data                                                                     | 947  |
| Base64ToBin               | Fast conversion from Base64 encoded text into binary data                                                                     | 947  |
| Base64ToBin               | Fast conversion from Base64 encoded text into binary data                                                                     | 947  |
| Base64ToBin               | Fast conversion from Base64 encoded text into binary data                                                                     | 947  |
| Base64ToBin               | Fast conversion from Base64 encoded text into binary data                                                                     | 947  |
| Base64ToBinLength         | Retrieve the expected undecoded length of a Base64 encoded buffer                                                             | 947  |
| Base64ToBinLengthSafe     | Retrieve the expected undecoded length of a Base64 encoded buffer                                                             | 947  |
| Base64ToBinSafe           | Fast conversion from Base64 encoded text into binary data                                                                     | 948  |
| Base64ToBinSafe           | Fast conversion from Base64 encoded text into binary data                                                                     | 948  |
| Base64ToBinSafe           | Fast conversion from Base64 encoded text into binary data                                                                     | 948  |
| Base64ToURI               | Conversion from any Base64 encoded value into URI-compatible encoded text                                                     | 948  |
| Base64uriDecode           | Direct low-level decoding of a Base64-URI encoded buffer                                                                      | 948  |
| Base64uriEncode           | Low-level conversion from a binary buffer into Base64-like URI-compatible encoded text                                        | 948  |
| Base64uriToBin            | Fast conversion from Base64-URI encoded text into binary data                                                                 | 949  |
| Base64uriToBin            | Fast conversion from Base64-URI encoded text into binary data                                                                 | 949  |
| Base64uriToBin            | Fast conversion from Base64-URI encoded text into binary data                                                                 | 949  |

| Functions or procedures | Description                                                                                                                        | Page |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------|------|
| Base64uriToBin          | Fast conversion from Base64-URI encoded text into binary data                                                                      | 949  |
| Base64uriToBin          | Fast conversion from Base64-URI encoded text into binary data                                                                      | 949  |
| Base64uriToBin          | Fast conversion from Base64-URI encoded text into binary data                                                                      | 949  |
| Base64uriToBinLength    | Retrieve the expected undecoded length of a Base64-URI encoded buffer                                                              | 949  |
| BaudotToAscii           | Convert some Baudot code binary, into ASCII-7 text                                                                                 | 949  |
| BaudotToAscii           | Convert some Baudot code binary, into ASCII-7 text                                                                                 | 949  |
| BinToBase64             | Fast conversion from binary data into Base64 encoded UTF-8 text                                                                    | 949  |
| BinToBase64             | Fast conversion from binary data into prefixed/suffixed Base64 encoded UTF-8 text                                                  | 949  |
| BinToBase64             | Fast conversion from binary data into Base64 encoded UTF-8 text                                                                    | 949  |
| BinToBase64Length       | Retrieve the expected encoded length after Base64 process                                                                          | 949  |
| BinToBase64Short        | Fast conversion from a small binary data into Base64 encoded UTF-8 text                                                            | 949  |
| BinToBase64Short        | Fast conversion from a small binary data into Base64 encoded UTF-8 text                                                            | 949  |
| BinToBase64uri          | Fast conversion from binary data into Base64-like URI-compatible encoded text                                                      | 950  |
| BinToBase64uri          | Fast conversion from a binary buffer into Base64-like URI-compatible encoded text                                                  | 950  |
| BinToBase64uriLength    | Retrieve the expected encoded length after Base64-URI process                                                                      | 950  |
| BinToBase64uriShort     | Fast conversion from a binary buffer into Base64-like URI-compatible encoded shortstring                                           | 950  |
| BinToBase64WithMagic    | Fast conversion from binary data into Base64 encoded UTF-8 text with JSON_BASE64_MAGIC prefix (UTF-8 encoded \uFFFF0 special code) | 950  |
| BinToBase64WithMagic    | Fast conversion from binary data into Base64 encoded UTF-8 text with JSON_BASE64_MAGIC prefix (UTF-8 encoded \uFFFF0 special code) | 950  |
| BinToHex                | Fast conversion from binary data into hexa chars                                                                                   | 950  |
| BinToHex                | Fast conversion from binary data into hexa chars                                                                                   | 950  |
| BinToHex                | Fast conversion from binary data into hexa chars                                                                                   | 950  |
| BinToHexDisplay         | Fast conversion from binary data into hexa chars, ready to be displayed                                                            | 950  |
| BinToHexDisplay         | Fast conversion from binary data into hexa chars, ready to be displayed                                                            | 950  |

| Functions or procedures     | Description                                                                                                   | Page |
|-----------------------------|---------------------------------------------------------------------------------------------------------------|------|
| BinToHexDisplayFile         | Fast conversion from binary data into hexa lowercase chars, ready to be used as a convenient TFileName prefix | 951  |
| BinToHexDisplayLower        | Fast conversion from binary data into lowercase hexa chars                                                    | 951  |
| BinToHexDisplayLower        | Fast conversion from binary data into lowercase hexa chars                                                    | 951  |
| BinToHexDisplayLowerShort   | Fast conversion from up to 127 bytes of binary data into lowercase hexa chars                                 | 951  |
| BinToHexDisplayLowerShort16 | Fast conversion from up to 64-bit of binary data into lowercase hexa chars                                    | 951  |
| BinToHexDisplayLowerVariant | Fast conversion of a binary buffer into hexa chars, as a variant string                                       | 951  |
| BinToHexLower               | Fast conversion from binary data into lowercase hexa chars                                                    | 951  |
| BinToHexLower               | Fast conversion from binary data into lowercase hexa chars                                                    | 951  |
| BinToHexLower               | Fast conversion from binary data into lowercase hexa chars                                                    | 951  |
| BinToHexLower               | Fast conversion from binary data into lowercase hexa chars                                                    | 951  |
| BinToSource                 | Generate some pascal source code holding some data binary as constant                                         | 952  |
| BinToSource                 | Generate some pascal source code holding some data binary as constant                                         | 952  |
| bswap32                     | Convert the endianness of a given unsigned 32-bit integer into BigEndian                                      | 952  |
| bswap64                     | Convert the endianness of a given unsigned 64-bit integer into BigEndian                                      | 952  |
| bswap64array                | Convert the endianness of an array of unsigned 64-bit integer into BigEndian                                  | 952  |
| BufferLineLength            | Compute the line length from a size-delimited source array of chars                                           | 952  |
| ByteScanIndex               | Fast search of an unsigned Byte value position in a Byte array                                                | 952  |
| BytesToRawByteString        | Creates a RawByteString memory buffer from a TBytes content                                                   | 952  |
| ByteToHex                   | Append one byte as hexadecimal char pairs, into a text buffer                                                 | 952  |
| CamelCase                   | Convert a string into an human-friendly CamelCase identifier                                                  | 952  |
| CamelCase                   | Convert a string into an human-friendly CamelCase identifier                                                  | 952  |
| CardinalToHex               | Fast conversion from a Cardinal value into hexa chars, ready to be displayed                                  | 953  |
| CardinalToHexLower          | Fast conversion from a Cardinal value into hexa chars, ready to be displayed                                  | 953  |

| Functions or procedures | Description                                                                      | Page |
|-------------------------|----------------------------------------------------------------------------------|------|
| CardinalToHexShort      | Fast conversion from a Cardinal value into hexa chars, ready to be displayed     | 953  |
| Char2ToByte             | Fast conversion of 2 digit characters into a 0..99 value                         | 953  |
| Char3ToWord             | Fast conversion of 3 digit characters into a 0..9999 value                       | 953  |
| Char4ToWord             | Fast conversion of 4 digit characters into a 0..9999 value                       | 953  |
| Chars3ToInt18           | Revert the value as encoded by TTextWriter.AddInt18ToChars3() or Int18ToChars3() | 953  |
| CharSetToCodePage       | Convert a char set to a code page                                                | 953  |
| ClassNameShort          | Just a wrapper around vmtClassName to avoid a string conversion                  | 953  |
| ClassNameShort          | Just a wrapper around vmtClassName to avoid a string conversion                  | 953  |
| CodePageToCharSet       | Convert a code page to a char set                                                | 953  |
| CompareCardinal         | A comparison function for sorting 32-bit unsigned integer values                 | 953  |
| CompareFloat            | A comparison function for sorting IEEE 754 double precision values               | 953  |
| CompareInt64            | A comparison function for sorting 64-bit signed integer values                   | 953  |
| CompareInteger          | A comparison function for sorting 32-bit signed integer values                   | 953  |
| CompareMem              | Our fast version of CompareMem() with optimized asm for x86 and tune pascal      | 954  |
| CompareMemSmall         | A CompareMem()-like function designed for small (a few bytes) content            | 954  |
| CompareQWord            | A comparison function for sorting 64-bit unsigned integer values                 | 954  |
| CompressSynLZ           | Compress a data content using the SynLZ algorithm                                | 954  |
| ContainsUTF8            | Return true if up^ is contained inside the UTF-8 buffer p^                       | 954  |
| ConvertCaseUTF8         | Fast conversion of the supplied text into 8 bit case sensitivity                 | 954  |
| CopyAndSortInt64        | Copy an integer array, then sort it, low values first                            | 954  |
| CopyAndSortInteger      | Copy an integer array, then sort it, low values first                            | 954  |
| CopyFile                | Copy one file to another, similar to the Windows API                             | 954  |
| CopyInt64               | Create a new 64-bit integer dynamic array with the values from another one       | 954  |
| CopyInteger             | Create a new 32-bit integer dynamic array with the values from another one       | 954  |
| crc128c                 | Compute a 128-bit checksum on the supplied buffer, cascading two crc32c          | 954  |

| Functions or procedures | Description                                                                                                                | Page |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------|------|
| crc16                   | Compute CRC16-CCITT checksum on the supplied buffer                                                                        | 955  |
| crc256c                 | Compute a 256-bit checksum on the supplied buffer using crc32c                                                             | 955  |
| crc32cfast              | Compute CRC32C checksum on the supplied buffer on processor-neutral code                                                   | 955  |
| crc32cinlined           | Compute CRC32C checksum on the supplied buffer using inlined code                                                          | 955  |
| crc32csse42             | Compute CRC32C checksum on the supplied buffer using SSE 4.2                                                               | 955  |
| crc32cUTF8ToHex         | Compute the hexadecimal representation of the crc32 checksum of a given text                                               | 955  |
| crc512c                 | Compute a 512-bit checksum on the supplied buffer using crc32c                                                             | 955  |
| crc63c                  | Compute CRC63C checksum on the supplied buffer, cascading two crc32c                                                       | 955  |
| crc64c                  | Compute CRC64C checksum on the supplied buffer, cascading two crc32c                                                       | 956  |
| crcblockNoSSE42         | Computation of our 128-bit CRC of a 128-bit binary buffer without SSE4.2                                                   | 956  |
| crcblocksfast           | Compute a proprietary 128-bit CRC of 128-bit binary buffers                                                                | 956  |
| CreateInternalWindow    | This function can be used to create a GDI compatible window, able to receive Windows Messages for fast local communication | 956  |
| CSVEncode               | Encode name/value pairs into CSV/INI raw format                                                                            | 956  |
| CSVOfValue              | Return a CSV list of the iterated same value                                                                               | 956  |
| CSVToInt64DynArray      | Convert the strings in the specified CSV text into a dynamic array of integer                                              | 956  |
| CSVToInt64DynArray      | Append the strings in the specified CSV text into a dynamic array of integer                                               | 956  |
| CSVToIntegerDynArray    | Append the strings in the specified CSV text into a dynamic array of integer                                               | 956  |
| CSVToRawUTF8DynArray    | Add the strings in the specified CSV text into a dynamic array of UTF-8 strings                                            | 956  |
| CSVToRawUTF8DynArray    | Add the strings in the specified CSV text into a dynamic array of UTF-8 strings                                            | 956  |
| Curr64ToPChar           | Convert an INTEGER Curr64 (value*10000) into a string                                                                      | 957  |
| Curr64ToStr             | Convert an INTEGER Curr64 (value*10000) into a string                                                                      | 957  |
| Curr64ToStr             | Convert an INTEGER Curr64 (value*10000) into a string                                                                      | 957  |

| Functions or procedures        | Description                                                                                                      | Page |
|--------------------------------|------------------------------------------------------------------------------------------------------------------|------|
| Curr64ToString                 | Convert a currency value from its Int64 binary representation into its numerical text equivalency                | 957  |
| CurrencyToStr                  | Convert a currency value into a string                                                                           | 957  |
| DACntDecFree                   | Low-level dynarray reference counter unprocess                                                                   | 957  |
| DateTimeMSToString             | Convert some date/time to the ISO 8601 text layout, including milliseconds                                       | 957  |
| DateTimeMSToString             | Convert some date/time to the ISO 8601 text layout, including milliseconds                                       | 957  |
| DateTimeToFileShort            | Delphi 2007 is buggy as hell convert some TDateTime to a small text layout, perfect e.g. for naming a local file | 958  |
| DateTimeToFileShort            | Convert some TDateTime to a small text layout, perfect e.g. for naming a local file                              | 958  |
| DateTimeToHTTPDate             | Convert some date/time to the "HTTP-date" format as defined by RFC 7231                                          | 958  |
| DateTimeToi18n                 | Wrapper calling global i18nDateTimeText() callback if set, or returning ISO-8601 standard layout on default      | 958  |
| DateTimeToIso8601              | Basic Date/Time conversion into ISO-8601                                                                         | 958  |
| DateTimeToIso8601              | Basic Date/Time conversion into ISO-8601                                                                         | 958  |
| DateTimeToIso8601ExpandedPChar | Write a TDateTime value, expanded as Iso-8601 encoded text into P^ Ansi buffer                                   | 958  |
| DateTimeToIso8601StringVar     | Write a TDateTime into strict ISO-8601 date and/or time text                                                     | 959  |
| DateTimeToIso8601Text          | Write a TDateTime into strict ISO-8601 date and/or time text                                                     | 959  |
| DateTimeToIso8601TextVar       | Write a TDateTime into strict ISO-8601 date and/or time text                                                     | 959  |
| DateTimeToUnixMSTime           | Convert a TDateTime into a millisecond-based c-encoded time (from Unix epoch 1/1/1970)                           | 959  |
| DateTimeToUnixTime             | Convert a TDateTime into a second-based c-encoded time                                                           | 959  |
| DateToIso8601                  | Basic Date conversion into ISO-8601                                                                              | 959  |
| DateToIso8601                  | Basic Date conversion into ISO-8601                                                                              | 959  |
| DateToIso8601PChar             | Write a Date/Time to P^ Ansi buffer                                                                              | 960  |
| DateToIso8601PChar             | Write a Date to P^ Ansi buffer                                                                                   | 960  |
| DateToIso8601Text              | Convert a date into 'YYYY-MM-DD' date format                                                                     | 960  |
| DaysToIso8601                  | Basic Date period conversion into ISO-8601                                                                       | 960  |

| Functions or procedures       | Description                                                                                         | Page |
|-------------------------------|-----------------------------------------------------------------------------------------------------|------|
| DeduplicateInt64              | Sort and remove any 64-bit duplicated integer from Values[]                                         | 960  |
| DeduplicateInt64              | Sort and remove any 64-bit duplicated integer from Values[]                                         | 960  |
| DeduplicateInt64Sorted        | Low-level function called by DeduplicateInt64()                                                     | 960  |
| DeduplicateInteger            | Sort and remove any 32-bit duplicated integer from Values[]                                         | 960  |
| DeduplicateInteger            | Sort and remove any 32-bit duplicated integer from Values[]                                         | 960  |
| DeduplicateIntegerSorted      | Low-level function called by DeduplicateInteger()                                                   | 960  |
| DeleteCriticalSectionIfNeeded | On need finalization of a mutex                                                                     | 960  |
| DeleteInt64                   | Delete any 64-bit integer in Values[]                                                               | 960  |
| DeleteInt64                   | Delete any 64-bit integer in Values[]                                                               | 960  |
| DeleteInteger                 | Delete any 32-bit integer in Values[]                                                               | 960  |
| DeleteInteger                 | Delete any 32-bit integer in Values[]                                                               | 960  |
| DeleteRawUTF8                 | Delete a RawUTF8 item in a dynamic array of RawUTF8;                                                | 961  |
| DeleteRawUTF8                 | Delete a RawUTF8 item in a dynamic array of RawUTF8                                                 | 961  |
| DeleteSection                 | Delete a whole [Section]                                                                            | 961  |
| DeleteSection                 | Delete a whole [Section]                                                                            | 961  |
| DeleteWord                    | Delete any 16-bit integer in Values[]                                                               | 961  |
| DirectoryDelete               | Delete the content of a specified directory                                                         | 961  |
| DirectoryDeleteOlderFiles     | Delete the files older than a given age in a specified directory                                    | 961  |
| Div100                        | Simple wrapper to efficiently compute both division and modulo per 100                              | 961  |
| DocVariantData                | Direct access to a TDocVariantData from a given variant instance                                    | 962  |
| DoubleToJSON                  | Convert a 64-bit floating-point value to its JSON text equivalency                                  | 962  |
| DoubleToShort                 | Convert a 64-bit floating-point value to its numerical text equivalency                             | 962  |
| DoubleToShortNoExp            | Convert a 64-bit floating-point value to its numerical text equivalency without scientific notation | 962  |
| DoubleToStr                   | Convert a 64-bit floating-point value to its numerical text equivalency                             | 962  |
| DoubleToStr                   | Convert a 64-bit floating-point value to its numerical text equivalency                             | 962  |
| DoubleToString                | Convert a floating-point value to its numerical text equivalency                                    | 962  |

| Functions or procedures        | Description                                                                                                             | Page |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------|------|
| DynArray                       | Initialize the structure with a one-dimension dynamic array                                                             | 963  |
| DynArrayBlobSaveJSON           | Serialize a dynamic array content, supplied as raw binary buffer, as JSON                                               | 963  |
| DynArrayCopy                   | Copy a dynamic array content from source to Dest                                                                        | 963  |
| DynArrayElementTypeName        | Compute a dynamic array element information                                                                             | 963  |
| DynArrayEquals                 | Compare two dynamic arrays by calling TDynArray.Equals                                                                  | 963  |
| DynArrayItemTypeIsSimpleBinary | Was dynamic array item after RegisterCustomJSONSerializerFromTextBinaryType()                                           | 963  |
| DynArrayItemTypeLen            | Trim ending 'DynArray' or 's' chars from a dynamic array type name                                                      | 964  |
| DynArrayLoad                   | Fill a dynamic array content from a binary serialization as saved by DynArraySave() / TDynArray.Save()                  | 964  |
| DynArrayLoadJSON               | Fill a dynamic array content from a JSON serialization as saved by TTextWriter.AddDynArrayJSON                          | 964  |
| DynArrayLoadJSON               | Fill a dynamic array content from a JSON serialization as saved by TTextWriter.AddDynArrayJSON, which won't be modified | 964  |
| DynArraySave                   | Serialize a dynamic array content as binary, ready to be loaded by DynArrayLoad() / TDynArray.Load()                    | 964  |
| DynArraySaveJSON               | Serialize a dynamic array content as JSON                                                                               | 964  |
| DynArraySortIndexed            | Sort any dynamic array, via an external array of indexes                                                                | 964  |
| DynArrayTypeInfoToRecordInfo   | Retrieve the item type information of a dynamic array low-level RTTI                                                    | 965  |
| Elapsed                        | Check if the current timestamp, in ms, matched a given period                                                           | 965  |
| EndWith                        | Check matching ending of p^ in upText                                                                                   | 965  |
| EndWithArray                   | Returns the index of a matching ending of p^ in upArray[]                                                               | 965  |
| EnsureDirectoryExists          | Creates a directory if not already existing                                                                             | 965  |
| EscapeBuffer                   | Fast conversion from binary data to escaped text                                                                        | 965  |
| EscapeToShort                  | Fill a shortstring with the (hexadecimal) chars of the input text/binary                                                | 965  |
| EscapeToShort                  | Fill a shortstring with the (hexadecimal) chars of the input text/binary                                                | 965  |
| EventEquals                    | Compare two TMethod instances                                                                                           | 966  |
| ExcludeInt64                   | Remove some 64-bit integer from Values[]                                                                                | 966  |
| ExcludeInteger                 | Remove some 32-bit integer from Values[]                                                                                | 966  |

| Functions or procedures      | Description                                                                                       | Page |
|------------------------------|---------------------------------------------------------------------------------------------------|------|
| ExistsIniName                | Return TRUE if Value of UpperName does exist in P, till end of current section                    | 966  |
| ExistsIniNameValue           | Return TRUE if one of the Value of UpperName exists in P, till end of current section             | 966  |
| ExtendedToJSON               | Convert a floating-point value to its JSON text equivalency                                       | 966  |
| ExtendedToShort              | Convert a floating-point value to its numerical text equivalency                                  | 966  |
| ExtendedToShortNoExp         | Convert a floating-point value to its numerical text equivalency without scientification notation | 966  |
| ExtendedToStr                | Convert a floating-point value to its numerical text equivalency                                  | 967  |
| ExtendedToStr                | Convert a floating-point value to its numerical text equivalency                                  | 967  |
| FastDynArrayClear            | Low-level finalization of a dynamic array of variants                                             | 967  |
| FastFindIndexedPUTF8Char     | Retrieve the index of a PUTF8Char in a PUTF8Char array via a sort indexed                         | 967  |
| FastFindInt64Sorted          | Fast $O(\log(n))$ binary search of a 64-bit signed integer value in a sorted array                | 967  |
| FastFindIntegerSorted        | Fast $O(\log(n))$ binary search of an integer value in a sorted integer array                     | 967  |
| FastFindIntegerSorted        | Fast $O(\log(n))$ binary search of an integer value in a sorted integer array                     | 967  |
| FastFindPointerSorted        | Fast $O(\log(n))$ binary search of a Pointer value in a sorted array                              | 967  |
| FastFindPtrIntSorted         | Fast $O(\log(n))$ binary search of a PtrInt value in a sorted array                               | 967  |
| FastFindPUTF8CharSorted      | Retrieve the index where is located a PUTF8Char in a sorted PUTF8Char array                       | 968  |
| FastFindPUTF8CharSorted      | Retrieve the index where is located a PUTF8Char in a sorted PUTF8Char array                       | 968  |
| FastFindQWordSorted          | Fast $O(\log(n))$ binary search of a 64-bit unsigned integer value in a sorted array              | 968  |
| FastFindUpperPUTF8CharSorted | Retrieve the index where is located a PUTF8Char in a sorted uppercase PUTF8Char array             | 968  |
| FastFindWordSorted           | Fast $O(\log(n))$ binary search of a 16 bit unsigned integer value in a sorted array              | 968  |
| FastLocateIntegerSorted      | Retrieve the index where to insert an integer value in a sorted integer array                     | 968  |
| FastLocatePUTF8CharSorted    | Retrieve the index where to insert a PUTF8Char in a sorted PUTF8Char array                        | 969  |
| FastLocatePUTF8CharSorted    | Retrieve the index where to insert a PUTF8Char in a sorted PUTF8Char array                        | 969  |

| Functions or procedures  | Description                                                                                                                      | Page |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------|------|
| FastLocateWordSorted     | Retrieve the index where to insert a word value in a sorted word array                                                           | 969  |
| FastSetString            | Equivalence to SetString(s,nil,len) function                                                                                     | 969  |
| FastSetStringCP          | Equivalence to SetString(s,nil,len) function with a specific code page                                                           | 969  |
| FileAgeToDateTime        | Get a file date and time, from its name                                                                                          | 969  |
| FileFromString           | Create a File from a string content                                                                                              | 969  |
| FileInfoByHandle         | Get low-level file information, in a cross-platform way                                                                          | 969  |
| FileIsSynLZ              | Returns TRUE if the supplied file name is a SynLZ compressed file, matching the Magic number as supplied to FileSynLZ() function | 969  |
| FileOpenSequentialRead   | Overloaded function optimized for one pass file reading                                                                          | 970  |
| FileSeek64               | FileSeek() overloaded function, working with huge files                                                                          | 970  |
| FileSetDateFrom          | Copy the date of one file to another                                                                                             | 970  |
| FileSize                 | Get a file size, from its name                                                                                                   | 970  |
| FileSize                 | Get a file size, from its handle                                                                                                 | 970  |
| FileStreamSequentialRead | Returns a TFileStream optimized for one pass file reading                                                                        | 970  |
| FileSynLZ                | Compress a file content using the SynLZ algorithm                                                                                | 970  |
| FileTimeToInt64          | Low-level wrapper to get the 64-bit value from a TFileTime                                                                       | 970  |
| FileTimeToUnixMSTime     | Low-level conversion of a Windows 64-bit TFileTime into a Unix time ms stamp                                                     | 970  |
| FileTimeToUnixTime       | Low-level conversion of a Windows 64-bit TFileTime into a Unix time seconds stamp                                                | 970  |
| FileUnSynLZ              | Uncompress a file previously compressed via FileSynLZ()                                                                          | 970  |
| FillIncreasing           | Fill some values with i,i+1,i+2...i+Count-1                                                                                      | 971  |
| FillRandom               | Fill some memory buffer with random values                                                                                       | 971  |
| FillZero                 | Fill all 20 bytes of this 160-bit buffer with zero                                                                               | 972  |
| FillZero                 | Fill all 32 bytes of this 384-bit buffer with zero                                                                               | 972  |
| FillZero                 | Fill a GUID with 0                                                                                                               | 972  |
| FillZero                 | Fill all entries of a supplied array of 64-bit integers with 0                                                                   | 972  |
| FillZero                 | Fill all 32 bytes of this 256-bit buffer with zero                                                                               | 972  |
| FillZero                 | Fill all 16 bytes of this 128-bit buffer with zero                                                                               | 972  |

| Functions or procedures      | Description                                                                                                       | Page |
|------------------------------|-------------------------------------------------------------------------------------------------------------------|------|
| FillZero                     | Fill all entries of a supplied array of RawUTF8 with ''                                                           | 972  |
| FillZero                     | Fill all bytes of this memory buffer with zeros, i.e. 'toto' -> #0#0#0#0                                          | 972  |
| FillZero                     | Fill all bytes of this UTF-8 string with zeros, i.e. 'toto' -> #0#0#0#0                                           | 972  |
| FillZero                     | Fill all bytes of the value's memory buffer with zeros, i.e. 'toto' -> #0#0#0#0                                   | 972  |
| FillZero                     | Fill all entries of a supplied array of 32-bit integers with 0                                                    | 972  |
| FillZero                     | Fill all bytes of a memory buffer with zero                                                                       | 972  |
| FillZero                     | Fill all 64 bytes of this 512-bit buffer with zero                                                                | 972  |
| FindAnsi                     | Return true if UpperValue (Ansi) is contained in A^ (Ansi)                                                        | 972  |
| FindCSVIndex                 | Return the index of a Value in a CSV string                                                                       | 972  |
| FindFiles                    | Search for matching file names                                                                                    | 972  |
| FindFilesDynArrayToFileNames | Convert a result list, as returned by FindFiles(), into an array of Files[].Name                                  | 972  |
| FindIniEntry                 | Find a Name= Value in a [Section] of a INI RawUTF8 Content                                                        | 972  |
| FindIniEntryFile             | Find a Name= Value in a [Section] of a .INI file                                                                  | 973  |
| FindIniEntryInteger          | Find a Name= numeric Value in a [Section] of a INI RawUTF8 Content and return it as an integer, or 0 if not found | 973  |
| FindIniNameValue             | Find the Value of UpperName in P, till end of current section                                                     | 973  |
| FindIniNameValueInteger      | Find the integer Value of UpperName in P, till end of current section                                             | 973  |
| FindNameValue                | Search for a value from its uppercased named entry                                                                | 973  |
| FindNameValue                | Search and returns a value from its uppercased named entry                                                        | 973  |
| FindNextUTF8WordBegin        | Points to the beginning of the next word stored in U                                                              | 973  |
| FindObjectEntry              | Retrieve a property value in a text-encoded class                                                                 | 973  |
| FindObjectEntryWithoutText   | Retrieve a filename property value in a text-encoded class                                                        | 974  |
| FindPropName                 | Return the index of Value in Values[], -1 if not found                                                            | 974  |
| FindPropName                 | Return the index of Value in Values[] using IdemPropNameU(), -1 if not found                                      | 974  |
| FindRawUTF8                  | Return the index of Value in Values[], -1 if not found                                                            | 974  |
| FindRawUTF8                  | Low-level efficient search of Value in Values[]                                                                   | 974  |
| FindRawUTF8                  | Return the index of Value in Values[], -1 if not found                                                            | 974  |

| Functions or procedures               | Description                                                                                   | Page |
|---------------------------------------|-----------------------------------------------------------------------------------------------|------|
| FindSectionFirstLine                  | Find the position of the [SEARCH] section in source                                           | 974  |
| FindSectionFirstLineW                 | Find the position of the [SEARCH] section in source                                           | 974  |
| FindShortStringListExact              | Fast search of an exact case-insensitive match of a RTTI's PShortString array                 | 974  |
| FindShortStringListTrimLowerCase      | Fast case-insensitive search of a left-trimmed lowercase match of a RTTI's PShortString array | 974  |
| FindShortStringListTrimLowerCaseExact | Fast case-sensitive search of a left-trimmed lowercase match of a RTTI's PShortString array   | 974  |
| FindUnicode                           | Return true if Upper (Unicode encoded) is contained in U^ (UTF-8 encoded)                     | 975  |
| FindUTF8                              | Return true if UpperValue (Ansi) is contained in U^ (UTF-8 encoded)                           | 975  |
| FindWinAnsiIniEntry                   | Find a Name= Value in a [Section] of a INI WinAnsi Content                                    | 975  |
| FloatStrCopy                          | Copy a floating-point text buffer with proper correction and validation                       | 975  |
| FloatToJSONNan                        | Recognize if the supplied text is NAN/INF/+INF/-INF, i.e. not a number                        | 975  |
| FloatToShortNan                       | Check if the supplied text is NAN/INF/+INF/-INF, i.e. not a number                            | 975  |
| FloatToStrNan                         | Check if the supplied text is NAN/INF/+INF/-INF, i.e. not a number                            | 975  |
| fnv32                                 | Simple FNV-1a hashing function                                                                | 975  |
| FormatBuffer                          | Fast Format() function replacement, tuned for direct memory buffer write                      | 975  |
| FormatShort                           | Fast Format() function replacement, for UTF-8 content stored in shortstring                   | 976  |
| FormatShort16                         | Fast Format() function replacement, for UTF-8 content stored in TShort16                      | 976  |
| FormatString                          | Fast Format() function replacement, tuned for small content                                   | 976  |
| FormatString                          | Fast Format() function replacement, tuned for small content                                   | 976  |
| FormatToShort                         | Fast Format() function replacement, for UTF-8 content stored in shortstring                   | 976  |
| FormatUTF8                            | Fast Format() function replacement, handling % and ? parameters                               | 977  |
| FormatUTF8                            | Fast Format() function replacement, optimized for RawUTF8                                     | 977  |
| FormatUTF8                            | Fast Format() function replacement, optimized for RawUTF8                                     | 977  |
| FormatUTF8ToVariant                   | Convert a FormatUTF8() UTF-8 encoded string into a variant RawUTF8 varString                  | 977  |
| FromI32                               | Initializes a dynamic array from a set of 32-bit integer signed values                        | 977  |

| Functions or procedures    | Description                                                                                                         | Page |
|----------------------------|---------------------------------------------------------------------------------------------------------------------|------|
| FromI64                    | Initializes a dynamic array from a set of 64-bit integer signed values                                              | 977  |
| FromU32                    | Initializes a dynamic array from a set of 32-bit integer unsigned values                                            | 977  |
| FromU64                    | Initializes a dynamic array from a set of 64-bit integer unsigned values                                            | 977  |
| FromVarBlob                | Retrieve pointer and length to a variable-length text/blob buffer                                                   | 977  |
| FromVarInt32               | Convert a 32-bit variable-length integer buffer into an integer                                                     | 977  |
| FromVarInt64               | Convert a 64-bit variable-length integer buffer into a Int64                                                        | 977  |
| FromVarInt64Value          | Convert a 64-bit variable-length integer buffer into a Int64                                                        | 977  |
| FromVarString              | Retrieve a variable-length UTF-8 encoded text buffer in a temporary buffer                                          | 978  |
| FromVarString              | Retrieve a variable-length UTF-8 encoded text buffer in a temporary buffer                                          | 978  |
| FromVarString              | Retrieve a variable-length text buffer                                                                              | 978  |
| FromVarString              | Safe retrieve a variable-length UTF-8 encoded text buffer in a newly allocation RawUTF8                             | 978  |
| FromVarString              | Retrieve a variable-length UTF-8 encoded text buffer in a newly allocation RawUTF8                                  | 978  |
| FromVarString              | Retrieve a variable-length text buffer                                                                              | 978  |
| FromVarUInt32              | Convert a 32-bit variable-length integer buffer into a cardinal                                                     | 978  |
| FromVarUInt32              | Convert a 32-bit variable-length integer buffer into a cardinal                                                     | 978  |
| FromVarUInt32Big           | Convert a 32-bit variable-length integer buffer into a cardinal                                                     | 978  |
| FromVarUInt32High          | Convert a 32-bit variable-length integer buffer into a cardinal                                                     | 978  |
| FromVarUInt32Safe          | Safely convert a 32-bit variable-length integer buffer into a cardinal                                              | 978  |
| FromVarUInt32Up128         | Convert a 32-bit variable-length integer buffer into a cardinal                                                     | 979  |
| FromVarUInt64              | Convert a 64-bit variable-length integer buffer into a UInt64                                                       | 979  |
| FromVarUInt64              | Convert a 64-bit variable-length integer buffer into a UInt64                                                       | 979  |
| FromVarUInt64Safe          | Safely convert a 64-bit variable-length integer buffer into a UInt64                                                | 979  |
| FromVarVariant             | Retrieve a variant value from variable-length buffer                                                                | 979  |
| GarbageCollectorFree       | Force the global "Garbage collector" list to be released immediately                                                | 979  |
| GarbageCollectorFreeAndNil | A global "Garbage collector" for some TObject global variables which must live during whole main executable process | 979  |

| Functions or procedures  | Description                                                                                     | Page |
|--------------------------|-------------------------------------------------------------------------------------------------|------|
| gcd                      | Compute GCD of two integers using subtraction-based Euclidean algorithm                         | 979  |
| GetAllBits               | Returns TRUE if all BitCount bits are set in the input 32-bit cardinal                          | 980  |
| GetBit                   | Retrieve a particular bit status from a bit array                                               | 980  |
| GetBit64                 | Retrieve a particular bit status from a 64-bit integer bits (max alndex is 63)                  | 980  |
| GetBitCSV                | Convert a set of bit into a CSV content                                                         | 980  |
| GetBitPtr                | Retrieve a particular bit status from a bit array                                               | 980  |
| GetBitsCount             | Compute the number of bits set in a bit array                                                   | 980  |
| GetBitsCountPas          | Pure pascal version of GetBitsCountPtrInt()                                                     | 980  |
| GetBitsCountSSE42        | SSE 4.2 version of GetBitsCountPtrInt()                                                         | 980  |
| GetBoolean               | Get a boolean value stored as true/false text in P^                                             | 980  |
| GetCaptionFromClass      | UnCamelCase and translate the class name, trimming any left 'T', 'TSyn', 'TSQL' or 'TSQLRecord' | 980  |
| GetCaptionFromEnum       | UnCamelCase and translate the enumeration item                                                  | 980  |
| GetCaptionFromPCharLen   | UnCamelCase and translate a char buffer                                                         | 980  |
| GetCaptionFromTrimmed    | Low-level helper to retrieve a (translated) caption from a PShortString                         | 980  |
| GetCardinal              | Get the unsigned 32-bit integer value stored in P^                                              | 981  |
| GetCardinalDef           | Get the unsigned 32-bit integer value stored in P^                                              | 981  |
| GetCardinalW             | Get the unsigned 32-bit integer value stored as Unicode string in P^                            | 981  |
| GetClassParent           | Just a wrapper around vmtParent to avoid a function call                                        | 981  |
| GetCSVItem               | Return n-th indexed CSV string in P, starting at Index=0 for first one                          | 981  |
| GetCSVItemString         | Return n-th indexed CSV string in P, starting at Index=0 for first one                          | 981  |
| GetDelphiCompilerVersion | Return the Delphi/FPC Compiler Version                                                          | 981  |
| GetDisplayNameFromClass  | Will get a class name as UTF-8                                                                  | 981  |
| GetEnumCaptions          | Helper to retrieve all (translated) caption texts of an enumerate                               | 981  |
| GetEnumName              | Helper to retrieve the text of an enumerate item                                                | 981  |
| GetEnumNames             | Helper to retrieve all texts of an enumerate                                                    | 981  |
| GetEnumNameValue         | Helper to retrieve the index of an enumerate item from its text                                 | 982  |

| Functions or procedures      | Description                                                                                       | Page |
|------------------------------|---------------------------------------------------------------------------------------------------|------|
| GetEnumNameValue             | Helper to retrieve the index of an enumerate item from its text                                   | 982  |
| GetEnumNameValueTrimmed      | Retrieve the index of an enumerate item from its left-trimmed text                                | 982  |
| GetEnumNameValueTrimmedExact | Retrieve the index of an enumerate item from its left-trimmed text                                | 982  |
| GetEnumTrimmedNames          | Helper to retrieve all trimmed texts of an enumerate as UTF-8 strings                             | 982  |
| GetEnumTrimmedNames          | Helper to retrieve all trimmed texts of an enumerate                                              | 982  |
| GetExtended                  | Get the extended floating point value stored in P^                                                | 982  |
| GetExtended                  | Get the extended floating point value stored in P^                                                | 982  |
| GetFileNameExtIndex          | Extract a file extension from a file name, then compare with a comma separated list of extensions | 982  |
| GetFileNameWithoutExt        | Compute the file name, including its path if supplied, but without its extension                  | 982  |
| GetHighUTF8UCS4              | Internal function, used to retrieve a UCS4 char (>127) from UTF-8                                 | 983  |
| GetInt64                     | Get the 64-bit integer value stored in P^                                                         | 983  |
| GetInt64                     | Get the 64-bit signed integer value stored in P^                                                  | 983  |
| GetInt64Def                  | Get the 64-bit integer value stored in P^                                                         | 983  |
| GetInteger                   | Get the signed 32-bit integer value stored in P^                                                  | 983  |
| GetInteger                   | Get the signed 32-bit integer value stored in P^..PEnd^                                           | 983  |
| GetInteger                   | Get the signed 32-bit integer value stored in P^                                                  | 983  |
| GetIntegerDef                | Get the signed 32-bit integer value stored in P^                                                  | 983  |
| GetJpegSize                  | Fast guess of the size, in pixels, of a JPEG file                                                 | 984  |
| GetJpegSize                  | Fast guess of the size, in pixels, of a JPEG memory buffer                                        | 984  |
| GetJSONField                 | Efficient JSON field in-place decoding, within a UTF-8 encoded buffer                             | 984  |
| GetJSONFieldOrObjectOrArray  | Decode a JSON content in an UTF-8 encoded buffer                                                  | 984  |
| GetJSONItemAsRawJSON         | Retrieve the next JSON item as a RawJSON variable                                                 | 984  |
| GetJSONItemAsRawUTF8         | Retrieve the next JSON item as a RawUTF8 decoded buffer                                           | 985  |
| GetJSONPropName              | Decode a JSON field name in an UTF-8 encoded buffer                                               | 985  |
| GetJSONPropName              | Decode a JSON field name in an UTF-8 encoded shortstring variable                                 | 985  |
| GetLastCSVItem               | Return last CSV string in the supplied UTF-8 content                                              | 985  |

| Functions or procedures          | Description                                                                                     | Page |
|----------------------------------|-------------------------------------------------------------------------------------------------|------|
| GetLineContains                  | Returns TRUE if the supplied uppercased text is contained in the text buffer                    | 985  |
| GetLineSize                      | Compute the line length from source array of chars                                              | 985  |
| GetLineSizeSmallerThan           | Returns true if the line length from source array of chars is not less than the specified count | 985  |
| GetMemAligned                    | Initialize a RawByteString, ensuring returned "aligned" pointer is 16-bytes aligned             | 985  |
| GetMimeTypeContentType           | Retrieve the MIME content type from its file name or a supplied binary buffer                   | 986  |
| GetMimeTypeContentTypeFromBuffer | Retrieve the MIME content type from a supplied binary buffer                                    | 986  |
| GetMimeTypeContentTypeHeader     | Retrieve the HTTP header for MIME content type from a supplied binary buffer                    | 986  |
| GetNextFieldProp                 | Retrieve the next SQL-like identifier within the UTF-8 buffer                                   | 986  |
| GetNextFieldPropSameLine         | Retrieve the next identifier within the UTF-8 buffer on the same line                           | 986  |
| GetNextItem                      | Return next CSV string from P                                                                   | 986  |
| GetNextItem                      | Return next CSV string from P                                                                   | 986  |
| GetNextItem                      | Return next CSV string (unquoted if needed) from P                                              | 986  |
| GetNextItemCardinal              | Return next CSV string as unsigned integer from P, 0 if no more                                 | 986  |
| GetNextItemCardinalStrict        | Return next CSV string as unsigned integer from P, 0 if no more                                 | 987  |
| GetNextItemCardinalW             | Return next CSV string as unsigned integer from P, 0 if no more                                 | 987  |
| GetNextItemCurrency              | Return next CSV string as currency from P, 0.0 if no more                                       | 987  |
| GetNextItemCurrency              | Return next CSV string as currency from P, 0.0 if no more                                       | 987  |
| GetNextItemDouble                | Return next CSV string as double from P, 0.0 if no more                                         | 987  |
| GetNextItemHexa                  | Return next CSV hexadecimal string as 64-bit unsigned integer from P                            | 987  |
| GetNextItemHexDisplayToBin       | Decode next CSV hexadecimal string from P, nil if no more or not matching BinBytes              | 987  |
| GetNextItemInt64                 | Return next CSV string as 64-bit signed integer from P, 0 if no more                            | 987  |
| GetNextItemInteger               | Return next CSV string as signed integer from P, 0 if no more                                   | 987  |
| GetNextItemQWord                 | Return next CSV string as 64-bit unsigned integer from P, 0 if no more                          | 987  |
| GetNextItemShortString           | Return next CSV string from P, nil if no more                                                   | 987  |

| Functions or procedures       | Description                                                                                            | Page |
|-------------------------------|--------------------------------------------------------------------------------------------------------|------|
| GetNextItemString             | Return next CSV string from P, nil if no more                                                          | 988  |
| GetNextItemToVariant          | Convert the next CSV item from an UTF-8 encoded text buffer into a variant number or RawUTF8 varString | 988  |
| GetNextItemTrimed             | Return trimmed next CSV string from P                                                                  | 988  |
| GetNextItemTrimedCRLF         | Return next CRLF separated value string from P, ending #10 or #13#10 trimmed                           | 988  |
| GetNextLine                   | Extract a line from source array of chars                                                              | 988  |
| GetNextStringLineToRawUnicode | Return next string delimited with #13#10 from P, nil if no more                                        | 988  |
| GetNextTChar64                | Return next CSV string from P as a #0-ended buffer, false if no more                                   | 988  |
| GetNextUTF8Upper              | Retrieve the next UCS4 value stored in U, then update the U pointer                                    | 988  |
| GetNumericVariantFromJSON     | Low-level function to set a numerical variant from an unescaped JSON number                            | 988  |
| GetPublishedMethods           | Retrieve published methods information about any class instance                                        | 989  |
| GetQWord                      | Get the 64-bit unsigned integer value stored in P^                                                     | 989  |
| GetSectionContent             | Retrieve the whole content of a section as a string                                                    | 989  |
| GetSectionContent             | Retrieve the whole content of a section as a string                                                    | 989  |
| GetSetBaseEnum                | Low-level helper to retrieve the base enumeration RTTI of a given set                                  | 989  |
| GetSetName                    | Helper to retrieve the CSV text of all enumerate items defined in a set                                | 989  |
| GetSetNameShort               | Helper to retrieve the CSV text of all enumerate items defined in a set                                | 989  |
| GetSetNameValue               | Helper to retrieve the bit mapped integer value of a set from its JSON text                            | 989  |
| GetSystemPath                 | Returns an operating system folder                                                                     | 989  |
| GetUnQuoteCSVItem             | Return n-th indexed CSV string (unquoted if needed) in P, starting at Index=0 for first one            | 989  |
| GetUTF8Char                   | Get the WideChar stored in P^ (decode UTF-8 if necessary)                                              | 990  |
| GetVariantFromJSON            | Low-level function to set a variant from an unescaped JSON number or string                            | 990  |
| GetVariantFromNotStringJSON   | Low-level function to set a variant from an unescaped JSON non string                                  | 990  |
| GlobalLock                    | Enter a giant lock for thread-safe shared process                                                      | 990  |
| GlobalUnlock                  | Release the giant lock for thread-safe shared process                                                  | 990  |

| Functions or procedures      | Description                                                                  | Page |
|------------------------------|------------------------------------------------------------------------------|------|
| GotoEndJSONItem              | Reach position just after the current JSON item in the supplied UTF-8 buffer | 990  |
| GotoEndOfJSONString          | Get the next character after a quoted buffer                                 | 991  |
| GotoEndOfQuotedString        | Get the next character after a quoted buffer                                 | 991  |
| GotoNextJSONItem             | Reach the position of the next JSON item in the supplied UTF-8 buffer        | 991  |
| GotoNextJSONObjectOrArray    | Reach the position of the next JSON object of JSON array                     | 991  |
| GotoNextJSONObjectOrArray    | Reach the position of the next JSON object of JSON array                     | 991  |
| GotoNextJSONObjectOrArrayMax | Reach the position of the next JSON object of JSON array                     | 991  |
| GotoNextJSONPropName         | Read the position of the JSON value just after a property identifier         | 991  |
| GotoNextLine                 | Fast go to next text line, ended by #13 or #13#10                            | 991  |
| GotoNextNotSpace             | Get the next character not in [#1..' ']                                      | 991  |
| GotoNextNotSpaceSameLine     | Get the next character not in [#9,' ']                                       | 992  |
| GotoNextSpace                | Get the next character in [#1..' ']                                          | 992  |
| GotoNextVarInt               | Jump a value in the 32-bit or 64-bit variable-length integer buffer          | 992  |
| GotoNextVarString            | Jump a value in variable-length text buffer                                  | 992  |
| GUIDToRawUTF8                | Convert a TGUID into UTF-8 encoded text                                      | 992  |
| GUIDToShort                  | Convert a TGUID into text                                                    | 992  |
| GUIDToShort                  | Convert a TGUID into text                                                    | 992  |
| GUIDToString                 | Convert a TGUID into text                                                    | 992  |
| GUIDToText                   | Append a TGUID binary content as text                                        | 992  |
| Hash128                      | Hash one THash128 value with the supplied Hasher() function                  | 992  |
| Hash128Index                 | Fast O(n) search of a 128-bit item in an array of such values                | 992  |
| Hash256                      | Hash one THash256 value with the supplied Hasher() function                  | 992  |
| Hash256Index                 | Fast O(n) search of a 256-bit item in an array of such values                | 992  |
| Hash32                       | Our custom efficient 32-bit hash/checksum function                           | 993  |
| Hash32                       | Our custom efficient 32-bit hash/checksum function                           | 993  |
| Hash512                      | Hash one THash512 value with the supplied Hasher() function                  | 993  |
| HashAnsiString               | Hash one AnsiString content with the supplied Hasher() function              | 993  |

| Functions or procedures | Description                                                                                             | Page |
|-------------------------|---------------------------------------------------------------------------------------------------------|------|
| HashAnsiStringI         | Case-insensitive hash one AnsiString content with the supplied Hasher() function                        | 993  |
| HashByte                | Hash one Byte value                                                                                     | 993  |
| HashFile                | Compute the 32-bit default hash of a file content                                                       | 993  |
| HashInt64               | Hash one Int64/Qword value with the supplied Hasher() function                                          | 993  |
| HashInteger             | Hash one Integer/cardinal value - simply return the value ignore Hasher() parameter                     | 993  |
| HashPointer             | Hash one pointer value with the supplied Hasher() function                                              | 993  |
| HashPtrUInt             | Hash one PtrUInt (=NativeUInt) value with the supplied Hasher() function                                | 993  |
| HashSynUnicode          | Hash one SynUnicode content with the supplied Hasher() function                                         | 993  |
| HashSynUnicodeI         | Case-insensitive hash one SynUnicode content with the supplied Hasher() function                        | 994  |
| HashVariant             | Case-sensitive hash one variant content with the supplied Hasher() function                             | 994  |
| HashVariantI            | Case-insensitive hash one variant content with the supplied Hasher() function                           | 994  |
| HashWideString          | Hash one WideString content with the supplied Hasher() function                                         | 994  |
| HashWideStringI         | Case-insensitive hash one WideString content with the supplied Hasher() function                        | 994  |
| HashWord                | Hash one Word value                                                                                     | 994  |
| HexDisplayToBin         | Fast conversion from hexa chars into a binary buffer                                                    | 994  |
| HexDisplayToCardinal    | Fast conversion from hexa chars into a cardinal                                                         | 994  |
| HexDisplayToInt64       | Fast conversion from hexa chars into a cardinal                                                         | 994  |
| HexDisplayToInt64       | Inline gives an error under release conditions with FPC fast conversion from hexa chars into a cardinal | 994  |
| HexToBin                | Fast conversion from hexa chars into binary data                                                        | 994  |
| HexToBin                | Fast conversion from hexa chars into binary data                                                        | 994  |
| HexToBinFast            | Fast conversion with no validity check from hexa chars into binary data                                 | 995  |
| HexToChar               | Fast conversion from one hexa char pair into a 8 bit AnsiChar                                           | 995  |
| HexToCharValid          | Fast conversion from one hexa char pair into a 8 bit AnsiChar                                           | 995  |
| HexToWideChar           | Fast conversion from two hexa bytes into a 16 bit UTF-16 WideChar                                       | 995  |

| Functions or procedures                   | Description                                                                            | Page |
|-------------------------------------------|----------------------------------------------------------------------------------------|------|
| IdemFileExt                               | Returns true if the file name extension contained in p^ is the same same as extup^     | 995  |
| IdemFileExts                              | Returns matching file name extension index as extup^                                   | 995  |
| IdemPChar                                 | Returns true if the beginning of p^ is the same as up^                                 | 995  |
| IdemPCharAndGetNextItem                   | Return true if IdemPChar(source,searchUp), and retrieve the value item                 | 995  |
| IdemPCharAndGetNextLine                   | Return true if IdemPChar(source,searchUp), and go to the next line of source           | 995  |
| IdemPCharArray                            | Returns the index of a matching beginning of p^ in upArray[]                           | 996  |
| IdemPCharArray                            | Returns the index of a matching beginning of p^ in upArray two characters              | 996  |
| IdemPCharU                                | Returns true if the beginning of p^ is the same as up^                                 | 996  |
| IdemPCharW                                | Returns true if the beginning of p^ is same as up^                                     | 996  |
| IdemPCharWithoutWhite Space               | Returns true if the beginning of p^ is the same as up^, ignoring white spaces          | 996  |
| IdemPropName                              | Case insensitive comparison of ASCII identifiers                                       | 996  |
| IdemPropName                              | Case insensitive comparison of ASCII identifiers                                       | 996  |
| IdemPropName                              | Case insensitive comparison of ASCII identifiers                                       | 996  |
| IdemPropNameU                             | Case insensitive comparison of ASCII identifiers                                       | 997  |
| IdemPropNameU                             | Case insensitive comparison of ASCII identifiers                                       | 997  |
| IdemPropNameUSameLen                      | Case insensitive comparison of ASCII identifiers of same length                        | 997  |
| IncludeInt64                              | Ensure some 64-bit integer from Values[] will only contain Included[]                  | 997  |
| IncludeInteger                            | Ensure some 32-bit integer from Values[] will only contain Included[]                  | 997  |
| IncludeTrailingURIDelimiter               | Ensure the supplied URI contains a trailing '/' charater                               | 997  |
| InitializeCriticalSectionIfNeededAndEnter | On need initialization of a mutex, then enter the lock                                 | 997  |
| InsertInteger                             | Insert an integer value at the specified index position of a dynamic array of integers | 997  |
| Int18ToChars3                             | Compute the value as encoded by TTextWriter.AddInt18ToChars3() method                  | 997  |
| Int18ToChars3                             | Compute the value as encoded by TTextWriter.AddInt18ToChars3() method                  | 997  |
| Int32ToUTF8                               | Use our fast RawUTF8 version of IntToStr()                                             | 998  |

| Functions or procedures | Description                                                               | Page |
|-------------------------|---------------------------------------------------------------------------|------|
| Int32ToUtf8             | Use our fast RawUTF8 version of IntToStr()                                | 998  |
| Int64DynArrayToCSV      | Return the corresponding CSV text from a dynamic array of 64-bit integers | 998  |
| Int64DynArrayToCSV      | Return the corresponding CSV text from a dynamic array of 64-bit integers | 998  |
| Int64Scan               | Fast search of an integer position in a 64-bit integer array              | 998  |
| Int64ScanExists         | Fast search of an integer value in a 64-bit integer array                 | 998  |
| Int64ScanIndex          | Fast search of an integer position in a signed 64-bit integer array       | 998  |
| Int64ToHex              | Fast conversion from a Int64 value into hexa chars, ready to be displayed | 998  |
| Int64ToHex              | Fast conversion from a Int64 value into hexa chars, ready to be displayed | 998  |
| Int64ToHexShort         | Fast conversion from a Int64 value into hexa chars, ready to be displayed | 998  |
| Int64ToHexShort         | Fast conversion from a Int64 value into hexa chars, ready to be displayed | 998  |
| Int64ToHexString        | Fast conversion from a Int64 value into hexa chars, ready to be displayed | 999  |
| Int64ToUInt32           | Copy some Int64 values into an unsigned integer array                     | 999  |
| Int64ToUtf8             | Use our fast RawUTF8 version of IntToStr()                                | 999  |
| Int64ToUtf8             | Use our fast RawUTF8 version of IntToStr()                                | 999  |
| IntegerDynArrayLoadFrom | Wrap an Integer dynamic array BLOB content as stored by TDynArray.SaveTo  | 999  |
| IntegerDynArrayToCSV    | Return the corresponding CSV text from a dynamic array of 32-bit integer  | 999  |
| IntegerDynArrayToCSV    | Return the corresponding CSV text from a dynamic array of 32-bit integer  | 999  |
| IntegerScan             | Fast search of an unsigned integer position in an integer array           | 999  |
| IntegerScanExists       | Fast search of an unsigned integer in an integer array                    | 999  |
| IntegerScanIndex        | Fast search of an unsigned integer position in an integer array           | 1000 |
| InterfaceArrayAdd       | Wrapper to add an item to a T*InterfaceArray dynamic array storage        | 1000 |
| InterfaceArrayAddOnce   | Wrapper to add once an item to a T*InterfaceArray dynamic array storage   | 1000 |
| InterfaceArrayDelete    | Wrapper to delete an item in a T*InterfaceArray dynamic array storage     | 1000 |

| Functions or procedures   | Description                                                                    | Page |
|---------------------------|--------------------------------------------------------------------------------|------|
| InterfaceArrayDelete      | Wrapper to delete an item in a T*InterfaceArray dynamic array storage          | 1000 |
| InterfaceArrayFind        | Wrapper to search an item in a T*InterfaceArray dynamic array storage          | 1000 |
| InterlockedDecrement      | Compatibility function, to be implemented according to the running CPU         | 1000 |
| InterlockedIncrement      | Compatibility function, to be implemented according to the running CPU         | 1000 |
| IntervalTextToDateTime    | Interval date/time conversion from simple text                                 | 1000 |
| IntervalTextToDateTimeVar | Interval date/time conversion from simple text                                 | 1000 |
| IntToString               | Faster version than default SysUtils.IntToStr implementation                   | 1001 |
| IntToString               | Faster version than default SysUtils.IntToStr implementation                   | 1001 |
| IntToString               | Faster version than default SysUtils.IntToStr implementation                   | 1001 |
| IntToThousandString       | Convert an integer value into its textual representation with thousands marked | 1001 |
| IP4Text                   | Convert a 32-bit integer (storing a IP4 address) into its full notation        | 1001 |
| IP6Text                   | Convert a 128-bit buffer (storing an IP6 address) into its full notation       | 1001 |
| IP6Text                   | Convert a 128-bit buffer (storing an IP6 address) into its full notation       | 1001 |
| IsAnsiCompatible          | Return TRUE if the supplied buffer only contains 7-bits Ansi characters        | 1001 |
| IsAnsiCompatible          | Return TRUE if the supplied text only contains 7-bits Ansi characters          | 1001 |
| IsAnsiCompatible          | Return TRUE if the supplied buffer only contains 7-bits Ansi characters        | 1001 |
| IsAnsiCompatibleW         | Return TRUE if the supplied UTF-16 buffer only contains 7-bits Ansi characters | 1001 |
| IsAnsiCompatibleW         | Return TRUE if the supplied UTF-16 buffer only contains 7-bits Ansi characters | 1001 |
| IsBase64                  | Check if the supplied text is a valid Base64 encoded stream                    | 1001 |
| IsBase64                  | Check if the supplied text is a valid Base64 encoded stream                    | 1001 |
| IsCaseSensitive           | Check if the supplied text has some case-insensitive 'a'..'z','A'..'Z' chars   | 1001 |
| IsCaseSensitive           | Check if the supplied text has some case-insensitive 'a'..'z','A'..'Z' chars   | 1001 |
| IsContentCompressed       | Retrieve if some content is compressed, from a supplied binary buffer          | 1002 |
| IsDirectoryWritable       | Check if the directory is writable for the current user                        | 1002 |
| IsEqual                   | Returns TRUE if all bytes of both buffers do match                             | 1002 |

| Functions or procedures       | Description                                                                                                                                      | Page |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|------|
| IsEqual                       | Returns TRUE if all 20 bytes of both 160-bit buffers do match                                                                                    | 1002 |
| IsEqual                       | Returns TRUE if all 16 bytes of both 128-bit buffers do match                                                                                    | 1002 |
| IsEqual                       | Returns TRUE if all 48 bytes of both 384-bit buffers do match                                                                                    | 1002 |
| IsEqual                       | Returns TRUE if all 32 bytes of both 256-bit buffers do match                                                                                    | 1002 |
| IsEqual                       | Returns TRUE if all 64 bytes of both 512-bit buffers do match                                                                                    | 1002 |
| IsEqualGUID                   | Compare two TGUID values                                                                                                                         | 1002 |
| IsEqualGUID                   | Compare two TGUID values                                                                                                                         | 1002 |
| IsEqualGUIDArray              | Returns the index of a matching TGUID in an array                                                                                                | 1002 |
| IsFixedWidthCodePage          | Check if a codepage should be handled by a TSynAnsiFixedWidth page                                                                               | 1003 |
| IsHex                         | Fast check if the supplied Hex buffer is an hexadecimal representation of a binary buffer of a given number of bytes                             | 1003 |
| IsHTMLContentTypeTextual      | Returns TRUE if the supplied HTML Headers contains 'Content-Type: text/...', 'Content-Type: application/json' or 'Content-Type: application/xml' | 1003 |
| IsInitializedCriticalSection  | Returns TRUE if the supplied mutex has been initialized                                                                                          | 1003 |
| IsIso8601                     | Test if P^ contains a valid ISO-8601 text encoded value                                                                                          | 1003 |
| IsLeapYear                    | Our own fast version of the corresponding low-level RTL function                                                                                 | 1003 |
| IsNullGUID                    | Check if a TGUID value contains only 0 bytes                                                                                                     | 1003 |
| Iso8601CheckAndDecode         | Date/Time conversion from strict ISO-8601 content                                                                                                | 1003 |
| Iso8601ToDatePUTF8Char        | Date conversion from ISO-8601 (with no Time part)                                                                                                | 1003 |
| Iso8601ToDateTime             | Date/Time conversion from ISO-8601                                                                                                               | 1003 |
| Iso8601ToDateTimePUTF8Char    | Date/Time conversion from ISO-8601                                                                                                               | 1003 |
| Iso8601ToDateTimePUTF8CharVar | Date/Time conversion from ISO-8601                                                                                                               | 1004 |
| Iso8601ToTimeLog              | Convert a Iso8601 encoded string into a TTimeLog value                                                                                           | 1004 |
| Iso8601ToTimeLogPUTF8Char     | Convert a Iso8601 encoded string into a TTimeLog value                                                                                           | 1004 |
| Iso8601ToTimePUTF8Char        | Time conversion from ISO-8601 (with no Date part)                                                                                                | 1004 |
| Iso8601ToTimePUTF8Char        | Time conversion from ISO-8601 (with no Date part)                                                                                                | 1004 |

| Functions or procedures        | Description                                                                                                                          | Page |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|------|
| Iso8601ToTimePUTF8CharVar      | Time conversion from ISO-8601 (with no Date part)                                                                                    | 1004 |
| IsRawUTF8DynArray              | Check if the TypeInfo() points to an "array of RawUTF8"                                                                              | 1004 |
| IsRowID                        | Returns TRUE if the specified field name is either 'ID', either 'ROWID'                                                              | 1004 |
| IsRowID                        | Returns TRUE if the specified field name is either 'ID', either 'ROWID'                                                              | 1004 |
| IsRowIDShort                   | Returns TRUE if the specified field name is either 'ID', either 'ROWID'                                                              | 1005 |
| isSelect                       | Return true if the parameter is void or begin with a 'SELECT' SQL statement                                                          | 1005 |
| IsString                       | Test if the supplied buffer is a "string" value or a numerical value (floating point or integer), according to the characters within | 1005 |
| IsStringJSON                   | Test if the supplied buffer is a "string" value or a numerical value (floating or integer), according to the JSON encoding schema    | 1005 |
| IsUrlValid                     | Checks if the supplied UTF-8 text don't need URI encoding                                                                            | 1005 |
| IsValidJSON                    | Test if the supplied buffer is a correct JSON value                                                                                  | 1005 |
| IsValidJSON                    | Test if the supplied buffer is a correct JSON value                                                                                  | 1005 |
| IsValidUTF8WithoutControlChars | Returns TRUE if the supplied buffer has valid UTF-8 encoding with no #1..#31 control characters                                      | 1005 |
| IsValidUTF8WithoutControlChars | Returns TRUE if the supplied buffer has valid UTF-8 encoding with no #0..#31 control characters                                      | 1005 |
| IsVoid                         | Check all character within text are spaces or control chars                                                                          | 1005 |
| IsWinAnsi                      | Return TRUE if the supplied unicode buffer only contains WinAnsi characters                                                          | 1006 |
| IsWinAnsi                      | Return TRUE if the supplied unicode buffer only contains WinAnsi characters                                                          | 1006 |
| IsWinAnsiU                     | Return TRUE if the supplied UTF-8 buffer only contains WinAnsi characters                                                            | 1006 |
| IsWinAnsiU8Bit                 | Return TRUE if the supplied UTF-8 buffer only contains WinAnsi 8 bit characters                                                      | 1006 |
| IsZero                         | Returns TRUE if all 20 bytes of this 160-bit buffer equal zero                                                                       | 1006 |
| IsZero                         | Returns TRUE if all 32 bytes of this 256-bit buffer equal zero                                                                       | 1006 |
| IsZero                         | Returns TRUE if Value is nil or all supplied Values[] equal 0                                                                        | 1006 |
| IsZero                         | Returns TRUE if all 16 bytes of this 128-bit buffer equal zero                                                                       | 1006 |
| IsZero                         | Returns TRUE if all bytes equal zero                                                                                                 | 1006 |
| IsZero                         | Returns TRUE if Value is nil or all supplied Values[] equal "                                                                        | 1006 |

| Functions or procedures  | Description                                                                                         | Page |
|--------------------------|-----------------------------------------------------------------------------------------------------|------|
| IsZero                   | Returns TRUE if Value is nil or all supplied Values[] equal 0                                       | 1006 |
| IsZero                   | Returns TRUE if all 64 bytes of this 512-bit buffer equal zero                                      | 1006 |
| IsZero                   | Returns TRUE if all 48 bytes of this 384-bit buffer equal zero                                      | 1006 |
| IsZeroSmall              | Returns TRUE if all of a few bytes equal zero                                                       | 1006 |
| JSONArrayCount           | Compute the number of elements of a JSON array                                                      | 1007 |
| JSONArrayCount           | Compute the number of elements of a JSON array                                                      | 1007 |
| JSONArrayDecode          | Retrieve all elements of a JSON array                                                               | 1007 |
| JSONArrayItem            | Go to the #nth item of a JSON array                                                                 | 1007 |
| JSONBufferReformat       | Formats and indents a JSON array or document to the specified layout                                | 1007 |
| JSONBufferReformatToFile | Formats and indents a JSON array or document as a file                                              | 1007 |
| JSONBufferToXML          | Convert a JSON array or document into a simple XML content                                          | 1007 |
| JSONDecode               | Decode the supplied UTF-8 JSON content for the supplied names                                       | 1009 |
| JSONDecode               | Decode the supplied UTF-8 JSON content for the supplied names                                       | 1009 |
| JSONDecode               | Decode the supplied UTF-8 JSON content into an array of name/value pairs                            | 1009 |
| JSONDecode               | Decode the supplied UTF-8 JSON content for the supplied names                                       | 1009 |
| JSONDecode               | Decode the supplied UTF-8 JSON content for the one supplied name                                    | 1009 |
| JSONEncode               | Encode the supplied (extended) JSON content, with parameters, as an UTF-8 valid JSON object content | 1009 |
| JSONEncode               | Encode the supplied data as an UTF-8 valid JSON object content                                      | 1009 |
| JSONEncodeArrayDouble    | Encode the supplied floating-point array data as a valid JSON array                                 | 1009 |
| JSONEncodeArrayInteger   | Encode the supplied integer array data as a valid JSON array                                        | 1010 |
| JSONEncodeArrayOfConst   | Encode the supplied array data as a valid JSON array content                                        | 1010 |
| JSONEncodeArrayOfConst   | Encode the supplied array data as a valid JSON array content                                        | 1010 |
| JSONEncodeArrayUTF8      | Encode the supplied RawUTF8 array data as an UTF-8 valid JSON array content                         | 1010 |
| JSONEncodeNameSQLValue   | Encode as JSON {"name":value} object, from a potential SQL quoted value                             | 1010 |
| JSONObjectAsJSONArrays   | Convert one JSON object into two JSON arrays of keys and values                                     | 1010 |

| Functions or procedures | Description                                                                                            | Page |
|-------------------------|--------------------------------------------------------------------------------------------------------|------|
| JsonObjectByPath        | Go to a property of a JSON object, by its full path, e.g. 'parent.child'                               | 1010 |
| JsonObjectItem          | Go to a named property of a JSON object                                                                | 1010 |
| JSONObjectPropCount     | Compute the number of fields in a JSON object                                                          | 1011 |
| JsonObjectsByPath       | Return all matching properties of a JSON object                                                        | 1011 |
| JsonPropNameValid       | Returns TRUE if the given text buffer contains simple characters as recognized by JSON extended syntax | 1011 |
| JSONReformat            | Formats and indents a JSON array or document to the specified layout                                   | 1011 |
| JSONReformatToFile      | Formats and indents a JSON array or document as a file                                                 | 1011 |
| JSONRetrieveStringField | Retrieve a pointer to JSON string field content                                                        | 1011 |
| JSONToVariant           | Retrieve a variant value from a JSON UTF-8 text as per RFC 8259, RFC 7159, RFC 7158                    | 1011 |
| JSONToVariantDynArray   | Convert a JSON array into a dynamic array of variants                                                  | 1012 |
| JSONToVariantInPlace    | Retrieve a variant value from a JSON buffer as per RFC 8259, RFC 7159, RFC 7158                        | 1012 |
| JSONToXML               | Convert a JSON array or document into a simple XML content                                             | 1012 |
| KahanSum                | Compute the sum of values, using a running compensation for lost low-order bits                        | 1012 |
| KB                      | Delphi 2007 is buggy as hell convert a size to a human readable value                                  | 1012 |
| KB                      | Convert a size to a human readable value power-of-two metric value                                     | 1012 |
| KB                      | Convert a size to a human readable value                                                               | 1012 |
| KB                      | Delphi 2007 is buggy as hell convert a string size to a human readable value                           | 1012 |
| KBNoSpace               | Delphi 2007 is buggy as hell convert a size to a human readable value                                  | 1013 |
| KBU                     | Convert a size to a human readable value                                                               | 1013 |
| kr32                    | Standard Kernighan & Ritchie hash from "The C programming Language", 3rd edition                       | 1013 |
| LogEscape               | Fill TLogEscape stack buffer with the (hexadecimal) chars of the input binary                          | 1013 |
| LogEscapeFull           | Returns a text buffer with the (hexadecimal) chars of the input binary                                 | 1013 |
| LogEscapeFull           | Returns a text buffer with the (hexadecimal) chars of the input binary                                 | 1013 |
| LogToTextFile           | Log a message to a local text file                                                                     | 1013 |
| LowerCase               | Fast conversion of the supplied text into lowercase                                                    | 1013 |

| Functions or procedures   | Description                                                                                            | Page |
|---------------------------|--------------------------------------------------------------------------------------------------------|------|
| LowerCaseCopy             | Fast conversion of the supplied text into lowercase                                                    | 1013 |
| LowerCaseSelf             | Fast in-place conversion of the supplied variable text into lowercase                                  | 1014 |
| LowerCaseU                | Fast conversion of the supplied text into 8 bit lowercase                                              | 1014 |
| LowerCaseUnicode          | Accurate conversion of the supplied UTF-8 content into the corresponding lower-case Unicode characters | 1014 |
| MaxInteger                | Find the maximum 32-bit integer in Values[]                                                            | 1014 |
| MedianQuickSelect         | Compute the median of a serie of values, using "Quickselect"                                           | 1014 |
| MedianQuickSelectInteger  | Compute the median of an integer serie of values, using "Quickselect"                                  | 1014 |
| MicroSecToString          | Delphi 2007 is buggy as hell convert a micro seconds elapsed time into a human readable value          | 1014 |
| MicroSecToString          | Convert a micro seconds elapsed time into a human readable value                                       | 1014 |
| MoveSmall                 | An alternative Move() function tuned for small unaligned counts                                        | 1014 |
| mul64x64                  | Fast computation of two 64-bit unsigned integers into a 128-bit value                                  | 1014 |
| MultiEventAdd             | Low-level wrapper to add a callback to a dynamic list of events                                        | 1015 |
| MultiEventFind            | Low-level wrapper to check if a callback is in a dynamic list of events                                | 1015 |
| MultiEventMerge           | Low-level wrapper to add one or several callbacks from another list of events                          | 1015 |
| MultiEventRemove          | Low-level wrapper to remove a callback from a dynamic list of events                                   | 1016 |
| MultiEventRemove          | Low-level wrapper to remove a callback from a dynamic list of events                                   | 1016 |
| MultiPartFormDataAddField | Encode a field in a multipart array                                                                    | 1016 |
| MultiPartFormDataAddFile  | Encode a file in a multipart array                                                                     | 1016 |
| MultiPartFormDataDecode   | Decode multipart/form-data POST request content                                                        | 1016 |
| MultiPartFormDataEncode   | Encode multipart fields and files                                                                      | 1016 |
| NeedsJsonEscape           | Returns TRUE if the given text buffers would be escaped when written as JSON                           | 1017 |
| NeedsJsonEscape           | Returns TRUE if the given text buffers would be escaped when written as JSON                           | 1017 |
| NeedsJsonEscape           | Returns TRUE if the given text buffers would be escaped when written as JSON                           | 1017 |
| NewSynLocker              | Allocate and initialize a TSynLocker instance                                                          | 1017 |

| Functions or procedures    | Description                                                                                                                         | Page |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------|------|
| NextGrow                   | Compute the new capacity when expanding an array of items                                                                           | 1017 |
| NextNotSpaceCharIs         | Check if the next character not in [#1..' ']' matches a given value                                                                 | 1017 |
| NextUTF8UCS4               | Get the UCS4 char stored in P^ (decode UTF-8 if necessary)                                                                          | 1017 |
| NotifySortedIntegerChanges | Compares two 32-bit signed sorted integer arrays, and call event handlers to notify the corresponding modifications in an O(n) time | 1017 |
| NowToString                | Retrieve the current Date, in the ISO 8601 layout, but expanded and ready to be displayed                                           | 1017 |
| NowUTC                     | Returns the current UTC system date and time                                                                                        | 1017 |
| NowUTCToString             | Retrieve the current UTC Date, in the ISO 8601 layout, but expanded and ready to be displayed                                       | 1017 |
| ObjArrayAdd                | Wrapper to add an item to a T*ObjArray dynamic array storage                                                                        | 1018 |
| ObjArrayAddCount           | Wrapper to add an item to a T*ObjArray dynamic array storage                                                                        | 1018 |
| ObjArrayAddFrom            | Wrapper to add items to a T*ObjArray dynamic array storage                                                                          | 1018 |
| ObjArrayAddOnce            | Wrapper to add once an item to a T*ObjArray dynamic array storage                                                                   | 1018 |
| ObjArrayAddOnceFrom        |                                                                                                                                     | 1018 |
| ObjArrayAppend             | Wrapper to add and move items to a T*ObjArray dynamic array storage                                                                 | 1018 |
| ObjArrayClear              | Wrapper to release all items stored in a T*ObjArray dynamic array                                                                   | 1019 |
| ObjArrayClear              | Wrapper to release all items stored in a T*ObjArray dynamic array                                                                   | 1019 |
| ObjArrayClear              | Wrapper to release all items stored in a T*ObjArray dynamic array                                                                   | 1019 |
| ObjArrayCount              | Wrapper to count all not nil items in a T*ObjArray dynamic array storage                                                            | 1019 |
| ObjArrayDelete             | Wrapper to delete an item in a T*ObjArray dynamic array storage                                                                     | 1019 |
| ObjArrayDelete             | Wrapper to delete an item in a T*ObjArray dynamic array storage                                                                     | 1019 |
| ObjArrayDelete             | Wrapper to delete an item in a T*ObjArray dynamic array storage                                                                     | 1019 |
| ObjArrayFind               | Wrapper to search an item in a T*ObjArray dynamic array storage                                                                     | 1020 |
| ObjArrayFind               | Wrapper to search an item in a T*ObjArray dynamic array storage                                                                     | 1020 |
| ObjArrayObjArrayClear      | Wrapper to release all items stored in an array of T*ObjArray dynamic array                                                         | 1020 |
| ObjArraysClear             | Wrapper to release all items stored in several T*ObjArray dynamic arrays                                                            | 1020 |
| ObjArraySetLength          | Wrapper to set the length of a T*ObjArray dynamic array storage                                                                     | 1020 |

| Functions or procedures | Description                                                                 | Page |
|-------------------------|-----------------------------------------------------------------------------|------|
| ObjArraySort            | Wrapper to sort the items stored in a T*ObjArray dynamic array              | 1020 |
| ObjArrayToJSON          | Wrapper to serialize a T*ObjArray dynamic array as JSON                     | 1020 |
| ObjectsToJSON           | Will serialize set of TObj into its UTF-8 JSON representation               | 1020 |
| ObjectToJSON            | Will serialize any TObj into its UTF-8 JSON representation                  | 1020 |
| ObjectToVariant         | Will convert any TObj into a TDocVariant document instance                  | 1021 |
| ObjectToVariant         | Will convert any TObj into a TDocVariant document instance                  | 1021 |
| ObjectToVariant         | Will convert any TObj into a TDocVariant document instance                  | 1021 |
| OctToBin                | Conversion from octal C-like escape into binary data                        | 1021 |
| OctToBin                | Conversion from octal C-like escape into binary data                        | 1021 |
| OrMemory                | Logical OR of two memory buffers                                            | 1021 |
| PatchCode               | Self-modifying code - change some memory buffer in the code segment         | 1021 |
| PatchCodePtrUInt        | Self-modifying code - change one PtrUInt in the code segment                | 1021 |
| Plural                  | Write count number and append 's' (if needed) to form a plural English noun | 1021 |
| PointerToHex            | Fast conversion from a pointer data into hexa chars, ready to be displayed  | 1022 |
| PointerToHex            | Fast conversion from a pointer data into hexa chars, ready to be displayed  | 1022 |
| PointerToHexShort       | Fast conversion from a pointer data into hexa chars, ready to be displayed  | 1022 |
| PosChar                 | Fast retrieve the position of a given character                             | 1022 |
| PosCharAny              | Fast retrieve the position of any value of a given set of characters        | 1022 |
| PosEx                   | Faster RawUTF8 Equivalent of standard StrUtils.PosEx                        | 1022 |
| PosExChar               | Optimized version of PosEx() with search text as one AnsiChar               | 1022 |
| PosI                    | A non case-sensitive RawUTF8 version of Pos()                               | 1022 |
| PosIU                   | A non case-sensitive RawUTF8 version of Pos()                               | 1022 |
| PropNamesValid          | Returns TRUE if the given text buffers contains A..Z,0..9,_ characters      | 1022 |
| PropNameValid           | Returns TRUE if the given text buffer contains a..z,A..Z,0..9,_ characters  | 1022 |
| PtrArrayAdd             | Wrapper to add an item to a array of pointer dynamic array storage          | 1022 |
| PtrArrayAddOnce         | Wrapper to add once an item to a array of pointer dynamic array storage     | 1022 |

| Functions or procedures   | Description                                                                                | Page |
|---------------------------|--------------------------------------------------------------------------------------------|------|
| PtrArrayDelete            | Wrapper to delete an item from a array of pointer dynamic array storage                    | 1023 |
| PtrArrayDelete            | Wrapper to delete an item from a array of pointer dynamic array storage                    | 1023 |
| PtrArrayFind              | Wrapper to find an item to a array of pointer dynamic array storage                        | 1023 |
| PtrUIntScan               | Fast search of a pointer-sized unsigned integer in an pointer-sized integer array          | 1023 |
| PtrUIntScanExists         | Fast search of a pointer-sized unsigned integer position in an pointer-sized integer array | 1023 |
| PtrUIntScanIndex          | Fast search of a pointer-sized unsigned integer position in an pointer-sized integer array | 1023 |
| QuickSortCompare          | Performs a QuickSort using a comparison callback                                           | 1023 |
| QuickSortIndexedPUTF8Char | Sort a dynamic array of PUTF8Char items, via an external array of indexes                  | 1023 |
| QuickSortInt64            | Sort a 64-bit Integer array, low values first                                              | 1023 |
| QuickSortInt64            | Sort a 64-bit signed Integer array, low values first                                       | 1023 |
| QuickSortInteger          | Sort an Integer array, low values first                                                    | 1023 |
| QuickSortInteger          | Sort an Integer array, low values first                                                    | 1023 |
| QuickSortInteger          | Sort an Integer array, low values first                                                    | 1023 |
| QuickSortPointer          | Sort a pointer array, low values first                                                     | 1023 |
| QuickSortPtrInt           | Sort a PtrInt array, low values first                                                      | 1024 |
| QuickSortQWord            | Sort a 64-bit unsigned Integer array, low values first                                     | 1024 |
| QuickSortRawUTF8          | Sort a dynamic array of RawUTF8 items                                                      | 1024 |
| QuickSortWord             | Sort a 16 bit unsigned Integer array, low values first                                     | 1024 |
| QuotedStr                 | Format a text content with SQL-like quotes                                                 | 1024 |
| QuotedStr                 | Format a text content with SQL-like quotes                                                 | 1024 |
| QuotedStrJSON             | Convert UTF-8 content into a JSON string                                                   | 1024 |
| QuotedStrJSON             | Convert UTF-8 buffer into a JSON string                                                    | 1024 |
| QuotedStrJSON             | Convert UTF-8 content into a JSON string                                                   | 1024 |
| QWordScanIndex            | Fast search of an integer position in an unsigned 64-bit integer array                     | 1024 |
| Random32                  | Fast compute of some 32-bit random value                                                   | 1025 |

| Functions or procedures | Description                                                                     | Page |
|-------------------------|---------------------------------------------------------------------------------|------|
| Random32                | Fast compute of some 32-bit random value, with a maximum (excluded) upper value | 1025 |
| Random32gsl             | Fast compute of some 32-bit random value, using the gsl_rng_taus2 generator     | 1025 |
| Random32gsl             | Fast compute of bounded 32-bit random value, using the gsl_rng_taus2 generator  | 1025 |
| Random32Seed            | Seed the gsl_rng_taus2 Random32/Random32gsl generator                           | 1025 |
| RandomGUID              | Compute a random GUID value                                                     | 1025 |
| RandomGUID              | Compute a random GUID value                                                     | 1025 |
| RawByteArrayConcat      | Fast concatenation of several AnsiStrings                                       | 1025 |
| RawByteStringToBytes    | Creates a TBytes from a RawByteString memory buffer                             | 1025 |
| RawByteStringToStream   | Create a TStream from a string content                                          | 1026 |
| RawByteStringToVariant  | Convert a RawByteString content into a variant varString                        | 1026 |
| RawByteStringToVariant  | Convert a raw binary buffer into a variant RawByteString varString              | 1026 |
| RawObjectsClear         | Low-level function calling FreeAndNil(o^i) successively n times                 | 1026 |
| RawUnicodeToString      | Convert any Raw Unicode encoded buffer into a generic VCL Text                  | 1026 |
| RawUnicodeToString      | Convert any Raw Unicode encoded buffer into a generic VCL Text                  | 1026 |
| RawUnicodeToString      | Convert any Raw Unicode encoded string into a generic VCL Text                  | 1026 |
| RawUnicodeToSynUnicode  | Convert any Raw Unicode encoded String into a generic SynUnicode Text           | 1026 |
| RawUnicodeToSynUnicode  | Convert any Raw Unicode encoded String into a generic SynUnicode Text           | 1026 |
| RawUnicodeToUtf8        | Convert a RawUnicode PWideChar into a UTF-8 string                              | 1027 |
| RawUnicodeToUtf8        | Convert a RawUnicode PWideChar into a UTF-8 string                              | 1027 |
| RawUnicodeToUtf8        | Convert a RawUnicode UTF-16 PWideChar into a UTF-8 buffer                       | 1027 |
| RawUnicodeToUtf8        | Convert a RawUnicode PWideChar into a UTF-8 string                              | 1027 |
| RawUnicodeToUtf8        | Convert a RawUnicode string into a UTF-8 string                                 | 1027 |
| RawUnicodeToWinAnsi     | Convert a RawUnicode string into a WinAnsi (code page 1252) string              | 1027 |
| RawUnicodeToWinAnsi     | Convert a RawUnicode PWideChar into a WinAnsi (code page 1252) string           | 1027 |

| Functions or procedures         | Description                                                                    | Page |
|---------------------------------|--------------------------------------------------------------------------------|------|
| RawUnicodeToWinPChar            | Direct conversion of a Unicode encoded buffer into a WinAnsi PAnsiChar buffer  | 1027 |
| RawUTF8ArrayToCSV               | Return the corresponding CSV text from a dynamic array of UTF-8 strings        | 1027 |
| RawUTF8ArrayToQuotedCSV         | Return the corresponding CSV quoted text from a dynamic array of UTF-8 strings | 1027 |
| RawUTF8DynArrayClear            | Low-level finalization of a dynamic array of RawUTF8                           | 1027 |
| RawUTF8DynArrayEquals           | True if both TRawUTF8DynArray are the same                                     | 1027 |
| RawUTF8DynArrayEquals           | True if both TRawUTF8DynArray are the same for a given number of items         | 1027 |
| RawUTF8DynArrayLoadFromContains | Search in a RawUTF8 dynamic array BLOB content as stored by TDynArray.SaveTo   | 1028 |
| RawUTF8ToGUID                   | Convert some UTF-8 encoded text into a TGUID                                   | 1028 |
| RawUTF8ToVariant                | Convert an UTF-8 encoded text buffer into a variant RawUTF8 varString          | 1028 |
| RawUTF8ToVariant                | Convert an UTF-8 encoded string into a variant RawUTF8 varString               | 1028 |
| RawUTF8ToVariant                | Convert an UTF-8 encoded text buffer into a variant RawUTF8 varString          | 1028 |
| RawUTF8ToVariant                | Convert an UTF-8 encoded string into a variant RawUTF8 varString               | 1028 |
| RCU                             | Thread-safe move of a memory buffer using a simple Read-Copy-Update pattern    | 1028 |
| RCU128                          | Thread-safe move of a 128-bit value using a simple Read-Copy-Update pattern    | 1028 |
| RCU32                           | Thread-safe move of a 32-bit value using a simple Read-Copy-Update pattern     | 1028 |
| RCU64                           | Thread-safe move of a 64-bit value using a simple Read-Copy-Update pattern     | 1028 |
| RCUPtr                          | Thread-safe move of a pointer value using a simple Read-Copy-Update pattern    | 1028 |
| ReadStringFromStream            | Read an UTF-8 text from a TStream                                              | 1029 |
| RecordClear                     | Clear a record content                                                         | 1029 |
| RecordCopy                      | Copy a record content from source to Dest                                      | 1029 |
| RecordEquals                    | Check equality of two records by content                                       | 1029 |
| RecordLoad                      | Fill a record content from a memory buffer as saved by RecordSave()            | 1029 |
| RecordLoad                      | Fill a record content from a memory buffer as saved by RecordSave()            | 1029 |

| Functions or procedures      | Description                                                                                            | Page |
|------------------------------|--------------------------------------------------------------------------------------------------------|------|
| RecordLoadBase64             | Read a record content from a Base-64 encoded content                                                   | 1029 |
| RecordLoadJSON               | Fill a record content from a JSON serialization as saved by TTextWriter.AddRecordJSON / RecordSaveJSON | 1030 |
| RecordLoadJSON               | Fill a record content from a JSON serialization as saved by TTextWriter.AddRecordJSON / RecordSaveJSON | 1030 |
| RecordSave                   | Save a record content into a RawByteString                                                             | 1031 |
| RecordSave                   | Save a record content into a destination memory buffer                                                 | 1031 |
| RecordSave                   | Save a record content into a destination memory buffer                                                 | 1031 |
| RecordSave                   | Save a record content into a destination memory buffer                                                 | 1031 |
| RecordSaveBase64             | Save a record content into a Base-64 encoded UTF-8 text content                                        | 1031 |
| RecordSaveBytes              | Save a record content into a TBytes dynamic array                                                      | 1031 |
| RecordSaveJSON               | Save record into its JSON serialization as saved by TTextWriter.AddRecordJSON                          | 1031 |
| RecordSaveLength             | Compute the number of bytes needed to save a record content using the RecordSave() function            | 1031 |
| RecordTypeInfoSize           | Retrieve the record size from its low-level RTTI                                                       | 1032 |
| RecordZero                   | Initialize a record content                                                                            | 1032 |
| RedirectCode                 | Self-modifying code - add an asm JUMP to a redirected function                                         | 1032 |
| RedirectCodeRestore          | Self-modifying code - restore a code from its RedirectCode() backup                                    | 1032 |
| ReleaseInternalWindow        | Delete the window resources used to receive Windows Messages                                           | 1032 |
| RemoveCommentsFromJSON       | Remove comments and trailing commas from a text buffer before passing it to JSON parser                | 1032 |
| RenameInCSV                  | Change a Value within a CSV string                                                                     | 1032 |
| ReplaceSection               | Replace a whole [Section] content by a new content                                                     | 1032 |
| ReplaceSection               | Replace a whole [Section] content by a new content                                                     | 1032 |
| ResourceSynLZToRawByteString | Creates a RawByteString memory buffer from an SynLZ-compressed embedded resource                       | 1033 |
| ResourceToRawByteString      | Creates a RawByteString memory buffer from an embedded resource                                        | 1033 |
| Reverse                      | Fill already allocated Reversed[] so that Reversed[Values[i]]=i                                        | 1033 |
| SameTextU                    | SameText() overloaded function with proper UTF-8 decoding                                              | 1033 |
| SameValue                    | Compare to floating point values, with IEEE 754 double precision                                       | 1033 |

| Functions or procedures     | Description                                                                                                                                                     | Page |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| SameValueFloat              | Compare to floating point values, with IEEE 754 double precision                                                                                                | 1033 |
| SaveJSON                    | Serialize most kind of content as JSON, using its RTTI                                                                                                          | 1034 |
| SaveJSON                    | Serialize most kind of content as JSON, using its RTTI                                                                                                          | 1034 |
| ScanUTF8                    | Read text from P/PLen and store it into values[] according to fmt specifiers                                                                                    | 1034 |
| ScanUTF8                    | Read and store text into values[] according to fmt specifiers                                                                                                   | 1034 |
| SearchRecToDateTime         | Get a file date and time, from a FindFirst/FindNext search                                                                                                      | 1034 |
| SearchRecValidFile          | Check if a FindFirst/FindNext found instance is actually a file                                                                                                 | 1034 |
| SearchRecValidFolder        | Check if a FindFirst/FindNext found instance is actually a folder                                                                                               | 1034 |
| SetAppUserModelID           | Under Windows 7 and later, will set an unique application-defined Application User Model ID (AppUserModelID) that identifies the current process to the taskbar | 1034 |
| SetBit                      | Set a particular bit into a bit array                                                                                                                           | 1034 |
| SetBit64                    | Set a particular bit into a 64-bit integer bits (max aIndex is 63)                                                                                              | 1034 |
| SetBitCSV                   | Retrieve the next CSV separated bit index                                                                                                                       | 1035 |
| SetBitPtr                   | Set a particular bit into a bit array                                                                                                                           | 1035 |
| SetCurrentThreadName        | Name the current thread so that it would be easily identified in the IDE debugger                                                                               | 1035 |
| SetExecutableVersion        | Initialize ExeVersion global variable, supplying the version as text                                                                                            | 1035 |
| SetExecutableVersion        | Initialize ExeVersion global variable, supplying a custom version number                                                                                        | 1035 |
| SetInt64                    | Get the 64-bit signed integer value stored in P^                                                                                                                | 1035 |
| SetQWord                    | Get the 64-bit unsigned integer value stored in P^                                                                                                              | 1035 |
| SetThreadName               | Name a thread so that it would be easily identified in the IDE debugger                                                                                         | 1035 |
| SetThreadNameDefault        | Could be used to override SetThreadNameInternal()                                                                                                               | 1035 |
| SetVariantByRef             | Same as Dest := Source, but copying by reference                                                                                                                | 1035 |
| SetVariantByValue           | Same as Dest := Source, but copying by value                                                                                                                    | 1035 |
| SetVariantNull              | Same as Value := Null, but slightly faster                                                                                                                      | 1036 |
| SetVariantUnRefSimple Value | Same as Dest := TVarData(Source) for simple values                                                                                                              | 1036 |
| ShortStringToAnsi7String    | Direct conversion of an ANSI-7 shortstring into an AnsiString                                                                                                   | 1036 |

| Functions or procedures    | Description                                                                       | Page |
|----------------------------|-----------------------------------------------------------------------------------|------|
| ShortStringToAnsi7String   | Direct conversion of an ANSI-7 shortstring into an AnsiString                     | 1036 |
| ShortStringToUTF8          | Direct conversion of a WinAnsi shortstring into a UTF-8 text                      | 1036 |
| SimpleDynArrayLoadFrom     | Wrap a simple dynamic array BLOB content as stored by TDynArray.SaveTo            | 1036 |
| SimpleRoundTo2Digits       | Simple, no banker rounding of a Currency value to only 2 digits                   | 1036 |
| SimpleRoundTo2DigitsCurr64 | Simple, no banker rounding of a Currency value, stored as Int64, to only 2 digits | 1036 |
| SleepHiRes                 | Similar to Windows sleep() API call, to be truly cross-platform                   | 1036 |
| SortDynArray128            | Compare two "array of THash128" elements                                          | 1036 |
| SortDynArray256            | Compare two "array of THash256" elements                                          | 1037 |
| SortDynArray512            | Compare two "array of THash512" elements                                          | 1037 |
| SortDynArrayAnsiString     | Compare two "array of AnsiString" elements, with case sensitivity                 | 1037 |
| SortDynArrayAnsiStringI    | Compare two "array of AnsiString" elements, with no case sensitivity              | 1037 |
| SortDynArrayBoolean        | Compare two "array of boolean" elements                                           | 1037 |
| SortDynArrayByte           | Compare two "array of byte" elements                                              | 1037 |
| SortDynArrayCardinal       | Compare two "array of cardinal" elements                                          | 1037 |
| SortDynArrayDouble         | Compare two "array of double" elements                                            | 1037 |
| SortDynArrayFileName       | Compare two "array of TFileName" elements, as file names                          | 1037 |
| SortDynArrayInt64          | Compare two "array of Int64" or "array of Currency" elements                      | 1037 |
| SortDynArrayInteger        | Compare two "array of integer" elements                                           | 1037 |
| SortDynArrayPointer        | Compare two "array of TObject/pointer" elements                                   | 1037 |
| SortDynArrayPUTF8Char      | Compare two "array of PUTF8Char/PAnsiChar" elements, with case sensitivity        | 1037 |
| SortDynArrayPUTF8CharI     | Compare two "array of PUTF8Char/PAnsiChar" elements, with no case sensitivity     | 1037 |
| SortDynArrayQWord          | Compare two "array of QWord" elements                                             | 1037 |
| SortDynArrayRawByteString  | Compare two "array of RawByteString" elements, with case sensitivity              | 1037 |
| SortDynArrayShortint       | Compare two "array of shortint" elements                                          | 1038 |
| SortDynArraySingle         | Compare two "array of single" elements                                            | 1038 |

| Functions or procedures    | Description                                                                        | Page |
|----------------------------|------------------------------------------------------------------------------------|------|
| SortDynArraySmallint       | Compare two "array of smallint" elements                                           | 1038 |
| SortDynArrayString         | Compare two "array of generic string" elements, with case sensitivity              | 1038 |
| SortDynArrayStringI        | Compare two "array of generic string" elements, with no case sensitivity           | 1038 |
| SortDynArrayUnicodeString  | Compare two "array of WideString/UnicodeString" elements, with case sensitivity    | 1038 |
| SortDynArrayUnicodeStringI | Compare two "array of WideString/UnicodeString" elements, with no case sensitivity | 1038 |
| SortDynArrayVariant        | Compare two "array of variant" elements, with case sensitivity                     | 1038 |
| SortDynArrayVariantCompare | Compare two "array of variant" elements, with or without case sensitivity          | 1038 |
| SortDynArrayVariantI       | Compare two "array of variant" elements, with no case sensitivity                  | 1038 |
| SortDynArrayWord           | Compare two "array of word" elements                                               | 1038 |
| Split                      | Split a RawUTF8 string into two strings, according to SepStr separator             | 1039 |
| Split                      | Split a RawUTF8 string into two strings, according to SepStr separator             | 1039 |
| Split                      | Returns the left part of a RawUTF8 string, according to SepStr separator           | 1039 |
| Split                      | Split a RawUTF8 string into several strings, according to SepStr separator         | 1039 |
| SplitRight                 | Returns the last occurrence of the given SepChar separated context                 | 1039 |
| SplitRights                | Returns the last occurrence of the given SepChar separated context                 | 1039 |
| SQLAddWhereAnd             | Add a condition to a SQL WHERE clause, with an ' and ' if where is not void        | 1039 |
| SQLBegin                   | Go to the beginning of the SQL statement, ignoring all blanks and comments         | 1039 |
| StrCntDecFree              | Low-level string reference counter unprocess                                       | 1039 |
| StrCompFast                | Buffer-safe version of StrComp(), to be used with PUTF8Char/PAnsiChar              | 1039 |
| StrCompIL                  | Use our fast version of StrCompIL(), to be used with PUTF8Char                     | 1039 |
| StrCompL                   | Use our fast version of StrCompL(), to be used with PUTF8Char                      | 1039 |
| StrCompW                   | Use our fast version of StrComp(), to be used with PWideChar                       | 1039 |
| strcspnpas                 | Pure pascal version of strcspn(), to be used with PUTF8Char/PAnsiChar              | 1040 |
| strcspnsse42               | SSE 4.2 version of strcspn(), to be used with PUTF8Char/PAnsiChar                  | 1040 |
| StrCurr64                  | Internal fast INTEGER Curr64 (value*10000) value to text conversion                | 1040 |

| Functions or procedures         | Description                                                                    | Page |
|---------------------------------|--------------------------------------------------------------------------------|------|
| StreamSynLZ                     | Compress a data content using the SynLZ algorithm from one stream into a file  | 1040 |
| StreamSynLZ                     | Compress a data content using the SynLZ algorithm from one stream into another | 1040 |
| StreamSynLZComputeLen           | Compute the real length of a given StreamSynLZ-compressed buffer               | 1040 |
| StreamToRawByteString           | Read a TStream content into a String                                           | 1040 |
| StreamUnSynLZ                   | Uncompress using the SynLZ algorithm from one stream into another              | 1041 |
| StreamUnSynLZ                   | Uncompress using the SynLZ algorithm from one file into another                | 1041 |
| StrIComp                        | Use our fast version of StrIComp(), to be used with PUTF8Char/PAnsiChar        | 1041 |
| StringBufferToUtf8              | Convert any generic VCL 0-terminated Text buffer into an UTF-8 string          | 1041 |
| StringBufferToUtf8              | Convert any generic VCL Text buffer into an UTF-8 encoded buffer               | 1041 |
| StringDynArrayToRawUTF8DynArray | Convert the string dynamic array into a dynamic array of UTF-8 strings         | 1041 |
| StringFromFile                  | Read a File content into a String                                              | 1041 |
| StringListToRawUTF8DynArray     | Convert the string list into a dynamic array of UTF-8 strings                  | 1041 |
| StringReplaceAll                | Fast version of StringReplace(S, OldPattern, NewPattern,[rfReplaceAll]);       | 1041 |
| StringReplaceAll                | Fast version of several cascaded StringReplaceAll()                            | 1041 |
| StringReplaceAllProcess         | Actual replacement function called by StringReplaceAll() on first match        | 1042 |
| StringReplaceChars              | Fast replace of a specified char by a given string                             | 1042 |
| StringReplaceTabs               | Fast replace of all #9 chars by a given string                                 | 1042 |
| StringToAnsi7                   | Convert any generic VCL Text into Ansi 7 bit encoded String                    | 1042 |
| StringToGUID                    | Convert some text into a TGUID                                                 | 1042 |
| StringToRawUnicode              | Convert any generic VCL Text into a Raw Unicode encoded String                 | 1042 |
| StringToRawUnicode              | Convert any generic VCL Text into a Raw Unicode encoded String                 | 1042 |
| StringToSynUnicode              | Convert any generic VCL Text into a SynUnicode encoded String                  | 1042 |
| StringToSynUnicode              | Convert any generic VCL Text into a SynUnicode encoded String                  | 1042 |
| StringToUTF8                    | Convert any generic VCL Text buffer into an UTF-8 encoded String               | 1043 |
| StringToUTF8                    | Convert any generic VCL Text into an UTF-8 encoded String                      | 1043 |
| StringToUTF8                    | Convert any generic VCL Text into an UTF-8 encoded String                      | 1043 |

| Functions or procedures | Description                                                               | Page |
|-------------------------|---------------------------------------------------------------------------|------|
| StringToWinAnsi         | Convert any generic VCL Text into WinAnsi (Win-1252) 8 bit encoded String | 1043 |
| StrInt32                | Internal fast integer val to text conversion                              | 1043 |
| StrInt64                | Internal fast Int64 val to text conversion                                | 1043 |
| StrLenPas               | Slower version of StrLen(), but which will never read beyond the string   | 1043 |
| StrLenW                 | Our fast version of StrLen(), to be used with PWideChar                   | 1043 |
| StrPosI                 | A non case-sensitive version of Pos()                                     | 1043 |
| strspnpas               | Pure pascal version of strspn(), to be used with PUTF8Char/PAnsiChar      | 1043 |
| strspnsse42             | SSE 4.2 version of strspn(), to be used with PUTF8Char/PAnsiChar          | 1044 |
| StrToCurr64             | Convert a string into its INTEGER Curr64 (value*10000) representation     | 1044 |
| StrToCurrency           | Convert a string into its currency representation                         | 1044 |
| StrUInt32               | Internal fast unsigned integer val to text conversion                     | 1044 |
| StrUInt64               | Internal fast unsigned Int64 val to text conversion                       | 1044 |
| SumInteger              | Sum all 32-bit integers in Values[]                                       | 1044 |
| SymmetricEncrypt        | Naive symmetric encryption scheme using a 32-bit key                      | 1044 |
| SynchFolders            | Ensure all files in Dest folder(s) do match the one in Reference          | 1044 |
| SynLZCompress           | Deprecated function - please call AlgoSynLZ.Compress() method             | 1045 |
| SynLZCompress           | Deprecated function - please call AlgoSynLZ.Compress() method             | 1045 |
| SynLZCompress           | Deprecated function - please call AlgoSynLZ.Compress() method             | 1045 |
| SynLZCompressToBytes    | Deprecated function - please call AlgoSynLZ.DecompressToBytes() method    | 1045 |
| SynLZCompressToBytes    | Deprecated function - please call AlgoSynLZ.CompressToBytes() method      | 1045 |
| SynLZDecompress         | Deprecated function - please call AlgoSynLZ.Decompress() method           | 1045 |
| SynLZDecompress         | Deprecated function - please call AlgoSynLZ.Decompress() method           | 1045 |
| SynLZDecompress         | Deprecated function - please call AlgoSynLZ.Decompress() method           | 1045 |
| SynLZDecompress         | Deprecated function - please call AlgoSynLZ.Decompress() method           | 1045 |
| SynLZDecompress         | Deprecated function - please call AlgoSynLZ.Decompress() method           | 1045 |
| SynLZDecompress         | Deprecated function - please call AlgoSynLZ.Decompress() method           | 1045 |
| SynLZDecompressBody     | Deprecated function - please call AlgoSynLZ.DecompressBody() method       | 1045 |

| Functions or procedures         | Description                                                                      | Page |
|---------------------------------|----------------------------------------------------------------------------------|------|
| SynLZDecompressHeader           | Deprecated function - please call AlgoSynLZ.DecompressHeader() method            | 1045 |
| SynLZDecompressPartial          | Deprecated function - please call AlgoSynLZ.DecompressPartial() method           | 1045 |
| SynRegisterCustomVariantType    | Register a custom variant type to handle properties                              | 1045 |
| SynUnicodeToString              | Convert any SynUnicode encoded string into a generic VCL Text                    | 1045 |
| SynUnicodeToUtf8                | Convert a SynUnicode string into a UTF-8 string                                  | 1046 |
| TemporaryFileName               | Compute an unique temporary file name                                            | 1046 |
| TextToGUID                      | Convert some text into its TGUID binary value                                    | 1046 |
| TextToVariant                   | Convert an UTF-8 encoded text buffer into a variant number or RawUTF8 varString  | 1046 |
| TextToVariantNumberType         | Identify either varInt64, varDouble, varCurrency types following JSON format     | 1046 |
| TextToVariantNumberTypeNoDouble | Identify either varInt64 or varCurrency types following JSON format              | 1046 |
| TimeLogFromDateTime             | Get TTimeLog value from a given Delphi date and time                             | 1046 |
| TimeLogFromFile                 | Get TTimeLog value from a file date and time                                     | 1046 |
| TimeLogFromUnixTime             | Get TTimeLog value from a given Unix seconds since epoch timestamp               | 1046 |
| TimeLogNow                      | Get TTimeLog value from current local system date and time                       | 1047 |
| TimeLogNowUTC                   | Get TTimeLog value from current UTC system Date and Time                         | 1047 |
| TimeLogToDateTime               | Date/Time conversion from a TTimeLog value                                       | 1047 |
| TimeLogToUnixTime               | Unix seconds since epoch timestamp conversion from a TTimeLog value              | 1047 |
| TimeToIso8601                   | Basic Time conversion into ISO-8601                                              | 1047 |
| TimeToIso8601PChar              | Write a Time to P^ Ansi buffer                                                   | 1047 |
| TimeToIso8601PChar              | Write a Time to P^ Ansi buffer                                                   | 1047 |
| TimeToString                    | Retrieve the current Time (whithout Date), in the ISO 8601 layout                | 1047 |
| TInt64DynArrayFrom              | Quick helper to initialize a dynamic array of 64-bit integers from 32-bit values | 1047 |
| TIntegerDynArrayFrom            | Quick helper to initialize a dynamic array of integer from some constants        | 1048 |
| TIntegerDynArrayFrom64          | Quick helper to initialize a dynamic array of integer from 64-bit integers       | 1048 |

| Functions or procedures    | Description                                                                                              | Page |
|----------------------------|----------------------------------------------------------------------------------------------------------|------|
| ToCardinal                 | Get the unsigned 32-bit cardinal value stored in a RawUTF8 string                                        | 1048 |
| ToDouble                   | Get a 64-bit floating-point value stored in a RawUTF8 string                                             | 1048 |
| ToInt64                    | Get the signed 64-bit integer value stored in a RawUTF8 string                                           | 1048 |
| ToInteger                  | Get the signed 32-bit integer value stored in a RawUTF8 string                                           | 1048 |
| ToText                     | Just a wrapper around vmtClassName to avoid a string/RawUTF8 conversion                                  | 1048 |
| ToText                     | Just a wrapper around vmtClassName to avoid a string/RawUTF8 conversion                                  | 1048 |
| ToText                     | Retrieve the text representation of a TDocVairnatKind                                                    | 1048 |
| ToText                     | Convert Intel CPU features as plain CSV text                                                             | 1048 |
| ToUTF8                     | Convert a TGUID into UTF-8 encoded text                                                                  | 1049 |
| ToUTF8                     | Use our fast RawUTF8 version of IntToStr()                                                               | 1049 |
| ToUTF8                     | Use our fast RawUTF8 version of IntToStr()                                                               | 1049 |
| ToUTF8                     | Convert any Variant into UTF-8 encoded String                                                            | 1049 |
| ToUTF8                     | Convert any generic VCL Text into an UTF-8 encoded String                                                | 1049 |
| ToUTF8                     | Convert any UTF-8 encoded shortstring Text into an UTF-8 encoded String                                  | 1049 |
| ToVarInt32                 | Convert an integer into a 32-bit variable-length integer buffer                                          | 1049 |
| ToVarInt64                 | Convert a Int64 into a 64-bit variable-length integer buffer                                             | 1049 |
| ToVarString                | Convert a RawUTF8 into an UTF-8 encoded variable-length buffer                                           | 1049 |
| ToVarUInt32                | Convert a cardinal into a 32-bit variable-length integer buffer                                          | 1049 |
| ToVarUInt32Length          | Return the number of bytes necessary to store a 32-bit variable-length integer                           | 1049 |
| ToVarUInt32LengthWith Data | Return the number of bytes necessary to store some data with a its 32-bit variable-length integer legnth | 1049 |
| ToVarUInt64                | Convert a UInt64 into a 64-bit variable-length integer buffer                                            | 1049 |
| TQWordDynArrayFrom         | Quick helper to initialize a dynamic array of 64-bit integers from 32-bit values                         | 1049 |
| TRawUTF8DynArrayFrom       | Quick helper to initialize a dynamic array of RawUTF8 from some constants                                | 1049 |
| Trim                       | Fast dedicated RawUTF8 version of Trim()                                                                 | 1049 |
| TrimControlChars           | Returns the supplied text content, without any control char                                              | 1050 |

| Functions or procedures  | Description                                                                                                  | Page |
|--------------------------|--------------------------------------------------------------------------------------------------------------|------|
| TrimCopy                 | Single-allocation (therefore faster) alternative to Trim(copy())                                             | 1050 |
| TrimLeft                 | Trims leading whitespace characters from the string by removing new line, space, and tab characters          | 1050 |
| TrimLeftLowerCase        | Trim first lowercase chars ('otDone' will return 'Done' e.g.)                                                | 1050 |
| TrimLeftLowerCaseShort   | Trim first lowercase chars ('otDone' will return 'Done' e.g.)                                                | 1050 |
| TrimLeftLowerCaseToShort | Trim first lowercase chars ('otDone' will return 'Done' e.g.)                                                | 1050 |
| TrimLeftLowerCaseToShort | Trim first lowercase chars ('otDone' will return 'Done' e.g.)                                                | 1050 |
| TrimRight                | Trims trailing whitespace characters from the string by removing trailing newline, space, and tab characters | 1050 |
| TrimU                    | Fast dedicated RawUTF8 version of Trim()                                                                     | 1050 |
| TruncTo2Digits           | Truncate a Currency value to only 2 digits                                                                   | 1050 |
| TruncTo2Digits64         | Truncate a Currency value, stored as Int64, to only 2 digits                                                 | 1050 |
| TruncTo2DigitsCurr64     | Truncate a Currency value, stored as Int64, to only 2 digits                                                 | 1051 |
| TryEncodeDate            | Our own fast version of the corresponding low-level RTL function                                             | 1051 |
| TypeInfoToHash           | Compute a crc32c-based hash of the RTTI for a managed given type                                             | 1051 |
| TypeInfoToName           | Retrieve the type name from its low-level RTTI                                                               | 1051 |
| TypeInfoToName           | Retrieve the type name from its low-level RTTI                                                               | 1051 |
| TypeInfoToQualifiedName  | Retrieve the unit name and type name from its low-level RTTI                                                 | 1051 |
| TypeInfoToRttiType       | Recognize a simple type from a supplied type information                                                     | 1051 |
| UCS4ToUTF8               | UTF-8 encode one UCS4 character into Dest                                                                    | 1051 |
| UInt2DigitsToShort       | Creates a 2 digits short string from a 0..99 value                                                           | 1051 |
| UInt2DigitsToShortFast   | Creates a 2 digits short string from a 0..99 value                                                           | 1051 |
| UInt32ToUtf8             | Optimized conversion of a cardinal into RawUTF8                                                              | 1051 |
| UInt32ToUtf8             | Optimized conversion of a cardinal into RawUTF8                                                              | 1051 |
| UInt3DigitsToShort       | Creates a 3 digits short string from a 0..999 value                                                          | 1052 |
| UInt3DigitsToUTF8        | Creates a 3 digits string from a 0..999 value as '000'..'999'                                                | 1052 |
| UInt4DigitsToShort       | Creates a 4 digits short string from a 0..9999 value                                                         | 1052 |
| UInt4DigitsToUTF8        | Creates a 4 digits string from a 0..9999 value as '0000'..'9999'                                             | 1052 |

| Functions or procedures  | Description                                                                                                                                                              | Page |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| UInt64ToUtf8             | Fast RawUTF8 version of IntToStr(), with proper QWord conversion                                                                                                         | 1052 |
| UnCamelCase              | Convert a CamelCase string into a space separated one                                                                                                                    | 1052 |
| UnCamelCase              | Convert a CamelCase string into a space separated one                                                                                                                    | 1052 |
| UnicodeBufferToString    | Convert an Unicode buffer into a generic VCL string                                                                                                                      | 1052 |
| UnicodeBufferToWinAnsi   | Convert an Unicode buffer into a WinAnsi (code page 1252) string                                                                                                         | 1053 |
| UniqueRawUTF8            | Equivalence to @UTF8[1] expression to ensure a RawUTF8 variable is unique                                                                                                | 1053 |
| UniqueRawUTF8ZeroToTitle | Will fast replace all #0 chars as ~                                                                                                                                      | 1053 |
| UnixMSTimePeriodToString | Delphi 2007 is buggy as hell convert some millisecond-based c-encoded time to the ISO 8601 text layout, as time or date elapsed period                                   | 1053 |
| UnixMSTimeToDateTime     | Convert a millisecond-based c-encoded time (from Unix epoch 1/1/1970) as TDateTime                                                                                       | 1053 |
| UnixMSTimeToFileShort    | Convert some millisecond-based c-encoded time (from Unix epoch 1/1/1970) to a small text layout, trimming to the second resolution, perfect e.g. for naming a local file | 1053 |
| UnixMSTimeToString       | Convert some millisecond-based c-encoded time (from Unix epoch 1/1/1970) to the ISO 8601 text layout, including milliseconds                                             | 1053 |
| UnixMSTimeUTC            | Returns the current UTC date/time as a millisecond-based c-encoded time                                                                                                  | 1053 |
| UnixMSTimeUTCFast        | Returns the current UTC date/time as a millisecond-based c-encoded time                                                                                                  | 1054 |
| UnixTimePeriodToString   | Delphi 2007 is buggy as hell convert some second-based c-encoded time to the ISO 8601 text layout, either as time or date elapsed period                                 | 1054 |
| UnixTimeToDateTime       | Convert a second-based c-encoded time as TDateTime                                                                                                                       | 1054 |
| UnixTimeToFileShort      | Convert some second-based c-encoded time (from Unix epoch 1/1/1970) to a small text layout, perfect e.g. for naming a local file                                         | 1054 |
| UnixTimeToFileShort      | Convert some second-based c-encoded time (from Unix epoch 1/1/1970) to a small text layout, perfect e.g. for naming a local file                                         | 1054 |
| UnixTimeToString         | Convert some second-based c-encoded time (from Unix epoch 1/1/1970) to the ISO 8601 text layout                                                                          | 1054 |
| UnixTimeUTC              | Returns the current UTC date/time as a second-based c-encoded time                                                                                                       | 1054 |
| UnQuotedSQLSymbolName    | Unquote a SQL-compatible symbol name                                                                                                                                     | 1054 |
| UnQuoteSQLString         | Unquote a SQL-compatible string                                                                                                                                          | 1054 |
| UnQuoteSQLStringVar      | Unquote a SQL-compatible string                                                                                                                                          | 1055 |

| Functions or procedures | Description                                                                                            | Page |
|-------------------------|--------------------------------------------------------------------------------------------------------|------|
| UnSetBit                | Unset/clear a particular bit into a bit array                                                          | 1055 |
| UnSetBit64              | Unset/clear a particular bit into a 64-bit integer bits (max aIndex is 63)                             | 1055 |
| UnSetBitPtr             | Unset/clear a particular bit into a bit array                                                          | 1055 |
| UpdateIniEntry          | Update a Name= Value in a [Section] of a INI RawUTF8 Content                                           | 1055 |
| UpdateIniEntryFile      | Update a Name= Value in a [Section] of a .INI file                                                     | 1055 |
| UpdateIniNameValue      | Replace a value from a given set of name=value lines                                                   | 1055 |
| UpperCase               | Fast conversion of the supplied text into uppercase                                                    | 1055 |
| UpperCaseCopy           | Fast conversion of the supplied text into uppercase                                                    | 1056 |
| UpperCaseCopy           | Fast conversion of the supplied text into uppercase                                                    | 1056 |
| UpperCaseSelf           | Fast in-place conversion of the supplied variable text into uppercase                                  | 1056 |
| UpperCaseU              | Fast conversion of the supplied text into 8 bit uppercase                                              | 1056 |
| UpperCaseUnicode        | Accurate conversion of the supplied UTF-8 content into the corresponding upper-case Unicode characters | 1056 |
| UpperCopy               | Copy source into dest^ with 7 bits upper case conversion                                               | 1056 |
| UpperCopy255            | Copy source into a 256 chars dest^ buffer with 7 bits upper case conversion                            | 1056 |
| UpperCopy255BufPas      | Copy source^ into a 256 chars dest^ buffer with 7 bits upper case conversion                           | 1056 |
| UpperCopy255BufSSE42    | SSE 4.2 version of UpperCopy255Buf()                                                                   | 1057 |
| UpperCopy255W           | Copy WideChar source into dest^ with upper case conversion                                             | 1057 |
| UpperCopy255W           | Copy WideChar source into dest^ with upper case conversion                                             | 1057 |
| UpperCopyShort          | Copy source into dest^ with 7 bits upper case conversion                                               | 1057 |
| UpperCopyWin255         | Copy source into dest^ with WinAnsi 8 bits upper case conversion                                       | 1057 |
| UrlDecode               | Decode a string compatible with URI encoding into its original value                                   | 1057 |
| UrlDecode               | Decode a string compatible with URI encoding into its original value                                   | 1057 |
| UrlDecodeCardinal       | Decode a specified parameter compatible with URI encoding into its original cardinal numerical value   | 1057 |
| UrlDecodeDouble         | Decode a specified parameter compatible with URI encoding into its original floating-point value       | 1058 |
| UrlDecodeExtended       | Decode a specified parameter compatible with URI encoding into its original floating-point value       | 1058 |

| Functions or procedures      | Description                                                                                         | Page |
|------------------------------|-----------------------------------------------------------------------------------------------------|------|
| UrlDecodeInt64               | Decode a specified parameter compatible with URI encoding into its original Int64 numerical value   | 1058 |
| UrlDecodeInteger             | Decode a specified parameter compatible with URI encoding into its original integer numerical value | 1058 |
| UrlDecodeNeedParameters      | Returns TRUE if all supplied parameters do exist in the URI encoded text                            | 1058 |
| UrlDecodeNextName            | Decode a URI-encoded Name from an input buffer                                                      | 1058 |
| UrlDecodeNextNameValue       | Decode the next Name=Value&.... pair from input URI                                                 | 1059 |
| UrlDecodeNextValue           | Decode a URI-encoded Value from an input buffer                                                     | 1059 |
| UrlDecodeValue               | Decode a specified parameter compatible with URI encoding into its original textual value           | 1059 |
| UrlEncode                    | Encode a string to be compatible with URI encoding                                                  | 1059 |
| UrlEncode                    | Encode supplied parameters to be compatible with URI encoding                                       | 1059 |
| UrlEncode                    | Encode a string to be compatible with URI encoding                                                  | 1059 |
| UrlEncodeJsonObject          | Encode a JSON object UTF-8 buffer into URI parameters                                               | 1059 |
| UrlEncodeJsonObject          | Encode a JSON object UTF-8 buffer into URI parameters                                               | 1059 |
| UTF16CharToUtf8              | UTF-8 encode one UTF-16 encoded UCS4 character into Dest                                            | 1060 |
| Utf8DecodeToRawUnicode       | Convert a UTF-8 encoded buffer into a RawUnicode string                                             | 1060 |
| Utf8DecodeToRawUnicode       | Convert a UTF-8 string into a RawUnicode string                                                     | 1060 |
| Utf8DecodeToRawUnicodeUI     | Convert a UTF-8 string into a RawUnicode string                                                     | 1060 |
| Utf8DecodeToRawUnicodeUI     | Convert a UTF-8 string into a RawUnicode string                                                     | 1060 |
| UTF8DecodeToString           | Convert any UTF-8 encoded buffer into a generic VCL Text                                            | 1060 |
| UTF8DecodeToString           | Convert any UTF-8 encoded buffer into a generic VCL Text                                            | 1060 |
| Utf8FirstLineToUnicodeLength | Calculate the UTF-16 Unicode characters count of the UTF-8 encoded first line                       | 1060 |
| UTF8IComp                    | Fast UTF-8 comparison using the NormToUpper[] array for all 8 bits values                           | 1060 |
| UTF8ILComp                   | Fast UTF-8 comparison using the NormToUpper[] array for all 8 bits values                           | 1061 |
| UTF8ToInt64                  | Get the signed 64-bit integer value stored in a RawUTF8 string                                      | 1061 |

| Functions or procedures     | Description                                                                                                                                   | Page |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|------|
| UTF8ToInteger               | Get and check range of a signed 32-bit integer stored in a RawUTF8 string                                                                     | 1061 |
| UTF8ToInteger               | Get the signed 32-bit integer value stored in a RawUTF8 string                                                                                | 1061 |
| Utf8ToRawUTF8               | Direct conversion of a UTF-8 encoded zero terminated buffer into a RawUTF8 String                                                             | 1061 |
| UTF8ToShortString           | Direct conversion of a UTF-8 encoded buffer into a WinAnsi shortstring buffer                                                                 | 1061 |
| UTF8ToString                | Convert any UTF-8 encoded String into a generic VCL Text                                                                                      | 1061 |
| UTF8ToSynUnicode            | Convert any UTF-8 encoded String into a generic SynUnicode Text                                                                               | 1061 |
| UTF8ToSynUnicode            | Convert any UTF-8 encoded String into a generic SynUnicode Text                                                                               | 1061 |
| UTF8ToSynUnicode            | Convert any UTF-8 encoded buffer into a generic SynUnicode Text                                                                               | 1061 |
| Utf8ToUnicodeLength         | Calculate the UTF-16 Unicode characters count, UTF-8 encoded in source^                                                                       | 1061 |
| UTF8ToWideChar              | Convert an UTF-8 encoded text into a WideChar (UTF-16) buffer                                                                                 | 1062 |
| UTF8ToWideChar              | Convert an UTF-8 encoded text into a WideChar (UTF-16) buffer                                                                                 | 1062 |
| UTF8ToWideString            | Convert any UTF-8 encoded String into a generic WideString Text                                                                               | 1062 |
| UTF8ToWideString            | Convert any UTF-8 encoded String into a generic WideString Text                                                                               | 1062 |
| UTF8ToWideString            | Convert any UTF-8 encoded String into a generic WideString Text                                                                               | 1062 |
| Utf8ToWinAnsi               | Direct conversion of a UTF-8 encoded string into a WinAnsi String                                                                             | 1062 |
| Utf8ToWinAnsi               | Direct conversion of a UTF-8 encoded zero terminated buffer into a WinAnsi String                                                             | 1062 |
| UTF8ToWinPChar              | Direct conversion of a UTF-8 encoded buffer into a WinAnsi PAnsiChar buffer                                                                   | 1062 |
| Utf8TruncatedLength         | Compute the truncated length of the supplied UTF-8 value if it exceeds the specified bytes count                                              | 1062 |
| Utf8TruncatedLength         | Compute the truncated length of the supplied UTF-8 value if it exceeds the specified bytes count                                              | 1062 |
| Utf8TruncateToLength        | Will truncate the supplied UTF-8 value if its length exceeds the specified bytes count                                                        | 1063 |
| Utf8TruncateToUnicodeLength | Will truncate the supplied UTF-8 value if its length exceeds the specified UTF-16 Unicode characters count                                    | 1063 |
| UTF8UpperCopy               | Copy WideChar source into dest^ with upper case conversion, using the NormToUpper[] array for all 8 bits values, encoding the result as UTF-8 | 1063 |

| Functions or procedures | Description                                                                                                                                   | Page |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|------|
| UTF8UpperCopy255        | Copy WideChar source into dest^ with upper case conversion, using the NormToUpper[] array for all 8 bits values, encoding the result as UTF-8 | 1063 |
| ValuesToVariantDynArray | Convert an open array list into a dynamic array of variants                                                                                   | 1063 |
| VarDataIsEmptyOrNull    | Same as VarIsEmpty(PVariant(V)^) or VarIsEmpty(PVariant(V)^), but faster                                                                      | 1063 |
| VariantCompare          | TVariantCompare-compatible case-sensitive comparison function                                                                                 | 1063 |
| VariantCompareI         | TVariantCompare-compatible case-insensitive comparison function                                                                               | 1063 |
| VariantDynArrayClear    | Faster alternative to Finalize(aVariantDynArray)                                                                                              | 1063 |
| VariantDynArrayToJSON   | Convert a dynamic array of variants into its JSON serialization                                                                               | 1063 |
| VariantEquals           | Fast comparison of a Variant and UTF-8 encoded String (or number)                                                                             | 1064 |
| VariantHash             | Crc32c-based hash of a variant value                                                                                                          | 1064 |
| VariantHexDisplayToBin  | Fast conversion from hexa chars, supplied as a variant string, into a binary buffer                                                           | 1064 |
| VariantLoad             | Retrieve a variant value from our optimized binary serialization format                                                                       | 1064 |
| VariantLoad             | Retrieve a variant value from our optimized binary serialization format                                                                       | 1064 |
| VariantLoadJSON         | Retrieve a variant value from a JSON number or string                                                                                         | 1065 |
| VariantLoadJSON         | Retrieve a variant value from a JSON number or string                                                                                         | 1065 |
| VariantLoadJSON         | Retrieve a variant value from a JSON number or string                                                                                         | 1065 |
| VariantSave             | Save a Variant content into a destination memory buffer                                                                                       | 1065 |
| VariantSave             | Save a Variant content into a binary buffer                                                                                                   | 1065 |
| VariantSaveJSON         | Save a variant value into a JSON content                                                                                                      | 1066 |
| VariantSaveJSON         | Save a variant value into a JSON content                                                                                                      | 1066 |
| VariantSaveJSONLength   | Compute the number of chars needed to save a variant value into a JSON content                                                                | 1066 |
| VariantSaveLength       | Compute the number of bytes needed to save a Variant content using the VariantSave() function                                                 | 1066 |
| VariantToBoolean        | Convert any numerical Variant into a boolean value                                                                                            | 1066 |
| VariantToCurrency       | Convert any numerical Variant into a fixed decimals floating point value                                                                      | 1066 |
| VariantToDateTime       | Convert any date/time Variant into a TDateTime value                                                                                          | 1066 |
| VariantToDouble         | Convert any numerical Variant into a floating point value                                                                                     | 1066 |
| VariantToDoubleDef      | Convert any numerical Variant into a floating point value                                                                                     | 1067 |

| Functions or procedures | Description                                                                                                                                        | Page |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|------|
| VariantToInlineValue    | Convert any Variant into a value encoded as with :(...) inlined parameters in FormatUTF8(Format,Args,Params)                                       | 1067 |
| VariantToInt64          | Convert any numerical Variant into a 64-bit integer                                                                                                | 1067 |
| VariantToInt64Def       | Convert any numerical Variant into a 64-bit integer                                                                                                | 1067 |
| VariantToInteger        | Convert any numerical Variant into a 32-bit integer                                                                                                | 1067 |
| VariantToIntegerDef     | Convert any numerical Variant into an integer                                                                                                      | 1067 |
| VariantToRawByteString  | Convert back a RawByteString from a variant                                                                                                        | 1067 |
| VariantToString         | Convert any Variant into a VCL string type                                                                                                         | 1067 |
| VariantToUTF8           | Convert any Variant into UTF-8 encoded String                                                                                                      | 1068 |
| VariantToUTF8           | Convert any Variant into UTF-8 encoded String                                                                                                      | 1068 |
| VariantToUTF8           | Convert any Variant into UTF-8 encoded String                                                                                                      | 1068 |
| VariantToVariantUTF8    | Convert any Variant into another Variant storing an RawUTF8 of the value                                                                           | 1068 |
| VariantToVarRec         | Convert a variant to an open array (const Args: array of const) argument                                                                           | 1068 |
| VarIs                   | Allow to check for a specific set of TVarData.VType                                                                                                | 1068 |
| VarIsEmptyOrNull        | Same as VarIsEmpty(V) or VarIsEmpty(V), but faster                                                                                                 | 1068 |
| VarIsVoid               | Fastcheck if a variant hold a value                                                                                                                | 1068 |
| VarRecAsChar            | Get an open array (const Args: array of const) character argument                                                                                  | 1068 |
| VarRecToDouble          | Convert an open array (const Args: array of const) argument to a floating point value                                                              | 1068 |
| VarRecToInlineValue     | Convert an open array (const Args: array of const) argument to a value encoded as with :(...) inlined parameters in FormatUTF8(Format,Args,Params) | 1068 |
| VarRecToInt64           | Convert an open array (const Args: array of const) argument to an Int64                                                                            | 1069 |
| VarRecToTempUTF8        | Convert an open array (const Args: array of const) argument to an UTF-8 encoded text, using a specified temporary buffer                           | 1069 |
| VarRecToUTF8            | Convert an open array (const Args: array of const) argument to an UTF-8 encoded text                                                               | 1069 |
| VarRecToUTF8IsString    | Convert an open array (const Args: array of const) argument to an UTF-8 encoded text, returning FALSE if the argument was not a string value       | 1069 |
| VarRecToVariant         | Convert an open array (const Args: array of const) argument to a variant                                                                           | 1069 |

| Functions or procedures | Description                                                                         | Page |
|-------------------------|-------------------------------------------------------------------------------------|------|
| VarRecToVariant         | Convert an open array (const Args: array of const) argument to a variant            | 1069 |
| VarStringOrNull         | Returns a supplied string as variant, or null if v is void ('')                     | 1069 |
| WideCharToUtf8          | UTF-8 encode one UTF-16 character into Dest                                         | 1069 |
| WideCharToWinAnsi       | Conversion of a wide char into a WinAnsi (CodePage 1252) char index                 | 1069 |
| WideCharToWinAnsiChar   | Conversion of a wide char into a WinAnsi (CodePage 1252) char                       | 1070 |
| WideStringToUTF8        | Convert a WideString into a UTF-8 string                                            | 1070 |
| WideStringToWinAnsi     | Convert a WideString into a WinAnsi (code page 1252) string                         | 1070 |
| WinAnsiBufferToUtf8     | Direct conversion of a WinAnsi PAnsiChar buffer into a UTF-8 encoded buffer         | 1070 |
| WinAnsiToRawUnicode     | Direct conversion of a WinAnsi (CodePage 1252) string into a Unicode encoded String | 1070 |
| WinAnsiToUnicodeBuffer  | Direct conversion of a WinAnsi (CodePage 1252) string into a Unicode buffer         | 1070 |
| WinAnsiToUtf8           | Direct conversion of a WinAnsi (CodePage 1252) string into a UTF-8 encoded String   | 1070 |
| WinAnsiToUtf8           | Direct conversion of a WinAnsi (CodePage 1252) string into a UTF-8 encoded String   | 1070 |
| WordScanIndex           | Fast search of an unsigned Word value position in a Word array                      | 1070 |
| WriteStringToStream     | Write an UTF-8 text into a TStream                                                  | 1070 |
| XorMemory               | Logical XOR of two memory buffers into a third                                      | 1071 |
| XorMemory               | Logical XOR of two memory buffers                                                   | 1071 |
| xxHash32                | Perform very fast xxHash hashing in 32-bit mode                                     | 1071 |
| YearToPChar             | Add the 4 digits of integer Y to P^ as '0000'..'9999'                               | 1071 |
| ZeroFill                | Same as FillChar(Value^,SizeOf(TVarData),0)                                         | 1071 |
| _Arr                    | Initialize a variant instance to store some document-based array content            | 1071 |
| _ArrFast                | Initialize a variant instance to store some document-based array content            | 1071 |
| _ByRef                  | Copy a TDocVariant to another variable, changing the options on the fly             | 1071 |
| _ByRef                  | Copy a TDocVariant to another variable, changing the options on the fly             | 1071 |
| _Copy                   | Return a full nested copy of a document-based variant instance                      | 1072 |

| Functions or procedures     | Description                                                                                                                            | Page |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------|------|
| <code>_CopyFast</code>      | Return a full nested copy of a document-based variant instance                                                                         | 1072 |
| <code>_CSV</code>           | Convert a TDocVariantData array or a string value into a CSV                                                                           | 1072 |
| <code>_Json</code>          | Initialize a variant instance to store some document-based content from a supplied (extended) JSON content                             | 1073 |
| <code>_Json</code>          | Initialize a variant instance to store some document-based content from a supplied (extended) JSON content                             | 1073 |
| <code>_JsonFast</code>      | Initialize a variant instance to store some document-based content from a supplied (extended) JSON content                             | 1074 |
| <code>_JsonFastExt</code>   | Initialize a variant instance to store some extended document-based content                                                            | 1074 |
| <code>_JsonFastFloat</code> | Initialize a variant instance to store some document-based content from a supplied (extended) JSON content, parsing any kind of float  | 1074 |
| <code>_JsonFastFmt</code>   | Initialize a variant instance to store some document-based content from a supplied (extended) JSON content, with parameters formatting | 1074 |
| <code>_JsonFmt</code>       | Initialize a variant instance to store some document-based content from a supplied (extended) JSON content, with parameters formatting | 1075 |
| <code>_JsonFmt</code>       | Initialize a variant instance to store some document-based content from a supplied (extended) JSON content, with parameters formatting | 1075 |
| <code>_Obj</code>           | Initialize a variant instance to store some document-based object content                                                              | 1075 |
| <code>_ObjAddProps</code>   | Add some property values to a document-based object content                                                                            | 1075 |
| <code>_ObjAddProps</code>   | Add the property values of a document to a document-based object content                                                               | 1075 |
| <code>_ObjFast</code>       | Initialize a variant instance to store some document-based object content                                                              | 1076 |
| <code>_ObjFast</code>       | Initialize a variant instance to store any object as a TDocVariant                                                                     | 1076 |
| <code>_Safe</code>          | Direct access to a TDocVariantData from a given variant instance                                                                       | 1076 |
| <code>_Safe</code>          | Delphi has problems inlining this :( direct access to a TDocVariantData from a given variant instance                                  | 1076 |
| <code>_Unique</code>        | Ensure a document-based variant instance will have only per-value nested objects or array documents                                    | 1076 |
| <code>_UniqueFast</code>    | Ensure a document-based variant instance will have only per-value nested objects or array documents                                    | 1077 |

**procedure** `AddArrayOfConst`(**var** `Dest`: TTVarRecDynArray; **const** `Values`: array of **const**);  
*Append one or several values to a local "array of const" variable*

```
function AddGUID(var guides: TGUIDDynArray; const guid: TGUID; NoDuplications:
boolean=false): integer;
```

*Append one TGUID item to a TGUID dynamic array*

- returning the newly inserted index in guides[], or an existing index in guides[] if NoDuplications is TRUE and TGUID already exists

```
function AddInt64(var Values: TInt64DynArray; Value: Int64): PtrInt; overload;
 Add a 64-bit integer value at the end of a dynamic array
```

```
function AddInt64(var Values: TInt64DynArray; var ValuesCount: integer; Value:
Int64): PtrInt; overload;
```

*Add a 64-bit integer value at the end of a dynamic array of integers*

```
function AddInt64(var Values: TInt64DynArray; const Another: TInt64DynArray): PtrInt;
overload;
```

*Add a 64-bit integer array at the end of a dynamic array*

```
function AddInt64Once(var Values: TInt64DynArray; Value: Int64): PtrInt;
```

*If not already existing, add a 64-bit integer value to a dynamic array*

```
procedure AddInt64Sorted(var Values: TInt64DynArray; Value: Int64);
```

*If not already existing, add a 64-bit integer value to a sorted dynamic array*

```
function AddInteger(var Values: TIntegerDynArray; Value: integer; NoDuplications:
boolean=false): boolean; overload;
```

*Add an integer value at the end of a dynamic array of integers*

- returns TRUE if Value was added successfully in Values[], in this case length(Values) will be increased

```
procedure AddInteger(var Values: TIntegerDynArray; var ValuesCount: integer; Value:
integer); overload;
```

*Add an integer value at the end of a dynamic array of integers*

- this overloaded function will use a separate Count variable (faster)  
 - it won't search for any existing duplicate

```
function AddInteger(var Values: TIntegerDynArray; var ValuesCount: integer; Value:
integer; NoDuplications: boolean): boolean; overload;
```

*Add an integer value at the end of a dynamic array of integers*

- this overloaded function will use a separate Count variable (faster), and would allow to search for duplicates

- returns TRUE if Value was added successfully in Values[], in this case ValuesCount will be increased, but length(Values) would stay fixed most of the time (since it stores the Values[] array capacity)

```
function AddInteger(var Values: TIntegerDynArray; const Another: TIntegerDynArray):
PtrInt; overload;
```

*Add an integer array at the end of a dynamic array of integer*

```
function AddPrefixToCSV(CSV: PUTF8Char; const Prefix: RawUTF8; Sep: AnsiChar = ','):
RawUTF8;
```

*Append some prefix to all CSV values*

```
AddPrefixToCSV('One,Two,Three','Pre')='PreOne,PreTwo,PreThree'
```

```
function AddRawUTF8(var Values: TRawUTF8DynArray; const Value: RawUTF8; NoDuplicates:
boolean=false; CaseSensitive: boolean=true): boolean; overload;
```

*True if Value was added successfully in Values[]*

```
procedure AddRawUTF8(var Values: TRawUTF8DynArray; var ValuesCount: integer; const
Value: RawUTF8); overload;
```

*Add the Value to Values[], with an external count variable, for performance*

```
function AddSortedInteger(var Values: TIntegerDynArray; Value: integer; CoValues:
PIntegerDynArray=nil): PtrInt; overload;
```

*Add an integer value in a sorted dynamic array of integers*

- overloaded function which do not expect an external Count variable

```
function AddSortedInteger(var Values: TIntegerDynArray; var ValuesCount: integer;
Value: integer; CoValues: PIntegerDynArray=nil): PtrInt; overload;
```

*Add an integer value in a sorted dynamic array of integers*

- returns the index where the Value was added successfully in Values[]

- returns -1 if the specified Value was already present in Values[] (we must avoid any duplicate for O(log(n)) binary search)

- if CoValues is set, its content will be moved to allow inserting a new value at CoValues[result] position

```
function AddSortedRawUTF8(var Values: TRawUTF8DynArray; var ValuesCount: integer;
const Value: RawUTF8; CoValues: PIntegerDynArray=nil; ForcedIndex: PtrInt=-1;
Compare: TUTF8Compare=nil): PtrInt;
```

*Add a RawUTF8 value in an alphabetically sorted dynamic array of RawUTF8*

- returns the index where the Value was added successfully in Values[]

- returns -1 if the specified Value was already present in Values[] (we must avoid any duplicate for O(log(n)) binary search)

- if CoValues is set, its content will be moved to allow inserting a new value at CoValues[result] position - a typical usage of CoValues is to store the corresponding ID to each RawUTF8 item

- if FastLocatePUTF8CharSorted() has been already called, this index can be set to optional ForceIndex parameter

- by default, exact (case-sensitive) match is used; you can specify a custom compare function if needed in Compare optional parameter

```
procedure AddToCSV(const Value: RawUTF8; var CSV: RawUTF8; const Sep: RawUTF8 = ',');
```

*Append a Value to a CSV string*

```
function AddWord(var Values: TWordDynArray; var ValuesCount: integer; Value: Word):
PtrInt;
```

*Add a 16-bit integer value at the end of a dynamic array of integers*

```
procedure AndMemory(Dest,Source: PByteArray; size: PtrInt);
```

*Logical AND of two memory buffers*

- will perform on all buffer bytes:

Dest[i] := Dest[i] and Source[i];

```
function Ansi7ToString(const Text: RawByteString): string; overload;
```

*Convert any Ansi 7 bit encoded String into a generic VCL Text*

- the Text content must contain only 7 bit pure ASCII characters

**function** Ansi7ToString(Text: PWinAnsiChar; Len: PtrInt): **string**; overload;

*Convert any Ansi 7 bit encoded String into a generic VCL Text*

- the Text content must contain only 7 bit pure ASCII characters

**procedure** Ansi7ToString(Text: PWinAnsiChar; Len: PtrInt; **var** result: **string**); overload;

*Convert any Ansi 7 bit encoded String into a generic VCL Text*

- the Text content must contain only 7 bit pure ASCII characters

**procedure** AnsiCharToUTF8(P: PAnsiChar; L: Integer; **var** result: RawUTF8; ACP: integer);

*Convert an AnsiChar buffer (of a given code page) into a UTF-8 string*

**function** AnsiIComp(Str1, Str2: pointer): PtrInt;

*Fast WinAnsi comparison using the NormToUpper[] array for all 8 bits values*

**function** AnsiICompW(u1, u2: PWideChar): PtrInt;

*Fast case-insensitive Unicode comparison*

- use the NormToUpperAnsi7Byte[] array, i.e. compare 'a'..'z' as 'A'..'Z'

- this version expects u1 and u2 to be zero-terminated

**procedure** AnyAnsiToUTF8(**const** s: RawByteString; **var** result: RawUTF8); overload;

*Direct conversion of an AnsiString with an unknown code page into an UTF-8 encoded String*

- will assume CurrentAnsiConvert.CodePage prior to Delphi 2009

- newer UNICODE versions of Delphi will retrieve the code page from string

**function** AnyAnsiToUTF8(**const** s: RawByteString): RawUTF8; overload;

*Direct conversion of an AnsiString with an unknown code page into an UTF-8 encoded String*

- will assume CurrentAnsiConvert.CodePage prior to Delphi 2009

- newer UNICODE versions of Delphi will retrieve the code page from string

**function** AnyScanExists(P, Elem: pointer; Count, ElemSize: PtrInt): boolean;

*Fast search of a binary value position in a fixed-size array*

- Count is the number of entries in P^[]

**function** AnyScanIndex(P, Elem: pointer; Count, ElemSize: PtrInt): PtrInt;

*Fast search of a binary value position in a fixed-size array*

- Count is the number of entries in P^[]

- return index of P^[index]=Elem^, comparing ElemSize bytes

- return -1 if Value was not found

**function** AnyTextFileToRawUTF8(**const** FileName: TFileName; AssumeUTF8IfNoBOM: boolean=false): RawUTF8;

*Get text file contents (even Unicode or UTF8) and convert it into an UTF-8 string according to any BOM marker at the beginning of the file*

- if AssumeUTF8IfNoBOM is FALSE, the current string code page is used (i.e. CurrentAnsiConvert class) for conversion from ANSI into UTF-8

- if AssumeUTF8IfNoBOM is TRUE, any file without any BOM marker will be interpreted as UTF-8

**function** AnyTextFileToString(**const** FileName: TFileName; ForceUTF8: boolean=false): **string**;

*Get text File contents (even Unicode or UTF8) and convert it into a Charset-compatible AnsiString (for Delphi 7) or an UnicodeString (for Delphi 2009 and up) according to any BOM marker at the beginning of the file*

- before Delphi 2009, the current string code page is used (i.e. CurrentAnsiConvert)

**function** AnyTextFileToSynUnicode(**const** FileName: TFileName; ForceUTF8: boolean=false): SynUnicode;

*Get text file contents (even Unicode or UTF8) and convert it into an Unicode string according to any BOM marker at the beginning of the file*

- any file without any BOM marker will be interpreted as plain ASCII: in this case, the current string code page is used (i.e. CurrentAnsiConvert class)

**function** Append999ToBuffer(Buffer: PUTF8Char; Value: PtrUInt): PUTF8Char;

*Fast add text conversion of 0-999 integer value into a given buffer*

- warning: it won't check that Value is in 0-999 range

- up to 4 bytes may be written to the buffer (including trailing #0)

**procedure** AppendBuffersToRawUTF8(**var** Text: RawUTF8; **const** Buffers: **array of** PUTF8Char);

*Fast add some characters to a RawUTF8 string*

- faster than Text := Text+RawUTF8(Buffers[0])+RawUTF8(Buffers[0])+...

**procedure** AppendBufferToRawUTF8(**var** Text: RawUTF8; Buffer: **pointer**; BufferLen: PtrInt);

*Fast add some characters to a RawUTF8 string*

- faster than SetString(tmp,Buffer,BufferLen); Text := Text+tmp;

**procedure** AppendCharToRawUTF8(**var** Text: RawUTF8; Ch: AnsiChar);

*Fast add one character to a RawUTF8 string*

- faster than Text := Text + ch;

**procedure** AppendCSVValues(**const** CSV: **string**; **const** Values: **array of string**; **var** Result: **string**; **const** AppendBefore: **string**=#13#10);

*Append some text lines with the supplied Values[]*

- if any Values[] item is '', no line is added

- otherwise, appends 'Caption: Value', with Caption taken from CSV

**function** AppendRawUTF8ToBuffer(Buffer: PUTF8Char; **const** Text: RawUTF8): PUTF8Char;

*Fast add some characters from a RawUTF8 string into a given buffer*

- warning: the Buffer should contain enough space to store the Text, otherwise you may encounter buffer overflows and random memory errors

**procedure** AppendShortComma(text: PAnsiChar; len: PtrInt; **var** result: shortstring; trimlowercase: boolean);

*Fast append some UTF-8 text into a shortstring, with an ending ','*

**procedure** AppendToTextFile(aLine: RawUTF8; **const** aFileName: TFileName; aMaxSize: Int64=MAXLOGSIZE; aUTCTimeStamp: boolean=false);

*Log a message to a local text file*

- this version expects the filename to be specified

- format contains the current date and time, then the Msg on one line

- date and time format used is 'YYYYMMDD hh:mm:ss'

**function** AppendUInt32ToBuffer(Buffer: PUTF8Char; Value: PtrUInt): PUTF8Char;

*Fast add text conversion of a 32-bit unsigned integer value into a given buffer*

- warning: the Buffer should contain enough space to store the text, otherwise you may encounter buffer overflows and random memory errors

**function** AreUrlValid(const Url: array of RawUTF8): boolean;

*Checks if the supplied UTF-8 text values don't need URL encoding*

- returns TRUE if all its chars of all strings are non-void plain ASCII-7 RFC compatible identifiers (0..9a..zA..Z-\_.~)

**function** ArrayOfConstValueAsText(const NameValuePairs: array of const; const aName: RawUTF8): RawUTF8;

*Find a given name in name/value pairs, and returns the value as RawUTF8*

**function** AsciiToBaudot(const Text: RawUTF8): RawByteString; overload;

*Convert some ASCII-7 text into binary, using Emile Baudot code*

- as used in telegraphs, covering #10 #13 #32 a-z 0-9 - ' , ! : ( + ) \$ ? @ . / ; charset, following a custom static-huffman-like encoding with 5-bit masks  
 - any upper case char will be converted into lowercase during encoding  
 - other characters (e.g. UTF-8 accents, or controls chars) will be ignored  
 - resulting binary will consume 5 (or 10) bits per character  
 - reverse of the BaudotToAscii() function  
 - the "baud" symbol rate measurement comes from Emile's name ;)

**function** AsciiToBaudot(P: PAnsiChar; len: PtrInt): RawByteString; overload;

*Convert some ASCII-7 text into binary, using Emile Baudot code*

- as used in telegraphs, covering #10 #13 #32 a-z 0-9 - ' , ! : ( + ) \$ ? @ . / ; charset, following a custom static-huffman-like encoding with 5-bit masks  
 - any upper case char will be converted into lowercase during encoding  
 - other characters (e.g. UTF-8 accents, or controls chars) will be ignored  
 - resulting binary will consume 5 (or 10) bits per character  
 - reverse of the BaudotToAscii() function  
 - the "baud" symbol rate measurement comes from Emile's name ;)

**function** Base64Decode(sp,rp: PAnsiChar; len: PtrInt): boolean;

*Direct low-level decoding of a Base64 encoded buffer*

- here len is the number of 4 chars chunks in sp input  
 - deprecated low-level function: use Base64ToBin/Base64ToBinSafe instead

**function** Base64MagicCheckAndDecode(Value: PUTF8Char; ValueLen: Integer; var Blob: RawByteString): boolean; overload;

*Check and decode '\uFFF0base64encodedbinary' content into binary*

- this method will check the supplied value to match the expected JSON\_BASE64\_MAGIC pattern, decode and set Blob and return TRUE

**function** Base64MagicCheckAndDecode(Value: PUTF8Char; var Blob: RawByteString): boolean; overload;

*Check and decode '\uFFF0base64encodedbinary' content into binary*

- this method will check the supplied value to match the expected JSON\_BASE64\_MAGIC pattern, decode and set Blob and return TRUE

**function** Base64MagicCheckAndDecode(Value: PUTF8Char; var Blob: TSynTempBuffer): boolean; overload;

*Check and decode '\uFFF0base64encodedbinary' content into binary*

- this method will check the supplied value to match the expected JSON\_BASE64\_MAGIC pattern, decode and set Blob and return TRUE

**procedure** Base64MagicDecode(**var** ParamValue: RawUTF8);

*Just a wrapper around Base64ToBin() for in-place decode of JSON\_BASE64\_MAGIC*

*'\uFFFF0base64encodedbinary' content into binary*

- input ParamValue shall have been checked to match the expected pattern

**function** Base64ToBin(**const** base64: RawByteString; bin: PAnsiChar; binlen: PtrInt; nofullcheck: boolean=true): boolean; overload;

*Fast conversion from Base64 encoded text into binary data*

- returns TRUE on success, FALSE if base64 does not match binlen

- nofullcheck is deprecated and not used any more, since nofullcheck=false is now processed with no performance cost

**function** Base64ToBin(sp: PAnsiChar; len: PtrInt; **var** Blob: TSynTempBuffer): boolean; overload;

*Fast conversion from Base64 encoded text into binary data*

- returns TRUE on success, FALSE if sp/len buffer was invalid

**function** Base64ToBin(base64, bin: PAnsiChar; base64len, binlen: PtrInt; nofullcheck: boolean=true): boolean; overload;

*Fast conversion from Base64 encoded text into binary data*

- returns TRUE on success, FALSE if base64 does not match binlen

- nofullcheck is deprecated and not used any more, since nofullcheck=false is now processed with no performance cost

**function** Base64ToBin(sp: PAnsiChar; len: PtrInt; **var** data: RawByteString): boolean; overload;

*Fast conversion from Base64 encoded text into binary data*

- is now just an alias to Base64ToBinSafe() overloaded function

- returns false and data="" if sp/len buffer was invalid

**function** Base64ToBin(sp: PAnsiChar; len: PtrInt): RawByteString; overload;

*Fast conversion from Base64 encoded text into binary data*

- is now just an alias to Base64ToBinSafe() overloaded function

- returns "" if sp/len buffer was not a valid Base64-encoded input

**function** Base64ToBin(**const** s: RawByteString): RawByteString; overload;

*Fast conversion from Base64 encoded text into binary data*

- is now just an alias to Base64ToBinSafe() overloaded function

- returns "" if s was not a valid Base64-encoded input

**function** Base64ToBinLength(sp: PAnsiChar; len: PtrInt): PtrInt;

*Retrieve the expected undecoded length of a Base64 encoded buffer*

- here len is the number of bytes in sp

**function** Base64ToBinLengthSafe(sp: PAnsiChar; len: PtrInt): PtrInt;

*Retrieve the expected undecoded length of a Base64 encoded buffer*

- here len is the number of bytes in sp

- will check supplied text is a valid Base64 encoded stream

**function** Base64ToBinSafe(sp: PAnsiChar; len: PtrInt; **var** data: RawByteString): boolean; overload;

*Fast conversion from Base64 encoded text into binary data*

- will check supplied text is a valid Base64 encoded stream

**function** Base64ToBinSafe(sp: PAnsiChar; len: PtrInt): RawByteString; overload;

*Fast conversion from Base64 encoded text into binary data*  
- will check supplied text is a valid Base64 encoded stream

**function** Base64ToBinSafe(const s: RawByteString): RawByteString; overload;

*Fast conversion from Base64 encoded text into binary data*  
- will check supplied text is a valid Base64 encoded stream

**procedure** Base64ToURI(var base64: RawUTF8);

*Conversion from any Base64 encoded value into URI-compatible encoded text*  
- warning: will modify the supplied base64 string in-place  
- in comparison to Base64 standard encoding, will trim any right-sided '=' insignificant characters, and replace '+' or '/' by '\_' or '-'

**function** Base64uriDecode(sp, rp: PAnsiChar; len: PtrInt): boolean;

*Direct low-level decoding of a Base64-URI encoded buffer*  
- the buffer is expected to be at least Base64uriToBinLength() bytes long  
- returns true if the supplied sp[] buffer has been successfully decoded into rp[] - will break at any invalid character, so is always safe to use  
- in comparison to Base64 standard encoding, will trim any right-sided '=' insignificant characters, and replace '+' or '/' by '\_' or '-'  
- you should better not use this, but Base64uriToBin() overloaded functions

**procedure** Base64uriEncode(rp, sp: PAnsiChar; len: cardinal);

*Low-level conversion from a binary buffer into Base64-like URI-compatible encoded text*  
- you should rather use the overloaded BinToBase64uri() functions

**function** Base64uriToBin(base64, bin: PAnsiChar; base64len, binlen: PtrInt): boolean; overload;

*Fast conversion from Base64-URI encoded text into binary data*  
- in comparison to Base64 standard encoding, will trim any right-sided '=' insignificant characters, and replace '+' or '/' by '\_' or '-'  
- will check supplied text is a valid Base64-URI encoded stream

**function** Base64uriToBin(const base64: RawByteString; bin: PAnsiChar; binlen: PtrInt): boolean; overload;

*Fast conversion from Base64-URI encoded text into binary data*  
- in comparison to Base64 standard encoding, will trim any right-sided '=' insignificant characters, and replace '+' or '/' by '\_' or '-'  
- will check supplied text is a valid Base64-URI encoded stream

**function** Base64uriToBin(const s: RawByteString): RawByteString; overload;

*Fast conversion from Base64-URI encoded text into binary data*  
- in comparison to Base64 standard encoding, will trim any right-sided '=' insignificant characters, and replace '+' or '/' by '\_' or '-'

**function** Base64uriToBin(sp: PAnsiChar; len: PtrInt): RawByteString; overload;

*Fast conversion from Base64-URI encoded text into binary data*  
- in comparison to Base64 standard encoding, will trim any right-sided '=' insignificant characters, and replace '+' or '/' by '\_' or '-'

**procedure** Base64uriToBin(sp: PAnsiChar; len: PtrInt; **var** result: RawByteString);  
overload;

*Fast conversion from Base64-URI encoded text into binary data*

- in comparison to Base64 standard encoding, will trim any right-sided '=' insignificant characters,  
and replace '+' or '/' by '\_' or '-'

**function** Base64uriToBin(sp: PAnsiChar; len: PtrInt; **var** temp: TSynTempBuffer):  
boolean; overload;

*Fast conversion from Base64-URI encoded text into binary data*

- caller should always execute temp.Done when finished with the data  
- in comparison to Base64 standard encoding, will trim any right-sided '=' insignificant characters,  
and replace '+' or '/' by '\_' or '-'

**function** Base64uriToBinLength(len: PtrInt): PtrInt;

*Retrieve the expected undecoded length of a Base64-URI encoded buffer*

- here len is the number of bytes in sp  
- in comparison to Base64 standard encoding, will trim any right-sided '=' insignificant characters,  
and replace '+' or '/' by '\_' or '-'

**function** BaudotToAscii(**const** Baudot: RawByteString): RawUTF8; overload;

*Convert some Baudot code binary, into ASCII-7 text*

- reverse of the AsciiToBaudot() function  
- any uppercase character would be decoded as lowercase - and some characters may have  
disappeared  
- the "baud" symbol rate measurement comes from Emile's name ;)

**function** BaudotToAscii(Baudot: PByteArray; len: PtrInt): RawUTF8; overload;

*Convert some Baudot code binary, into ASCII-7 text*

- reverse of the AsciiToBaudot() function  
- any uppercase character would be decoded as lowercase - and some characters may have  
disappeared  
- the "baud" symbol rate measurement comes from Emile's name ;)

**function** BinToBase64(Bin: PAnsiChar; BinBytes: integer): RawUTF8; overload;

*Fast conversion from binary data into Base64 encoded UTF-8 text*

**function** BinToBase64(**const** data, Prefix, Suffix: RawByteString; WithMagic: boolean):  
RawUTF8; overload;

*Fast conversion from binary data into prefixed/suffixed Base64 encoded UTF-8 text*

- with optional JSON\_BASE64\_MAGIC prefix (UTF-8 encoded \uFFFF0 special code)

**function** BinToBase64(**const** s: RawByteString): RawUTF8; overload;

*Fast conversion from binary data into Base64 encoded UTF-8 text*

**function** BinToBase64Length(len: PtrUInt): PtrUInt;

*Retrieve the expected encoded length after Base64 process*

**function** BinToBase64Short(Bin: PAnsiChar; BinBytes: integer): shortstring; overload;

*Fast conversion from a small binary data into Base64 encoded UTF-8 text*

**function** BinToBase64Short(**const** s: RawByteString): shortstring; overload;

*Fast conversion from a small binary data into Base64 encoded UTF-8 text*

**function** BinToBase64uri(Bin: PAnsiChar; BinBytes: integer): RawUTF8; overload;

*Fast conversion from a binary buffer into Base64-like URI-compatible encoded text*

- in comparison to Base64 standard encoding, will trim any right-sided '=' insignificant characters, and replace '+' or '/' by '\_' or '-'

**function** BinToBase64uri(const s: RawByteString): RawUTF8; overload;

*Fast conversion from binary data into Base64-like URI-compatible encoded text*

- in comparison to Base64 standard encoding, will trim any right-sided '=' insignificant characters, and replace '+' or '/' by '\_' or '-'

**function** BinToBase64uriLength(len: PtrUInt): PtrUInt;

*Retrieve the expected encoded length after Base64-URI process*

- in comparison to Base64 standard encoding, will trim any right-sided '=' insignificant characters, and replace '+' or '/' by '\_' or '-'

**function** BinToBase64uriShort(Bin: PAnsiChar; BinBytes: integer): shortstring;

*Fast conversion from a binary buffer into Base64-like URI-compatible encoded shortstring*

- in comparison to Base64 standard encoding, will trim any right-sided '=' insignificant characters, and replace '+' or '/' by '\_' or '-'

- returns '' if BinBytes void or too big for the resulting shortstring

**function** BinToBase64WithMagic(const data: RawByteString): RawUTF8; overload;

*Fast conversion from binary data into Base64 encoded UTF-8 text with JSON\_BASE64\_MAGIC prefix (UTF-8 encoded \uFFFD special code)*

**function** BinToBase64WithMagic(Data: pointer; DataLen: integer): RawUTF8; overload;

*Fast conversion from binary data into Base64 encoded UTF-8 text with JSON\_BASE64\_MAGIC prefix (UTF-8 encoded \uFFFD special code)*

**procedure** BinToHex(Bin, Hex: PAnsiChar; BinBytes: integer); overload;

*Fast conversion from binary data into hexa chars*

- BinBytes contain the bytes count to be converted: Hex^ must contain enough space for at least BinBytes\*2 chars

- using this function with BinBytes^ as an integer value will encode it in low-endian order (less-significant byte first): don't use it for display

**function** BinToHex(const Bin: RawByteString): RawUTF8; overload;

*Fast conversion from binary data into hexa chars*

**function** BinToHex(Bin: PAnsiChar; BinBytes: integer): RawUTF8; overload;

*Fast conversion from binary data into hexa chars*

**function** BinToHexDisplay(Bin: PAnsiChar; BinBytes: integer): RawUTF8; overload;

*Fast conversion from binary data into hexa chars, ready to be displayed*

**procedure** BinToHexDisplay(Bin, Hex: PAnsiChar; BinBytes: integer); overload;

*Fast conversion from binary data into hexa chars, ready to be displayed*

- BinBytes contain the bytes count to be converted: Hex^ must contain enough space for at least BinBytes\*2 chars

- using this function with Bin^ as an integer value will encode it in big-endian order (most-significant byte first): use it for display

**function** BinToHexDisplayFile(Bin: PAnsiChar; BinBytes: integer): TFileName;

*Fast conversion from binary data into hexa lowercase chars, ready to be used as a convenient TFileName prefix*

**function** BinToHexDisplayLower(Bin: PAnsiChar; BinBytes: integer): RawUTF8; overload;

*Fast conversion from binary data into lowercase hexa chars*

**procedure** BinToHexDisplayLower(Bin, Hex: PAnsiChar; BinBytes: PtrInt); overload;

*Fast conversion from binary data into lowercase hexa chars*

- BinBytes contain the bytes count to be converted: Hex^ must contain enough space for at least BinBytes\*2 chars

- using this function with Bin^ as an integer value will encode it in big-endian order (most-significant byte first): use it for display

**function** BinToHexDisplayLowerShort(Bin: PAnsiChar; BinBytes: integer): shortstring;

*Fast conversion from up to 127 bytes of binary data into lowercase hexa chars*

**function** BinToHexDisplayLowerShort16(Bin: Int64; BinBytes: integer): TShort16;

*Fast conversion from up to 64-bit of binary data into lowercase hexa chars*

**function** BinToHexDisplayLowerVariant(Bin: pointer; BinBytes: integer): variant;

*Fast conversion of a binary buffer into hexa chars, as a variant string*

**function** BinToHexLower(const Bin: RawByteString): RawUTF8; overload;

*Fast conversion from binary data into lowercase hexa chars*

**procedure** BinToHexLower(Bin, Hex: PAnsiChar; BinBytes: integer); overload;

*Fast conversion from binary data into lowercase hexa chars*

- BinBytes contain the bytes count to be converted: Hex^ must contain enough space for at least BinBytes\*2 chars

- using this function with BinBytes^ as an integer value will encode it in low-endian order (less-significant byte first): don't use it for display

**procedure** BinToHexLower(Bin: PAnsiChar; BinBytes: integer; var result: RawUTF8); overload;

*Fast conversion from binary data into lowercase hexa chars*

**function** BinToHexLower(Bin: PAnsiChar; BinBytes: integer): RawUTF8; overload;

*Fast conversion from binary data into lowercase hexa chars*

**function** BinToSource(const ConstName, Comment: RawUTF8; Data: pointer; Len: integer; PerLine: integer=16; const Suffix: RawUTF8=''): RawUTF8; overload;

*Generate some pascal source code holding some data binary as constant*

- can store sensitive information (e.g. certificates) within the executable

- generates a source code snippet of the following format:

```
const
 // Comment
 ConstName: array[0..2] of byte = (
 $01,$02,$03);
```

**procedure** BinToSource(Dest: TTextWriter; **const** ConstName, Comment: RawUTF8; Data: pointer; Len: integer; PerLine: integer=16); overload;

*Generate some pascal source code holding some data binary as constant*

- can store sensitive information (e.g. certificates) within the executable
- generates a source code snippet of the following format:

```
const
 // Comment
 ConstName: array[0..2] of byte = (
 $01,$02,$03);
```

**function** bswap32(a: cardinal): cardinal;

*Convert the endianness of a given unsigned 32-bit integer into BigEndian*

**function** bswap64(**const** a: QWord): QWord;

*Convert the endianness of a given unsigned 64-bit integer into BigEndian*

**procedure** bswap64array(a,b: PQWordArray; n: PtrInt);

*Convert the endianness of an array of unsigned 64-bit integer into BigEndian*

- n is required to be > 0
- warning: on x86, a should be <> b

**function** BufferLineLength(Text, TextEnd: PUTF8Char): PtrInt;

*Compute the line length from a size-delimited source array of chars*

- will use fast assembly on x86-64 CPU, and expects TextEnd to be not nil
- is likely to read some bytes after the TextEnd buffer, so GetLineSize() may be preferred, e.g. on memory mapped files

**function** ByteScanIndex(P: PByteArray; Count: PtrInt; Value: Byte): PtrInt;

*Fast search of an unsigned Byte value position in a Byte array*

- Count is the number of Byte entries in P^
- return index of P^[index]=Value
- return -1 if Value was not found

**procedure** BytesToRawByteString(**const** bytes: TBytes; **out** buf: RawByteString);

*Creates a RawByteString memory buffer from a TBytes content*

**function** ByteToHex(P: PAnsiChar; Value: byte): PAnsiChar;

*Append one byte as hexadecimal char pairs, into a text buffer*

**procedure** CamelCase(**const** text: RawUTF8; **var** s: RawUTF8; **const** isWord: TSynByteSet=[ord('0')..ord('9'),ord('a')..ord('z'),ord('A')..ord('Z')]); overload;

*Convert a string into an human-friendly CamelCase identifier*

- replacing spaces or punctuations by an uppercase character
- as such, it is not the reverse function to UnCamelCase()

**procedure** CamelCase(P: PAnsiChar; len: PtrInt; **var** s: RawUTF8; **const** isWord: TSynByteSet=[ord('0')..ord('9'),ord('a')..ord('z'),ord('A')..ord('Z')]); overload;

*Convert a string into an human-friendly CamelCase identifier*

- replacing spaces or punctuations by an uppercase character
- as such, it is not the reverse function to UnCamelCase()

**function** CardinalToHex(aCardinal: Cardinal): RawUTF8;

*Fast conversion from a Cardinal value into hexa chars, ready to be displayed*

- use internally BinToHexDisplay()
- reverse function of HexDisplayToCardinal()

**function** CardinalToHexLower(aCardinal: Cardinal): RawUTF8;

*Fast conversion from a Cardinal value into hexa chars, ready to be displayed*

- use internally BinToHexDisplayLower()
- reverse function of HexDisplayToCardinal()

**function** CardinalToHexShort(aCardinal: Cardinal): TShort16;

*Fast conversion from a Cardinal value into hexa chars, ready to be displayed*

- use internally BinToHexDisplay()
- such result type would avoid a string allocation on heap

**function** Char2ToByte(P: PUTF8Char; out Value: Cardinal): Boolean;

*Fast conversion of 2 digit characters into a 0..99 value*

- returns FALSE on success, TRUE if P^ is not correct

**function** Char3ToWord(P: PUTF8Char; out Value: Cardinal): Boolean;

*Fast conversion of 3 digit characters into a 0..9999 value*

- returns FALSE on success, TRUE if P^ is not correct

**function** Char4ToWord(P: PUTF8Char; out Value: Cardinal): Boolean;

*Fast conversion of 4 digit characters into a 0..9999 value*

- returns FALSE on success, TRUE if P^ is not correct

**function** Chars3ToInt18(P: pointer): cardinal;

*Revert the value as encoded by TTextWriter.AddInt18ToChars3() or Int18ToChars3()*

- no range check is performed: you should ensure that the incoming text follows the expected 3-chars layout

**function** CharSetToCodePage(CharSet: integer): cardinal;

*Convert a char set to a code page*

**function** ClassNameShort(C: TClass): PShortString; overload;

*Just a wrapper around vmtClassName to avoid a string conversion*

**function** ClassNameShort(Instance: TObject): PShortString; overload;

*Just a wrapper around vmtClassName to avoid a string conversion*

**function** CodePageToCharSet(CodePage: Cardinal): Integer;

*Convert a code page to a char set*

**function** CompareCardinal(const A, B: cardinal): integer;

*A comparison function for sorting 32-bit unsigned integer values*

**function** CompareFloat(const A, B: double): integer;

*A comparison function for sorting IEEE 754 double precision values*

**function** CompareInt64(const A, B: Int64): integer;

*A comparison function for sorting 64-bit signed integer values*

**function** CompareInteger(const A, B: integer): integer;

*A comparison function for sorting 32-bit signed integer values*

**function** CompareMem(P1, P2: Pointer; Length: PtrInt): Boolean;

*Our fast version of CompareMem() with optimized asm for x86 and tune pascal*

**function** CompareMemSmall(P1, P2: Pointer; Length: PtrUInt): Boolean;

*A CompareMem()-like function designed for small (a few bytes) content*

**function** CompareQWord(A, B: QWord): integer;

*A comparison function for sorting 64-bit unsigned integer values*

- note that QWord(A)>QWord(B) is wrong on older versions of Delphi, so you should better use this function or SortDynArrayQWord() to properly compare two QWord values over CPUX86

**function** CompressSynLZ(var DataRawByteString; Compress: boolean): AnsiString;

*Compress a data content using the SynLZ algorithm*

- as expected by THttpSocket.RegisterCompress  
 - will return 'synlz' as ACCEPT-ENCODING: header parameter  
 - will store a hash of both compressed and uncompressed stream: if the data is corrupted during transmission, will instantly return ""

**function** ContainsUTF8(p, up: PUTF8Char): boolean;

*Return true if up^ is contained inside the UTF-8 buffer p^*

- search up^ at the beginning of every UTF-8 word (aka in Soundex)  
 - here a "word" is a Win-Ansi word, i.e. 'O'..'9', 'A'..'Z'  
 - up^ must be already Upper

**function** ConvertCaseUTF8(P: PUTF8Char; const Table: TNormTableByte): PtrInt;

*Fast conversion of the supplied text into 8 bit case sensitivity*

- convert the text in-place, returns the resulting length  
 - it will decode the supplied UTF-8 content to handle more than 7 bit of ascii characters during the conversion (leaving not WinAnsi characters untouched)  
 - will not set the last char to #0 (caller must do that if necessary)

**procedure** CopyAndSortInt64(Values: PInt64Array; ValuesCount: integer; var Dest: TInt64DynArray);

*Copy an integer array, then sort it, low values first*

**procedure** CopyAndSortInteger(Values: PIntegerArray; ValuesCount: integer; var Dest: TIntegerDynArray);

*Copy an integer array, then sort it, low values first*

**function** CopyFile(const Source, Target: TFileName; FailIfExists: boolean): boolean;

*Copy one file to another, similar to the Windows API*

**procedure** CopyInt64(const Source: TInt64DynArray; out Dest: TInt64DynArray);

*Create a new 64-bit integer dynamic array with the values from another one*

**procedure** CopyInteger(const Source: TIntegerDynArray; out Dest: TIntegerDynArray);

*Create a new 32-bit integer dynamic array with the values from another one*

**procedure** crc128c(buf: PAnsiChar; len: cardinal; out crc: THash128);

*Compute a 128-bit checksum on the supplied buffer, cascading two crc32c*

- will use SSE 4.2 hardware accelerated instruction, if available  
 - will combine two crc32c() calls into a single TAESBlock result  
 - by design, such combined hashes cannot be cascaded

**function** crc16(Data: PAnsiChar; Len: integer): cardinal;

*Compute CRC16-CCITT checksum on the supplied buffer*

- i.e. 16-bit CRC-CCITT, with polynomial  $x^{16} + x^{12} + x^5 + 1$  (\$1021) and \$ffff as initial value
- this version is not optimized for speed, but for correctness

**procedure** crc256c(buf: PAnsiChar; len: cardinal; out crc: THash256);

*Compute a 256-bit checksum on the supplied buffer using crc32c*

- will use SSE 4.2 hardware accelerated instruction, if available
- will combine two crc32c() calls into a single THash256 result
- by design, such combined hashes cannot be cascaded

**function** crc32cfast(crc: cardinal; buf: PAnsiChar; len: cardinal): cardinal;

*Compute CRC32C checksum on the supplied buffer on processor-neutral code*

- result is compatible with SSE 4.2 based hardware accelerated instruction
- will use fast x86/x64 asm or efficient pure pascal implementation on ARM
- result is not compatible with zlib's crc32() - not the same polynom
- crc32cfast() is 1.7 GB/s, crc32csse42() is 4.3 GB/s
- you should use crc32c() function instead of crc32cfast() or crc32csse42()

**function** crc32cinline(crc: cardinal; buf: PAnsiChar; len: cardinal): cardinal;

*Compute CRC32C checksum on the supplied buffer using inlined code*

- if the compiler supports inlining, will compute a slow but safe crc32c checksum of the binary buffer, without calling the main crc32c() function
- may be used e.g. to identify patched executable at runtime, for a licensing protection system

**function** crc32csse42(crc: cardinal; buf: PAnsiChar; len: cardinal): cardinal;

*Compute CRC32C checksum on the supplied buffer using SSE 4.2*

- use Intel Streaming SIMD Extensions 4.2 hardware accelerated instruction
- SSE 4.2 shall be available on the processor (i.e. cfSSE42 in CpuFeatures)
- result is not compatible with zlib's crc32() - not the same polynom
- crc32cfast() is 1.7 GB/s, crc32csse42() is 4.3 GB/s
- you should use crc32c() function instead of crc32cfast() or crc32csse42()

**function** crc32cUTF8ToHex(const str: RawUTF8): RawUTF8;

*Compute the hexadecimal representation of the crc32 checksum of a given text*

- wrapper around CardinalToHex(crc32c(...))

**procedure** crc512c(buf: PAnsiChar; len: cardinal; out crc: THash512);

*Compute a 512-bit checksum on the supplied buffer using crc32c*

- will use SSE 4.2 hardware accelerated instruction, if available
- will combine two crc32c() calls into a single THash512 result
- by design, such combined hashes cannot be cascaded

**function** crc63c(buf: PAnsiChar; len: cardinal): Int64;

*Compute CRC63C checksum on the supplied buffer, cascading two crc32c*

- similar to crc64c, but with 63-bit, so no negative value: may be used safely e.g. as mORMot's TID source
- will use SSE 4.2 hardware accelerated instruction, if available
- will combine two crc32c() calls into a single Int64 result
- by design, such combined hashes cannot be cascaded

**function** crc64c(buf: PAnsiChar; len: cardinal): Int64;

*Compute CRC64C checksum on the supplied buffer, cascading two crc32c*

- will use SSE 4.2 hardware accelerated instruction, if available
- will combine two crc32c() calls into a single Int64 result
- by design, such combined hashes cannot be cascaded

**procedure** crcblockNoSSE42(crc128, data128: PBlock128);

*Computation of our 128-bit CRC of a 128-bit binary buffer without SSE4.2*

- to be used for regression tests only: crcblock will use the fastest implementation available on the current CPU (e.g. with SSE 4.2 opcodes)

**procedure** crcblocksfast(crc128, data128: PBlock128; count: integer);

*Compute a proprietary 128-bit CRC of 128-bit binary buffers*

- to be used for regression tests only: crcblocks will use the fastest implementation available on the current CPU (e.g. with SSE 4.2 opcodes)

**function** CreateInternalWindow(const aWindowName: string; aObject: TObject): HWND;

*This function can be used to create a GDI compatible window, able to receive Windows Messages for fast local communication*

- will return 0 on failure (window name already existing e.g.), or the created HWND handle on success
- it will call the supplied message handler defined for a given Windows Message: for instance, define such a method in any object definition:

```
procedure WMCopyData(var Msg : TWMCopyData); message WM_COPYDATA;
```

**function** CSVEncode(const NameValuePairs: array of const; const KeySeparator: RawUTF8='='; const ValueSeparator: RawUTF8=#13#10): RawUTF8;

*Encode name/value pairs into CSV/INI raw format*

**function** CSVOfValue(const Value: RawUTF8; Count: cardinal; const Sep: RawUTF8=','): RawUTF8;

*Return a CSV list of the iterated same value*

- e.g. CSVOfValue('?',3)='?,?,?'

**procedure** CSVToInt64DynArray(CSV: PUTF8Char; var Result: TInt64DynArray; Sep: AnsiChar= ','); overload;

*Append the strings in the specified CSV text into a dynamic array of integer*

**function** CSVToInt64DynArray(CSV: PUTF8Char; Sep: AnsiChar= ','): TInt64DynArray; overload;

*Convert the strings in the specified CSV text into a dynamic array of integer*

**procedure** CSVToIntegerDynArray(CSV: PUTF8Char; var Result: TIntegerDynArray; Sep: AnsiChar= ',');

*Append the strings in the specified CSV text into a dynamic array of integer*

**procedure** CSVToRawUTF8DynArray(CSV: PUTF8Char; var Result: TRawUTF8DynArray; Sep: AnsiChar=','; TrimItems: boolean=false; AddVoidItems: boolean=false); overload;

*Add the strings in the specified CSV text into a dynamic array of UTF-8 strings*

**procedure** CSVToRawUTF8DynArray(const CSV, Sep, SepEnd: RawUTF8; var Result: TRawUTF8DynArray); overload;

*Add the strings in the specified CSV text into a dynamic array of UTF-8 strings*

**function** Curr64ToPChar(const Value: Int64; Dest: PUTF8Char): PtrInt;

*Convert an INTEGER Curr64 (value\*10000) into a string*

- this type is compatible with Delphi currency memory map with PInt64(@Curr)^
- fast conversion, using only integer operations
- decimals are joined by 2 (no decimal, 2 decimals, 4 decimals)
- return the number of chars written to Dest^

**function** Curr64ToStr(const Value: Int64): RawUTF8; overload;

*Convert an INTEGER Curr64 (value\*10000) into a string*

- this type is compatible with Delphi currency memory map with PInt64(@Curr)^
- fast conversion, using only integer operations
- decimals are joined by 2 (no decimal, 2 decimals, 4 decimals)

**procedure** Curr64ToStr(const Value: Int64; var result: RawUTF8); overload;

*Convert an INTEGER Curr64 (value\*10000) into a string*

- this type is compatible with Delphi currency memory map with PInt64(@Curr)^
- fast conversion, using only integer operations
- decimals are joined by 2 (no decimal, 2 decimals, 4 decimals)

**function** Curr64ToString(Value: Int64): string;

*Convert a currency value from its Int64 binary representation into its numerical text equivalency*

- decimals are joined by 2 (no decimal, 2 decimals, 4 decimals)

**function** CurrencyToStr(Value: currency): RawUTF8;

*Convert a currency value into a string*

- fast conversion, using only integer operations
- decimals are joined by 2 (no decimal, 2 decimals, 4 decimals)

**function** DACntDecFree(var refcnt: TDACnt): boolean;

*Low-level dynarray reference counter unprocess*

- caller should have tested that refcnt>=0

**function** DateTimeMSToString(DateTime: TDateTime; Expanded: boolean=true; FirstTimeChar: AnsiChar=' '; const TZD: RawUTF8='Z'): RawUTF8; overload;

*Convert some date/time to the ISO 8601 text layout, including milliseconds*

- i.e. 'YYYY-MM-DD hh:mm:ss.sssZ' or 'YYYYMMDD hhmmss.sssZ' format
- TZD is the ending time zone designator ('', 'Z' or '+hh:mm' or '-hh:mm')
- see also TTextWriter.AddDateTimeMS method

**function** DateTimeMSToString(HH,MM,SS,MS,Y,M,D: cardinal; Expanded: boolean; FirstTimeChar: AnsiChar=' '; const TZD: RawUTF8='Z'): RawUTF8; overload;

*Convert some date/time to the ISO 8601 text layout, including milliseconds*

- i.e. 'YYYY-MM-DD hh:mm:ss.sssZ' or 'YYYYMMDD hhmmss.sssZ' format
- TZD is the ending time zone designator ('', 'Z' or '+hh:mm' or '-hh:mm')
- see also TTextWriter.AddDateTimeMS method

**function** DateTimeToFileShort(const DateTime: TDateTime): TShort16; overload;

*Convert some TDateTime to a small text layout, perfect e.g. for naming a local file*

- use 'YYMMDDHHMMSS' format so year is truncated to last 2 digits, expecting a date > 1999 (a current date would be fine)

**procedure** DateTimeToFileShort(**const** DateTime: TDateTime; **out** result: TShort16);  
 overload;

*Delphi 2007 is buggy as hell convert some TDateTime to a small text layout, perfect e.g. for naming a local file*

- use 'YYMMDDHHMMSS' format so year is truncated to last 2 digits, expecting a date > 1999 (a current date would be fine)

**function** DateTimeToHTTPDate(dt: TDateTime; **const** tz: RawUTF8='GMT'): RawUTF8;  
 overload;

*Convert some date/time to the "HTTP-date" format as defined by RFC 7231*

- i.e. "Tue, 15 Nov 1994 12:45:26 GMT" to be used as a value of "Date", "Expires" or "Last-Modified" HTTP header
- if you care about timezones Value must be converted to UTC first using TSynTimeZone.LocalToUtc, or tz should be properly set

**function** DateTimeToi18n(**const** DateTime: TDateTime): **string**;

*Wrapper calling global i18nDateTimeText() callback if set, or returning ISO-8601 standard layout on default*

**function** DateTimeToIso8601(D: TDateTime; Expanded: boolean; FirstChar: AnsiChar='T';  
 WithMS: boolean=false; QuotedChar: AnsiChar=#0): RawUTF8; overload;

*Basic Date/Time conversion into ISO-8601*

- use 'YYYYMMDDThhmmss' format if not Expanded
- use 'YYYY-MM-DDThh:mm:ss' format if Expanded
- if WithMS is TRUE, will append '.sss' for milliseconds resolution
- if QuotedChar is not default #0, will (double) quote the resulted text
- you may rather use DateTimeToIso8601Text() to handle 0 or date-only values

**function** DateTimeToIso8601(P: PUTF8Char; D: TDateTime; Expanded: boolean; FirstChar:  
 AnsiChar='T'; WithMS: boolean=false; QuotedChar: AnsiChar=#0): integer; overload;

*Basic Date/Time conversion into ISO-8601*

- use 'YYYYMMDDThhmmss' format if not Expanded
- use 'YYYY-MM-DDThh:mm:ss' format if Expanded
- if WithMS is TRUE, will append '.sss' for milliseconds resolution
- if QuotedChar is not default #0, will (double) quote the resulted text
- you may rather use DateTimeToIso8601Text() to handle 0 or date-only values
- returns the number of chars written to P^ buffer

**function** DateTimeToIso8601ExpandedPChar(**const** Value: TDateTime; Dest: PUTF8Char;  
 FirstChar: AnsiChar='T'; WithMS: boolean=false): PUTF8Char;

*Write a TDateTime value, expanded as Iso-8601 encoded text into P^ Ansi buffer*

- if DT=0, returns ""
- if DT contains only a date, returns the date encoded as 'YYYY-MM-DD'
- if DT contains only a time, returns the time encoded as 'Thh:mm:ss'
- otherwise, returns the ISO-8601 date and time encoded as 'YYYY-MM-DDThh:mm:ss'
- if WithMS is TRUE, will append '.sss' for milliseconds resolution

```
procedure DateTimeToIso8601StringVar(DT: TDateTime; FirstChar: AnsiChar; var result:
string; WithMS: boolean=false);
```

*Write a TDateTime into strict ISO-8601 date and/or time text*

- if DT=0, returns ''
- if DT contains only a date, returns the date encoded as 'YYYY-MM-DD'
- if DT contains only a time, returns the time encoded as 'Thh:mm:ss'
- otherwise, returns the ISO-8601 date and time encoded as 'YYYY-MM-DDThh:mm:ss'
- if WithMS is TRUE, will append '.sss' for milliseconds resolution
- used e.g. by TPropInfo.GetValue() and TPropInfo.NormalizeValue() methods

```
function DateTimeToIso8601Text(DT: TDateTime; FirstChar: AnsiChar='T'; WithMS:
boolean=false): RawUTF8;
```

*Write a TDateTime into strict ISO-8601 date and/or time text*

- if DT=0, returns ''
- if DT contains only a date, returns the date encoded as 'YYYY-MM-DD'
- if DT contains only a time, returns the time encoded as 'Thh:mm:ss'
- otherwise, returns the ISO-8601 date and time encoded as 'YYYY-MM-DDThh:mm:ss'
- if WithMS is TRUE, will append '.sss' for milliseconds resolution
- used e.g. by TPropInfo.GetValue() and TPropInfo.NormalizeValue() methods

```
procedure DateTimeToIso8601TextVar(DT: TDateTime; FirstChar: AnsiChar; var result:
RawUTF8; WithMS: boolean=false);
```

*Write a TDateTime into strict ISO-8601 date and/or time text*

- if DT=0, returns ''
- if DT contains only a date, returns the date encoded as 'YYYY-MM-DD'
- if DT contains only a time, returns the time encoded as 'Thh:mm:ss'
- otherwise, returns the ISO-8601 date and time encoded as 'YYYY-MM-DDThh:mm:ss'
- if WithMS is TRUE, will append '.sss' for milliseconds resolution
- used e.g. by TPropInfo.GetValue() and TPropInfo.NormalizeValue() methods

```
function DateTimeToUnixMSTime(const AValue: TDateTime): TUnixMSTime;
```

*Convert a TDateTime into a millisecond-based c-encoded time (from Unix epoch 1/1/1970)*

- if AValue is 0, will return 0 (since is likely to be an error constant)

```
function DateTimeToUnixTime(const AValue: TDateTime): TUnixTime;
```

*Convert a TDateTime into a second-based c-encoded time*

- i.e. TDateTime into number of seconds elapsed since Unix epoch 1/1/1970

```
function DateToIso8601(Y,M,D: cardinal; Expanded: boolean): RawUTF8; overload;
```

*Basic Date conversion into ISO-8601*

- use 'YYYYMMDD' format if not Expanded
- use 'YYYY-MM-DD' format if Expanded

```
function DateToIso8601(Date: TDateTime; Expanded: boolean): RawUTF8; overload;
```

*Basic Date conversion into ISO-8601*

- use 'YYYYMMDD' format if not Expanded
- use 'YYYY-MM-DD' format if Expanded

```
function DateToIso8601PChar(P: PUTF8Char; Expanded: boolean; Y,M,D: PtrUInt):
PUTF8Char; overload;
```

*Write a Date to P^Ansi buffer*

- if Expanded is false, 'YYYYMMDD' date format is used
- if Expanded is true, 'YYYY-MM-DD' date format is used

**function** DateToIso8601PChar(Date: TDateTime; P: PUTF8Char; Expanded: boolean): PUTF8Char; overload;

*Write a Date/Time to P^ Ansi buffer*

**function** DateToIso8601Text(Date: TDateTime): RawUTF8;

*Convert a date into 'YYYY-MM-DD' date format*

- resulting text is compatible with all ISO-8601 functions

**function** DaysToIso8601(Days: cardinal; Expanded: boolean): RawUTF8;

*Basic Date period conversion into ISO-8601*

- will convert an elapsed number of days as ISO-8601 text

- use 'YYYYMMDD' format if not Expanded

- use 'YYYY-MM-DD' format if Expanded

**procedure** DeduplicateInt64(var Values: TInt64DynArray); overload;

*Sort and remove any 64-bit duplicated integer from Values[]*

**function** DeduplicateInt64(var Values: TInt64DynArray; Count: integer): integer; overload;

*Sort and remove any 64-bit duplicated integer from Values[]*

- returns the new Values[] length

**function** DeduplicateInt64Sorted(val: PInt64Array; last: PtrInt): PtrInt;

*Low-level function called by DeduplicateInt64()*

- warning: caller should ensure that last>0

**function** DeduplicateInteger(var Values: TIntegerDynArray; Count: integer): integer; overload;

*Sort and remove any 32-bit duplicated integer from Values[]*

- returns the new Values[] length

**procedure** DeduplicateInteger(var Values: TIntegerDynArray); overload;

*Sort and remove any 32-bit duplicated integer from Values[]*

**function** DeduplicateIntegerSorted(val: PIntegerArray; last: PtrInt): PtrInt;

*Low-level function called by DeduplicateInteger()*

**procedure** DeleteCriticalSectionIfNeeded(var CS: TRTLCriticalSection);

*On need finalization of a mutex*

- if the supplied mutex has been initialized, delete it

- if the supplied mutex is void (i.e. all filled with 0), do nothing

**procedure** DeleteInt64(var Values: TInt64DynArray; var ValuesCount: Integer; Index: PtrInt); overload;

*Delete any 64-bit integer in Values[]*

**procedure** DeleteInt64(var Values: TInt64DynArray; Index: PtrInt); overload;

*Delete any 64-bit integer in Values[]*

**procedure** DeleteInteger(var Values: TIntegerDynArray; Index: PtrInt); overload;

*Delete any 32-bit integer in Values[]*

**procedure** DeleteInteger(var Values: TIntegerDynArray; var ValuesCount: Integer; Index: PtrInt); overload;

*Delete any 32-bit integer in Values[]*

**function** DeleteRawUTF8(**var** Values: TRawUTF8DynArray; **var** ValuesCount: integer; **Index**: integer; CoValues: PIntegerDynArray=nil): boolean; overload;

*Delete a RawUTF8 item in a dynamic array of RawUTF8*

- if CoValues is set, the integer item at the same index is also deleted

**function** DeleteRawUTF8(**var** Values: TRawUTF8DynArray; **Index**: integer): boolean; overload;

*Delete a RawUTF8 item in a dynamic array of RawUTF8;*

**function** DeleteSection(**var** Content: RawUTF8; **const** SectionName: RawUTF8; EraseSectionHeader: boolean=true): boolean; overload;

*Delete a whole [Section]*

- if EraseSectionHeader is TRUE (default), then the [Section] line is also deleted together with its content lines

- return TRUE if something was changed in Content

- return FALSE if [Section] doesn't exist or is already void

**function** DeleteSection(SectionFirstLine: PUTF8Char; **var** Content: RawUTF8; EraseSectionHeader: boolean=true): boolean; overload;

*Delete a whole [Section]*

- if EraseSectionHeader is TRUE (default), then the [Section] line is also deleted together with its content lines

- return TRUE if something was changed in Content

- return FALSE if [Section] doesn't exist or is already void

- SectionFirstLine may have been obtained by FindSectionFirstLine() function above

**procedure** DeleteWord(**var** Values: TWordDynArray; **Index**: PtrInt);

*Delete any 16-bit integer in Values[]*

**function** DirectoryDelete(**const** Directory: TFileName; **const** Mask: TFileName=FILES\_ALL; DeleteOnlyFilesNotDirectory: Boolean=false; DeletedCount: PInteger=nil): Boolean;

*Delete the content of a specified directory*

- only one level of file is deleted within the folder: no recursive deletion is processed by this function (for safety)

- if DeleteOnlyFilesNotDirectory is TRUE, it won't remove the folder itself, but just the files found in it

**function** DirectoryDeleteOlderFiles(**const** Directory: TFileName; TimePeriod: TDateTime; **const** Mask: TFileName=FILES\_ALL; Recursive: Boolean=false; TotalSize: PInt64=nil): Boolean;

*Delete the files older than a given age in a specified directory*

- for instance, to delete all files older than one day:

DirectoryDeleteOlderFiles(FolderName, 1);

- only one level of file is deleted within the folder: no recursive deletion is processed by this function, unless Recursive is TRUE

- if Recursive=true, caller should set TotalSize^=0 to have an accurate value

**procedure** Div100(**Y**: cardinal; **var** res: TDiv100Rec);

*Simple wrapper to efficiently compute both division and modulo per 100*

- compute result.D = Y div 100 and result.M = Y mod 100

- under FPC, will use fast multiplication by reciprocal so can be inlined

- under Delphi, we use our own optimized asm version (which can't be inlined)

**function** DocVariantData(const DocVariant: variant): PDocVariantData;

*Direct access to a TDocVariantData from a given variant instance*

- return a pointer to the TDocVariantData corresponding to the variant instance, which may be of kind varByRef (e.g. when retrieved by late binding)
- raise an EDocVariant exception if the instance is not a TDocVariant
- the following direct trans-typing may fail, e.g. for varByRef value:  
TDocVariantData(aVarDoc.ArrayProp).Add('new item');
- so you can write the following:  
DocVariantData(aVarDoc.ArrayProp).AddItem('new item');

**function** DoubleToJSON(var tmp: ShortString; Value: double; NoExp: boolean): PShortString;

*Convert a 64-bit floating-point value to its JSON text equivalency*

- on Delphi Win32, calls FloatToText() in ffGeneral mode
- on other platforms, i.e. Delphi Win64 and all FPC targets, will use our own faster Fabian Loitsch's Grisu algorithm
- returns the number as text (stored into tmp variable), or "Infinity", "-Infinity", and "NaN" for corresponding IEEE special values
- result is a PShortString either over tmp, or JSON\_NAN[]

**function** DoubleToShort(var S: ShortString; const Value: double): integer;

*Convert a 64-bit floating-point value to its numerical text equivalency*

- on Delphi Win32, calls FloatToText() in ffGeneral mode
- on other platforms, i.e. Delphi Win64 and all FPC targets, will use our own faster Fabian Loitsch's Grisu algorithm implementation
- returns the count of chars stored into S, i.e. length(S)

**function** DoubleToShortNoExp(var S: ShortString; const Value: double): integer;

*Convert a 64-bit floating-point value to its numerical text equivalency without scientific notation*

- on Delphi Win32, calls FloatToText() in ffGeneral mode
- on other platforms, i.e. Delphi Win64 and all FPC targets, will use our own faster Fabian Loitsch's Grisu algorithm implementation
- returns the count of chars stored into S, i.e. length(S)

**function** DoubleToStr(Value: Double): RawUTF8; overload;

*Convert a 64-bit floating-point value to its numerical text equivalency*

**procedure** DoubleToStr(Value: Double; var result: RawUTF8); overload;

*Convert a 64-bit floating-point value to its numerical text equivalency*

**function** DoubleToString(Value: Double): string;

*Convert a floating-point value to its numerical text equivalency*

**function** DynArray(aTypeInfo: pointer; var aValue; aCountPointer: PInteger=nil): TDynArray;

*Initialize the structure with a one-dimension dynamic array*

- the dynamic array must have been defined with its own type (e.g. TIntegerDynArray = array of Integer)
- if aCountPointer is set, it will be used instead of length() to store the dynamic array items count - it will be much faster when adding elements to the array, because the dynamic array won't need to be resized each time - but in this case, you should use the Count property instead of length(array) or high(array) when accessing the data: in fact length(array) will store the memory size reserved, not the items count
- if aCountPointer is set, its content will be set to 0, whatever the array length is, or the current aCountPointer^ value is
- a typical usage could be:

```
var IntArray: TIntegerDynArray;
begin
 with DynArray(TypeInfo(TIntegerDynArray), IntArray) do
 begin
 (...)
 end;
 (...)
 DynArray(TypeInfo(TIntegerDynArray), IntArrayA).SaveTo
```

**function** DynArrayBlobSaveJSON(TypeInfo, BlobValue: pointer): RawUTF8;

*Serialize a dynamic array content, supplied as raw binary buffer, as JSON*

- Value shall be set to the source dynamic array field
- is just a wrapper around TTextWriter.AddDynArrayJSON(), creating a temporary TDynArray wrapper on the stack
- to be used e.g. for custom record JSON serialization, within a TDynArrayJSONCustomWriter callback or RegisterCustomJSONSerializerFromText()

**procedure** DynArrayCopy(var Dest; const Source; SourceMaxElem: integer; TypeInfo: pointer);

*Copy a dynamic array content from source to Dest*

- uses internally the TDynArray.CopyFrom() method and two temporary TDynArray wrappers

**function** DynArrayElementTypeName(TypeInfo: pointer; ElemTypeInfo: PPointer=nil; ExactType: boolean=false): RawUTF8;

*Compute a dynamic array element information*

- will raise an exception if the supplied RTTI is not a dynamic array
- will return the element type name and set ElemTypeInfo otherwise
- if there is no element type information, an approximative element type name will be returned (e.g. 'byte' for an array of 1 byte items), and ElemTypeInfo will be set to nil
- this low-level function is used e.g. by mORMotWrappers unit

**function** DynArrayEquals(TypeInfo: pointer; var Array1, Array2; Array1Count: PInteger=nil; Array2Count: PInteger=nil): boolean;

*Compare two dynamic arrays by calling TDynArray.Equals*

**function** DynArrayItemTypeIsSimpleBinary(const aDynArrayType: RawUTF8): boolean;

*Was dynamic array item after RegisterCustomJSONSerializerFromTextBinaryType()*

- calls DynArrayItemTypeLen() to guess the internal type name

**function** DynArrayItemTypeLen(**const** aDynArrayType: RawUTF8): PtrInt;

*Trim ending 'DynArray' or 's' chars from a dynamic array type name*  
 - used internally to guess the associated item type name

**function** DynArrayLoad(**var** Value; Source: PAnsiChar; TypeInfo: pointer): PAnsiChar;

*Fill a dynamic array content from a binary serialization as saved by DynArraySave() / TDynArray.Save()*  
 - Value shall be set to the target dynamic array field  
 - just a function helper around TDynArray.Init + TDynArray.\*

**function** DynArrayLoadJSON(**var** Value; **const** JSON: RawUTF8; TypeInfo: pointer): boolean; overload;

*Fill a dynamic array content from a JSON serialization as saved by TTextWriter.AddDynArrayJSON, which won't be modified*  
 - this overloaded function will make a private copy before parsing it, so is safe with a read/only or shared string - but slightly slower

**function** DynArrayLoadJSON(**var** Value; JSON: PUTF8Char; TypeInfo: pointer; EndOfObject: PUTF8Char=nil): PUTF8Char; overload;

*Fill a dynamic array content from a JSON serialization as saved by TTextWriter.AddDynArrayJSON*  
 - Value shall be set to the target dynamic array field  
 - is just a wrapper around TDynArray.LoadFromJSON(), creating a temporary TDynArray wrapper on the stack  
 - return a pointer at the end of the data read from JSON, nil in case of an invalid input buffer  
 - to be used e.g. for custom record JSON unserialization, within a TDynArrayJSONCustomReader callback  
 - warning: the JSON buffer will be modified in-place during process - use a temporary copy if you need to access it later or if the string comes from a constant (refcount=-1) - see e.g. the overloaded DynArrayLoadJSON()

**function** DynArraySave(**var** Value; TypeInfo: pointer): RawByteString;

*Serialize a dynamic array content as binary, ready to be loaded by DynArrayLoad() / TDynArray.Load()*  
 - Value shall be set to the source dynamic array field  
 - just a function helper around TDynArray.Init + TDynArray.SaveTo

**function** DynArraySaveJSON(**const** Value; TypeInfo: pointer; EnumSetsAsText: boolean=false): RawUTF8;

*Serialize a dynamic array content as JSON*  
 - Value shall be set to the source dynamic array field  
 - is just a wrapper around TTextWriter.AddDynArrayJSON(), creating a temporary TDynArray wrapper on the stack  
 - to be used e.g. for custom record JSON serialization, within a TDynArrayJSONCustomWriter callback or RegisterCustomJSONSerializerFromText() (following EnumSetsAsText optional parameter for nested enumerates and sets)

**procedure** DynArraySortIndexed(Values: pointer; ElemSize, Count: Integer; **out** Indexes: TSynTempBuffer; Compare: TDynArraySortCompare);

*Sort any dynamic array, via an external array of indexes*  
 - this function will use the supplied TSynTempBuffer for index storage, so use PIntegerArray(Indexes.buf) to access the values  
 - caller should always make Indexes.Done once done

**function** DynArrayTypeInfoToRecordInfo(aDynArrayTypeInfo: pointer; aDataSize: PInteger=nil): pointer;

*Retrieve the item type information of a dynamic array low-level RTTI*

**function** Elapsed(var PreviousTix: Int64; Interval: Integer): Boolean;

*Check if the current timestamp, in ms, matched a given period*

- will compare the current GetTickCount64 to the supplied PreviousTix
- returns TRUE if the Internal ms period was not elapsed
- returns TRUE, and set PreviousTix, if the Interval ms period was elapsed
- possible use case may be:

```
var Last: Int64;
...
Last := GetTickCount64;
repeat
 ...
 if Elapsed(Last,1000) then begin
 ... // do something every second
 end;
until Terminated;
...
```

**function** EndWith(const text, upText: RawUTF8): boolean;

*Check matching ending of p^ in upText*

- returns true if the item matched
- ignore case - upText^ must be already Upper
- chars are compared as 7 bit Ansi only (no accentuated characters)

**function** EndWithArray(const text: RawUTF8; const upArray: array of RawUTF8): integer;

*Returns the index of a matching ending of p^ in upArray[]*

- returns -1 if no item matched
- ignore case - upArray^ must be already Upper
- chars are compared as 7 bit Ansi only (no accentuated characters)

**function** EnsureDirectoryExists(const Directory: TFileName;  
 RaiseExceptionOnCreationFailure: boolean=false): TFileName;

*Creates a directory if not already existing*

- returns the full expanded directory name, including trailing backslash
- returns "" on error, unless RaiseExceptionOnCreationFailure=true

**function** EscapeBuffer(s,d: PAnsiChar; len,max: integer): PAnsiChar;

*Fast conversion from binary data to escaped text*

- non printable characters will be written as \$xx hexadecimal codes
- will be #0 terminated, with '...' characters trailing on overflow
- ensure the destination buffer contains at least max\*3+3 bytes, which is always the case when using LogEscape() and its local TLogEscape variable

**function** EscapeToShort(source: PAnsiChar; sourcelen: integer): shortstring;  
 overload;

*Fill a shortstring with the (hexadecimal) chars of the input text/binary*

**function** EscapeToShort(const source: RawByteString): shortstring; overload;

*Fill a shortstring with the (hexadecimal) chars of the input text/binary*

**function** EventEquals(const eventA,eventB): boolean;

*Compare two TMethod instances*

**procedure** ExcludeInt64(var Values, Excluded: TInt64DynArray; ExcludedSortSize: Integer=32);

*Remove some 64-bit integer from Values[]*

- Excluded is declared as var, since it will be sorted in-place during process if it contains more than ExcludedSortSize items (i.e. if the sort is worth it)

**procedure** ExcludeInteger(var Values, Excluded: TIntegerDynArray; ExcludedSortSize: Integer=32);

*Remove some 32-bit integer from Values[]*

- Excluded is declared as var, since it will be sorted in-place during process if it contains more than ExcludedSortSize items (i.e. if the sort is worth it)

**function** ExistsIniName(P: PUTF8Char; UpperName: PAnsiChar): boolean;

*Return TRUE if Value of UpperName does exist in P, till end of current section*

- expect UpperName as 'NAME='

**function** ExistsIniNameValue(P: PUTF8Char; const UpperName: RawUTF8; const UpperValues: array of PAnsiChar): boolean;

*Return TRUE if one of the Value of UpperName exists in P, till end of current section*

- expect UpperName e.g. as 'CONTENT-TYPE: '

- expect UpperValues to be any upper value with left side matching, e.g. as used by IsHTMLContentTypeTextual() function:

```
result := ExistsIniNameValue(htmlHeaders,HEADER_CONTENT_TYPE_UPPER,
 ['TEXT/', 'APPLICATION/JSON', 'APPLICATION/XML']);
```

- warning: this function calls IdempCharArray(), so expects UpperValues[] items to have AT LEAST TWO CHARS (it will use fast initial 2 bytes compare)

**function** ExtendedToJSON(var tmp: ShortString; Value: TSynExtended; Precision: integer; NoExp: boolean): PShortString;

*Convert a floating-point value to its JSON text equivalency*

- depending on the platform, it may either call str() or FloatToText() in ffGeneral mode (the shortest possible decimal string using fixed or scientific format)

- returns the number as text (stored into tmp variable), or "Infinity", "-Infinity", and "NaN" for corresponding IEEE special values

- result is a PShortString either over tmp, or JSON\_NAN[]

**function** ExtendedToShort(var S: ShortString; Value: TSynExtended; Precision: integer): integer;

*Convert a floating-point value to its numerical text equivalency*

- on Delphi Win32, calls FloatToText() in ffGeneral mode; on FPC uses str()

- DOUBLE\_PRECISION will redirect to DoubleToShort() and its faster Fabian Loitsch's Grisu algorithm if available

- returns the count of chars stored into S, i.e. length(S)

**function** ExtendedToShortNoExp(var S: ShortString; Value: TSynExtended; Precision: integer): integer;

*Convert a floating-point value to its numerical text equivalency without scientific notation*

- DOUBLE\_PRECISION will redirect to DoubleToShortNoExp() and its faster Fabian Loitsch's Grisu algorithm if available - or calls str(Value:0:precision,S)

- returns the count of chars stored into S, i.e. length(S)

**function** ExtendedToStr(Value: TSynExtended; Precision: integer): RawUTF8; overload;  
*Convert a floating-point value to its numerical text equivalency*

**procedure** ExtendedToStr(Value: TSynExtended; Precision: integer; var result: RawUTF8); overload;  
*Convert a floating-point value to its numerical text equivalency*

**procedure** FastDynArrayClear(Value: PPointer; ElemTypeInfo: pointer);  
*Low-level finalization of a dynamic array of variants*  
 - faster than RTL Finalize() or setting nil

**function** FastFindIndexedPUTF8Char(P: PPUTF8CharArray; R: PtrInt; var SortedIndexes: TCardinalDynArray; Value: PUTF8Char; ItemComp: TUTF8Compare): PtrInt;  
*Retrieve the index of a PUTF8Char in a PUTF8Char array via a sort indexed*  
 - will use fast  $O(\log(n))$  binary search algorithm

**function** FastFindInt64Sorted(P: PInt64Array; R: PtrInt; const Value: Int64): PtrInt; overload;  
*Fast  $O(\log(n))$  binary search of a 64-bit signed integer value in a sorted array*  
 - R is the last index of available integer entries in P<sup>^</sup> (i.e. Count-1)  
 - return index of P<sup>^</sup>[result]=Value  
 - return -1 if Value was not found

**function** FastFindIntegerSorted(const Values: TIntegerDynArray; Value: integer): PtrInt; overload;  
*Fast  $O(\log(n))$  binary search of an integer value in a sorted integer array*  
 - return index of Values[result]=Value  
 - return -1 if Value was not found

**function** FastFindIntegerSorted(P: PIntegerArray; R: PtrInt; Value: integer): PtrInt; overload;  
*Fast  $O(\log(n))$  binary search of an integer value in a sorted integer array*  
 - R is the last index of available integer entries in P<sup>^</sup> (i.e. Count-1)  
 - return index of P<sup>^</sup>[result]=Value  
 - return -1 if Value was not found

**function** FastFindPointerSorted(P: PPointerArray; R: PtrInt; Value: Pointer): PtrInt; overload;  
*Fast  $O(\log(n))$  binary search of a Pointer value in a sorted array*

**function** FastFindPtrIntSorted(P: PPtrIntArray; R: PtrInt; Value: PtrInt): PtrInt; overload;  
*Fast  $O(\log(n))$  binary search of a PtrInt value in a sorted array*

**function** FastFindPUTF8CharSorted(P: PPUTF8CharArray; R: PtrInt; Value: PUTF8Char; Compare: TUTF8Compare): PtrInt; overload;  
*Retrieve the index where is located a PUTF8Char in a sorted PUTF8Char array*  
 - R is the last index of available entries in P<sup>^</sup> (i.e. Count-1)  
 - string comparison will use the specified Compare function  
 - returns -1 if the specified Value was not found  
 - will use fast  $O(\log(n))$  binary search algorithm

**function** FastFindPUTF8CharSorted(P: PPUTF8CharArray; R: PtrInt; Value: PUTF8Char): PtrInt; overload;

*Retrieve the index where is located a PUTF8Char in a sorted PUTF8Char array*

- R is the last index of available entries in P^ (i.e. Count-1)
- string comparison is case-sensitive StrComp (so will work with any PAnsiChar)
- returns -1 if the specified Value was not found
- will use inlined binary search algorithm with optimized x86\_64 branchless asm
- slightly faster than plain FastFindPUTF8CharSorted(P,R,Value,@StrComp)

**function** FastFindQWordSorted(P: PQWordArray; R: PtrInt; **const** Value: QWord): PtrInt; overload;

*Fast  $O(\log(n))$  binary search of a 64-bit unsigned integer value in a sorted array*

- R is the last index of available integer entries in P^ (i.e. Count-1)
- return index of P^[result]=Value
- return -1 if Value was not found
- QWord comparison are implemented correctly under FPC or Delphi 2009+ - older compilers will fast and exact SortDynArrayQWord()

**function** FastFindUpperPUTF8CharSorted(P: PPUTF8CharArray; R: PtrInt; Value: PUTF8Char; ValueLen: PtrInt): PtrInt;

*Retrieve the index where is located a PUTF8Char in a sorted uppercase PUTF8Char array*

- P[] array is expected to be already uppercased
- searched Value is converted to uppercase before search via UpperCopy255Buf(), so is expected to be short, i.e. length < 250
- R is the last index of available entries in P^ (i.e. Count-1)
- returns -1 if the specified Value was not found
- will use fast  $O(\log(n))$  binary search algorithm
- slightly faster than plain FastFindPUTF8CharSorted(P,R,Value,@StrIComp)

**function** FastFindWordSorted(P: PWordArray; R: PtrInt; Value: Word): PtrInt;

*Fast  $O(\log(n))$  binary search of a 16 bit unsigned integer value in a sorted array*

**function** FastLocateIntegerSorted(P: PIntegerArray; R: PtrInt; Value: integer): PtrInt;

*Retrieve the index where to insert an integer value in a sorted integer array*

- R is the last index of available integer entries in P^ (i.e. Count-1)
- returns -1 if the specified Value was found (i.e. adding will duplicate a value)

**function** FastLocatePUTF8CharSorted(P: PPUTF8CharArray; R: PtrInt; Value: PUTF8Char): PtrInt; overload;

*Retrieve the index where to insert a PUTF8Char in a sorted PUTF8Char array*

- R is the last index of available entries in P^ (i.e. Count-1)
- string comparison is case-sensitive StrComp (so will work with any PAnsiChar)
- returns -1 if the specified Value was found (i.e. adding will duplicate a value)
- will use fast  $O(\log(n))$  binary search algorithm

**function** FastLocatePUTF8CharSorted(P: PPUTF8CharArray; R: PtrInt; Value: PUTF8Char; Compare: TUTF8Compare): PtrInt; overload;

*Retrieve the index where to insert a PUTF8Char in a sorted PUTF8Char array*

- this overloaded function accept a custom comparison function for sorting
- R is the last index of available entries in P^ (i.e. Count-1)
- string comparison is case-sensitive (so will work with any PAnsiChar)
- returns -1 if the specified Value was found (i.e. adding will duplicate a value)
- will use fast  $O(\log(n))$  binary search algorithm

**function** FastLocateWordSorted(P: PWordArray; R: integer; Value: word): PtrInt;

*Retrieve the index where to insert a word value in a sorted word array*

- R is the last index of available integer entries in P^ (i.e. Count-1)
- returns -1 if the specified Value was found (i.e. adding will duplicate a value)

**procedure** FastSetString(var s: RawUTF8; p: pointer; len: PtrInt);

*Equivalence to SetString(s,nil,len) function*

- faster especially under FPC

**procedure** FastSetStringCP(var s; p: pointer; len, codepage: PtrInt);

*Equivalence to SetString(s,nil,len) function with a specific code page*

- faster especially under FPC

**function** FileAgeToDateTime(const FileName: TFileName): TDateTime;

*Get a file date and time, from its name*

- returns 0 if file doesn't exist
- under Windows, will use GetFileAttributesEx fast API

**function** FileFromString(const Content: RawByteString; const FileName: TFileName; FlushOnDisk: boolean=false; FileDate: TDateTime=0): boolean;

*Create a File from a string content*

- uses RawByteString for byte storage, whatever the codepage is

**function** FileInfoByHandle(aFileHandle: THandle; out FileId, FileSize, LastWriteAccess, FileCreateDateTime: Int64): Boolean;

*Get low-level file information, in a cross-platform way*

- returns true on success
- here file write/creation time are given as TUnixMSTime values, for better cross-platform process
- note that FileCreateDateTime may not be supported by most Linux file systems, so the oldest timestamp available is returned as failover on such systems (probably the latest file metadata writing)

**function** FileIsSynLZ(const Name: TFileName; Magic: Cardinal): boolean;

*Returns TRUE if the supplied file name is a SynLZ compressed file, matching the Magic number as supplied to FileSynLZ() function*

**function** FileOpenSequentialRead(**const** FileName: **string**): Integer;

*Overloaded function optimized for one pass file reading*

- will use e.g. the FILE\_FLAG\_SEQUENTIAL\_SCAN flag under Windows, as stated by <http://blogs.msdn.com/b/oldnewthing/archive/2012/01/20/10258690.aspx>
- note: under XP, we observed ERROR\_NO\_SYSTEM\_RESOURCES problems when calling FileRead() for chunks bigger than 32MB on files opened with this flag, so it would use regular FileOpen() on this deprecated OS
- under POSIX, calls plain fopen(FileName,O\_RDONLY) which would avoid a syscall to flock() which is not needed here
- is used e.g. by StringFromFile() and TSynMemoryStreamMapped.Create()

**function** FileSeek64(Handle: THandle; **const** Offset: Int64; Origin: cardinal): Int64;

*FileSeek() overloaded function, working with huge files*

- Delphi FileSeek() is buggy -> use this function to safe access files > 2 GB (thanks to sanyin for the report)

**function** FileSetDateFrom(**const** Dest: TFileName; SourceHandle: integer): boolean;

*Copy the date of one file to another*

**function** FileSize(F: THandle): Int64; overload;

*Get a file size, from its handle*

- returns 0 if file doesn't exist

**function** FileSize(**const** FileName: TFileName): Int64; overload;

*Get a file size, from its name*

- returns 0 if file doesn't exist
- under Windows, will use GetFileAttributesEx fast API

**function** FileStreamSequentialRead(**const** FileName: **string**): THandleStream;

*Returns a TFileStream optimized for one pass file reading*

- will use FileOpenSequentialRead(), i.e. FILE\_FLAG\_SEQUENTIAL\_SCAN under Windows, and plain fopen(FileName, O\_RDONLY) on POSIX

**function** FileSynLZ(**const** Source, Dest: TFileName; Magic: Cardinal): boolean;

*Compress a file content using the SynLZ algorithm*

- source file is split into 128 MB blocks for fast in-memory compression of any file size, then SynLZ compressed and including a Hash32 checksum
- it is not compatible with StreamSynLZ format, which has no 128 MB chunking
- you should specify a Magic number to be used to identify the compressed file format

**procedure** FileTimeToInt64(**const** FT: TFileTime; **out** I64: Int64);

*Low-level wrapper to get the 64-bit value from a TFileTime*

- as recommended by MSDN to avoid dword alignment issue

**function** FileTimeToUnixMSTime(**const** FT: TFileTime): TUnixMSTime;

*Low-level conversion of a Windows 64-bit TFileTime into a Unix time ms stamp*

**function** FileTimeToUnixTime(**const** FT: TFileTime): TUnixTime;

*Low-level conversion of a Windows 64-bit TFileTime into a Unix time seconds stamp*

**function** FileUnSynLZ(**const** Source, Dest: TFileName; Magic: Cardinal): boolean;

*Uncompress a file previously compressed via FileSynLZ()*

- you should specify a Magic number to be used to identify the compressed file format

**procedure** FillIncreasing(Values: PIntegerArray; StartValue: integer; Count: PtrUInt);

*Fill some values with i,i+1,i+2...i+Count-1*

**procedure** FillRandom(Dest: PCardinalArray; CardinalCount: integer; ForceGsl: boolean=false);

*Fill some memory buffer with random values*

- the destination buffer is expected to be allocated as 32-bit items
- use internally crc32c() with some rough entropy source, and Random32 gsl\_rng\_taus2 generator or hardware RDRAND Intel x86/x64 opcode if available (and ForceGsl is kept to its default false)
- consider using instead the cryptographic secure TAESPRNG.Main.FillRandom() method from the SynCrypto unit, or set ForceGsl=true - in particular, RDRAND is reported as very slow: see <https://en.wikipedia.org/wiki/RdRand#Performance>

**procedure** FillZero(var value: variant); overload;

*Fill all bytes of the value's memory buffer with zeros, i.e. 'toto' -> #0#0#0#0*

- may be used to cleanup stack-allocated content

**procedure** FillZero(var secret: RawUTF8); overload;

*Fill all bytes of this UTF-8 string with zeros, i.e. 'toto' -> #0#0#0#0*

- will write the memory buffer directly, so if this string instance is shared (i.e. has refcount>1), all other variables will contains zeros
  - may be used to cleanup stack-allocated content
- ... finally FillZero(secret); end;

**procedure** FillZero(var secret: RawByteString); overload;

*Fill all bytes of this memory buffer with zeros, i.e. 'toto' -> #0#0#0#0*

- will write the memory buffer directly, so if this string instance is shared (i.e. has refcount>1), all other variables will contains zeros
  - may be used to cleanup stack-allocated content
- ... finally FillZero(secret); end;

**procedure** FillZero(out dig: THash512); overload;

*Fill all 64 bytes of this 512-bit buffer with zero*

- may be used to cleanup stack-allocated content
- ... finally FillZero(digest); end;

**procedure** FillZero(var dest; count: PtrInt); overload;

*Fill all bytes of a memory buffer with zero*

- just redirect to FillCharFast(.,...,0)

**procedure** FillZero(var Values: TIntegerDynArray); overload;

*Fill all entries of a supplied array of 32-bit integers with 0*

**procedure** FillZero(var Values: TRawUTF8DynArray); overload;

*Fill all entries of a supplied array of RawUTF8 with "*

**procedure** FillZero(var result: TGUID); overload;

*Fill a GUID with 0*

**procedure** FillZero(out dig: THash384); overload;

*Fill all 32 bytes of this 384-bit buffer with zero*  
 - may be used to cleanup stack-allocated content  
 ... finally FillZero(digest); end;

**procedure** FillZero(out dig: THash160); overload;

*Fill all 20 bytes of this 160-bit buffer with zero*  
 - may be used to cleanup stack-allocated content  
 ... finally FillZero(digest); end;

**procedure** FillZero(out dig: THash128); overload;

*Fill all 16 bytes of this 128-bit buffer with zero*  
 - may be used to cleanup stack-allocated content  
 ... finally FillZero(digest); end;

**procedure** FillZero(out dig: THash256); overload;

*Fill all 32 bytes of this 256-bit buffer with zero*  
 - may be used to cleanup stack-allocated content  
 ... finally FillZero(digest); end;

**procedure** FillZero(var Values: TInt64DynArray); overload;

*Fill all entries of a supplied array of 64-bit integers with 0*

**function** FindAnsi(A, UpperValue: PAnsiChar): boolean;

*Return true if UpperValue (Ansi) is contained in A^ (Ansi)*  
 - find UpperValue starting at word beginning, not inside words

**function** FindCSVIndex(CSV: PUTF8Char; const Value: RawUTF8; Sep: AnsiChar = ','; CaseSensitive: boolean=true; TrimValue: boolean=false): integer;

*Return the index of a Value in a CSV string*  
 - start at Index=0 for first one  
 - return -1 if specified Value was not found in CSV items

**function** FindFiles(const Directory,Mask: TFileName; const IgnoreFileName: TFileName=''; SortByName: boolean=false; IncludesDir: boolean=true; SubFolder: Boolean=false): TFindFilesDynArray;

*Search for matching file names*  
 - just a wrapper around FindFirst/FindNext  
 - you may specify several masks in Mask, e.g. as '\*.jpg;\*.jpeg'

**function** FindFilesDynArrayToFileNames(const Files: TFindFilesDynArray): TFileNameDynArray;

*Convert a result list, as returned by FindFiles(), into an array of Files[].Name*

**function** FindIniEntry(const Content, Section,Name: RawUTF8): RawUTF8;

*Find a Name= Value in a [Section] of a INI RawUTF8 Content*  
 - this function scans the Content memory buffer, and is therefore very fast (no temporary TMemIniFile is created)  
 - if Section equals "", find the Name= value before any [Section]

**function** FindIniEntryFile(const FileName: TFileName; const Section, Name: RawUTF8): RawUTF8;

*Find a Name= Value in a [Section] of a .INI file*

- if Section equals "", find the Name= value before any [Section]
- use internally fast FindIniEntry() function above

**function** FindIniEntryInteger(const Content, Section, Name: RawUTF8): integer;

*Find a Name= numeric Value in a [Section] of a INI RawUTF8 Content and return it as an integer, or 0 if not found*

- this function scans the Content memory buffer, and is therefore very fast (no temporary TMemIniFile is created)
- if Section equals "", find the Name= value before any [Section]

**function** FindIniNameValue(P: PUTF8Char; UpperName: PAnsiChar): RawUTF8;

*Find the Value of UpperName in P, till end of current section*

- expect UpperName as 'NAME='

**function** FindIniNameValueInteger(P: PUTF8Char; UpperName: PAnsiChar): PtrInt;

*Find the integer Value of UpperName in P, till end of current section*

- expect UpperName as 'NAME='
- return 0 if no NAME= entry was found

**function** FindNameValue(const NameValuePairs: RawUTF8; UpperName: PAnsiChar; var Value: RawUTF8): boolean; overload;

*Search and returns a value from its uppercased named entry*

- i.e. iterate IdemPChar(source, UpperName) over every line of the source
- returns true and the trimmed text just after UpperName if it has been found at line beginning
- returns false if UpperName was not found at any line beginning
- could be used e.g. to efficiently extract a value from HTTP headers, whereas FindIniNameValue() is tuned for [section]-oriented INI files

**function** FindNameValue(P: PUTF8Char; UpperName: PAnsiChar): PUTF8Char; overload;

*Search for a value from its uppercased named entry*

- i.e. iterate IdemPChar(source, UpperName) over every line of the source
- returns the text just after UpperName if it has been found at line beginning
- returns nil if UpperName was not found at any line beginning
- could be used as alternative to FindIniNameValue() and FindIniNameValueInteger() if there is no section, i.e. if search should not stop at '[' but at source end

**function** FindNextUTF8WordBegin(U: PUTF8Char): PUTF8Char;

*Points to the beginning of the next word stored in U*

- returns nil if reached the end of U (i.e. #0 char)
- here a "word" is a Win-Ansi word, i.e. 'O'..'9', 'A'..'Z'

**function** FindObjectEntry(const Content, Name: RawUTF8): RawUTF8;

*Retrieve a property value in a text-encoded class*

- follows the Delphi serialized text object format, not standard .ini
- if the property is a string, the simple quotes ' are trimmed

**function** FindObjectEntryWithoutExt(const Content, Name: RawUTF8): RawUTF8;

*Retrieve a filename property value in a text-encoded class*

- follows the Delphi serialized text object format, not standard .ini
- if the property is a string, the simple quotes ' are trimmed
- any file path and any extension are trimmed

**function** FindPropName(Values: PRawUTF8; const Value: RawUTF8; ValuesCount: integer): integer; overload;

*Return the index of Value in Values[] using IdemPropNameU(), -1 if not found*

- typical use with a dynamic array is like:

```
index := FindPropName(pointer(aDynArray), length(aDynArray), aValue);
```

**function** FindPropName(const Names: array of RawUTF8; const Name: RawUTF8): integer; overload;

*Return the index of Value in Values[], -1 if not found*

- here name search would use fast IdemPropNameU() function

**function** FindRawUTF8(const Values: TRawUTF8DynArray; const Value: RawUTF8; CaseSensitive: boolean=true): integer; overload;

*Return the index of Value in Values[], -1 if not found*

- CaseSensitive=false will use StrICmp() for A..Z / a..z equivalence

**function** FindRawUTF8(Values: PRawUTF8; const Value: RawUTF8; ValuesCount: integer; CaseSensitive: boolean): integer; overload;

*Low-level efficient search of Value in Values[]*

- CaseSensitive=false will use StrICmp() for A..Z / a..z equivalence

**function** FindRawUTF8(const Values: array of RawUTF8; const Value: RawUTF8; CaseSensitive: boolean=true): integer; overload;

*Return the index of Value in Values[], -1 if not found*

- CaseSensitive=false will use StrICmp() for A..Z / a..z equivalence

**function** FindSectionFirstLine(var source: PUTF8Char; search: PAnsiChar): boolean;

*Find the position of the [SEARCH] section in source*

- return true if [SEARCH] was found, and store pointer to the line after it in source

**function** FindSectionFirstLineW(var source: PWideChar; search: PUTF8Char): boolean;

*Find the position of the [SEARCH] section in source*

- return true if [SEARCH] was found, and store pointer to the line after it in source
- this version expects source^ to point to an Unicode char array

**function** FindShortStringListExact(List: PShortString; MaxValue: integer; aValue: PUTF8Char; aValueLen: PtrInt): integer;

*Fast search of an exact case-insensitive match of a RTTI's PShortString array*

**function** FindShortStringListTrimLowerCase(List: PShortString; MaxValue: integer; aValue: PUTF8Char; aValueLen: PtrInt): integer;

*Fast case-insensitive search of a left-trimmed lowercase match of a RTTI's PShortString array*

**function** FindShortStringListTrimLowerCaseExact(List: PShortString; MaxValue: integer; aValue: PUTF8Char; aValueLen: PtrInt): integer;

*Fast case-sensitive search of a left-trimmed lowercase match of a RTTI's PShortString array*

**function** FindUnicode(PW: PWideChar; Upper: PWideChar; UpperLen: PtrInt): boolean;

*Return true if Upper (Unicode encoded) is contained in U^ (UTF-8 encoded)*

- will use the slow but accurate Operating System API to perform the comparison at Unicode-level

**function** FindUTF8(U: PUTF8Char; UpperValue: PAnsiChar): boolean;

*Return true if UpperValue (Ansi) is contained in U^ (UTF-8 encoded)*

- find UpperValue starting at word beginning, not inside words

- UTF-8 decoding is done on the fly (no temporary decoding buffer is used)

**function** FindWinAnsiIniEntry(const Content, Section, Name: RawUTF8): RawUTF8;

*Find a Name= Value in a [Section] of a INI WinAnsi Content*

- same as FindIniEntry(), but the value is converted from WinAnsi into UTF-8

**function** FloatStrCopy(s, d: PUTF8Char): PUTF8Char;

*Copy a floating-point text buffer with proper correction and validation*

- will correct on the fly '.5' -> '0.5' and '-.5' -> '-0.5'

- will end not only on #0 but on any char not matching 1[.2[e[-]3]] pattern

- is used when the input comes from a third-party source with no regular output, e.g. a database driver, via TTextWriter.AddFloatStr

**function** FloatToJSONNan(const s: ShortString): PShortString;

*Recognize if the supplied text is NAN/INF/+INF/-INF, i.e. not a number*

- returns the number as text (stored into tmp variable), or "Infinity", "-Infinity", and "NaN" for corresponding IEEE special values

- result is a PShortString either over tmp, or JSON\_NAN[]

**function** FloatToShortNan(const s: shortstring): TFloatNan;

*Check if the supplied text is NAN/INF/+INF/-INF, i.e. not a number*

- as returned by ExtendedToShort/DoubleToShort textual conversion

- such values do appear as IEEE floating points, but are not defined in JSON

**function** FloatToStrNan(const s: RawUTF8): TFloatNan;

*Check if the supplied text is NAN/INF/+INF/-INF, i.e. not a number*

- as returned e.g. by ExtendedToStr/DoubleToStr textual conversion

- such values do appear as IEEE floating points, but are not defined in JSON

**function** fnv32(crc: cardinal; buf: PAnsiChar; len: PtrInt): cardinal;

*Simple FNV-1a hashing function*

- when run over our regression suite, is similar to crc32c() about collisions, and 4 times better than kr32(), but also slower than the others

- fnv32() is 715.5 MB/s - kr32() 898.8 MB/s

- this hash function should not be usefull, unless you need several hashing algorithms at once (e.g. if crc32c with diverse seeds is not enough)

**function** FormatBuffer(const Format: RawUTF8; const Args: array of const; Dest: pointer; DestLen: PtrInt): PtrInt;

*Fast Format() function replacement, tuned for direct memory buffer write*

- use the same single token % (and implementation) than FormatUTF8()

- returns the number of UTF-8 bytes appended to Dest^

**procedure** FormatShort(**const** Format: RawUTF8; **const** Args: **array of const**; **var** result: shortstring);

*Fast Format() function replacement, for UTF-8 content stored in shortstring*

- use the same single token % (and implementation) than FormatUTF8()
- shortstring allows fast stack allocation, so is perfect for small content
- truncate result if the text size exceeds 255 bytes

**procedure** FormatShort16(**const** Format: RawUTF8; **const** Args: **array of const**; **var** result: TShort16);

*Fast Format() function replacement, for UTF-8 content stored in TShort16*

- truncate result if the text size exceeds 16 bytes

**function** FormatString(**const** Format: RawUTF8; **const** Args: **array of const**): **string**; overload;

*Fast Format() function replacement, tuned for small content*

- use the same single token % (and implementation) than FormatUTF8()

**procedure** FormatString(**const** Format: RawUTF8; **const** Args: **array of const**; **out** result: **string**); overload;

*Fast Format() function replacement, tuned for small content*

- use the same single token % (and implementation) than FormatUTF8()

**function** FormatToShort(**const** Format: RawUTF8; **const** Args: **array of const**): shortstring;

*Fast Format() function replacement, for UTF-8 content stored in shortstring*

**procedure** FormatUTF8(**const** Format: RawUTF8; **const** Args: **array of const**; **out** result: RawUTF8); overload;

*Fast Format() function replacement, optimized for RawUTF8*

- overloaded function, which avoid a temporary RawUTF8 instance on stack

**function** FormatUTF8(**const** Format: RawUTF8; **const** Args: **array of const**): RawUTF8; overload;

*Fast Format() function replacement, optimized for RawUTF8*

- only supported token is %, which will be written in the resulting string according to each Args[] supplied items - so you will never get any exception as with the SysUtils.Format() when a specifier is incorrect
- resulting string has no length limit and uses fast concatenation
- there is no escape char, so to output a '%' character, you need to use '%' as place-holder, and specify '%' as value in the Args array
- note that, due to a Delphi compiler limitation, cardinal values should be type-casted to Int64() (otherwise the integer mapped value will be converted)
- any supplied TObject instance will be written as their class name

**function** FormatUTF8(const Format: RawUTF8; const Args, Params: array of const; JSONFormat: boolean=false): RawUTF8; overload;

*Fast Format() function replacement, handling % and ? parameters*

- will include Args[] for every % in Format
- will inline Params[] for every ? in Format, handling special "inlined" parameters, as expected by mORMot.pas unit, i.e. :(1234): for numerical values, and :('quoted " string'): for textual values
- if optional JSONFormat parameter is TRUE, ? parameters will be written as JSON quoted strings, without :(...): tokens, e.g. "quoted "" string"
- resulting string has no length limit and uses fast concatenation
- note that, due to a Delphi compiler limitation, cardinal values should be type-casted to Int64() (otherwise the integer mapped value will be converted)
- any supplied TObject instance will be written as their class name

**procedure** FormatUTF8ToVariant(const Fmt: RawUTF8; const Args: array of const; var Value: variant);

*Convert a FormatUTF8() UTF-8 encoded string into a variant RawUTF8 varString*

**function** FromI32(const Values: array of integer): TIntegerDynArray;

*Initializes a dynamic array from a set of 32-bit integer signed values*

**function** FromI64(const Values: array of Int64): TInt64DynArray;

*Initializes a dynamic array from a set of 64-bit integer signed values*

**function** FromU32(const Values: array of cardinal): TCardinalDynArray;

*Initializes a dynamic array from a set of 32-bit integer unsigned values*

**function** FromU64(const Values: array of QWord): TQWordDynArray;

*Initializes a dynamic array from a set of 64-bit integer unsigned values*

**function** FromVarBlob(Data: PByte): TValueResult;

*Retrieve pointer and length to a variable-length text/blob buffer*

**function** FromVarInt32(var Source: PByte): integer;

*Convert a 32-bit variable-length integer buffer into an integer*  
 - decode negative values from cardinal two-complement, i.e. 0=0,1=1,2=-1,3=2,4=-2...

**function** FromVarInt64(var Source: PByte): Int64;

*Convert a 64-bit variable-length integer buffer into a Int64*

**function** FromVarInt64Value(Source: PByte): Int64;

*Convert a 64-bit variable-length integer buffer into a Int64*  
 - this version won't update the Source pointer

**function** FromVarString(var Source: PByte; SourceMax: PByte): RawUTF8; overload;

*Safe retrieve a variable-length UTF-8 encoded text buffer in a newly allocation RawUTF8*  
 - supplied SourceMax value will avoid any potential buffer overflow

**function** FromVarString(var Source: PByte): RawUTF8; overload;

*Retrieve a variable-length UTF-8 encoded text buffer in a newly allocation RawUTF8*

**procedure** FromVarString(var Source: PByte; var Value: RawByteString; CodePage: integer); overload;

*Retrieve a variable-length text buffer*  
 - this overloaded function will set the supplied code page to the AnsiString

**function** FromVarString(**var** Source: PByte; SourceMax: PByte; **var** Value: TSynTempBuffer): boolean; overload;

*Retrieve a variable-length UTF-8 encoded text buffer in a temporary buffer*

- caller should call Value.Done after use of the Value.buf memory
- this overloaded function will also check for the SourceMax end of buffer, returning TRUE on success, or FALSE on any buffer overload detection

**procedure** FromVarString(**var** Source: PByte; **var** Value: TSynTempBuffer); overload;

*Retrieve a variable-length UTF-8 encoded text buffer in a temporary buffer*

- caller should call Value.Done after use of the Value.buf memory
- this overloaded function would include a trailing #0, so Value.buf could be parsed as a valid PUTF8Char buffer (e.g. containing JSON)

**function** FromVarString(**var** Source: PByte; SourceMax: PByte; **var** Value: RawByteString; CodePage: integer): boolean; overload;

*Retrieve a variable-length text buffer*

- this overloaded function will set the supplied code page to the AnsiString and will also check for the SourceMax end of buffer
- returns TRUE on success, or FALSE on any buffer overload detection

**function** FromVarUInt32(**var** Source: PByte; SourceMax: PByte; **out** Value: cardinal): boolean; overload;

*Convert a 32-bit variable-length integer buffer into a cardinal*

- will call FromVarUInt32() if SourceMax=nil, or FromVarUInt32Safe() if set
- returns false on error, true if Value has been set properly

**function** FromVarUInt32(**var** Source: PByte): cardinal; overload;

*Convert a 32-bit variable-length integer buffer into a cardinal*

- fast inlined process for any number < 128
- use overloaded FromVarUInt32() or FromVarUInt32Safe() with a SourceMax pointer to avoid any potential buffer overflow

**function** FromVarUInt32Big(**var** Source: PByte): cardinal;

*Convert a 32-bit variable-length integer buffer into a cardinal*

- this version could be called if number is likely to be > \$7f, so it inlining the first byte won't make any benefit

**function** FromVarUInt32High(**var** Source: PByte): cardinal;

*Convert a 32-bit variable-length integer buffer into a cardinal*

- this version must be called if Source^ has already been checked to be > \$7f

**function** FromVarUInt32Safe(Source, SourceMax: PByte; **out** Value: cardinal): PByte;

*Safely convert a 32-bit variable-length integer buffer into a cardinal*

- slower but safer process checking out of boundaries memory access in Source
- SourceMax is expected to be not nil, and to point to the first byte just after the Source memory buffer
- returns nil on error, or point to next input data on successful decoding

**function** FromVarUInt32Up128(**var** Source: PByte): cardinal;

*Convert a 32-bit variable-length integer buffer into a cardinal*

- used e.g. when inlining FromVarUInt32()
  - this version must be called if Source^ has already been checked to be > \$7f
- ```

result := Source^;
inc(Source);
if result>$7f then
  result := (result and $7F) or FromVarUInt32Up128(Source);
  
```

function FromVarUInt64(**var** Source: PByte): QWord; overload;

Convert a 64-bit variable-length integer buffer into a UInt64

function FromVarUInt64(**var** Source: PByte; SourceMax: PByte; **out** Value: QWord): boolean; overload;

Convert a 64-bit variable-length integer buffer into a UInt64

- will call FromVarUInt64() if SourceMax=nil, or FromVarUInt64Safe() if set
- returns false on error, true if Value has been set properly

function FromVarUInt64Safe(Source, SourceMax: PByte; **out** Value: QWord): PByte;

Safely convert a 64-bit variable-length integer buffer into a UInt64

- slower but safer process checking out of boundaries memory access in Source
- SourceMax is expected to be not nil, and to point to the first byte just after the Source memory buffer
- returns nil on error, or point to next input data on successful decoding

procedure FromVarVariant(**var** Source: PByte; **var** Value: **variant**; CustomVariantOptions: PDocVariantOptions=nil);

Retrieve a variant value from variable-length buffer

- matches TFileBufferWriter.Write()
- how custom type variants are created can be defined via CustomVariantOptions
- is just a wrapper around VariantLoad()

procedure GarbageCollectorFree;

Force the global "Garbage collector" list to be released immediately

- this function is called in the finalization section of this unit
- you should NEVER have to call this function, unless some specific cases (e.g. when using Delphi packages, just before releasing the package)

procedure GarbageCollectorFreeAndNil(**var** InstanceVariable; Instance: TObject);

A global "Garbage collector" for some TObject global variables which must live during whole main executable process

- this list expects a pointer to the TObject instance variable to be specified, and will be set to nil (like a FreeAndNil)
- this may be useful when used when targetting Delphi IDE packages, to circumvent the bug of duplicated finalization of units, in the scope of global variables
- to be used, e.g. as:

```

if SynAnsiConvertList=nil then
  GarbageCollectorFreeAndNil(SynAnsiConvertList, TObjectList.Create);
      
```

function gcd(a, b: cardinal): cardinal;

Compute GCD of two integers using subtraction-based Euclidean algorithm

function GetAllBits(Bits, BitCount: cardinal): boolean;

Returns TRUE if all BitCount bits are set in the input 32-bit cardinal

function GetBit(const Bits; aIndex: PtrInt): boolean;

Retrieve a particular bit status from a bit array

- this function can't be inlined, whereas GetBitPtr() function can

function GetBit64(const Bits: Int64; aIndex: PtrInt): boolean;

Retrieve a particular bit status from a 64-bit integer bits (max aIndex is 63)

function GetBitCSV(const Bits; BitsCount: integer): RawUTF8;

Convert a set of bit into a CSV content

- each bit is stored as BitIndex+1, and separated by a ','

- several bits set to one can be regrouped via 'first-last,' syntax

- ',0' is always appended at the end of the CSV chunk to mark its end

function GetBitPtr(Bits: pointer; aIndex: PtrInt): boolean;

Retrieve a particular bit status from a bit array

- GetBit() can't be inlined, whereas this pointer-oriented function can

function GetBitsCount(const Bits; Count: PtrInt): PtrInt;

Compute the number of bits set in a bit array

- Count is the bit count, not byte size

- will use fast SSE4.2 popcnt instruction if available on the CPU

function GetBitsCountPas(value: PtrInt): PtrInt;

Pure pascal version of GetBitsCountPtrInt()

- defined just for regression tests - call GetBitsCountPtrInt() instead

- has optimized asm on x86_64 and i386

function GetBitsCountSSE42(value: PtrInt): PtrInt;

SSE 4.2 version of GetBitsCountPtrInt()

- defined just for regression tests - call GetBitsCountPtrInt() instead

function GetBoolean(P: PUTF8Char): boolean;

Get a boolean value stored as true/false text in P^

- would also recognize any non 0 integer as true

function GetCaptionFromClass(C: TClass): string;

UnCamelCase and translate the class name, trimming any left 'T', 'TSyn', 'TSQL' or 'TSQLRecord'

- return generic VCL string type, i.e. UnicodeString for Delphi 2009+

function GetCaptionFromEnum(aTypeInfo: pointer; aIndex: integer): string;

UnCamelCase and translate the enumeration item

procedure GetCaptionFromPCharLen(P: PUTF8Char; out result: string);

UnCamelCase and translate a char buffer

- P is expected to be #0 ended

- return "string" type, i.e. UnicodeString for Delphi 2009+

procedure GetCaptionFromTrimmed(PS: PShortString; var result: string);

Low-level helper to retrieve a (translated) caption from a PShortString

- as used e.g. by GetEnumCaptions or GetCaptionFromEnum

function GetCardinal(P: PUTF8Char): PtrUInt;

Get the unsigned 32-bit integer value stored in P^

- we use the PtrUInt result type, even if expected to be 32-bit, to use native CPU register size (don't want any 32-bit overflow here)

function GetCardinalDef(P: PUTF8Char; Default: PtrUInt): PtrUInt;

Get the unsigned 32-bit integer value stored in P^

- if P is nil or not start with a valid numerical value, returns Default

function GetCardinalW(P: PWideChar): PtrUInt;

Get the unsigned 32-bit integer value stored as Unicode string in P^

function GetClassParent(C: TClass): TClass;

Just a wrapper around vmtParent to avoid a function call

- slightly faster than TClass.ClassParent thanks to proper inlining

function GetCSVItem(P: PUTF8Char; Index: PtrUInt; Sep: AnsiChar=','): RawUTF8;
 overload;

Return n-th indexed CSV string in P, starting at Index=0 for first one

function GetCSVItemString(P: PChar; Index: PtrUInt; Sep: Char=','): string;

Return n-th indexed CSV string in P, starting at Index=0 for first one

- this function return the generic string type of the compiler, and therefore can be used with ready to be displayed text (i.e. the VCL)

function GetDelphiCompilerVersion: RawUTF8;

Return the Delphi/FPC Compiler Version

- returns 'Delphi 2007', 'Delphi 2010' or 'Free Pascal 3.3.1' e.g.

function GetDisplayNameFromClass(C: TClass): RawUTF8;

Will get a class name as UTF-8

- will trim 'T', 'TSyn', 'TSQL' or 'TSQLRecord' left side of the class name
 - will encode the class name as UTF-8 (for Unicode Delphi versions)
 - is used e.g. to extract the SQL table name for a TSQLRecord class

procedure GetEnumCaptions(aTypeInfo: pointer; aDest: PString);

Helper to retrieve all (translated) caption texts of an enumerate

- may be used as cache for overloaded ToCaption() content

function GetEnumName(aTypeInfo: pointer; aIndex: integer): PShortString;

Helper to retrieve the text of an enumerate item

- see also RTTI related classes of mORMot.pas unit, e.g. TEnumType

procedure GetEnumNames(aTypeInfo: pointer; aDest: PPShortString);

Helper to retrieve all texts of an enumerate

- may be used as cache for overloaded ToText() content

function GetEnumNameValue(aTypeInfo: pointer; const aValue: RawUTF8;
 AlsoTrimLowerCase: boolean=false): Integer; overload;

Helper to retrieve the index of an enumerate item from its text

function GetEnumNameValue(aTypeInfo: pointer; aValue: PUTF8Char; aValueLen: PtrInt; AlsoTrimLowerCase: boolean=false): Integer; overload;

Helper to retrieve the index of an enumerate item from its text

- returns -1 if aValue was not found
- will search for the exact text and also trim the lowercase 'a'..'z' chars on left side of the text if no exact match is found and AlsoTrimLowerCase is TRUE
- see also RTTI related classes of mORMot.pas unit, e.g. TEnumType

function GetEnumNameValueTrimmed(aTypeInfo: pointer; aValue: PUTF8Char; aValueLen: PtrInt): integer;

Retrieve the index of an enumerate item from its left-trimmed text

- text comparison is case-insensitive for A-Z characters
- will trim the lowercase 'a'..'z' chars on left side of the supplied aValue text
- returns -1 if aValue was not found

function GetEnumNameValueTrimmedExact(aTypeInfo: pointer; aValue: PUTF8Char; aValueLen: PtrInt): integer;

Retrieve the index of an enumerate item from its left-trimmed text

- text comparison is case-sensitive for A-Z characters
- will trim the lowercase 'a'..'z' chars on left side of the supplied aValue text
- returns -1 if aValue was not found

procedure GetEnumTrimmedNames(aTypeInfo: pointer; aDest: PRawUTF8); overload;

Helper to retrieve all trimmed texts of an enumerate

- may be used as cache to retrieve UTF-8 text without lowercase 'a'..'z' chars

function GetEnumTrimmedNames(aTypeInfo: pointer): TRawUTF8DynArray; overload;

Helper to retrieve all trimmed texts of an enumerate as UTF-8 strings

function GetExtended(P: PUTF8Char): TSynExtended; overload;

Get the extended floating point value stored in P^

- this overloaded version returns 0 as a result if the content of P is invalid

function GetExtended(P: PUTF8Char; out err: integer): TSynExtended; overload;

Get the extended floating point value stored in P^

- set the err content to the index of any faulty character, 0 if conversion was successful (same as the standard val function)

function GetFileNameExtIndex(const FileName, CSVExt: TFileName): integer;

Extract a file extension from a file name, then compare with a comma separated list of extensions

- e.g. GetFileNameExtIndex('test.log','exe,log,map')=1
- will return -1 if no file extension match
- will return any matching extension, starting count at 0
- extension match is case-insensitive

function GetFileNameWithoutExt(const FileName: TFileName; Extension: PFileName=nil): TFileName;

Compute the file name, including its path if supplied, but without its extension

- e.g. GetFileNameWithoutExt('/var/toto.ext') = '/var/toto'
- may optionally return the extracted extension, as '.ext'

function GetHighUTF8UCS4(**var** U: PUTF8Char): PtrUInt;

Internal function, used to retrieve a UCS4 char (>127) from UTF-8

- not to be called directly, but from inlined higher-level functions
- here U^ shall be always >= #80
- typical use is as such:

```
ch := ord(P^);
if ch and $80=0 then
  inc(P) else
  ch := GetHighUTF8UCS4(P);
```

function GetInt64(P: PUTF8Char; **var** err: integer): Int64; overload;

Get the 64-bit signed integer value stored in P^

- set the err content to the index of any faulty character, 0 if conversion was successful (same as the standard val function)

function GetInt64(P: PUTF8Char): Int64; overload;

Get the 64-bit integer value stored in P^

function GetInt64Def(P: PUTF8Char; **const** Default: Int64): Int64;

Get the 64-bit integer value stored in P^

- if P if nil or not start with a valid numerical value, returns Default

function GetInteger(P: PUTF8Char; **var** err: integer): PtrInt; overload;

Get the signed 32-bit integer value stored in P^

- this version return 0 in err if no error occurred, and 1 if an invalid character was found, not its exact index as for the val() function

function GetInteger(P, PEnd: PUTF8Char): PtrInt; overload;

Get the signed 32-bit integer value stored in P^..PEnd^

- will end parsing when P^ does not contain any number (e.g. it reaches any ending #0 char), or when P reached PEnd (avoiding any buffer overflow)

function GetInteger(P: PUTF8Char): PtrInt; overload;

Get the signed 32-bit integer value stored in P^

- we use the PtrInt result type, even if expected to be 32-bit, to use native CPU register size (don't want any 32-bit overflow here)
- will end parsing when P^ does not contain any number (e.g. it reaches any ending #0 char)

function GetIntegerDef(P: PUTF8Char; **Default**: PtrInt): PtrInt;

Get the signed 32-bit integer value stored in P^

- if P if nil or not start with a valid numerical value, returns Default

function GetJpegSize(jpeg: PAnsiChar; len: PtrInt; **out** Height, Width: integer): boolean; overload;

Fast guess of the size, in pixels, of a JPEG memory buffer

- will only scan for basic JPEG structure, up to the StartOfFrame (SOF) chunk
- returns TRUE if the buffer is likely to be a JPEG picture, and set the Height + Width variable with its dimensions - but there may be false positive recognition, and no warranty that the memory buffer holds a valid JPEG picture
- returns FALSE if the buffer does not have any expected SOI/SOF markers

```
function GetJpegSize(const jpeg: TFileName; out Height, Width: integer): boolean;  
overload;
```

Fast guess of the size, in pixels, of a JPEG file

- will only scan for basic JPEG structure, up to the StartOfFrame (SOF) chunk
- returns TRUE if the buffer is likely to be a JPEG picture, and set the Height + Width variable with its dimensions - but there may be false positive recognition, and no warranty that the file is a valid JPEG picture
- returns FALSE if the file content does not have any expected SOI/SOF markers

```
function GetJSONField(P: PUTF8Char; out PDest: PUTF8Char; wasString: PBoolean=nil;  
EndOfObject: PUTF8Char=nil; Len: PInteger=nil): PUTF8Char;
```

Efficient JSON field in-place decoding, within a UTF-8 encoded buffer

- this function decodes in the P^ buffer memory itself (no memory allocation or copy), for faster process - so take care that P^ is not shared
- PDest points to the next field to be decoded, or nil on JSON parsing error
- EndOfObject (if not nil) is set to the JSON value char (',' ':' or '} e.g.)
- optional wasString is set to true if the JSON value was a JSON "string"
- returns a PUTF8Char to the decoded value, with its optional length in Len^
- "strings" are decoded as 'strings', with wasString=true, properly JSON unescaped (e.g. any \u0123 pattern would be converted into UTF-8 content)
- null is decoded as nil, with wasString=false
- true/false boolean values are returned as 'true'/'false', with wasString=false
- any number value is returned as its ascii representation, with wasString=false
- works for both field names or values (e.g. "FieldName":' or 'Value,')

Used for DI-2.1.2 (page 2555).

```
function GetJSONFieldOrObjectOrArray(var P: PUTF8Char; wasString: PBoolean=nil;  
EndOfObject: PUTF8Char=nil; HandleValuesAsObjectOrArray: Boolean=false;  
NormalizeBoolean: Boolean=true; Len: PInteger=nil): PUTF8Char;
```

Decode a JSON content in an UTF-8 encoded buffer

- GetJSONField() will only handle JSON "strings" or numbers - if HandleValuesAsObjectOrArray is TRUE, this function will process JSON { objects } or [arrays] and add a #0 at the end of it
- this function decodes in the P^ buffer memory itself (no memory allocation or copy), for faster process - so take care that it is a unique string
- returns a pointer to the value start, and moved P to the next field to be decoded, or P=nil in case of any unexpected input
- wasString is set to true if the JSON value was a "string"
- EndOfObject (if not nil) is set to the JSON value end char (',' ':' or '}')
- if Len is set, it will contain the length of the returned pointer value

```
procedure GetJSONItemAsRawJSON(var P: PUTF8Char; var result: RawJSON; EndOfObject:  
PAnsiChar=nil);
```

Retrieve the next JSON item as a RawJSON variable

- buffer can be either any JSON item, i.e. a string, a number or even a JSON array (ending with]) or a JSON object (ending with })
- EndOfObject (if not nil) is set to the JSON value end char (',' ':' or '}')

function GetJSONItemAsRawUTF8(**var** P: PUTF8Char; **var** output: RawUTF8; wasString: PBoolean=nil; EndOfObject: PUTF8Char=nil): boolean;

Retrieve the next JSON item as a RawUTF8 decoded buffer

- buffer can be either any JSON item, i.e. a string, a number or even a JSON array (ending with]) or a JSON object (ending with })
- EndOfObject (if not nil) is set to the JSON value end char (',', ':' or '}')
- just call GetJSONField(), and create a new RawUTF8 from the returned value, after proper unescape if wasString=true

procedure GetJSONPropName(**var** P: PUTF8Char; **out** PropName: shortstring); overload;

Decode a JSON field name in an UTF-8 encoded shortstring variable

- this function would left the P^ buffer memory untouched, so may be safer than the overloaded GetJSONPropName() function in some cases
- it will return the property name as a local UTF-8 encoded shortstring, or PropName="" on error
- this function won't unescape the property name, as strict JSON (i.e. a "st\"ring")
- but it will handle MongoDB syntax, e.g. {age:{\$gt:18}} or {'people.age':{\$gt:18}} see [@http://docs.mongodb.org/manual/reference/mongodb-extended-json](http://docs.mongodb.org/manual/reference/mongodb-extended-json)

function GetJSONPropName(**var** P: PUTF8Char; Len: PInteger=nil): PUTF8Char; overload;

Decode a JSON field name in an UTF-8 encoded buffer

- this function decodes in the P^ buffer memory itself (no memory allocation or copy), for faster process - so take care that P^ is not shared
- it will return the property name (with an ending #0) or nil on error
- this function will handle strict JSON property name (i.e. a "string"), but also MongoDB extended syntax, e.g. {age:{\$gt:18}} or {'people.age':{\$gt:18}} see [@http://docs.mongodb.org/manual/reference/mongodb-extended-json](http://docs.mongodb.org/manual/reference/mongodb-extended-json)

function GetLastCSVItem(**const** CSV: RawUTF8; Sep: AnsiChar=','): RawUTF8;

Return last CSV string in the supplied UTF-8 content

function GetLineContains(p, pEnd, up: PUTF8Char): boolean;

Returns TRUE if the supplied uppercased text is contained in the text buffer

function GetLineSize(P, PEnd: PUTF8Char): PtrUInt;

Compute the line length from source array of chars

- if PEnd = nil, end counting at either #0, #13 or #10
- otherwise, end counting at either #13 or #10
- just a wrapper around BufferLineLength() checking PEnd=nil case

function GetLineSizeSmallerThan(P, PEnd: PUTF8Char; aMinimalCount: integer): boolean;

Returns true if the line length from source array of chars is not less than the specified count

procedure GetMemAligned(**var** s: RawByteString; p: pointer; len: PtrInt; **out** aligned: pointer);

Initialize a RawByteString, ensuring returned "aligned" pointer is 16-bytes aligned

- to be used e.g. for proper SSE process

```
function GetMimeType(Content: Pointer; Len: PtrInt; const FileName: TFileName=''): RawUTF8;
```

Retrieve the MIME content type from its file name or a supplied binary buffer

- will first check for known file extensions, then inspect the binary content
- return the MIME type, ready to be appended to a 'Content-Type: ' HTTP header
- default is 'application/octet-stream' (BINARY_CONTENT_TYPE) or 'application/fileextension' if FileName was specified
- see @http://en.wikipedia.org/wiki/Internet_media_type for most common values

```
function GetMimeTypeFromBuffer(Content: Pointer; Len: PtrInt; const DefaultContentType: RawUTF8): RawUTF8;
```

Retrieve the MIME content type from a supplied binary buffer

- inspect the first bytes, to guess from standard known headers
- return the MIME type, ready to be appended to a 'Content-Type: ' HTTP header
- returns DefaultContentType if the binary buffer has an unknown layout

```
function GetMimeTypeHeader(const Content: RawByteString; const FileName: TFileName=''): RawUTF8;
```

Retrieve the HTTP header for MIME content type from a supplied binary buffer

- just append HEADER_CONTENT_TYPE and GetMimeType() result
- can be used as such:
Call.OutHead := GetMimeTypeHeader(Call.OutBody,aFileName);

```
function GetNextFieldProp(var P: PUTF8Char; var Prop: RawUTF8): boolean;
```

Retrieve the next SQL-like identifier within the UTF-8 buffer

- will also trim any space (or line feeds) and trailing ';
- any comment like '/*nocache*/' will be ignored
- returns true if something was set to Prop

```
function GetNextFieldPropSameLine(var P: PUTF8Char; var Prop: ShortString): boolean;
```

Retrieve the next identifier within the UTF-8 buffer on the same line

- GetNextFieldProp() will just handle line feeds (and ';') as spaces - which is fine e.g. for SQL, but not for regular config files with name/value pairs
- returns true if something was set to Prop

```
procedure GetNextItem(var P: PUTF8Char; Sep, Quote: AnsiChar; var result: RawUTF8); overload;
```

Return next CSV string (unquoted if needed) from P

- P=nil after call when end of text is reached

```
function GetNextItem(var P: PUTF8Char; Sep: AnsiChar= ','): RawUTF8; overload;
```

Return next CSV string from P

- P=nil after call when end of text is reached

```
procedure GetNextItem(var P: PUTF8Char; Sep: AnsiChar; var result: RawUTF8); overload;
```

Return next CSV string from P

- P=nil after call when end of text is reached

```
function GetNextItemCardinal(var P: PUTF8Char; Sep: AnsiChar=','): PtrUInt;
```

Return next CSV string as unsigned integer from P, 0 if no more

- if Sep is #0, it won't be searched for

function GetNextItemCardinalStrict(**var** P: PUTF8Char): PtrUInt;

Return next CSV string as unsigned integer from P, 0 if no more
- P^ will point to the first non digit character (the item separator, e.g. ',' for CSV)

function GetNextItemCardinalW(**var** P: PWideChar; Sep: WideChar=','): PtrUInt;

Return next CSV string as unsigned integer from P, 0 if no more
- this version expects P^ to point to an Unicode char array

function GetNextItemCurrency(**var** P: PUTF8Char; Sep: AnsiChar=','): currency;
overload;

Return next CSV string as currency from P, 0.0 if no more
- if Sep is #0, will return all characters until next whitespace char

procedure GetNextItemCurrency(**var** P: PUTF8Char; **out** result: currency; Sep: AnsiChar=','); overload;

Return next CSV string as currency from P, 0.0 if no more
- if Sep is #0, will return all characters until next whitespace char

function GetNextItemDouble(**var** P: PUTF8Char; Sep: AnsiChar=','): double;

Return next CSV string as double from P, 0.0 if no more
- if Sep is #0, will return all characters until next whitespace char

function GetNextItemHexa(**var** P: PUTF8Char; Sep: AnsiChar=','): QWord;

Return next CSV hexadecimal string as 64-bit unsigned integer from P
- returns 0 if no valid hexadecimal text is available in P
- if Sep is #0, it won't be searched for
- will first fill the 64-bit value with 0, then decode each two hexadecimal characters available in P
- could be used to decode TTextWriter.AddBinToHexDisplayMinChars() output

function GetNextItemHexDisplayToBin(**var** P: PUTF8Char; Bin: PByte; BinBytes: integer;
Sep: AnsiChar=','): boolean;

Decode next CSV hexadecimal string from P, nil if no more or not matching BinBytes
- Bin is filled with 0 if the supplied CSV content is invalid
- if Sep is #0, it will read the hexadecimal chars until a whitespace is reached

function GetNextItemInt64(**var** P: PUTF8Char; Sep: AnsiChar=','): Int64;

Return next CSV string as 64-bit signed integer from P, 0 if no more
- if Sep is #0, it won't be searched for

function GetNextItemInteger(**var** P: PUTF8Char; Sep: AnsiChar=','): PtrInt;

Return next CSV string as signed integer from P, 0 if no more
- if Sep is #0, it won't be searched for

function GetNextItemQWord(**var** P: PUTF8Char; Sep: AnsiChar=','): QWord;

Return next CSV string as 64-bit unsigned integer from P, 0 if no more
- if Sep is #0, it won't be searched for

procedure GetNextItemShortString(**var** P: PUTF8Char; **out** Dest: ShortString; Sep: AnsiChar=',');

Return next CSV string from P, nil if no more
- output text would be trimmed from any left or right space

function GetNextItemString(**var** P: PChar; Sep: Char= ','): **string**;

Return next CSV string from P, nil if no more

- this function returns the generic string type of the compiler, and therefore can be used with ready to be displayed text (e.g. for the VCL)

function GetNextItemToVariant(**var** P: PUTF8Char; **out** Value: **Variant**; Sep: AnsiChar= ','; AllowDouble: boolean=true): boolean;

Convert the next CSV item from an UTF-8 encoded text buffer into a variant number or RawUTF8 varString

- first try with GetNumericVariantFromJSON(), then fallback to RawUTF8ToVariant
 - is a wrapper around GetNextItem() + TextToVariant()

procedure GetNextItemTrimmed(**var** P: PUTF8Char; Sep: AnsiChar; **var** result: RawUTF8);

Return trimmed next CSV string from P

- P=nil after call when end of text is reached

procedure GetNextItemTrimmedCRLF(**var** P: PUTF8Char; **var** result: RawUTF8);

Return next CRLF separated value string from P, ending #10 or #13#10 trimmed

- any kind of line feed (CRLF or LF) will be handled, on all operating systems
 - as used e.g. by TSynNameValue.InitFromCSV and TDocVariantData.InitCSV
 - P=nil after call when end of text is reached

function GetNextLine(source: PUTF8Char; **out** next: PUTF8Char; andtrim: boolean=false): RawUTF8;

Extract a line from source array of chars

- next will contain the beginning of next line, or nil if source if ended

function GetNextStringLineToRawUnicode(**var** P: PChar): RawUnicode;

Return next string delimited with #13#10 from P, nil if no more

- this function returns a RawUnicode string type

function GetNextTChar64(**var** P: PUTF8Char; Sep: AnsiChar; **out** Buf: TChar64): PtrInt;

Return next CSV string from P as a #0-ended buffer, false if no more

- if Sep is #0, will copy all characters until next whitespace char
 - returns the number of bytes stored into Buf[]

function GetNextUTF8Upper(**var** U: PUTF8Char): PtrUInt;

Retrieve the next UCS4 value stored in U, then update the U pointer

- this function will decode the UTF-8 content before using NormToUpper[]
 - will return '?' if the UCS4 value is higher than #255: so use this function only if you need to deal with ASCII characters (e.g. it's used for Soundex and for ContainsUTF8 function)

function GetNumericVariantFromJSON(JSON: PUTF8Char; **var** Value: TVarData; AllowVarDouble: boolean): boolean;

Low-level function to set a numerical variant from an unescaped JSON number

- returns TRUE if TextToVariantNumberType/TextToVariantNumberTypeNoDouble(JSON) identified it as a number and set Value to the corresponding content
 - returns FALSE if JSON is a string, or null/true/false

function GetPublishedMethods(Instance: TObject; out Methods: TPublishedMethodInfoDynArray; aClass: TClass = nil): integer;

Retrieve published methods information about any class instance

- will optionally accept a Class, in this case Instance is ignored
- will work with FPC and Delphi RTTI

function GetQWord(P: PUTF8Char; var err: integer): QWord;

Get the 64-bit unsigned integer value stored in P^

- set the err content to the index of any faulty character, 0 if conversion was successful (same as the standard val function)

function GetSectionContent(SectionFirstLine: PUTF8Char): RawUTF8; overload;

Retrieve the whole content of a section as a string

- SectionFirstLine may have been obtained by FindSectionFirstLine() function above

function GetSectionContent(const Content, SectionName: RawUTF8): RawUTF8; overload;

Retrieve the whole content of a section as a string

- use SectionFirstLine() then previous GetSectionContent()

function GetSetBaseEnum(aTypeInfo: pointer): pointer;

Low-level helper to retrieve the base enumeration RTTI of a given set

function GetSetName(aTypeInfo: pointer; const value): RawUTF8;

Helper to retrieve the CSV text of all enumerate items defined in a set

- you'd better use RTTI related classes of mORMot.pas unit, e.g. TEnumType

procedure GetSetNameShort(aTypeInfo: pointer; const value; out result: ShortString; trimlowercase: boolean=false);

Helper to retrieve the CSV text of all enumerate items defined in a set

- you'd better use RTTI related classes of mORMot.pas unit, e.g. TEnumType

function GetSetNameValue(aTypeInfo: pointer; var P: PUTF8Char; out EndOfObject: AnsiChar): cardinal;

Helper to retrieve the bit mapped integer value of a set from its JSON text

- if supplied P^ is a JSON integer number, will read it directly
- if P^ maps some ["item1","item2"] content, would fill all matching bits
- if P^ contains ['*'], would fill all bits
- returns P=nil if reached prematurely the end of content, or returns the value separator (e.g. , or }) in EndOfObject (like GetJsonField)

function GetSystemPath(kind: TSystemPath): TFileName;

Returns an operating system folder

- will return the full path of a given kind of private or shared folder, depending on the underlying operating system
- will use SHGetFolderPath and the corresponding CSIDL constant under Windows
- under POSIX, will return \$TMP/\$TMPDIR folder for spTempFolder, ~/.cache/appname for spUserData, /var/log for spLog, or the \$HOME folder
- returned folder name contains the trailing path delimiter (\ or /)

function GetUnQuoteCSVItem(P: PUTF8Char; Index: PtrUInt; Sep: AnsiChar=','; Quote: AnsiChar=''): RawUTF8; overload;

Return n-th indexed CSV string (unquoted if needed) in P, starting at Index=0 for first one

function GetUTF8Char(P: PUTF8Char): cardinal;

Get the WideChar stored in P^ (decode UTF-8 if necessary)
 - any surrogate (UCS4>\$ffff) will be returned as '?'

procedure GetVariantFromJSON(JSON: PUTF8Char; wasString: Boolean; var Value: variant;
 TryCustomVariants: PDocVariantOptions=nil; AllowDouble: boolean=false);

Low-level function to set a variant from an unescaped JSON number or string
 - expect the JSON input buffer to be already unescaped, e.g. by GetJSONField()
 - is called e.g. by function VariantLoadJSON()
 - will instantiate either a null, boolean, Integer, Int64, currency, double (if AllowDouble is true or dvoAllowDoubleValue is in TryCustomVariants^) or string value (as RawUTF8), guessing the best numeric type according to the textual content, and string in all other cases, except if TryCustomVariants points to some options (e.g. @JSON_OPTIONS[true] for fast instance) and input is a known object or array, either encoded as strict-JSON (i.e. {...} or [...]), or with some extended (e.g. BSON) syntax

function GetVariantFromNotStringJSON(JSON: PUTF8Char; var Value: TVarData;
 AllowDouble: boolean): boolean;

Low-level function to set a variant from an unescaped JSON non string
 - expect the JSON input buffer to be already unescaped, e.g. by GetJSONField(), and having returned wasString=TRUE (i.e. not surrounded by double quotes)
 - is called e.g. by function GetVariantFromJSON()
 - will recognize null, boolean, Integer, Int64, currency, double (if AllowDouble is true) input, then set Value and return TRUE
 - returns FALSE if the supplied input has no expected JSON format

procedure GlobalLock;

Enter a giant lock for thread-safe shared process

- shall be protected as such:
 GlobalLock;
 try
 do something thread-safe but as short as possible
 finally
 GlobalUnlock;
 end;

- you should better not use such a giant-lock, but an instance-dedicated critical section - these functions are just here to be convenient, for non time-critical process

procedure GlobalUnlock;

Release the giant lock for thread-safe shared process

- you should better not use such a giant-lock, but an instance-dedicated critical section - these functions are just here to be convenient, for non time-critical process

function GotoEndJSONItem(P: PUTF8Char; strict: boolean=false): PUTF8Char;

Reach position just after the current JSON item in the supplied UTF-8 buffer
 - buffer can be either any JSON item, i.e. a string, a number or even a JSON array (ending with]) or a JSON object (ending with })
 - returns nil if the specified buffer is not valid JSON content
 - returns the position in buffer just after the item excluding the separator character - i.e. result^ may be ',', '}', ']'

function GotoEndOfJSONString(P: PUTF8Char): PUTF8Char;

Get the next character after a quoted buffer

- the first character in P^ must be "
- it will return the latest " position, ignoring \" within

function GotoEndOfQuotedString(P: PUTF8Char): PUTF8Char;

Get the next character after a quoted buffer

- the first character in P^ must be either ', either "
- it will return the latest quote position, ignoring double quotes within

function GotoNextJSONItem(P: PUTF8Char; NumberOfItemsToJump: cardinal=1; EndOfObject: PAnsiChar=nil): PUTF8Char;

Reach the position of the next JSON item in the supplied UTF-8 buffer

- buffer can be either any JSON item, i.e. a string, a number or even a JSON array (ending with]) or a JSON object (ending with })
- returns nil if the specified number of items is not available in buffer
- returns the position in buffer after the item including the separator character (optionally in EndOfObject) - i.e. result will be at the start of the next object, and EndOfObject may be ',','}',']'

function GotoNextJSONObjectOrArray(P: PUTF8Char): PUTF8Char; overload;

Reach the position of the next JSON object of JSON array

- first char is expected to be either '[' or '{'
- will return nil in case of parsing error or unexpected end (#0)
- will return the next character after ending] or } - i.e. may be , }]

function GotoNextJSONObjectOrArray(P: PUTF8Char; EndChar: AnsiChar): PUTF8Char; overload;

Reach the position of the next JSON object of JSON array

- first char is expected to be just after the initial '[' or '{'
- specify ']' or '}' as the expected EndChar
- will return nil in case of parsing error or unexpected end (#0)
- will return the next character after ending] or } - i.e. may be , }]

function GotoNextJSONObjectOrArrayMax(P, PMax: PUTF8Char): PUTF8Char;

Reach the position of the next JSON object of JSON array

- first char is expected to be either '[' or '{'
- this version expects a maximum position in PMax: it may be handy to break the parsing for HUGE content - used e.g. by JSONArrayCount(P, PMax)
- will return nil in case of parsing error or if P reached PMax limit
- will return the next character after ending] or { - i.e. may be , }]

function GotoNextJSONPropName(P: PUTF8Char): PUTF8Char;

Read the position of the JSON value just after a property identifier

- this function will handle strict JSON property name (i.e. a "string"), but also MongoDB extended syntax, e.g. {age:{\$gt:18}} or {people.age:{\$gt:18}} see
[@http://docs.mongodb.org/manual/reference/mongodb-extended-json](http://docs.mongodb.org/manual/reference/mongodb-extended-json)

function GotoNextLine(source: PUTF8Char): PUTF8Char;

Fast go to next text line, ended by #13 or #13#10

- returns the beginning of next line, or nil if source^=#0 was reached

function GotoNextNotSpace(P: PUTF8Char): PUTF8Char;

Get the next character not in [#1..' ']

function GotoNextNotSpaceSameLine(P: PUTF8Char): PUTF8Char;

Get the next character not in [#9, ' ']

function GotoNextSpace(P: PUTF8Char): PUTF8Char;

Get the next character in [#1.. ' ']

function GotoNextVarInt(Source: PByte): pointer;

Jump a value in the 32-bit or 64-bit variable-length integer buffer

function GotoNextVarString(Source: PByte): pointer;

Jump a value in variable-length text buffer

function GUIDToRawUTF8(const guid: TGUID): RawUTF8;

Convert a TGUID into UTF-8 encoded text

- will return e.g. '{3F2504E0-4F89-11D3-9A0C-0305E82C3301}' (with the {})
- if you do not need the embracing { }, use ToUTF8() overloaded function

function GUIDToShort(const guid: TGUID): TGUIDShortString; overload;

Convert a TGUID into text

- will return e.g. '{3F2504E0-4F89-11D3-9A0C-0305E82C3301}' (with the {})
- using a shortstring will allow fast allocation on the stack, so is preferred e.g. when providing a GUID to a ESynException.CreateUTF8()

procedure GUIDToShort(const guid: TGUID; out dest: TGUIDShortString); overload;

Convert a TGUID into text

- will return e.g. '{3F2504E0-4F89-11D3-9A0C-0305E82C3301}' (with the {})
- using a shortstring will allow fast allocation on the stack, so is preferred e.g. when providing a GUID to a ESynException.CreateUTF8()

function GUIDToString(const guid: TGUID): string;

Convert a TGUID into text

- will return e.g. '{3F2504E0-4F89-11D3-9A0C-0305E82C3301}' (with the {})
- this version is faster than the one supplied by SysUtils

function GUIDToText(P: PUTF8Char; guid: PByteArray): PUTF8Char;

Append a TGUID binary content as text

- will store e.g. '3F2504E0-4F89-11D3-9A0C-0305E82C3301' (without any {})
- this will be the format used for JSON encoding, e.g.

```
{ "UID": "C9A646D3-9C61-4CB7-BFCD-EE2522C8F633" }
```

function Hash128(const Elem; Hasher: THasher): cardinal;

Hash one THash128 value with the supplied Hasher() function

function Hash128Index(P: PHash128Rec; Count: integer; h: PHash128Rec): integer;

Fast O(n) search of a 128-bit item in an array of such values

function Hash256(const Elem; Hasher: THasher): cardinal;

Hash one THash256 value with the supplied Hasher() function

function Hash256Index(P: PHash256Rec; Count: integer; h: PHash256Rec): integer;
overload;

Fast O(n) search of a 256-bit item in an array of such values

function Hash32(const Text: RawByteString): cardinal; overload;

Our custom efficient 32-bit hash/checksum function

- a Fletcher-like checksum algorithm, not a hash function: has less colisions than Adler32 for short strings, but more than xxhash32 or crc32/crc32c
- overloaded function using RawByteString for binary content hashing, whatever the codepage is

function Hash32(Data: PCardinalArray; Len: integer): cardinal; overload;

Our custom efficient 32-bit hash/checksum function

- a Fletcher-like checksum algorithm, not a hash function: has less colisions than Adler32 for short strings, but more than xxhash32 or crc32/crc32c
- written in simple plain pascal, with no L1 CPU cache pollution, but we also provide optimized x86/x64 assembly versions, since the algorithm is used heavily e.g. for TDynArray binary serialization, TSQLRestStorageInMemory binary persistence, or CompressSynLZ/StreamSynLZ/FileSynLZ
- some numbers on Linux x86_64:
 2500 hash32 in 707us i.e. 3536067/s or 7.3 GB/s
 2500 xxhash32 in 1.34ms i.e. 1861504/s or 3.8 GB/s
 2500 crc32c in 943us i.e. 2651113/s or 5.5 GB/s (SSE4.2 disabled)
 2500 crc32c in 387us i.e. 6459948/s or 13.4 GB/s (SSE4.2 enabled)

function Hash512(const Elem; Hasher: THasher): cardinal;

Hash one THash512 value with the supplied Hasher() function

function HashAnsiString(const Elem; Hasher: THasher): cardinal;

Hash one AnsiString content with the supplied Hasher() function

function HashAnsiStringI(const Elem; Hasher: THasher): cardinal;

Case-insensitive hash one AnsiString content with the supplied Hasher() function

function HashByte(const Elem; Hasher: THasher): cardinal;

Hash one Byte value

function HashFile(const FileName: TFileName; Hasher: THasher=nil): cardinal;

Compute the 32-bit default hash of a file content

- you can specify your own hashing function if DefaultHasher is not what you expect

function HashInt64(const Elem; Hasher: THasher): cardinal;

Hash one Int64/Qword value with the supplied Hasher() function

function HashInteger(const Elem; Hasher: THasher): cardinal;

Hash one Integer/cardinal value - simply return the value ignore Hasher() parameter

function HashPointer(const Elem; Hasher: THasher): cardinal;

Hash one pointer value with the supplied Hasher() function

- this version is not the same as HashPtrUInt, since it will always use the hasher function

function HashPtrUInt(const Elem; Hasher: THasher): cardinal;

Hash one PtrUInt (=NativeUInt) value with the supplied Hasher() function

function HashSynUnicode(const Elem; Hasher: THasher): cardinal;

Hash one SynUnicode content with the supplied Hasher() function

- work with WideString for all Delphi versions, or UnicodeString in Delphi 2009+

function HashSynUnicodeI(**const** Elem; Hasher: THasher): cardinal;

Case-insensitive hash one SynUnicode content with the supplied Hasher() function
 - work with WideString for all Delphi versions, or UnicodeString in Delphi 2009+

function HashVariant(**const** Elem; Hasher: THasher): cardinal;

Case-sensitive hash one variant content with the supplied Hasher() function

function HashVariantI(**const** Elem; Hasher: THasher): cardinal;

Case-insensitive hash one variant content with the supplied Hasher() function

function HashWideString(**const** Elem; Hasher: THasher): cardinal;

Hash one WideString content with the supplied Hasher() function
 - work with WideString for all Delphi versions

function HashWideStringI(**const** Elem; Hasher: THasher): cardinal;

Case-insensitive hash one WideString content with the supplied Hasher() function
 - work with WideString for all Delphi versions

function HashWord(**const** Elem; Hasher: THasher): cardinal;

Hash one Word value

function HexDisplayToBin(Hex: PAnsiChar; Bin: PByte; BinBytes: integer): boolean;

Fast conversion from hexa chars into a binary buffer

function HexDisplayToCardinal(Hex: PAnsiChar; **out** aValue: cardinal): boolean;

Fast conversion from hexa chars into a cardinal

- reverse function of CardinalToHex()
- returns false and set aValue=0 if Hex is not a valid hexadecimal 32-bit unsigned integer
- returns true and set aValue with the decoded number, on success

function HexDisplayToInt64(Hex: PAnsiChar; **out** aValue: Int64): boolean; overload;

Inline gives an error under release conditions with FPC fast conversion from hexa chars into a cardinal

- reverse function of Int64ToHex()
- returns false and set aValue=0 if Hex is not a valid hexadecimal 64-bit signed integer
- returns true and set aValue with the decoded number, on success

function HexDisplayToInt64(**const** Hex: RawByteString): Int64; overload;

Fast conversion from hexa chars into a cardinal

- reverse function of Int64ToHex()
- returns 0 if the supplied text buffer is not a valid hexadecimal 64-bit signed integer

function HexToBin(Hex: PAnsiChar; Bin: PByte; BinBytes: Integer): boolean; overload;

Fast conversion from hexa chars into binary data

- BinBytes contain the bytes count to be converted: Hex^ must contain at least BinBytes*2 chars to be converted, and Bin^ enough space
- if Bin=nil, no output data is written, but the Hex^ format is checked
- return false if any invalid (non hexa) char is found in Hex^
- using this function with Bin^ as an integer value will decode in big-endian order (most-significant byte first)

function HexToBin(**const** Hex: RawUTF8): RawByteString; overload;

Fast conversion from hexa chars into binary data

procedure HexToBinFast(Hex: PAnsiChar; Bin: PByte; BinBytes: Integer);

Fast conversion with no validity check from hexa chars into binary data

function HexToChar(Hex: PAnsiChar; Bin: PUTF8Char): boolean;

Fast conversion from one hexa char pair into a 8 bit AnsiChar

- return false if any invalid (non hexa) char is found in Hex^
- similar to HexToBin(Hex,Bin,1) but with Bin<>nil
- use HexToCharValid if you want to check a hexadecimal char content

function HexToCharValid(Hex: PAnsiChar): boolean;

Fast conversion from one hexa char pair into a 8 bit AnsiChar

- return false if any invalid (non hexa) char is found in Hex^
- similar to HexToBin(Hex,nil,1)

function HexToWideChar(Hex: PAnsiChar): cardinal;

Fast conversion from two hexa bytes into a 16 bit UTF-16 WideChar

- similar to HexToBin(Hex,@wordvar,2) + bswap(wordvar)

function IdemFileExt(p: PUTF8Char; extup: PAnsiChar; sepChar: AnsiChar='.'): Boolean;

Returns true if the file name extension contained in p^ is the same same as extup^

- ignore case - extup^ must be already Upper
- chars are compared as WinAnsi (codepage 1252), not as UTF-8
- could be used e.g. like IdemFileExt(aFileName,'.JP');

function IdemFileExts(p: PUTF8Char; const extup: array of PAnsiChar; sepChar: AnsiChar='.'): integer;

Returns matching file name extension index as extup^

- ignore case - extup[] must be already Upper
- chars are compared as WinAnsi (codepage 1252), not as UTF-8
- could be used e.g. like IdemFileExts(aFileName,['.PAS','.INC']);

function IdemPChar(p: PUTF8Char; up: PAnsiChar): boolean;

Returns true if the beginning of p^ is the same as up^

- ignore case - up^ must be already Upper
- chars are compared as 7 bit Ansi only (no accentuated characters): but when you only need to search for field names e.g. IdemPChar() is preferred, because it'll be faster than IdemPCharU(), if UTF-8 decoding is not mandatory
- if p is nil, will return FALSE
- if up is nil, will return TRUE

function IdemPCharAndGetNextItem(var source: PUTF8Char; const searchUp: RawUTF8; var Item: RawUTF8; Sep: AnsiChar=#13): boolean;

Return true if IdemPChar(source,searchUp), and retrieve the value item

- typical use may be:

```
if IdemPCharAndGetNextItem(P,
  'CONTENT-DISPOSITION: FORM-DATA; NAME="",Name, ''') then ...
```

function IdemPCharAndGetNextLine(var source: PUTF8Char; searchUp: PAnsiChar): boolean;

Return true if IdemPChar(source,searchUp), and go to the next line of source

function IdemPCharArray(p: PUTF8Char; **const** upArrayBy2Chars: RawUTF8): integer; overload;

Returns the index of a matching beginning of p^ in upArray two characters

- returns -1 if no item matched
- ignore case - upArray^ must be already Upper
- chars are compared as 7 bit Ansi only (no accentuated characters)

function IdemPCharArray(p: PUTF8Char; **const** upArray: array of PAnsiChar): integer; overload;

Returns the index of a matching beginning of p^ in upArray[]

- returns -1 if no item matched
- ignore case - upArray^ must be already Upper
- chars are compared as 7 bit Ansi only (no accentuated characters)
- warning: this function expects upArray[] items to have AT LEAST TWO CHARS (it will use a fast comparison of initial 2 bytes)

function IdemPCharU(p, up: PUTF8Char): boolean;

Returns true if the beginning of p^ is the same as up^

- ignore case - up^ must be already Upper
- this version will decode the UTF-8 content before using NormToUpper[], so it will be slower than the IdemPChar() function above, but will handle WinAnsi accentuated characters (e.g. 'e' acute will be matched as 'E')

function IdemPCharW(p: PWideChar; up: PUTF8Char): boolean;

Returns true if the beginning of p^ is same as up^

- ignore case - up^ must be already Upper
- this version expects p^ to point to an Unicode char array

function IdemPCharWithoutWhiteSpace(p: PUTF8Char; up: PAnsiChar): boolean;

Returns true if the beginning of p^ is the same as up^, ignoring white spaces

- ignore case - up^ must be already Upper
- any white space in the input p^ buffer is just ignored
- chars are compared as 7 bit Ansi only (no accentuated characters): but when you only need to search for field names e.g. IdemPChar() is preferred, because it'll be faster than IdemPCharU(), if UTF-8 decoding is not mandatory
- if p is nil, will return FALSE
- if up is nil, will return TRUE

function IdemPropName(P1,P2: PUTF8Char; P1Len,P2Len: PtrInt): boolean; overload;

Case insensitive comparison of ASCII identifiers

- use it with property names values (i.e. only including A..Z,0..9,_ chars)
- this version expects P1 and P2 to be a PAnsiChar with specified lengths

function IdemPropName(**const** P1: shortstring; P2: PUTF8Char; P2Len: PtrInt): boolean; overload;

Case insensitive comparison of ASCII identifiers

- use it with property names values (i.e. only including A..Z,0..9,_ chars)
- this version expects P2 to be a PAnsiChar with a specified length

function IdemPropName(**const** P1,P2: shortstring): boolean; overload;

Case insensitive comparison of ASCII identifiers

- use it with property names values (i.e. only including A..Z,0..9,_ chars)

function IdemPropNameU(const P1,P2: RawUTF8): boolean; overload;

Case insensitive comparison of ASCII identifiers

- use it with property names values (i.e. only including A..Z,0..9,_ chars)

function IdemPropNameU(const P1: RawUTF8; P2: PUTF8Char; P2Len: PtrInt): boolean; overload;

Case insensitive comparison of ASCII identifiers

- use it with property names values (i.e. only including A..Z,0..9,_ chars)

- this version expects P2 to be a PAnsiChar with specified length

function IdemPropNameUSameLen(P1,P2: PUTF8Char; P1P2Len: PtrInt): boolean;

Case insensitive comparison of ASCII identifiers of same length

- use it with property names values (i.e. only including A..Z,0..9,_ chars)

- this version expects P1 and P2 to be a PAnsiChar with an already checked identical length, so may be used for a faster process, e.g. in a loop

- if P1 and P2 are RawUTF8, you should better call overloaded function IdemPropNameU(const P1,P2: RawUTF8), which would be slightly faster by using the length stored before the actual text buffer of each RawUTF8

procedure IncludeInt64(var Values, Included: TInt64DynArray; IncludedSortSize: Integer=32);

Ensure some 64-bit integer from Values[] will only contain Included[]

- Included is declared as var, since it will be sorted in-place during process if it contains more than IncludedSortSize items (i.e. if the sort is worth it)

procedure IncludeInteger(var Values, Included: TIntegerDynArray; IncludedSortSize: Integer=32);

Ensure some 32-bit integer from Values[] will only contain Included[]

- Included is declared as var, since it will be sorted in-place during process if it contains more than IncludedSortSize items (i.e. if the sort is worth it)

function IncludeTrailingURIDelimiter(const URI: RawByteString): RawByteString;

Ensure the supplied URI contains a trailing '/' charater

procedure InitializeCriticalSectionIfNeededAndEnter(var CS: TRTLCriticalSection);

On need initialization of a mutex, then enter the lock

- if the supplied mutex has been initialized, do nothing

- if the supplied mutex is void (i.e. all filled with 0), initialize it

function InsertInteger(var Values: TIntegerDynArray; var ValuesCount: integer; Value: Integer; Index: PtrInt; CoValues: PIntegerDynArray=nil): PtrInt;

Insert an integer value at the specified index position of a dynamic array of integers

- if Index is invalid, the Value is inserted at the end of the array

function Int18ToChars3(Value: cardinal): RawUTF8; overload;

Compute the value as encoded by TTextWriter.AddInt18ToChars3() method

procedure Int18ToChars3(Value: cardinal; var result: RawUTF8); overload;

Compute the value as encoded by TTextWriter.AddInt18ToChars3() method

function Int32ToUtf8(Value: PtrInt): RawUTF8; overload;

Use our fast RawUTF8 version of IntToStr()

- without any slow UnicodeString=String->AnsiString conversion for Delphi 2009

- only useful if our Enhanced Runtime (or LVCL) library is not installed

procedure Int32ToUTF8(Value: PtrInt; **var** result: RawUTF8); overload;

Use our fast RawUTF8 version of IntToStr()

- without any slow UnicodeString=String->AnsiString conversion for Delphi 2009
- result as var parameter saves a local assignment and a try..finally

function Int64DynArrayToCSV(Values: PInt64Array; ValuesCount: integer; **const** Prefix: RawUTF8=''; **const** Suffix: RawUTF8=''; InlinedValue: boolean=false): RawUTF8; overload;

Return the corresponding CSV text from a dynamic array of 64-bit integers

- you can set some custom Prefix and Suffix text

function Int64DynArrayToCSV(**const** Values: TInt64DynArray; **const** Prefix: RawUTF8=''; **const** Suffix: RawUTF8=''; InlinedValue: boolean=false): RawUTF8; overload;

Return the corresponding CSV text from a dynamic array of 64-bit integers

- you can set some custom Prefix and Suffix text

function Int64Scan(P: PInt64Array; Count: PtrInt; **const** Value: Int64): PInt64;

Fast search of an integer position in a 64-bit integer array

- Count is the number of Int64 entries in P^
- returns P where P^=Value
- returns nil if Value was not found

function Int64ScanExists(P: PInt64Array; Count: PtrInt; **const** Value: Int64): boolean;

Fast search of an integer value in a 64-bit integer array

- returns true if P^=Value within Count entries
- returns false if Value was not found

function Int64ScanIndex(P: PInt64Array; Count: PtrInt; **const** Value: Int64): PtrInt;

Fast search of an integer position in a signed 64-bit integer array

- Count is the number of Int64 entries in P^
- returns index of P^[index]=Value
- returns -1 if Value was not found

function Int64ToHex(aInt64: Int64): RawUTF8; overload;

Fast conversion from a Int64 value into hexa chars, ready to be displayed

- use internally BinToHexDisplay()
- reverse function of HexDisplayToInt64()

procedure Int64ToHex(aInt64: Int64; **var** result: RawUTF8); overload;

Fast conversion from a Int64 value into hexa chars, ready to be displayed

- use internally BinToHexDisplay()
- reverse function of HexDisplayToInt64()

function Int64ToHexShort(aInt64: Int64): TShort16; overload;

Fast conversion from a Int64 value into hexa chars, ready to be displayed

- use internally BinToHexDisplay()
- such result type would avoid a string allocation on heap

procedure Int64ToHexShort(aInt64: Int64; **out** result: TShort16); overload;

Fast conversion from a Int64 value into hexa chars, ready to be displayed

- use internally BinToHexDisplay()
- such result type would avoid a string allocation on heap

function Int64ToHexString(aInt64: Int64): string;

Fast conversion from a Int64 value into hexa chars, ready to be displayed

- use internally BinToHexDisplay()
- reverse function of HexDisplayToInt64()

procedure Int64ToUInt32(Values64: PInt64Array; Values32: PCardinalArray; Count: PtrInt);

Copy some Int64 values into an unsigned integer array

procedure Int64ToUtf8(Value: Int64; var result: RawUTF8); overload;

Use our fast RawUTF8 version of IntToStr()

- without any slow UnicodeString=String->AnsiString conversion for Delphi 2009
- result as var parameter saves a local assignment and a try..finally

function Int64ToUtf8(Value: Int64): RawUTF8; overload;

Use our fast RawUTF8 version of IntToStr()

- without any slow UnicodeString=String->AnsiString conversion for Delphi 2009
- only useful if our Enhanced Runtime (or LVCL) library is not installed

function IntegerDynArrayLoadFrom(Source: PAnsiChar; var Count: integer; NoHash32Check: boolean=false): PIntegerArray;

Wrap an Integer dynamic array BLOB content as stored by TDynArray.SaveTo

- same as TDynArray.LoadFrom() with no memory allocation nor memory copy: so is much faster than creating a temporary dynamic array to load the data
- will return nil if no or invalid data, or a pointer to the integer array otherwise, with the items number stored in Count
- slightly faster than SimpleDynArrayLoadFrom(Source,TypeInfo(TIntegerDynArray),Count)

function IntegerDynArrayToCSV(Values: PIntegerArray; ValuesCount: integer; const Prefix: RawUTF8=''; const Suffix: RawUTF8=''; InlinedValue: boolean=false): RawUTF8; overload;

Return the corresponding CSV text from a dynamic array of 32-bit integer

- you can set some custom Prefix and Suffix text

function IntegerDynArrayToCSV(const Values: TIntegerDynArray; const Prefix: RawUTF8=''; const Suffix: RawUTF8=''; InlinedValue: boolean=false): RawUTF8; overload;

Return the corresponding CSV text from a dynamic array of 32-bit integer

- you can set some custom Prefix and Suffix text

function IntegerScan(P: PCardinalArray; Count: PtrInt; Value: cardinal): PCardinal;

Fast search of an unsigned integer position in an integer array

- Count is the number of cardinal entries in P^
- returns P where P^=Value
- returns nil if Value was not found

function IntegerScanExists(P: PCardinalArray; Count: PtrInt; Value: cardinal): boolean;

Fast search of an unsigned integer in an integer array

- returns true if P^=Value within Count entries
- returns false if Value was not found

function IntegerScanIndex(P: PCardinalArray; Count: PtrInt; Value: cardinal): PtrInt;

Fast search of an unsigned integer position in an integer array

- Count is the number of integer entries in P^
- return index of P^[index]=Value
- return -1 if Value was not found

function InterfaceArrayAdd(var aInterfaceArray; const aItem: IUnknown): PtrInt;

*Wrapper to add an item to a T*InterfaceArray dynamic array storage*

procedure InterfaceArrayAddOnce(var aInterfaceArray; const aItem: IUnknown);

*Wrapper to add once an item to a T*InterfaceArray dynamic array storage*

procedure InterfaceArrayDelete(var aInterfaceArray; aItemIndex: PtrInt); overload;

*Wrapper to delete an item in a T*InterfaceArray dynamic array storage*

- do nothing if the item is not found in the dynamic array

function InterfaceArrayDelete(var aInterfaceArray; const aItem: IUnknown): PtrInt;
 overload;

*Wrapper to delete an item in a T*InterfaceArray dynamic array storage*

- search is performed by address/reference, not by content
- do nothing if the item is not found in the dynamic array

function InterfaceArrayFind(const aInterfaceArray; const aItem: IUnknown): PtrInt;

*Wrapper to search an item in a T*InterfaceArray dynamic array storage*

- search is performed by address/reference, not by content
- return -1 if the item is not found in the dynamic array, or the index of the matching entry otherwise

function InterlockedDecrement(var I: Integer): Integer;

Compatibility function, to be implemented according to the running CPU

- expect the same result as the homonymous Win32 API function

function InterlockedIncrement(var I: Integer): Integer;

Compatibility function, to be implemented according to the running CPU

- expect the same result as the homonymous Win32 API function

function IntervalTextToDateTime(Text: PUTF8Char): TDateTime;

Interval date/time conversion from simple text

- expected format does not match ISO-8601 Time intervals format, but Oracle interval literal representation, i.e. '+/-D HH:MM:SS'

- e.g. IntervalTextToDateTime('+0 06:03:20') will return 0.25231481481 and IntervalTextToDateTime('-20 06:03:20') -20.252314815

- as a consequence, negative intervals will be written as TDateTime values:

DateTimeToIso8601Text(IntervalTextToDateTime('+0 06:03:20'))='T06:03:20'

DateTimeToIso8601Text(IntervalTextToDateTime('+1 06:03:20'))='1899-12-31T06:03:20'

DateTimeToIso8601Text(IntervalTextToDateTime('-2 06:03:20'))='1899-12-28T06:03:20'

procedure IntervalTextToDateTimeVar(Text: PUTF8Char; var result: TDateTime);

Interval date/time conversion from simple text

- expected format does not match ISO-8601 Time intervals format, but Oracle interval literal representation, i.e. '+/-D HH:MM:SS'

- e.g. '+1 06:03:20' will return 1.25231481481

function IntToString(Value: cardinal): string; overload;

Faster version than default SysUtils.IntToStr implementation

function IntToString(Value: Int64): string; overload;

Faster version than default SysUtils.IntToStr implementation

function IntToString(Value: integer): string; overload;

Faster version than default SysUtils.IntToStr implementation

function IntToThousandString(Value: integer; **const** ThousandSep: TShort4=','): shortstring;

Convert an integer value into its textual representation with thousands marked

- ThousandSep is the character used to separate thousands in numbers with more than three digits to the left of the decimal separator

function IP4Text(ip4: cardinal): shortstring; overload;

Convert a 32-bit integer (storing a IP4 address) into its full notation

- returns e.g. '1.2.3.4' for any valid address, or '' if ip4=0

function IP6Text(ip6: PHash128): shortstring; overload;

Convert a 128-bit buffer (storing an IP6 address) into its full notation

- returns e.g. '2001:0db8:0a0b:12f0:0000:0000:0000:0001'

procedure IP6Text(ip6: PHash128; result: PShortString); overload;

Convert a 128-bit buffer (storing an IP6 address) into its full notation

- returns e.g. '2001:0db8:0a0b:12f0:0000:0000:0000:0001'

function IsAnsiCompatible(PC: PAnsiChar; Len: PtrUInt): boolean; overload;

Return TRUE if the supplied buffer only contains 7-bits Ansi characters

function IsAnsiCompatible(**const** Text: RawByteString): boolean; overload;

Return TRUE if the supplied text only contains 7-bits Ansi characters

function IsAnsiCompatible(PC: PAnsiChar): boolean; overload;

Return TRUE if the supplied buffer only contains 7-bits Ansi characters

function IsAnsiCompatibleW(PW: PWideChar; Len: PtrInt): boolean; overload;

Return TRUE if the supplied UTF-16 buffer only contains 7-bits Ansi characters

function IsAnsiCompatibleW(PW: PWideChar): boolean; overload;

Return TRUE if the supplied UTF-16 buffer only contains 7-bits Ansi characters

function IsBase64(**const** s: RawByteString): boolean; overload;

Check if the supplied text is a valid Base64 encoded stream

function IsBase64(sp: PAnsiChar; len: PtrInt): boolean; overload;

Check if the supplied text is a valid Base64 encoded stream

function IsCaseSensitive(P: PUTF8Char; PLen: PtrInt): boolean; overload;

Check if the supplied text has some case-insensitive 'a'..'z','A'..'Z' chars

- will therefore be correct with true UTF-8 content, but only for 7 bit

function IsCaseSensitive(**const** S: RawUTF8): boolean; overload;

Check if the supplied text has some case-insensitive 'a'..'z','A'..'Z' chars

- will therefore be correct with true UTF-8 content, but only for 7 bit

function IsContentCompressed(Content: Pointer; Len: PtrInt): boolean;

Retrieve if some content is compressed, from a supplied binary buffer

- returns TRUE, if the header in binary buffer "may" be compressed (this method can trigger false positives), e.g. begin with most common already compressed zip/gz/gif/png/jpeg/avi/mp3/mp4 markers (aka "magic numbers")

function IsDirectoryWritable(const Directory: TFileName): boolean;

Check if the directory is writable for the current user

- try to write a small file with a random name

function IsEqual(const A,B: THash384): boolean; overload;

Returns TRUE if all 48 bytes of both 384-bit buffers do match

- e.g. a SHA-384 digest

- this function is not sensitive to any timing attack, so is designed for cryptographic purpose

function IsEqual(const A,B: THash256): boolean; overload;

Returns TRUE if all 32 bytes of both 256-bit buffers do match

- e.g. a SHA-256 digest, or a TECCSignature result

- this function is not sensitive to any timing attack, so is designed for cryptographic purpose

function IsEqual(const A,B: THash512): boolean; overload;

Returns TRUE if all 64 bytes of both 512-bit buffers do match

- e.g. two SHA-512 digests

- this function is not sensitive to any timing attack, so is designed for cryptographic purpose

function IsEqual(const A,B; count: PtrInt): boolean; overload;

Returns TRUE if all bytes of both buffers do match

- this function is not sensitive to any timing attack, so is designed for cryptographic purposes - use CompareMem/CompareMemSmall/CompareMemFixed as faster alternatives for general-purpose code

function IsEqual(const A,B: THash160): boolean; overload;

Returns TRUE if all 20 bytes of both 160-bit buffers do match

- e.g. a SHA-1 digest

- this function is not sensitive to any timing attack, so is designed for cryptographic purpose

function IsEqual(const A,B: THash128): boolean; overload;

Returns TRUE if all 16 bytes of both 128-bit buffers do match

- e.g. a MD5 digest, or an AES block

- this function is not sensitive to any timing attack, so is designed for cryptographic purpose - and it is also branchless therefore fast

function IsEqualGUID(const guid1, guid2: TGUID): Boolean; overload;

Compare two TGUID values

- this version is faster than the one supplied by SysUtils

function IsEqualGUID(guid1, guid2: PGUID): Boolean; overload;

Compare two TGUID values

- this version is faster than the one supplied by SysUtils

function IsEqualGUIDArray(const guid: TGUID; const guids: array of TGUID): integer;

Returns the index of a matching TGUID in an array

- returns -1 if no item matched

function IsFixedWidthCodePage(aCodePage: cardinal): boolean;

Check if a codepage should be handled by a TSynAnsiFixedWidth page

function IsHex(const Hex: RawByteString; BinBytes: integer): boolean;

Fast check if the supplied Hex buffer is an hexadecimal representation of a binary buffer of a given number of bytes

function IsHTMLContentTypeTextual(Headers: PUTF8Char): Boolean;

Returns TRUE if the supplied HTML Headers contains 'Content-Type: text/...', 'Content-Type: application/json' or 'Content-Type: application/xml'

function IsInitializedCriticalSection(const CS: TRTLCriticalSection): Boolean;

Returns TRUE if the supplied mutex has been initialized
 - will check if the supplied mutex is void (i.e. all filled with 0 bytes)

function IsIso8601(P: PUTF8Char; L: integer): boolean;

Test if P^ contains a valid ISO-8601 text encoded value
 - calls internally Iso8601ToTimeLogPUTF8Char() and returns true if contains at least a valid year (YYYY)

function IsLeapYear(Year: cardinal): boolean;

Our own fast version of the corresponding low-level RTL function

function IsNullGUID(const guid: TGUID): Boolean;

Check if a TGUID value contains only 0 bytes
 - this version is faster than the one supplied by SysUtils

function Iso8601CheckAndDecode(P: PUTF8Char; L: integer; var Value: TDateTime): boolean;

Date/Time conversion from strict ISO-8601 content
 - recognize 'YYYY-MM-DDThh:mm:ss[.sss]' or 'YYYY-MM-DD' or 'Thh:mm:ss[.sss]' patterns, as e.g. generated by TTextWriter.AddDateTime() or RecordSaveJSON()
 - will also recognize '.sss' milliseconds suffix, if any

function Iso8601ToDatePUTF8Char(P: PUTF8Char; L: integer; var Y,M,D: cardinal): boolean;

Date conversion from ISO-8601 (with no Time part)
 - recognize 'YYYY-MM-DD' and 'YYYYMMDD' format into Y,M,D variables
 - if L is left to default 0, it will be computed from StrLen(P)

function Iso8601ToDateTime(const S: RawByteString): TDateTime; overload;

Date/Time conversion from ISO-8601
 - handle 'YYYYMMDDThhmmss' and 'YYYY-MM-DD hh:mm:ss' format
 - will also recognize '.sss' milliseconds suffix, if any

function Iso8601ToDateTimePUTF8Char(P: PUTF8Char; L: integer=0): TDateTime;

Date/Time conversion from ISO-8601
 - handle 'YYYYMMDDThhmmss' and 'YYYY-MM-DD hh:mm:ss' format
 - will also recognize '.sss' milliseconds suffix, if any
 - if L is left to default 0, it will be computed from StrLen(P)

```
procedure Iso8601ToDateTimePUTF8CharVar(P: PUTF8Char; L: integer; var result: TDateTime);
```

Date/Time conversion from ISO-8601

- handle 'YYYYMMDDThhmmss' and 'YYYY-MM-DD hh:mm:ss' format, with potentially shorten versions has handled by the ISO-8601 standard (e.g. 'YYYY')
- will also recognize '.sss' milliseconds suffix, if any
- if L is left to default 0, it will be computed from StrLen(P)

```
function Iso8601ToTimeLog(const S: RawByteString): TTimeLog;
```

Convert a Iso8601 encoded string into a TTimeLog value

- handle TTimeLog bit-encoded Int64 format
- use this function only for fast comparison between two Iso8601 date/time
- conversion is faster than Iso8601ToDateTime: use only binary integer math

```
function Iso8601ToTimeLogPUTF8Char(P: PUTF8Char; L: integer; ContainsNoTime: PBoolean=nil): TTimeLog;
```

Convert a Iso8601 encoded string into a TTimeLog value

- handle TTimeLog bit-encoded Int64 format
- use this function only for fast comparison between two Iso8601 date/time
- conversion is faster than Iso8601ToDateTime: use only binary integer math
- ContainsNoTime optional pointer can be set to a boolean, which will be set according to the layout in P (e.g. TRUE for '2012-05-26')
- returns 0 in case of invalid input string

```
function Iso8601ToTimePUTF8Char(P: PUTF8Char; L: integer=0): TDateTime; overload;
```

Time conversion from ISO-8601 (with no Date part)

- handle 'hhmmss' and 'hh:mm:ss' format
- will also recognize '.sss' milliseconds suffix, if any
- if L is left to default 0, it will be computed from StrLen(P)

```
function Iso8601ToTimePUTF8Char(P: PUTF8Char; L: integer; var H,M,S,MS: cardinal): boolean; overload;
```

Time conversion from ISO-8601 (with no Date part)

- recognize 'hhmmss' and 'hh:mm:ss' format into H,M,S variables
- will also recognize '.sss' milliseconds suffix, if any, into MS
- if L is left to default 0, it will be computed from StrLen(P)

```
procedure Iso8601ToTimePUTF8CharVar(P: PUTF8Char; L: integer; var result: TDateTime);
```

Time conversion from ISO-8601 (with no Date part)

- handle 'hhmmss' and 'hh:mm:ss' format
- will also recognize '.sss' milliseconds suffix, if any
- if L is left to default 0, it will be computed from StrLen(P)

```
function IsRawUTF8DynArray(typeinfo: pointer): boolean;
```

Check if the TypeInfo() points to an "array of RawUTF8"

- e.g. returns true for TypeInfo(TRawUTF8DynArray) or other sub-types defined as "type aNewType = type TRawUTF8DynArray"

```
function IsRowID(FieldName: PUTF8Char; FieldLen: integer): boolean; overload;
```

Returns TRUE if the specified field name is either 'ID', either 'ROWID'

```
function IsRowID(FieldName: PUTF8Char): boolean; overload;
```

Returns TRUE if the specified field name is either 'ID', either 'ROWID'

function IsRowIDShort(const FieldName: shortstring): boolean; overload;

Returns TRUE if the specified field name is either 'ID', either 'ROWID'

function isSelect(P: PUTF8Char; SelectClause: PRawUTF8=nil): boolean;

Return true if the parameter is void or begin with a 'SELECT' SQL statement

- used to avoid code injection and to check if the cache must be flushed
- VACUUM, PRAGMA, or EXPLAIN statements also return true, since they won't change the data content
- WITH recursive statement expect no INSERT/UPDATE/DELETE pattern in the SQL
- if P^ is a SELECT and SelectClause is set to a variable, it would contain the field names, from SELECT ...field names... FROM

function IsString(P: PUTF8Char): boolean;

Test if the supplied buffer is a "string" value or a numerical value (floating point or integer), according to the characters within

- this version will recognize null/false/true as strings
- e.g. IsString('0')=false, IsString('abc')=true, IsString('null')=true

function IsStringJSON(P: PUTF8Char): boolean;

Test if the supplied buffer is a "string" value or a numerical value (floating or integer), according to the JSON encoding schema

- this version will NOT recognize JSON null/false/true as strings
- e.g. IsStringJSON('0')=false, IsStringJSON('abc')=true, but IsStringJSON('null')=false
- will follow the JSON definition of number, i.e. '0123' is a string (i.e. '0' is excluded at the beginning of a number) and '123' is not a string

function IsValidURL(P: PUTF8Char): boolean;

Checks if the supplied UTF-8 text don't need URI encoding

- returns TRUE if all its chars are non-void plain ASCII-7 RFC compatible identifiers (0..9a..zA..Z-_.~)

function IsValidJSON(const s: RawUTF8): boolean; overload;

Test if the supplied buffer is a correct JSON value

function IsValidJSON(P: PUTF8Char; len: PtrInt): boolean; overload;

Test if the supplied buffer is a correct JSON value

function IsValidUTF8WithoutControlChars(const source: RawUTF8): Boolean; overload;

Returns TRUE if the supplied buffer has valid UTF-8 encoding with no #0..#31 control characters

- supplied input is a RawUTF8 variable

function IsValidUTF8WithoutControlChars(source: PUTF8Char): Boolean; overload;

Returns TRUE if the supplied buffer has valid UTF-8 encoding with no #1..#31 control characters

- supplied input is a pointer to a #0 ended text buffer

function IsVoid(const text: RawUTF8): boolean;

Check all character within text are spaces or control chars

- i.e. a faster alternative to trim(text)=""

function IsWinAnsi(WideText: PWideChar; Length: integer): boolean; overload;

Return TRUE if the supplied unicode buffer only contains WinAnsi characters

- i.e. if the text can be displayed using ANSI_CHARSET

function IsWinAnsi(WideText: PWideChar): boolean; overload;

Return TRUE if the supplied unicode buffer only contains WinAnsi characters
- i.e. if the text can be displayed using ANSI_CHARSET

function IsWinAnsiU(UTF8Text: PUTF8Char): boolean;

Return TRUE if the supplied UTF-8 buffer only contains WinAnsi characters
- i.e. if the text can be displayed using ANSI_CHARSET

function IsWinAnsiU8Bit(UTF8Text: PUTF8Char): boolean;

Return TRUE if the supplied UTF-8 buffer only contains WinAnsi 8 bit characters
- i.e. if the text can be displayed using ANSI_CHARSET with only 8 bit unicode characters (e.g. no "tm" or such)

function IsZero(const Values: TIntegerDynArray): boolean; overload;

Returns TRUE if Value is nil or all supplied Values[] equal 0

function IsZero(const Values: TRawUTF8DynArray): boolean; overload;

Returns TRUE if Value is nil or all supplied Values[] equal ""

function IsZero(const dig: THash384): boolean; overload;

Returns TRUE if all 48 bytes of this 384-bit buffer equal zero
- e.g. a SHA-384 digest

function IsZero(const dig: THash512): boolean; overload;

Returns TRUE if all 64 bytes of this 512-bit buffer equal zero
- e.g. a SHA-512 digest

function IsZero(P: pointer; Length: integer): boolean; overload;

Returns TRUE if all bytes equal zero

function IsZero(const dig: THash256): boolean; overload;

Returns TRUE if all 32 bytes of this 256-bit buffer equal zero
- e.g. a SHA-256 digest, or a TECCSignature result

function IsZero(const dig: THash160): boolean; overload;

Returns TRUE if all 20 bytes of this 160-bit buffer equal zero
- e.g. a SHA-1 digest

function IsZero(const dig: THash128): boolean; overload;

Returns TRUE if all 16 bytes of this 128-bit buffer equal zero
- e.g. a MD5 digest, or an AES block

function IsZero(const Values: TInt64DynArray): boolean; overload;

Returns TRUE if Value is nil or all supplied Values[] equal 0

function IsZeroSmall(P: pointer; Length: PtrInt): boolean;

Returns TRUE if all of a few bytes equal zero
- to be called instead of IsZero() e.g. for 1..8 bytes

function JSONArrayCount(P, PMax: PUTF8Char): integer; overload;

Compute the number of elements of a JSON array

- this will handle any kind of arrays, including those with nested JSON objects or arrays
- incoming P^ should point to the first char after the initial '[' (which may be a closing ']')
- this overloaded method will abort if P reaches a certain position: for really HUGE arrays, it is faster to allocate the content within the loop, not ahead of time

function JSONArrayCount(P: PUTF8Char): integer; overload;

Compute the number of elements of a JSON array

- this will handle any kind of arrays, including those with nested JSON objects or arrays
- incoming P^ should point to the first char AFTER the initial '[' (which may be a closing ']')
- returns -1 if the supplied input is invalid, or the number of identified items in the JSON array buffer

function JSONArrayDecode(P: PUTF8Char; out Values: TPUTF8CharDynArray): boolean;

Retrieve all elements of a JSON array

- this will handle any kind of arrays, including those with nested JSON objects or arrays
- incoming P^ should point to the first char AFTER the initial '[' (which may be a closing ']')
- returns false if the supplied input is invalid
- returns true on success, with Values[] pointing to each unescaped value, may be a JSON string, object, array of constant

function JSONArrayItem(P: PUTF8Char; Index: integer): PUTF8Char;

Go to the #nth item of a JSON array

- implemented via a fast SAX-like approach: the input buffer is not changed, nor no memory buffer allocated neither content copied
- returns nil if the supplied index is out of range
- returns a pointer to the index-nth item in the JSON array (first index=0)
- this will handle any kind of arrays, including those with nested JSON objects or arrays
- incoming P^ should point to the first initial '[' char

procedure JSONBufferReformat(P: PUTF8Char; out result: RawUTF8; Format: TTextWriterJSONFormat=jsonHumanReadable);

Formats and indents a JSON array or document to the specified layout

- just a wrapper around TTextWriter.AddJSONReformat() method
- WARNING: the JSON buffer is decoded in-place, so P^ WILL BE modified

function JSONBufferReformatToFile(P: PUTF8Char; const Dest: TFileName; Format: TTextWriterJSONFormat=jsonHumanReadable): boolean;

Formats and indents a JSON array or document as a file

- just a wrapper around TTextWriter.AddJSONReformat() method
- WARNING: the JSON buffer is decoded in-place, so P^ WILL BE modified

procedure JSONBufferToXML(P: PUTF8Char; const Header, NameSpace: RawUTF8; out result: RawUTF8);

Convert a JSON array or document into a simple XML content

- just a wrapper around TTextWriter.AddJSONToXML, with an optional header before the XML converted data (e.g. XMLUTF8_HEADER), and an optional name space content node which will nest the generated XML data (e.g. '<contents xmlns="http://www.w3.org/2001/XMLSchema-instance">') - the corresponding ending token will be appended after (e.g. '</contents>')
- WARNING: the JSON buffer is decoded in-place, so P^ WILL BE modified

```
function JSONDecode(P: PUTF8Char; const Names: array of RawUTF8; Values: PValuePUTF8CharArray; HandleValuesAsObjectOrArray: Boolean=false): PUTF8Char; overload;
```

Decode the supplied UTF-8 JSON content for the supplied names

- data will be set in Values, according to the Names supplied e.g.
JSONDecode(P,['name','year'],Values) -> Values[0]^='John'; Values[1]^='1972';
- if any supplied name wasn't found its corresponding Values[] will be nil
- this procedure will decode the JSON content in-memory, i.e. the PUTf8Char array is created inside P, which is therefore modified: make a private copy first if you want to reuse the JSON content
- if HandleValuesAsObjectOrArray is TRUE, then this procedure will handle JSON arrays or objects
- if ValuesLen is set, ValuesLen[] will contain the length of each Values[]
- returns a pointer to the next content item in the JSON buffer

Used for DI-2.1.2 (page 2555).

```
function JSONDecode(var JSON: RawUTF8; const aName: RawUTF8='result'; wasString: PBoolean=nil; HandleValuesAsObjectOrArray: Boolean=false): RawUTF8; overload;
```

Decode the supplied UTF-8 JSON content for the one supplied name

- this function will decode the JSON content in-memory, so will unescape it in-place: it must be called only once with the same JSON data

Used for DI-2.1.2 (page 2555).

```
function JSONDecode(P: PUTF8Char; out Values: TNameValuePUTF8CharDynArray; HandleValuesAsObjectOrArray: Boolean=false): PUTF8Char; overload;
```

Decode the supplied UTF-8 JSON content into an array of name/value pairs

- this procedure will decode the JSON content in-memory, i.e. the PUTf8Char array is created inside JSON, which is therefore modified: make a private copy first if you want to reuse the JSON content
- the supplied JSON buffer should stay available until Name/Value pointers from returned Values[] are accessed
- if HandleValuesAsObjectOrArray is TRUE, then this procedure will handle JSON arrays or objects
- support enhanced JSON syntax, e.g. '{name:"John",year:1972}' is decoded just like '{"name":"John","year":1972}'

Used for DI-2.1.2 (page 2555).

```
procedure JSONDecode(var JSON: RawJSON; const Names: array of RawUTF8; Values: PValuePUTF8CharArray; HandleValuesAsObjectOrArray: Boolean=false); overload;
```

Decode the supplied UTF-8 JSON content for the supplied names

- an overloaded function when the JSON is supplied as a RawJSON variable

Used for DI-2.1.2 (page 2555).

```
procedure JSONDecode(var JSON: RawUTF8; const Names: array of RawUTF8; Values: PValuePUTF8CharArray; HandleValuesAsObjectOrArray: Boolean=false); overload;
```

Decode the supplied UTF-8 JSON content for the supplied names

- data will be set in Values, according to the Names supplied e.g.
JSONDecode(JSON, ['name', 'year'], @Values) -> Values[0].Value='John'; Values[1].Value='1972';
- if any supplied name wasn't found its corresponding Values[] will be nil
- this procedure will decode the JSON content in-memory, i.e. the PUTF8Char array is created inside JSON, which is therefore modified: make a private copy first if you want to reuse the JSON content
- if HandleValuesAsObjectOrArray is TRUE, then this procedure will handle JSON arrays or objects
- support enhanced JSON syntax, e.g. '{name:"John",year:1972}' is decoded just like '{name:"John","year":1972}'

Used for DI-2.1.2 (page 2555).

```
function JSONEncode(const NameValuePairs: array of const): RawUTF8; overload;
```

Encode the supplied data as an UTF-8 valid JSON object content

- data must be supplied two by two, as Name,Value pairs, e.g.
JSONEncode(['name', 'John', 'year', 1972]) = '{"name":"John","year":1972}'
- or you can specify nested arrays or objects with '['..'']' or '{'..'}':
J := JSONEncode(['doc', ['name', 'John', 'abc', ['a', 'b', 'c']], ['id', 123]]);
assert(J='{"doc":{"name":"John","abc":["a","b","c"]},"id":123}');
- note that, due to a Delphi compiler limitation, cardinal values should be type-casted to Int64() (otherwise the integer mapped value will be converted)
- you can pass nil as parameter for a null JSON value

Used for DI-2.1.2 (page 2555).

```
function JSONEncode(const Format: RawUTF8; const Args,Params: array of const): RawUTF8; overload;
```

Encode the supplied (extended) JSON content, with parameters, as an UTF-8 valid JSON object content

- in addition to the JSON RFC specification strict mode, this method will handle some BSON-like extensions, e.g. unquoted field names:
aJSON := JSONEncode('{id:?,%:{name:?,birthyear:??}}', ['doc'], [10, 'John', 1982]);
- you can use nested _Obj() / _Arr() instances
aJSON := JSONEncode('%:{in:[?,?]}', ['type'], ['food', 'snack']);
aJSON := JSONEncode('{type:{in:??}}', [], [_Arr(['food', 'snack'])]);
// will both return
'{"type":{"in":["food","snack"]}}'
- if the SynMongoDB unit is used in the application, the MongoDB Shell syntax will also be recognized to create TBSONVariant, like
new Date() ObjectId() MinKey MaxKey /<jRegex>/<jOptions>
see @<http://docs.mongodb.org/manual/reference/mongodb-extended-json>
aJSON := JSONEncode('{name:?,field:/%/i}', ['acme.*corp'], ['John'])
// will return
'{"name":"John","field":{"\$regex":"acme.*corp","\$options":"i"}}'
- will call internally _JSONFastFmt() to create a temporary TDocVariant with all its features - so is slightly slower than other JSONEncode* functions

Used for DI-2.1.2 (page 2555).

```
function JSONEncodeArrayDouble(const Values: array of double): RawUTF8; overload;
```

Encode the supplied floating-point array data as a valid JSON array

function JSONEncodeArrayInteger(**const** Values: **array of integer**): RawUTF8; overload;
Encode the supplied integer array data as a valid JSON array

function JSONEncodeArrayOfConst(**const** Values: **array of const**; WithoutBraces: boolean=false): RawUTF8; overload;

Encode the supplied array data as a valid JSON array content

- if WithoutBraces is TRUE, no [] will be generated
- note that, due to a Delphi compiler limitation, cardinal values should be type-casted to Int64() (otherwise the integer mapped value will be converted)

procedure JSONEncodeArrayOfConst(**const** Values: **array of const**; WithoutBraces: boolean; **var** result: RawUTF8); overload;

Encode the supplied array data as a valid JSON array content

- if WithoutBraces is TRUE, no [] will be generated
- note that, due to a Delphi compiler limitation, cardinal values should be type-casted to Int64() (otherwise the integer mapped value will be converted)

function JSONEncodeArrayUTF8(**const** Values: **array of RawUTF8**): RawUTF8; overload;
Encode the supplied RawUTF8 array data as an UTF-8 valid JSON array content

procedure JSONEncodeNameSQLValue(**const** Name,SQLValue: RawUTF8; **var** result: RawUTF8);

Encode as JSON {"name":value} object, from a potential SQL quoted value

- will unquote the SQLValue using TTextWriter.AddQuotedStringAsJSON()

function JSONObjectAsJSONArrays(JSON: PUTF8Char; **out** keys,values: RawUTF8): boolean;

Convert one JSON object into two JSON arrays of keys and values

- i.e. makes the following transformation:
{key1:value1,key2,value2...} -> [key1,key2...] + [value1,value2...]
- this function won't allocate any memory during its process, nor modify the JSON input buffer
- is the reverse of the TTextWriter.AddJSONArraysAsJSONObject() method

function JsonObjectByPath(JsonObject,PropPath: PUTF8Char): PUTF8Char;

Go to a property of a JSON object, by its full path, e.g. 'parent.child'

- implemented via a fast SAX-like approach: the input buffer is not changed, nor no memory buffer allocated neither content copied
- returns nil if the supplied property path does not exist
- returns a pointer to the matching item in the JSON object
- this will handle any kind of objects, including those with nested JSON objects or arrays
- incoming P^ should point to the first initial '{' char

function JsonObjectItem(P: PUTF8Char; **const** PropName: RawUTF8; PropNameFound: PRawUTF8=nil): PUTF8Char;

Go to a named property of a JSON object

- implemented via a fast SAX-like approach: the input buffer is not changed, nor no memory buffer allocated neither content copied
- returns nil if the supplied property name does not exist
- returns a pointer to the matching item in the JSON object
- this will handle any kind of objects, including those with nested JSON objects or arrays
- incoming P^ should point to the first initial '{' char

function JSONObjectPropCount(P: PUTF8Char): integer;

Compute the number of fields in a JSON object

- this will handle any kind of objects, including those with nested JSON objects or arrays
- incoming P^ should point to the first char after the initial '{' (which may be a closing '}')

function JsonObjectByPath(JsonObject, PropPath: PUTF8Char): RawUTF8;

Return all matching properties of a JSON object

- here the PropPath could be a comma-separated list of full paths, e.g. 'Prop1,Prop2' or 'Obj1.Obj2.Prop1,Obj1.Prop2'
- returns "" if no property did match
- returns a JSON object of all matching properties
- this will handle any kind of objects, including those with nested JSON objects or arrays
- incoming P^ should point to the first initial '{' char

function JsonPropNameValid(P: PUTF8Char): boolean;

Returns TRUE if the given text buffer contains simple characters as recognized by JSON extended syntax

- follow GetJSONPropName and GotoNextJSONObjectOrArray expectations

function JSONReformat(const JSON: RawUTF8; Format: TTextWriterJSONFormat=jsonHumanReadable): RawUTF8;

Formats and indents a JSON array or document to the specified layout

- just a wrapper around TTextWriter.AddJSONReformat, making a private of the supplied JSON buffer (so that JSON content would stay untouched)

function JSONReformatToFile(const JSON: RawUTF8; const Dest: TFileName; Format: TTextWriterJSONFormat=jsonHumanReadable): boolean;

Formats and indents a JSON array or document as a file

- just a wrapper around TTextWriter.AddJSONReformat, making a private of the supplied JSON buffer (so that JSON content would stay untouched)

function JSONRetrieveStringField(P: PUTF8Char; out Field: PUTF8Char; out FieldLen: integer; ExpectNameField: boolean): PUTF8Char;

Retrieve a pointer to JSON string field content

- returns either ':' for name field, either '}',',' for value field
- returns nil on JSON content error
- this function won't touch the JSON buffer, so you can call it before using in-place escape process via JSONDecode() or GetJSONField()

function JSONToVariant(const JSON: RawUTF8; Options: TDocVariantOptions=[dvoReturnNullForUnknownProperty]; AllowDouble: boolean=false): variant;

Retrieve a variant value from a JSON UTF-8 text as per RFC 8259, RFC 7159, RFC 7158

- follows TTextWriter.AddVariant() format (calls GetVariantFromJSON)
- will instantiate either an Integer, Int64, currency, double or string value (as RawUTF8), guessing the best numeric type according to the textual content, and string in all other cases, except TryCustomVariants points to some options (e.g. @JSON_OPTIONS[true] for fast instance) and input is a known object or array, either encoded as strict-JSON (i.e. {...} or [...]), or with some extended (e.g. BSON) syntax
- this overloaded procedure will make a temporary copy before JSON parsing and return the variant as result

function JSONToVariantDynArray(**const** JSON: RawUTF8): TVariantDynArray;

Convert a JSON array into a dynamic array of variants
- will use a TDocVariantData temporary storage

procedure JSONToVariantInPlace(**var** Value: **Variant**; JSON: PUTF8Char; Options: TDocVariantOptions=[dvoReturnNullForUnknownProperty]; AllowDouble: **boolean**=false);

Retrieve a variant value from a JSON buffer as per RFC 8259, RFC 7159, RFC 7158
- follows TTextWriter.AddVariant() format (calls GetVariantFromJSON)
- will instantiate either an Integer, Int64, currency, double or string value (as RawUTF8), guessing the best numeric type according to the textual content, and string in all other cases, except TryCustomVariants points to some options (e.g. @JSON_OPTIONS[true] for fast instance) and input is a known object or array, either encoded as strict-JSON (i.e. {...} or [...]), or with some extended (e.g. BSON) syntax
- warning: the JSON buffer will be modified in-place during process - use a temporary copy or the overloaded functions with RawUTF8 parameter if you need to access it later

function JSONToXML(**const** JSON: RawUTF8; **const** Header: RawUTF8=XMLUTF8_HEADER; **const** Namespace: RawUTF8=''): RawUTF8;

Convert a JSON array or document into a simple XML content
- just a wrapper around TTextWriter.AddJSONToXML, making a private copy of the supplied JSON buffer using TSynTempBuffer (so that JSON content would stay untouched)
- the optional header is added at the beginning of the resulting string
- an optional name space content node could be added around the generated XML, e.g. '<content>'

procedure KahanSum(**const** Data: **double**; **var** Sum, Carry: **double**);

Compute the sum of values, using a running compensation for lost low-order bits
- a naive "Sum := Sum + Data" will be restricted to 53 bits of resolution, so will eventually result in an incorrect number
- Kahan algorithm keeps track of the accumulated error in integer operations, to achieve a precision of more than 100 bits
- see https://en.wikipedia.org/wiki/Kahan_summation_algorithm

function KB(bytes: Int64): TShort16; overload;

Convert a size to a human readable value
- append EB, PB, TB, GB, MB, KB or B symbol with preceding space
- for EB, PB, TB, GB, MB and KB, add one fractional digit

function KB(**const** buffer: RawByteString): TShort16; overload;

Delphi 2007 is buggy as hell convert a string size to a human readable value
- append EB, PB, TB, GB, MB, KB or B symbol
- for EB, PB, TB, GB, MB and KB, add one fractional digit

function KB(bytes: Int64; nospace: **boolean**): TShort16; overload;

Delphi 2007 is buggy as hell convert a size to a human readable value
- append EB, PB, TB, GB, MB, KB or B symbol with or without preceding space
- for EB, PB, TB, GB, MB and KB, add one fractional digit

procedure KB(bytes: Int64; **out** result: TShort16; nospace: **boolean**); overload;

Convert a size to a human readable value power-of-two metric value
- append EB, PB, TB, GB, MB, KB or B symbol with or without preceding space
- for EB, PB, TB, GB, MB and KB, add one fractional digit

function KBNoSpace(bytes: Int64): TShort16;

Delphi 2007 is buggy as hell convert a size to a human readable value

- append EB, PB, TB, GB, MB, KB or B symbol without preceding space
- for EB, PB, TB, GB, MB and KB, add one fractional digit

procedure KBU(bytes: Int64; var result: RawUTF8);

Convert a size to a human readable value

- append EB, PB, TB, GB, MB, KB or B symbol
- for EB, PB, TB, GB, MB and KB, add one fractional digit

function kr32(crc: cardinal; buf: PAnsiChar; len: PtrInt): cardinal;

Standard Kernighan & Ritchie hash from "The C programming Language", 3rd edition

- simple and efficient code, but too much collisions for THasher
- kr32() is 898.8 MB/s - crc32cfast() 1.7 GB/s, crc32csse42() 4.3 GB/s

function LogEscape(source: PAnsiChar; sourcelen: integer; var temp: TLogEscape; enabled: boolean=true): PAnsiChar;

Fill TLogEscape stack buffer with the (hexadecimal) chars of the input binary

- up to LOGESCAPELEN (i.e. 200) bytes will be escaped and appended to a Local temp: TLogEscape variable, using the EscapeBuffer() low-level function
- you can then log the resulting escaped text by passing the returned PAnsiChar as % parameter to a TSynLog.Log() method
- the "enabled" parameter can be assigned from a process option, avoiding to process the escape if verbose logs are disabled
- used e.g. to implement logBinaryFrameContent option for WebSockets

function LogEscapeFull(source: PAnsiChar; sourcelen: integer): RawUTF8; overload;

Returns a text buffer with the (hexadecimal) chars of the input binary

- is much slower than LogEscape/EscapeToShort, but has no size limitation

function LogEscapeFull(const source: RawByteString): RawUTF8; overload;

Returns a text buffer with the (hexadecimal) chars of the input binary

- is much slower than LogEscape/EscapeToShort, but has no size limitation

procedure LogToTextFile(Msg: RawUTF8);

Log a message to a local text file

- the text file is located in the executable directory, and its name is simply the executable file name with the '.log' extension instead of '.exe'
- format contains the current date and time, then the Msg on one line
- date and time format used is 'YYYYMMDD hh:mm:ss (i.e. ISO-8601)'

function LowerCase(const S: RawUTF8): RawUTF8;

Fast conversion of the supplied text into lowercase

- this will only convert 'A'..'Z' into 'a'..'z' (no NormToLower use), and will therefore be correct with true UTF-8 content

procedure LowerCaseCopy(Text: PUTF8Char; Len: PtrInt; var result: RawUTF8);

Fast conversion of the supplied text into lowercase

- this will only convert 'A'..'Z' into 'a'..'z' (no NormToLower use), and will therefore be correct with true UTF-8 content

procedure LowerCaseSelf(**var** S: RawUTF8);

Fast in-place conversion of the supplied variable text into lowercase

- this will only convert 'A'..'Z' into 'a'..'z' (no NormToLower use), and will therefore be correct with true UTF-8 content, but only for 7 bit

function LowerCaseU(**const** S: RawUTF8): RawUTF8;

Fast conversion of the supplied text into 8 bit lowercase

- this will not only convert 'A'..'Z' into 'a'..'z', but also accentuated latin characters ('E' acute into 'e' e.g.), using NormToLower[] array

- it will therefore decode the supplied UTF-8 content to handle more than 7 bit of ascii characters

function LowerCaseUnicode(**const** S: RawUTF8): RawUTF8;

Accurate conversion of the supplied UTF-8 content into the corresponding lower-case Unicode characters

- this version will use the Operating System API, and will therefore be much slower than LowerCase/LowerCaseU versions, but will handle all kind of unicode characters

function MaxInteger(**const** Values: TIntegerDynArray; ValuesCount: PtrInt; MaxStart: integer=-1): Integer;

Find the maximum 32-bit integer in Values[]

function MedianQuickSelect(**const** OnCompare: TOnValueGreater; n: integer; **var** TempBuffer: TSynTempBuffer): integer;

Compute the median of a serie of values, using "Quickselect"

- based on the algorithm described in "Numerical recipes in C", Second Edition

- expect the values information to be available from a comparison callback

- this version will use a temporary index list to exchange items order (supplied as a TSynTempBuffer), so won't change the supplied values themselves

- returns the index of the median Value

function MedianQuickSelectInteger(Values: PIntegerArray; n: integer): integer;

Compute the median of an integer serie of values, using "Quickselect"

- based on the algorithm described in "Numerical recipes in C", Second Edition, translated from Nicolas Devillard's C code: <http://ndevilla.free.fr/median/median>

- warning: the supplied Integer array is modified in-place during the process, and won't be fully sorted on output (this is no QuickSort alternative)

function MicroSecToString(Micro: QWord): TShort16; overload;

Convert a micro seconds elapsed time into a human readable value

- append 'us', 'ms', 's', 'm', 'h' and 'd' symbol for the given value range, with two fractional digits

procedure MicroSecToString(Micro: QWord; **out** result: TShort16); overload;

Delphi 2007 is buggy as hell convert a micro seconds elapsed time into a human readable value

- append 'us', 'ms', 's', 'm', 'h' and 'd' symbol for the given value range, with two fractional digits

procedure MoveSmall(Source, Dest: Pointer; Count: PtrUInt);

An alternative Move() function tuned for small unaligned counts

- warning: expects Count>0 and Source/Dest not nil

- warning: doesn't support buffers overlapping

procedure mul64x64(**const** left, right: QWord; **out** product: THash128Rec);

Fast computation of two 64-bit unsigned integers into a 128-bit value

function MultiEventAdd(**var** EventList; **const** Event: TMethod): boolean;

Low-level wrapper to add a callback to a dynamic list of events

- by default, you can assign only one callback to an Event: but by storing it as a dynamic array of events, you can use this wrapper to add one callback to this list of events
- if the event was already registered, do nothing (i.e. won't call it twice)
- since this function uses an unsafe typeless EventList parameter, you should not use it in high-level code, but only as wrapper within dedicated methods
- will add Event to EventList[] unless Event is already registered
- is used e.g. by TTextWriter as such:

```
...
  fEchos: array of TOnTextWriterEcho;
...
  procedure EchoAdd(const aEcho: TOnTextWriterEcho);
...
procedure TTextWriter.EchoAdd(const aEcho: TOnTextWriterEcho);
begin
  MultiEventAdd(fEchos, TMethod(aEcho));
end;
```

then callbacks are then executed as such:

```
if fEchos<>nil then
  for i := 0 to length(fEchos)-1 do
    fEchos[i](self, fEchoBuf);
```

- use MultiEventRemove() to un-register a callback from the list

function MultiEventFind(**const** EventList; **const** Event: TMethod): integer;

Low-level wrapper to check if a callback is in a dynamic list of events

- by default, you can assign only one callback to an Event: but by storing it as a dynamic array of events, you can use this wrapper to check if a callback has already been registered to this list of events
- used internally by MultiEventAdd() and MultiEventRemove() functions

procedure MultiEventMerge(**var** DestList; **const** ToBeAddedList);

Low-level wrapper to add one or several callbacks from another list of events

- all events of the ToBeAddedList would be added to DestList
- the list is not checked for duplicates

procedure MultiEventRemove(**var** EventList; **Index**: Integer); overload;

Low-level wrapper to remove a callback from a dynamic list of events

- same as the same overloaded procedure, but accepting an EventList[] index to identify the Event to be suppressed

procedure MultiEventRemove(**var** EventList; **const** Event: TMethod); overload;

Low-level wrapper to remove a callback from a dynamic list of events

- by default, you can assign only one callback to an Event: but by storing it as a dynamic array of events, you can use this wrapper to remove one callback already registered by MultiEventAdd() to this list of events

- since this function uses an unsafe typeless EventList parameter, you should not use it in high-level code, but only as wrapper within dedicated methods

- is used e.g. by TTextWriter as such:

```
...
  fEchos: array of TOnTextWriterEcho;
...
  procedure EchoRemove(const aEcho: TOnTextWriterEcho);
...
procedure TTextWriter.EchoRemove(const aEcho: TOnTextWriterEcho);
begin
  MultiEventRemove(fEchos, TMethod(aEcho));
end;
```

function MultiPartFormDataAddField(**const** FieldName, FieldValue: RawUTF8; **var** MultiPart: TMultiPartDynArray): boolean;

Encode a field in a multipart array

- FieldName: field name of the part

- FieldValue: value of the field

- Multipart: where the part is added

function MultiPartFormDataAddFile(**const** FileName: TFileName; **var** MultiPart: TMultiPartDynArray; **const** Name: RawUTF8 = ''): boolean;

Encode a file in a multipart array

- FileName: file to encode

- Multipart: where the part is added

- Name: name of the part, is empty the name 'File###' is generated

function MultiPartFormDataDecode(**const** MimeType, Body: RawUTF8; **var** MultiPart: TMultiPartDynArray): boolean;

Decode multipart/form-data POST request content

- following RFC1867

function MultiPartFormDataEncode(**const** MultiPart: TMultiPartDynArray; **var** MultiPartContentType, MultiPartContent: RawUTF8): boolean;

Encode multipart fields and files

- only one of them can be used because MultiPartFormDataDecode must implement both decodings

- MultiPart: parts to build the multipart content from, which may be created using MultiPartFormDataAddFile/MultiPartFormDataAddField

- MultiPartContentType: variable returning

Content-Type: multipart/form-data; boundary=xxx

where xxx is the first generated boundary

- MultiPartContent: generated multipart content

function NeedsJsonEscape(P: PUTF8Char): boolean; overload;

Returns TRUE if the given text buffers would be escaped when written as JSON

- e.g. if contains " or \ characters, as defined by <http://www.ietf.org/rfc/rfc4627.txt>

function NeedsJsonEscape(const Text: RawUTF8): boolean; overload;

Returns TRUE if the given text buffers would be escaped when written as JSON

- e.g. if contains " or \ characters, as defined by <http://www.ietf.org/rfc/rfc4627.txt>

function NeedsJsonEscape(P: PUTF8Char; PLen: integer): boolean; overload;

Returns TRUE if the given text buffers would be escaped when written as JSON

- e.g. if contains " or \ characters, as defined by <http://www.ietf.org/rfc/rfc4627.txt>

function NewSynLocker: PSynLocker;

Allocate and initialize a TSynLocker instance

- caller should call result^.DoneAndFreemem when not used any more

function NextGrow(capacity: integer): integer;

Compute the new capacity when expanding an array of items

- handle tiny, small, medium, large and huge sizes properly to reduce memory usage and maximize performance

function NextNotSpaceCharIs(var P: PUTF8Char; ch: AnsiChar): boolean;

Check if the next character not in [#1..''] matches a given value

- first ignore any non space character

- then returns TRUE if P^=ch, setting P to the character after ch

- or returns FALSE if P^<>ch, leaving P at the level of the unexpected char

function NextUTF8UCS4(var P: PUTF8Char): cardinal;

Get the UCS4 char stored in P^ (decode UTF-8 if necessary)

procedure NotifySortedIntegerChanges(old, new: PIntegerArray; oldn, newn: PtrInt;
const added, deleted: TOnNotifySortedIntegerChange; const sender);

Compares two 32-bit signed sorted integer arrays, and call event handlers to notify the corresponding modifications in an O(n) time

- items in both old[] and new[] arrays are required to be sorted

function NowToString(Expanded: boolean=true; FirstTimeChar: AnsiChar=' '): RawUTF8;

Retrieve the current Date, in the ISO 8601 layout, but expanded and ready to be displayed

function NowUTC: TDateTime;

Returns the current UTC system date and time

- SysUtils.Now returns local time: this function returns the system time expressed in Coordinated Universal Time (UTC)

- under Windows, will use GetSystemTimeAsFileTime() so will achieve about 16 ms of resolution

- under POSIX, will call clock_gettime(CLOCK_REALTIME_COARSE)

function NowUTCToString(Expanded: boolean=true; FirstTimeChar: AnsiChar=' '):
RawUTF8;

Retrieve the current UTC Date, in the ISO 8601 layout, but expanded and ready to be displayed

function ObjArrayAdd(**var** aObjArray; aItem: TObject): PtrInt;

*Wrapper to add an item to a T*ObjArray dynamic array storage*

- as expected by TJSONSerializer.RegisterObjArrayForJSON()
- could be used as such (note the T*ObjArray type naming convention):

```
TUserObjArray = array of TUser;
...
var arr: TUserObjArray;
    user: TUser;
..
try
  user := TUser.Create;
  user.Name := 'Name';
  index := ObjArrayAdd(arr,user);
...
finally
  ObjArrayClear(arr); // release all items
end;
```

- return the index of the item in the dynamic array

function ObjArrayAddCount(**var** aObjArray; aItem: TObject; **var** aObjArrayCount: integer): PtrInt;

*Wrapper to add an item to a T*ObjArray dynamic array storage*

- this overloaded function will use a separated variable to store the items count, so will be slightly faster: but you should call SetLength() when done, to have an array as expected by TJSONSerializer.RegisterObjArrayForJSON()
- return the index of the item in the dynamic array

function ObjArrayAddFrom(**var** aDestObjArray; **const** aSourceObjArray): PtrInt;

*Wrapper to add items to a T*ObjArray dynamic array storage*

- aSourceObjArray[] items are just copied to aDestObjArray, which remains untouched
- return the new number of the items in aDestObjArray

procedure ObjArrayAddOnce(**var** aObjArray; aItem: TObject);

*Wrapper to add once an item to a T*ObjArray dynamic array storage*

- as expected by TJSONSerializer.RegisterObjArrayForJSON()
- if the object is already in the array (searching by address/reference, not by content), return its current index in the dynamic array
- if the object does not appear in the array, add it at the end

function ObjArrayAddOnceFrom(**var** aDestObjArray; **const** aSourceObjArray): PtrInt;

- aSourceObjArray[] items are just copied to aDestObjArray, which remains untouched
- will first check if aSourceObjArray[] items are not already in aDestObjArray
- return the new number of the items in aDestObjArray

function ObjArrayAppend(**var** aDestObjArray, aSourceObjArray): PtrInt;

*Wrapper to add and move items to a T*ObjArray dynamic array storage*

- aSourceObjArray[] items will be owned by aDestObjArray[], therefore aSourceObjArray is set to nil
- return the new number of the items in aDestObjArray

procedure ObjArrayClear(**var** aObjArray; aCount: integer); overload;

*Wrapper to release all items stored in a T*ObjArray dynamic array*

- this overloaded function will use the supplied array length as parameter
- you should always use ObjArrayClear() before the array storage is released, e.g. in the owner class destructor
- will also set the dynamic array length to 0, so could be used to re-use an existing T*ObjArray

procedure ObjArrayClear(**var** aObjArray); overload;

*Wrapper to release all items stored in a T*ObjArray dynamic array*

- as expected by TJSONSerializer.RegisterObjArrayForJSON()
- you should always use ObjArrayClear() before the array storage is released, e.g. in the owner class destructor
- will also set the dynamic array length to 0, so could be used to re-use an existing T*ObjArray

procedure ObjArrayClear(**var** aObjArray; aContinueOnException: boolean; aCount: PInteger=nil); overload;

*Wrapper to release all items stored in a T*ObjArray dynamic array*

- as expected by TJSONSerializer.RegisterObjArrayForJSON()
- you should always use ObjArrayClear() before the array storage is released, e.g. in the owner class destructor
- will also set the dynamic array length to 0, so could be used to re-use an existing T*ObjArray

function ObjArrayCount(**const** aObjArray): integer;

*Wrapper to count all not nil items in a T*ObjArray dynamic array storage*

- as expected by TJSONSerializer.RegisterObjArrayForJSON()

function ObjArrayDelete(**var** aObjArray; aItem: TObject): PtrInt; overload;

*Wrapper to delete an item in a T*ObjArray dynamic array storage*

- as expected by TJSONSerializer.RegisterObjArrayForJSON()
- search is performed by address/reference, not by content
- do nothing if the item is not found in the dynamic array

procedure ObjArrayDelete(**var** aObjArray; aItemIndex: PtrInt; aContinueOnException: boolean=false; aCount: PInteger=nil); overload;

*Wrapper to delete an item in a T*ObjArray dynamic array storage*

- as expected by TJSONSerializer.RegisterObjArrayForJSON()
- do nothing if the index is out of range in the dynamic array

function ObjArrayDelete(**var** aObjArray; aCount: integer; aItem: TObject): PtrInt; overload;

*Wrapper to delete an item in a T*ObjArray dynamic array storage*

- as expected by TJSONSerializer.RegisterObjArrayForJSON()
- search is performed by address/reference, not by content
- do nothing if the item is not found in the dynamic array

function ObjArrayFind(**const** aObjArray; aItem: TObject): PtrInt; overload;

*Wrapper to search an item in a T*ObjArray dynamic array storage*

- as expected by TJSONSerializer.RegisterObjArrayForJSON()
- search is performed by address/reference, not by content
- returns -1 if the item is not found in the dynamic array

function ObjArrayFind(**const** aObjArray; aCount: integer; aItem: TObjet): PtrInt;
overload;

*Wrapper to search an item in a T*ObjArray dynamic array storage*

- as expected by TJSONSerializer.RegisterObjArrayForJSON()
- search is performed by address/reference, not by content
- returns -1 if the item is not found in the dynamic array

procedure ObjArrayObjArrayClear(**var** aObjArray);

*Wrapper to release all items stored in an array of T*ObjArray dynamic array*

- e.g. aObjArray may be defined as "array of array of TSynFilter"

procedure ObjArraysClear(**const** aObjArray: array of pointer);

*Wrapper to release all items stored in several T*ObjArray dynamic arrays*

- as expected by TJSONSerializer.RegisterObjArrayForJSON()

procedure ObjArraySetLength(**var** aObjArray; aLength: integer);

*Wrapper to set the length of a T*ObjArray dynamic array storage*

- could be used as an alternative to SetLength() when you do not know the exact T*ObjArray type

procedure ObjArraySort(**var** aObjArray; Compare: TDynArraySortCompare);

*Wrapper to sort the items stored in a T*ObjArray dynamic array*

- as expected by TJSONSerializer.RegisterObjArrayForJSON()

function ObjArrayToJSON(**const** aObjArray; aOptions:
TTextWriterWriteObjectOptions=[woDontStoreDefault]): RawUTF8;

*Wrapper to serialize a T*ObjArray dynamic array as JSON*

- as expected by TJSONSerializer.RegisterObjArrayForJSON()

function ObjectsToJSON(**const** Names: array of RawUTF8; **const** Values: array of TObjet;
Options: TTextWriterWriteObjectOptions=[woDontStoreDefault]): RawUTF8;

Will serialize set of TObjet into its UTF-8 JSON representation

- follows ObjectToJSON()/TTextWriter.WriterObject() functions output
- if Names is not supplied, the corresponding class names would be used

function ObjectToJSON(Value: TObjet; Options:
TTextWriterWriteObjectOptions=[woDontStoreDefault]): RawUTF8;

Will serialize any TObjet into its UTF-8 JSON representation

- serialize as JSON the published integer, Int64, floating point values, TDateTime (stored as ISO 8601 text), string, variant and enumerate (e.g. boolean) properties of the object (and its parents)
- would set twoForceJSONStandard to force standard (non-extended) JSON
- the enumerates properties are stored with their integer index value
- will write also the properties published in the parent classes
- nested properties are serialized as nested JSON objects
- any TCollection property will also be serialized as JSON arrays
- you can add some custom serializers for ANY Delphi class, via mORMot.pas' TJSONSerializer.RegisterCustomSerializer() class method
- call internally TJSONSerializer.WriteObject() method (or fallback to TJSONWriter if mORMot.pas is not linked to the executable)

function ObjectToVariant(Value: TObject; EnumSetsAsText: boolean=false): **variant**;
 overload;

Will convert any TObject into a TDocVariant document instance
 - a faster alternative to _JsonFast(ObjectToJSON(Value))
 - if you expect lazy-loading of a TObject, see TObjectVariant.New()

procedure ObjectToVariant(Value: TObject; **var** result: **variant**; Options: TTextWriterWriteObjectOptions); overload;

Will convert any TObject into a TDocVariant document instance
 - a faster alternative to _Json(ObjectToJSON(Value),Options)
 - note that the result variable should already be cleared: no VarClear() is done by this function
 - would be used e.g. by VarRecToVariant() function
 - if you expect lazy-loading of a TObject, see TObjectVariant.New()

procedure ObjectToVariant(Value: TObject; **out** Dest: **variant**); overload;

Will convert any TObject into a TDocVariant document instance
 - a slightly faster alternative to Dest := _JsonFast(ObjectToJSON(Value))
 - this would convert the TObject by representation, using only serializable published properties: do not use this function to store temporary a class instance, but e.g. to store an object values in a NoSQL database
 - if you expect lazy-loading of a TObject, see TObjectVariant.New()

function OctToBin(const Oct: RawUTF8): RawByteString; overload;

Conversion from octal C-like escape into binary data
 - \xxx is converted into a single xxx byte from octal, and \\ into \

function OctToBin(Oct: PAnsiChar; Bin: PByte): PtrInt; overload;

Conversion from octal C-like escape into binary data
 - \xxx is converted into a single xxx byte from octal, and \\ into \
 - will stop the conversion when Oct^=#0 or when invalid \xxx is reached
 - returns the number of bytes written to Bin^

procedure OrMemory(Dest,Source: PByteArray; size: PtrInt);

Logical OR of two memory buffers
 - will perform on all buffer bytes:
 Dest[i] := Dest[i] or Source[i];

procedure PatchCode(Old,New: pointer; Size: integer; Backup: pointer=nil;
 LeaveUnprotected: boolean=false);

Self-modifying code - change some memory buffer in the code segment
 - if Backup is not nil, it should point to a Size array of bytes, ready to contain the overridden code buffer, for further hook disabling

procedure PatchCodePtrUInt(Code: PPtrUInt; Value: PtrUInt; LeaveUnprotected: boolean=false);

Self-modifying code - change one PtrUInt in the code segment
 Used for DI-2.1.4 (page 2557).

function Plural(const itemname: shortstring; itemcount: cardinal): shortstring;

Write count number and append 's' (if needed) to form a plural English noun
 - for instance, Plural('row',100) returns '100 rows' with no heap allocation

function PointerToHex(aPointer: Pointer): RawUTF8; overload;

Fast conversion from a pointer data into hexa chars, ready to be displayed
- use internally BinToHexDisplay()

procedure PointerToHex(aPointer: Pointer; var result: RawUTF8); overload;

Fast conversion from a pointer data into hexa chars, ready to be displayed
- use internally BinToHexDisplay()

function PointerToHexShort(aPointer: Pointer): TShort16; overload;

Fast conversion from a pointer data into hexa chars, ready to be displayed
- use internally BinToHexDisplay()
- such result type would avoid a string allocation on heap

function PosChar(Str: PUTF8Char; Chr: AnsiChar): PUTF8Char;

Fast retrieve the position of a given character

function PosCharAny(Str: PUTF8Char; Characters: PAnsiChar): PUTF8Char;

Fast retrieve the position of any value of a given set of characters
- see also strspn() function which is likely to be faster

function PosEx(const SubStr, S: RawUTF8; Offset: PtrUInt=1): integer;

Faster RawUTF8 Equivalent of standard StrUtils.PosEx

function PosExChar(Chr: AnsiChar; const Str: RawUTF8): PtrInt;

Optimized version of PosEx() with search text as one AnsiChar

function PosI(uppersubstr: PUTF8Char; const str: RawUTF8): PtrInt;

A non case-sensitive RawUTF8 version of Pos()
- uppersubstr is expected to be already in upper case
- this version handle only 7 bit ASCII (no accentuated characters)

function PosIU(substr: PUTF8Char; const str: RawUTF8): Integer;

A non case-sensitive RawUTF8 version of Pos()
- substr is expected to be already in upper case
- this version will decode the UTF-8 content before using NormToUpper[]

function PropNamesValid(const Values: array of RawUTF8): boolean;

Returns TRUE if the given text buffers contains A..Z,0..9,_ characters
- use it with property names values (i.e. only including A..Z,0..9,_ chars)
- this function won't check the first char the same way than PropNameValid()

function PropNameValid(P: PUTF8Char): boolean;

Returns TRUE if the given text buffer contains a..z,A..Z,0..9,_ characters
- should match most usual property names values or other identifier names in the business logic source code
- i.e. can be tested via IdemPropName*() functions, and the MongoDB-like extended JSON syntax as generated by dvoSerializeAsExtendedJson
- first char must be alphabetical or '_', following chars can be alphanumerical or '_'

function PtrArrayAdd(var aPtrArray; aItem: pointer): integer;

Wrapper to add an item to a array of pointer dynamic array storage

function PtrArrayAddOnce(var aPtrArray; aItem: pointer): integer;

Wrapper to add once an item to a array of pointer dynamic array storage

```
function PtrArrayDelete(var aPtrArray; aItem: pointer; aCount: PInteger=nil):  
integer; overload;
```

Wrapper to delete an item from a array of pointer dynamic array storage

```
procedure PtrArrayDelete(var aPtrArray; aIndex: integer; aCount: PInteger=nil);  
overload;
```

Wrapper to delete an item from a array of pointer dynamic array storage

```
function PtrArrayFind(var aPtrArray; aItem: pointer): integer;
```

Wrapper to find an item to a array of pointer dynamic array storage

```
function PtrUIntScan(P: PPtrUIntArray; Count: PtrInt; Value: PtrUInt): pointer;
```

Fast search of a pointer-sized unsigned integer in an pointer-sized integer array

- Count is the number of pointer-sized integer entries in P^
- returns true if P^=Value within Count entries
- returns false if Value was not found

```
function PtrUIntScanExists(P: PPtrUIntArray; Count: PtrInt; Value: PtrUInt): boolean;
```

Fast search of a pointer-sized unsigned integer position in an pointer-sized integer array

- Count is the number of pointer-sized integer entries in P^
- returns true if P^=Value within Count entries
- returns false if Value was not found

```
function PtrUIntScanIndex(P: PPtrUIntArray; Count: PtrInt; Value: PtrUInt): PtrInt;
```

Fast search of a pointer-sized unsigned integer position in an pointer-sized integer array

- Count is the number of pointer-sized integer entries in P^
- return index of P^[index]=Value
- return -1 if Value was not found

```
procedure QuickSortCompare(const OnCompare: TOnValueGreater; Index: PIntegerArray;  
L,R: PtrInt);
```

Performs a QuickSort using a comparison callback

```
procedure QuickSortIndexedPUTF8Char(Values: PPUTf8CharArray; Count: Integer; var  
SortedIndexes: TCardinalDynArray; CaseSensitive: boolean=false);
```

Sort a dynamic array of PUTF8Char items, via an external array of indexes

- you can use FastFindIndexedPUTF8Char() for fast O(log(n)) binary search

```
procedure QuickSortInt64(ID: PInt64Array; L, R: PtrInt); overload;
```

Sort a 64-bit signed Integer array, low values first

```
procedure QuickSortInt64(ID,CoValues: PInt64Array; L, R: PtrInt); overload;
```

Sort a 64-bit Integer array, low values first

```
procedure QuickSortInteger(ID: PIntegerArray; L, R: PtrInt); overload;
```

Sort an Integer array, low values first

```
procedure QuickSortInteger(ID,CoValues: PIntegerArray; L, R: PtrInt); overload;
```

Sort an Integer array, low values first

```
procedure QuickSortInteger(var ID: TIntegerDynArray); overload;
```

Sort an Integer array, low values first

```
procedure QuickSortPointer(P: PPointerArray; L, R: PtrInt);
```

Sort a pointer array, low values first

procedure QuickSortPtrInt(P: PPtrIntArray; L, R: PtrInt);

Sort a PtrInt array, low values first

procedure QuickSortQWord(ID: PQWordArray; L, R: PtrInt); overload;

Sort a 64-bit unsigned Integer array, low values first

- QWord comparison are implemented correctly under FPC or Delphi 2009+ - older compilers will use fast and exact SortDynArrayQWord()

procedure QuickSortRawUTF8(var Values: TRawUTF8DynArray; ValuesCount: integer; CoValues: PIntegerDynArray=nil; Compare: TUTF8Compare=nil);

Sort a dynamic array of RawUTF8 items

- if CoValues is set, the integer items are also synchronized
- by default, exact (case-sensitive) match is used; you can specify a custom compare function if needed in Compare optional parameter

procedure QuickSortWord(ID: PWordArray; L, R: PtrInt);

Sort a 16 bit unsigned Integer array, low values first

procedure QuotedStr(const S: RawUTF8; Quote: AnsiChar; var result: RawUTF8); overload;

Format a text content with SQL-like quotes

- UTF-8 version of the function available in SysUtils
- this function implements what is specified in the official SQLite3 documentation: "A string constant is formed by enclosing the string in single quotes ('). A single quote within the string can be encoded by putting two single quotes in a row - as in Pascal."

function QuotedStr(const S: RawUTF8; Quote: AnsiChar=''): RawUTF8; overload;

Format a text content with SQL-like quotes

- UTF-8 version of the function available in SysUtils
- this function implements what is specified in the official SQLite3 documentation: "A string constant is formed by enclosing the string in single quotes ('). A single quote within the string can be encoded by putting two single quotes in a row - as in Pascal."

procedure QuotedStrJSON(const aText: RawUTF8; var result: RawUTF8; const aPrefix: RawUTF8=''; const aSuffix: RawUTF8=''); overload;

Convert UTF-8 content into a JSON string

- with proper escaping of the content, and surrounding " characters

procedure QuotedStrJSON(P: PUTF8Char; PLen: PtrInt; var result: RawUTF8; const aPrefix: RawUTF8=''; const aSuffix: RawUTF8=''); overload;

Convert UTF-8 buffer into a JSON string

- with proper escaping of the content, and surrounding " characters

function QuotedStrJSON(const aText: RawUTF8): RawUTF8; overload;

Convert UTF-8 content into a JSON string

- with proper escaping of the content, and surrounding " characters

function QWordScanIndex(P: PQWordArray; Count: PtrInt; const Value: QWord): PtrInt;

Fast search of an integer position in an unsigned 64-bit integer array

- Count is the number of QWord entries in P^
- returns index of P^[index]=Value
- returns -1 if Value was not found

function Random32(max: cardinal): cardinal; overload;

Fast compute of some 32-bit random value, with a maximum (excluded) upper value

- i.e. returns a value in range [0..max-1]
- calls internally the overloaded Random32 function

function Random32: cardinal; overload;

Fast compute of some 32-bit random value

- will use (slow but) hardware-derived RDRAND Intel x86/x64 opcode if available, or fast gsl_rng_taus2 generator by Pierre L'Ecuyer (which period is 2^{88} , i.e. about 10^{26}) if the CPU doesn't support it
- will detect known AMD CPUs RDRAND bugs, and fallback to gsl_rng_taus2
- consider Random32gsl to avoid slow RDRAND call (up to 1500 cycles needed!)
- use rather TAESPRNG.Main.FillRandom() for cryptographic-level randomness
- thread-safe function: each thread will maintain its own TLeuyer table

function Random32gsl(max: cardinal): cardinal; overload;

Fast compute of bounded 32-bit random value, using the gsl_rng_taus2 generator

- calls internally the overloaded Random32gsl function

function Random32gsl: cardinal; overload;

Fast compute of some 32-bit random value, using the gsl_rng_taus2 generator

- Random32 may call RDRAND opcode on Intel CPUs, whereas this function will use well documented, much faster, and proven Pierre L'Ecuyer software generator
- may be used if you don't want/trust RDRAND, if you expect a well defined cross-platform generator, or have higher performance expectations
- use rather TAESPRNG.Main.FillRandom() for cryptographic-level randomness
- thread-safe function: each thread will maintain its own TLeuyer table

procedure Random32Seed(entropy: pointer=nil; entropylen: PtrInt=0);

Seed the gsl_rng_taus2 Random32/Random32gsl generator

- this seeding won't affect RDRAND Intel x86/x64 opcode generation
- by default, gsl_rng_taus2 generator is re-seeded every 256KB, much more often than the Pierre L'Ecuyer's algorithm period of 2^{88}
- you can specify some additional entropy buffer; note that calling this function with the same entropy again WON'T seed the generator with the same sequence (as with RTL's RandomSeed function), but initiate a new one
- thread-specific function: each thread will maintain its own seed table

procedure RandomGUID(out result: TGUID); overload;

Compute a random GUID value

function RandomGUID: TGUID; overload;

Compute a random GUID value

function RawByteArrayConcat(const Values: array of RawByteString):
RawByteString;

Fast concatenation of several AnsiStrings

procedure RawByteStringToBytes(const buf: RawByteString; out bytes: TBytes);

Creates a TBytes from a RawByteString memory buffer

function RawByteStringToStream(**const** aString: RawByteString): TStream;

Create a TStream from a string content

- uses RawByteString for byte storage, whatever the codepage is
- in fact, the returned TStream is a TRawByteString instance, since this function is just a wrapper around:

```
result := TRawByteStringStream.Create(aString);
```

procedure RawByteStringToVariant(Data: PByte; DataLen: Integer; **var** Value: **variant**);
overload;

Convert a raw binary buffer into a variant RawByteString varString

- you can then use VariantToRawByteString() to retrieve the binary content

procedure RawByteStringToVariant(**const** Data: RawByteString; **var** Value: **variant**);
overload;

Convert a RawByteString content into a variant varString

- you can then use VariantToRawByteString() to retrieve the binary content

procedure RawObjectsClear(o: PObject; n: integer);

Low-level function calling FreeAndNil(o^i) successively n times

function RawUnicodeToString(**const** U: RawUnicode): **string**; overload;

Convert any Raw Unicode encoded string into a generic VCL Text

- uses StrLenW() and not length(U) to handle case when was used as buffer

procedure RawUnicodeToString(P: PWideChar; L: integer; **var** result: **string**); overload;

Convert any Raw Unicode encoded buffer into a generic VCL Text

function RawUnicodeToString(P: PWideChar; L: integer): **string**; overload;

Convert any Raw Unicode encoded buffer into a generic VCL Text

function RawUnicodeToSynUnicode(**const** Unicode: RawUnicode): SynUnicode; overload;

Convert any Raw Unicode encoded String into a generic SynUnicode Text

function RawUnicodeToSynUnicode(WideChar: PWideChar; WideCharCount: integer):
SynUnicode; overload;

Convert any Raw Unicode encoded String into a generic SynUnicode Text

function RawUnicodeToUtf8(WideChar: PWideChar; WideCharCount: integer; **out**
UTF8Length: integer): RawUTF8; overload;

Convert a RawUnicode PWideChar into a UTF-8 string

- this version doesn't resize the resulting RawUTF8 string, but return the new resulting RawUTF8 byte count into UTF8Length

function RawUnicodeToUtf8(**const** Unicode: RawUnicode): RawUTF8; overload;

Convert a RawUnicode string into a UTF-8 string

function RawUnicodeToUtf8(Dest: PUTF8Char; DestLen: PtrInt; Source: PWideChar; SourceLen: PtrInt; Flags: TCharConversionFlags): PtrInt; overload;

Convert a RawUnicode UTF-16 PWideChar into a UTF-8 buffer

- replace system.UnicodeToUtf8 implementation, which is rather slow since Delphi 2009+
- append a trailing #0 to the ending PUTF8Char, unless ccfNoTrailingZero is set
- if ccfReplacementCharacterForUnmatchedSurrogate is set, this function will identify unmatched surrogate pairs and replace them with EF BF BD / FFFD Unicode Replacement character - see [https://en.wikipedia.org/wiki/Specials_\(Unicode_block\)](https://en.wikipedia.org/wiki/Specials_(Unicode_block))

procedure RawUnicodeToUtf8(WideChar: PWideChar; WideCharCount: integer; var result: RawUTF8; Flags: TCharConversionFlags = [ccfNoTrailingZero]); overload;

Convert a RawUnicode PWideChar into a UTF-8 string

function RawUnicodeToUtf8(WideChar: PWideChar; WideCharCount: integer; Flags: TCharConversionFlags = [ccfNoTrailingZero]): RawUTF8; overload;

Convert a RawUnicode PWideChar into a UTF-8 string

function RawUnicodeToWinAnsi(WideChar: PWideChar; WideCharCount: integer): WinAnsiString; overload;

Convert a RawUnicode PWideChar into a WinAnsi (code page 1252) string

function RawUnicodeToWinAnsi(const Unicode: RawUnicode): WinAnsiString; overload;

Convert a RawUnicode string into a WinAnsi (code page 1252) string

procedure RawUnicodeToWinPChar(dest: PAnsiChar; source: PWideChar; WideCharCount: integer);

Direct conversion of a Unicode encoded buffer into a WinAnsi PAnsiChar buffer

function RawUTF8ArrayToCSV(const Values: array of RawUTF8; const Sep: RawUTF8= ','): RawUTF8;

Return the corresponding CSV text from a dynamic array of UTF-8 strings

function RawUTF8ArrayToQuotedCSV(const Values: array of RawUTF8; const Sep: RawUTF8=','; Quote: AnsiChar=''): RawUTF8;

Return the corresponding CSV quoted text from a dynamic array of UTF-8 strings
 - apply QuoteStr() function to each Values[] item

procedure RawUTF8DynArrayClear(var Value: TRawUTF8DynArray);

Low-level finalization of a dynamic array of RawUTF8
 - faster than RTL Finalize() or setting nil

function RawUTF8DynArrayEquals(const A,B: TRawUTF8DynArray; Count: integer): boolean; overload;

True if both TRawUTF8DynArray are the same for a given number of items
 - A and B are expected to have at least Count items
 - comparison is case-sensitive

function RawUTF8DynArrayEquals(const A,B: TRawUTF8DynArray): boolean; overload;

True if both TRawUTF8DynArray are the same
 - comparison is case-sensitive

function RawUTF8DynArrayLoadFromContains(Source: PAnsiChar; Value: PUTF8Char; ValueLen: PtrInt; CaseSensitive: boolean): PtrInt;

Search in a RawUTF8 dynamic array BLOB content as stored by TDynArray.SaveTo

- same as search within TDynArray.LoadFrom() with no memory allocation nor memory copy: so is much faster

- will return -1 if no match or invalid data, or the matched entry index

function RawUTF8ToGUID(const text: RawByteString): TGUID;

Convert some UTF-8 encoded text into a TGUID

- expect e.g. '{3F2504E0-4F89-11D3-9A0C-0305E82C3301}' (with the {})

- return {00000000-0000-0000-0000-000000000000} if the supplied text buffer is not a valid TGUID

procedure RawUTF8ToVariant(const Txt: RawUTF8; var Value: TVarData; ExpectedValueType: cardinal); overload;

Convert an UTF-8 encoded text buffer into a variant RawUTF8 varString

- this overloaded version expects a destination variant type (e.g. varString varOleStr / varUString) - if the type is not handled, will raise an EVariantTypeCastError

function RawUTF8ToVariant(const Txt: RawUTF8): variant; overload;

Convert an UTF-8 encoded string into a variant RawUTF8 varString

procedure RawUTF8ToVariant(Txt: PUTF8Char; TxtLen: integer; var Value: variant); overload;

Convert an UTF-8 encoded text buffer into a variant RawUTF8 varString

procedure RawUTF8ToVariant(const Txt: RawUTF8; var Value: variant); overload;

Convert an UTF-8 encoded string into a variant RawUTF8 varString

procedure RCU(var src,dst; len: integer);

Thread-safe move of a memory buffer using a simple Read-Copy-Update pattern

procedure RCU128(var src,dst);

Thread-safe move of a 128-bit value using a simple Read-Copy-Update pattern

procedure RCU32(var src,dst);

Thread-safe move of a 32-bit value using a simple Read-Copy-Update pattern

procedure RCU64(var src,dst);

Thread-safe move of a 64-bit value using a simple Read-Copy-Update pattern

procedure RCUPtr(var src,dst);

Thread-safe move of a pointer value using a simple Read-Copy-Update pattern

function ReadStringFromStream(S: TStream; MaxAllowedSize: integer=255): RawUTF8;

Read an UTF-8 text from a TStream

- format is Length(Integer):Text, i.e. the one used by WriteStringToStream
- will return "" if there is no such text in the stream
- you can set a MaxAllowedSize value, if you know how long the size should be
- it will read from the current position in S: so if you just write into S, it could be a good idea to rewind it before call, e.g.:

```
WriteStringToStream(Stream,aUTF8Text);
Stream.Seek(0,soBeginning);
str := ReadStringFromStream(Stream);
```

procedure RecordClear(var Dest; TypeInfo: pointer);

Clear a record content

- this unit includes a fast optimized asm version for x86 on Delphi

procedure RecordCopy(var Dest; const Source; TypeInfo: pointer);

Copy a record content from source to Dest

- this unit includes a fast optimized asm version for x86 on Delphi

function RecordEquals(const RecA, RecB; TypeInfo: pointer; PRecSize: PInteger=nil): boolean;

Check equality of two records by content

- will handle packed records, with binaries (byte, word, integer...) and string types properties
- will use binary-level comparison: it could fail to match two floating-point values because of rounding issues (Currency won't have this problem)

function RecordLoad(var Res; const Source: RawByteString; TypeInfo: pointer): boolean; overload;

Fill a record content from a memory buffer as saved by RecordSave()

- will use the Source length to detect and avoid any buffer overflow
- returns false if the Source buffer was incorrect, true on success

function RecordLoad(var Rec; Source: PAnsiChar; TypeInfo: pointer; Len: PInteger=nil; SourceMax: PAnsiChar=nil): PAnsiChar; overload;

Fill a record content from a memory buffer as saved by RecordSave()

- return nil if the Source buffer is incorrect
- in case of success, return the memory buffer pointer just after the read content, and set the Rec size, in bytes, into Len reference variable
- will use a proprietary binary format, with some variable-length encoding of the string length - note that if you change the type definition, any previously-serialized content will fail, maybe triggering unexpected GPF: you may use TypeInfoToHash() if you share this binary data accross executables
- you can optionally provide in SourceMax the first byte after the input memory buffer, which will be used to avoid any unexpected buffer overflow - would be mandatory when decoding the content from any external process (e.g. a maybe-forged client) - only with slightly performance penalty

function RecordLoadBase64(Source: PAnsiChar; Len: PtrInt; var Rec; TypeInfo: pointer; UriCompatible: boolean=false): boolean;

Read a record content from a Base-64 encoded content

- expects RecordSaveBase64() format, with a left-sided binary CRC

```
function RecordLoadJSON(var Rec; JSON: PUTF8Char; TypeInfo: pointer; EndOfObject:
PUTF8Char=nil; CustomVariantOptions: PDocVariantOptions=nil): PUTF8Char; overload;
```

*Fill a record content from a JSON serialization as saved by TTextWriter.AddRecordJSON /
 RecordSaveJSON*

- will use default Base64 encoding over RecordSave() binary - or custom true JSON format (as set by TTextWriter.RegisterCustomJSONSerializer or via enhanced RTTI), if available
- returns nil on error, or the end of buffer on success
- warning: the JSON buffer will be modified in-place during process - use a temporary copy if you need to access it later or if the string comes from a constant (refcount=-1) - see e.g. the overloaded RecordLoadJSON()

```
function RecordLoadJSON(var Rec; const JSON: RawUTF8; TypeInfo: pointer;
CustomVariantOptions: PDocVariantOptions=nil): boolean; overload;
```

*Fill a record content from a JSON serialization as saved by TTextWriter.AddRecordJSON /
 RecordSaveJSON*

- this overloaded function will make a private copy before parsing it, so is safe with a read/only or shared string - but slightly slower
- will use default Base64 encoding over RecordSave() binary - or custom true JSON format (as set by TTextWriter.RegisterCustomJSONSerializer or via enhanced RTTI), if available

```
function RecordSave(const Rec; Dest: PAnsiChar; TypeInfo: pointer): PAnsiChar;
overload;
```

Save a record content into a destination memory buffer

- Dest must be at least RecordSaveLength() bytes long
- will handle packed records, with binaries (byte, word, integer...) and string types properties (but not with internal raw pointers, of course)
- will use a proprietary binary format, with some variable-length encoding of the string length - note that if you change the type definition, any previously-serialized content will fail, maybe triggering unexpected GPF: you may use TypeInfoToHash() if you share this binary data accross executables
- warning: will encode generic string fields as AnsiString (one byte per char) prior to Delphi 2009, and as UnicodeString (two bytes per char) since Delphi 2009: if you want to use this function between UNICODE and NOT UNICODE versions of Delphi, you should use some explicit types like RawUTF8, WinAnsiString, SynUnicode or even RawUnicode/WideString

```
procedure RecordSave(const Rec; var Dest: TSynTempBuffer; TypeInfo: pointer);
overload;
```

Save a record content into a destination memory buffer

- caller should make Dest.Done once finished with Dest.buf/Dest.len buffer

function RecordSave(const Rec; TypeInfo: pointer): RawByteString; overload;

Save a record content into a RawByteString

- will handle packed records, with binaries (byte, word, integer...) and string types properties (but not with internal raw pointers, of course)
- will use a proprietary binary format, with some variable-length encoding of the string length - note that if you change the type definition, any previously-serialized content will fail, maybe triggering unexpected GPF: you may use TypeInfoToHash() if you share this binary data accross executables
- warning: will encode generic string fields as AnsiString (one byte per char) prior to Delphi 2009, and as UnicodeString (two bytes per char) since Delphi 2009: if you want to use this function between UNICODE and NOT UNICODE versions of Delphi, you should use some explicit types like RawUTF8, WinAnsiString, SynUnicode or even RawUnicode/WideString

function RecordSave(const Rec; Dest: PAnsiChar; TypeInfo: pointer; out Len: integer): PAnsiChar; overload;

Save a record content into a destination memory buffer

- Dest must be at least RecordSaveLength() bytes long
- will return the Rec size, in bytes, into Len reference variable
- will handle packed records, with binaries (byte, word, integer...) and string types properties (but not with internal raw pointers, of course)
- will use a proprietary binary format, with some variable-length encoding of the string length - note that if you change the type definition, any previously-serialized content will fail, maybe triggering unexpected GPF: you may use TypeInfoToHash() if you share this binary data accross executables
- warning: will encode generic string fields as AnsiString (one byte per char) prior to Delphi 2009, and as UnicodeString (two bytes per char) since Delphi 2009: if you want to use this function between UNICODE and NOT UNICODE versions of Delphi, you should use some explicit types like RawUTF8, WinAnsiString, SynUnicode or even RawUnicode/WideString

function RecordSaveBase64(const Rec; TypeInfo: pointer; UriCompatible: boolean=false): RawUTF8;

Save a record content into a Base-64 encoded UTF-8 text content

- will use RecordSave() format, with a left-sided binary CRC32C

function RecordSaveBytes(const Rec; TypeInfo: pointer): TBytes;

Save a record content into a TBytes dynamic array

- could be used as an alternative to RawByteString's RecordSave()

function RecordSaveJSON(const Rec; TypeInfo: pointer; EnumSetsAsText: boolean=false): RawUTF8;

Save record into its JSON serialization as saved by TTextWriter.AddRecordJSON

- will use default Base64 encoding over RecordSave() binary - or custom true JSON format (as set by TTextWriter.RegisterCustomJSONSerializer or via enhanced RTTI), if available (following EnumSetsAsText optional parameter for nested enumerates and sets)

function RecordSaveLength(const Rec; TypeInfo: pointer; Len: PInteger=nil): integer;

Compute the number of bytes needed to save a record content using the RecordSave() function

- will return 0 in case of an invalid (not handled) record type (e.g. if it contains an unknown variant)
- optional Len parameter will contain the Rec memory buffer length, in bytes

function RecordTypeInfoSize(aRecordTypeInfo: pointer): integer;

Retrieve the record size from its low-level RTTI

procedure RecordZero(var Dest; TypeInfo: pointer);

Initialize a record content

- calls RecordClear() and FillCharFast() with 0
- do nothing if the TypeInfo is not from a record/object

procedure RedirectCode(Func, RedirectFunc: Pointer; Backup: PPatchCode=nil);

Self-modifying code - add an asm JUMP to a redirected function

- if Backup is not nil, it should point to a TPatchCode buffer, ready to contain the overridden code buffer, for further hook disabling

procedure RedirectCodeRestore(Func: pointer; const Backup: TPatchCode);

Self-modifying code - restore a code from its RedirectCode() backup

function ReleaseInternalWindow(var aWindowName: string; var aWindow: HWND): boolean;

Delete the window resources used to receive Windows Messages

- must be called for each CreateInternalWindow() function
- both parameter values are then reset to ''/0

procedure RemoveCommentsFromJSON(P: PUTF8Char);

Remove comments and trailing commas from a text buffer before passing it to JSON parser

- handle two types of comments: starting from // till end of line or /* */ blocks anywhere in the text content
- trailing commas is replaced by ', so resulting JSON is valid for parsers what not allows trailing commas (browsers for example)
- may be used to prepare configuration files before loading; for example we store server configuration in file config.json and put some comments in this file then code for loading is:

```
var cfg: RawUTF8;
  cfg := StringFromFile(ExtractFilePath(paramstr(0))+'Config.json');
  RemoveCommentsFromJSON(@cfg[1]);
  pLastChar := JSONToObject(sc,pointer(cfg),configValid);
```

function RenameInCSV(const OldValue, NewValue: RawUTF8; var CSV: RawUTF8; const Sep: RawUTF8 = ','): boolean;

Change a Value within a CSV string

procedure ReplaceSection(SectionFirstLine: PUTF8Char; var Content: RawUTF8; const NewSectionContent: RawUTF8); overload;

Replace a whole [Section] content by a new content

- create a new [Section] if none was existing
- SectionFirstLine may have been obtained by FindSectionFirstLine() function above

procedure ReplaceSection(var Content: RawUTF8; const SectionName, NewSectionContent: RawUTF8); overload;

Replace a whole [Section] content by a new content

- create a new [Section] if none was existing

procedure ResourceSynLZToRawByteString(**const** ResName: **string**; **out** buf: RawByteString; Instance: THandle=0);

Creates a RawByteString memory buffer from an SynLZ-compressed embedded resource

- returns "" if the resource is not found
- this method would use SynLZDecompress() after ResourceToRawByteString(), with a ResType=PChar(10) (i.e. RC_DATA)
- you can specify a library (dll) resource instance handle, if needed

procedure ResourceToRawByteString(**const** ResName: **string**; ResType: PChar; **out** buf: RawByteString; Instance: THandle=0);

Creates a RawByteString memory buffer from an embedded resource

- returns "" if the resource is not found
- warning: resources size may be rounded up to alignment
- you can specify a library (dll) resource instance handle, if needed

procedure Reverse(**const** Values: TIntegerDynArray; ValuesCount: PtrInt; Reversed: PIntegerArray);

Fill already allocated Reversed[] so that Reversed[Values[i]]=i

function SameTextU(**const** S1, S2: RawUTF8): Boolean;

SameText() overloaded function with proper UTF-8 decoding

- fast version using NormToUpper[] array for all Win-Ansi characters
- this version will decode each UTF-8 glyph before using NormToUpper[]
- current implementation handles UTF-16 surrogates as UTF8IComp()

function SameValue(**const** A, B: Double; DoublePrec: double = DOUBLE_SAME): Boolean;

Compare to floating point values, with IEEE 754 double precision

- use this function instead of raw = operator
- the precision is calculated from the A and B value range
- faster equivalent than SameValue() in Math unit
- if you know the precision range of A and B, it's faster to check abs(A-B)<range

function SameValueFloat(**const** A, B: TSynExtended; DoublePrec: TSynExtended = DOUBLE_SAME): Boolean;

Compare to floating point values, with IEEE 754 double precision

- use this function instead of raw = operator
- the precision is calculated from the A and B value range
- faster equivalent than SameValue() in Math unit
- if you know the precision range of A and B, it's faster to check abs(A-B)<range

procedure SaveJSON(**const** Value; TypeInfo: pointer; Options: TTextWriterOptions; **var** result: RawUTF8); overload;

Serialize most kind of content as JSON, using its RTTI

- is just a wrapper around TTextWriter.AddTypedJSON()
- so would handle tkClass, tkEnumeration, tkSet, tkRecord, tkDynArray, tkVariant kind of content - other kinds would return 'null'
- you can override serialization options if needed

function SaveJSON(const Value; TypeInfo: pointer; EnumSetsAsText: boolean=false): RawUTF8; overload;

Serialize most kind of content as JSON, using its RTTI

- is just a wrapper around TTextWriter.AddTypedJSON()
- so would handle tkClass, tkEnumeration, tkSet, tkRecord, tkDynArray, tkVariant kind of content - other kinds would return 'null'

function ScanUTF8(const text, fmt: RawUTF8; const values: array of pointer; ident: PRawUTF8DynArray=nil): integer; overload;

Read and store text into values[] according to fmt specifiers

- %d as PInteger, %D as PInt64, %u as PCardinal, %U as PQWord, %f as PDouble, %F as PCurrency, %x as 8 hexa chars to PInteger, %X as 16 hexa chars to PInt64, %s as PShortString (UTF-8 encoded), %S as PRawUTF8, %L as PRawUTF8 (getting all text until the end of the line)
- optionally, specifiers and any whitespace separated identifiers may be extracted and stored into the ident[] array, e.g. '%dFirstInt %s %DOneInt64' will store ['dFirstInt', 's', 'DOneInt64'] into ident

function ScanUTF8(P: PUTF8Char; PLen: PtrInt; const fmt: RawUTF8; const values: array of pointer; ident: PRawUTF8DynArray): integer; overload;

Read text from P/PLen and store it into values[] according to fmt specifiers

function SearchRecToDateTime(const F: TSearchRec): TDateTime;

Get a file date and time, from a FindFirst/FindNext search

- the returned timestamp is in local time, not UTC
- this method would use the F.Timestamp field available since Delphi XE2

function SearchRecValidFile(const F: TSearchRec): boolean;

Check if a FindFirst/FindNext found instance is actually a file

function SearchRecValidFolder(const F: TSearchRec): boolean;

Check if a FindFirst/FindNext found instance is actually a folder

function SetAppUserModelID(const AppUserModelID: string): boolean;

Under Windows 7 and later, will set an unique application-defined Application User Model ID (AppUserModelID) that identifies the current process to the taskbar

- this identifier allows an application to group its associated processes and windows under a single taskbar button

- value can have no more than 128 characters, cannot contain spaces, and each section should be camel-cased, as such:

CompanyName.ProductName.SubProduct.VersionInformation

CompanyName and ProductName should always be used, while the SubProduct and VersionInformation portions are optional and depend on the application's requirements

- if the supplied text does not contain an '.', 'ID.ID' will be used

procedure SetBit(var Bits; aIndex: PtrInt);

Set a particular bit into a bit array

- this function can't be inlined, whereas SetBitPtr() function can

procedure SetBit64(var Bits: Int64; aIndex: PtrInt);

Set a particular bit into a 64-bit integer bits (max aIndex is 63)

procedure SetBitCSV(**var** Bits; BitsCount: integer; **var** P: PUTF8Char);

Retrieve the next CSV separated bit index

- each bit was stored as BitIndex+1, i.e. 0 to mark end of CSV chunk
- several bits set to one can be regrouped via 'first-last,' syntax

procedure SetBitPtr(Bits: pointer; aIndex: PtrInt);

Set a particular bit into a bit array

- SetBit() can't be inlined, whereas this pointer-oriented function can

procedure SetCurrentThreadName(**const** Format: RawUTF8; **const** Args: array of **const**);

Name the current thread so that it would be easily identified in the IDE debugger

procedure SetExecutableVersion(aMajor, aMinor, aRelease, aBuild: integer); overload;

Initialize ExeVersion global variable, supplying a custom version number

- by default, the version numbers will be retrieved at startup from the executable itself (if it was included at build time)
- but you can use this function to set any custom version numbers

procedure SetExecutableVersion(**const** aVersionText: RawUTF8); overload;

Initialize ExeVersion global variable, supplying the version as text

- e.g. SetExecutableVersion('7.1.2.512');

procedure SetInt64(P: PUTF8Char; **var** result: Int64);

Get the 64-bit signed integer value stored in P^

procedure SetQWord(P: PUTF8Char; **var** result: QWord);

Get the 64-bit unsigned integer value stored in P^

procedure SetThreadName(ThreadID: TThreadID; **const** Format: RawUTF8; **const** Args: array of **const**);

Name a thread so that it would be easily identified in the IDE debugger

- you can force this function to do nothing by setting the NOSETTHREADNAME conditional, if you have issues with this feature when debugging your app
- most meaning less characters (like 'TSQL') are trimmed to reduce the resulting length - which is convenient e.g. with POSIX truncation to 16 chars

procedure SetThreadNameDefault(ThreadID: TThreadID; **const** Name: RawUTF8);

Could be used to override SetThreadNameInternal()

- under Linux/FPC, calls pthread_setname_np API which truncates to 16 chars

procedure SetVariantByRef(**const** Source: Variant; **var** Dest: Variant);

Same as Dest := Source, but copying by reference

- i.e. VType is defined as varVariant or varByRef
- for instance, it will be used for late binding of TDocVariant properties, to let following statements work as expected:

```
V := _Json('{arr:[1,2]}');  
V.arr.Add(3);    // will work, since V.arr will be returned by reference  
writeln(V);      // will write '{"arr":[1,2,3]}'
```

procedure SetVariantByValue(**const** Source: Variant; **var** Dest: Variant);

Same as Dest := Source, but copying by value

- will unreference any varByRef content
- will convert any string value into RawUTF8 (varString) for consistency

procedure SetVariantNull(**var** Value: **variant**);

Same as Value := Null, but slightly faster

function SetVariantUnRefSimpleValue(**const** Source: **variant**; **var** Dest: TVarData): boolean;

Same as Dest := TVarData(Source) for simple values

- will return TRUE for all simple values after varByRef unreference, and copying the unreferenced Source value into Dest raw storage
- will return FALSE for not varByRef values, or complex values (e.g. string)

function ShortStringToAnsi7String(**const** source: shortstring): RawByteString;
overload;

Direct conversion of an ANSI-7 shortstring into an AnsiString

- can be used e.g. for names retrieved from RTTI to convert them into RawUTF8

procedure ShortStringToAnsi7String(**const** source: shortstring; **var** result: RawUTF8);
overload;

Direct conversion of an ANSI-7 shortstring into an AnsiString

- can be used e.g. for names retrieved from RTTI to convert them into RawUTF8

function ShortStringToUTF8(**const** source: ShortString): RawUTF8;

Direct conversion of a WinAnsi shortstring into a UTF-8 text

- call internally WinAnsiConvert fast conversion class

function SimpleDynArrayLoadFrom(Source: PAnsiChar; aTypeInfo: pointer; **var** Count, ElemSize: integer; NoHash32Check: boolean=false): pointer;

Wrap a simple dynamic array BLOB content as stored by TDynArray.SaveTo

- a "simple" dynamic array contains data with no reference count, e.g. byte, word, integer, cardinal, Int64, double or Currency
- same as TDynArray.LoadFrom() with no memory allocation nor memory copy: so is much faster than creating a temporary dynamic array to load the data
- will return nil if no or invalid data, or a pointer to the data array otherwise, with the items number stored in Count and the individual element size in ElemSize (e.g. 2 for a TWordDynArray)

function SimpleRoundTo2Digits(Value: Currency): Currency;

Simple, no banker rounding of a Currency value to only 2 digits

- #.##51 will round to #.##+0.01 and #.##50 will be truncated to #.##
- implementation will use fast Int64 math to avoid any precision loss due to temporary floating-point conversion

procedure SimpleRoundTo2DigitsCurr64(**var** Value: Int64);

Simple, no banker rounding of a Currency value, stored as Int64, to only 2 digits

- #.##51 will round to #.##+0.01 and #.##50 will be truncated to #.##
- implementation will use fast Int64 math to avoid any precision loss due to temporary floating-point conversion

procedure SleepHiRes(ms: cardinal);

Similar to Windows sleep() API call, to be truly cross-platform

- it should have a millisecond resolution, and handle ms=0 as a switch to another pending thread, i.e. under Windows will call SwitchToThread API

function SortDynArray128(**const** A,B): integer;

Compare two "array of THash128" elements

function SortDynArray256(**const** A,B): integer;

Compare two "array of THash256" elements

function SortDynArray512(**const** A,B): integer;

Compare two "array of THash512" elements

function SortDynArrayAnsiString(**const** A,B): integer;

Compare two "array of AnsiString" elements, with case sensitivity

function SortDynArrayAnsiStringI(**const** A,B): integer;

Compare two "array of AnsiString" elements, with no case sensitivity

function SortDynArrayBoolean(**const** A,B): integer;

Compare two "array of boolean" elements

function SortDynArrayByte(**const** A,B): integer;

Compare two "array of byte" elements

function SortDynArrayCardinal(**const** A,B): integer;

Compare two "array of cardinal" elements

function SortDynArrayDouble(**const** A,B): integer;

Compare two "array of double" elements

function SortDynArrayFileName(**const** A,B): integer;

Compare two "array of TFileName" elements, as file names
- i.e. with no case sensitivity, and grouped by file extension
- the expected string type is the generic RTL string, i.e. TFileName
- calls internally GetFileNameWithoutExt() and AnsiCompareFileName()

function SortDynArrayInt64(**const** A,B): integer;

Compare two "array of Int64" or "array of Currency" elements

function SortDynArrayInteger(**const** A,B): integer;

Compare two "array of integer" elements

function SortDynArrayPointer(**const** A,B): integer;

Compare two "array of TObject/pointer" elements

function SortDynArrayPUTF8Char(**const** A,B): integer;

Compare two "array of PUTF8Char/PAnsiChar" elements, with case sensitivity

function SortDynArrayPUTF8CharI(**const** A,B): integer;

Compare two "array of PUTF8Char/PAnsiChar" elements, with no case sensitivity

function SortDynArrayQWord(**const** A,B): integer;

Compare two "array of QWord" elements
- note that QWord(A)>QWord(B) is wrong on older versions of Delphi, so you should better use this function or CompareQWord() to properly compare two QWord values over CPUX86

function SortDynArrayRawByteString(**const** A,B): integer;

Compare two "array of RawByteString" elements, with case sensitivity
- can't use StrComp() or similar functions since RawByteString may contain #0

function SortDynArrayShortint(**const** A,B): integer;

Compare two "array of shortint" elements

function SortDynArraySingle(**const** A,B): integer;

Compare two "array of single" elements

function SortDynArraySmallint(**const** A,B): integer;

Compare two "array of smallint" elements

function SortDynArrayString(**const** A,B): integer;

Compare two "array of generic string" elements, with case sensitivity

- the expected string type is the generic VCL string

function SortDynArrayStringI(**const** A,B): integer;

Compare two "array of generic string" elements, with no case sensitivity

- the expected string type is the generic VCL string

function SortDynArrayUnicodeString(**const** A,B): integer;

Compare two "array of WideString/UnicodeString" elements, with case sensitivity

function SortDynArrayUnicodeStringI(**const** A,B): integer;

Compare two "array of WideString/UnicodeString" elements, with no case sensitivity

function SortDynArrayVariant(**const** A,B): integer;

Compare two "array of variant" elements, with case sensitivity

function SortDynArrayVariantComp(**const** A,B: TVarData; caseInsensitive: boolean): integer;

Compare two "array of variant" elements, with or without case sensitivity

- this low-level function is called by SortDynArrayVariant/VariantCompare

- more optimized than the RTL function if A and B share the same type

function SortDynArrayVariantI(**const** A,B): integer;

Compare two "array of variant" elements, with no case sensitivity

function SortDynArrayWord(**const** A,B): integer;

Compare two "array of word" elements

function Split(**const** Str, SepStr: RawUTF8; StartPos: integer=1): RawUTF8; overload;

Returns the left part of a RawUTF8 string, according to SepStr separator

- if SepStr is found, returns Str first chars until (and excluding) SepStr

- if SepStr is not found, returns Str

function Split(**const** Str: RawUTF8; **const** SepStr: array of RawUTF8; **const** DestPtr: array of PRawUTF8): PtrInt; overload;

Split a RawUTF8 string into several strings, according to SepStr separator

- this overloaded function will fill a DestPtr[] array of PRawUTF8

- if any DestPtr[]=nil, the item will be skipped

- if input Str end before all SepStr[] are found, DestPtr[] is set to "

- returns the number of values extracted into DestPtr[]

function Split(const Str, SepStr: RawUTF8; var LeftStr: RawUTF8; ToUpperCase: boolean=false): RawUTF8; overload;

Split a RawUTF8 string into two strings, according to SepStr separator
 - this overloaded function returns the right string as function result
 - if SepStr is not found, LeftStr=Str and result=""
 - if ToUpperCase is TRUE, then LeftStr and result will be made uppercase

procedure Split(const Str, SepStr: RawUTF8; var LeftStr, RightStr: RawUTF8; ToUpperCase: boolean=false); overload;

Split a RawUTF8 string into two strings, according to SepStr separator
 - if SepStr is not found, LeftStr=Str and RightStr=""
 - if ToUpperCase is TRUE, then LeftStr and RightStr will be made uppercase

function SplitRight(const Str: RawUTF8; SepChar: AnsiChar; LeftStr: PRawUTF8=nil): RawUTF8;

Returns the last occurrence of the given SepChar separated context
 - e.g. SplitRight('01/2/34','/')='34'
 - if SepChar doesn't appear, will return Str, e.g. SplitRight('123','/')='123'
 - if LeftStr is supplied, the RawUTF8 it points to will be filled with the left part just before SepChar (" if SepChar doesn't appear)

function SplitRights(const Str, SepChar: RawUTF8): RawUTF8;

Returns the last occurrence of the given SepChar separated context
 - e.g. SplitRight('path/one/two/file.ext','/')='file.ext', i.e. SepChars='/' will be like ExtractFileName() over RawUTF8 string
 - if SepChar doesn't appear, will return Str, e.g. SplitRight('123','/')='123'

procedure SQLAddWhereAnd(var where: RawUTF8; const condition: RawUTF8);

Add a condition to a SQL WHERE clause, with an 'and' if where is not void

function SQLBegin(P: PUTF8Char): PUTF8Char;

Go to the beginning of the SQL statement, ignoring all blanks and comments
 - used to check the SQL statement command (e.g. is it a SELECT?)

function StrCntDecFree(var refcnt: TStrCnt): boolean;

Low-level string reference counter unprocess
 - caller should have tested that refcnt>=0
 - returns true if the managed variable should be released (i.e. refcnt was 1)

function StrCompFast(Str1, Str2: pointer): PtrInt;

Buffer-safe version of StrComp(), to be used with PUTF8Char/PAnsiChar
 - pure pascal StrComp() won't access the memory beyond the string, but this function is defined for compatibility with SSE 4.2 expectations

function StrCompIL(P1,P2: PUTF8Char; L: Integer; Default: Integer=0): PtrInt;

Use our fast version of StrCompIL(), to be used with PUTF8Char

function StrCompL(P1,P2: PUTF8Char; L, Default: Integer): PtrInt;

Use our fast version of StrCompL(), to be used with PUTF8Char

function StrCompW(Str1, Str2: PWideChar): PtrInt;

Use our fast version of StrComp(), to be used with PWideChar

function strcspnpas(s, reject: pointer): integer;

Pure pascal version of strcspn(), to be used with PUTF8Char/PAnsiChar

- please note that this optimized version may read up to 3 bytes beyond reject but never after s end, so is safe e.g. over memory mapped files

function strcspnsse42(s, reject: pointer): integer;

SSE 4.2 version of strcspn(), to be used with PUTF8Char/PAnsiChar

- please note that this optimized version may read up to 15 bytes beyond the string; this is rarely a problem but it may generate protection violations, which could trigger fatal SIGABRT or SIGSEGV on Posix system
- could be used instead of strcspn() when you are confident about your s/reject input buffers, checking if cfSSE42 in CpuFeatures

function StrCurr64(P: PAnsiChar; const Value: Int64): PAnsiChar;

*Internal fast INTEGER Curr64 (value*10000) value to text conversion*

- expect the last available temporary char position in P
- return the last written char position (write in reverse order in P^)
- will return 0 for Value=0, or a string representation with always 4 decimals (e.g. 1->'0.0001' 500->'0.0500' 25000->'2.5000' 30000->'3.0000')
- is called by Curr64ToPChar() and Curr64ToStr() functions

function StreamSynLZ(Source: TCustomMemoryStream; Dest: TStream; Magic: cardinal): integer; overload;

Compress a data content using the SynLZ algorithm from one stream into another

- returns the number of bytes written to Dest
- you should specify a Magic number to be used to identify the block

function StreamSynLZ(Source: TCustomMemoryStream; const DestFile: TFileName; Magic: cardinal): integer; overload;

Compress a data content using the SynLZ algorithm from one stream into a file

- returns the number of bytes written to the destination file
- you should specify a Magic number to be used to identify the block

function StreamSynLZComputeLen(P: PAnsiChar; Len, aMagic: cardinal): integer;

Compute the real length of a given StreamSynLZ-compressed buffer

- allows to replace an existing appended content, for instance

function StreamToRawByteString(aStream: TStream): RawByteString;

Read a TStream content into a String

- it will read binary or text content from the current position until the end (using TStream.Size)
- uses RawByteString for byte storage, whatever the codepage is

function StreamUnSynLZ(const Source: TFileName; Magic: cardinal): TMemoryStream; overload;

Uncompress using the SynLZ algorithm from one file into another

- returns a newly create memory stream containing the uncompressed data
- returns nil if source file is invalid (e.g. invalid name or invalid content)
- you should specify a Magic number to be used to identify the block
- this function will also recognize the block at the end of the source file (if was appended to an existing data - e.g. a .mab at the end of a .exe)

function StreamUnSynLZ(Source: TStream; Magic: cardinal): TMemoryStream; overload;

Uncompress using the SynLZ algorithm from one stream into another

- returns a newly create memory stream containing the uncompressed data
- returns nil if source data is invalid
- you should specify a Magic number to be used to identify the block
- this function will also recognize the block at the end of the source stream (if was appended to an existing data - e.g. a .mab at the end of a .exe)
- on success, Source will point after all read data (so that you can e.g. append several data blocks to the same stream)

function StrIComp(Str1, Str2: pointer): PtrInt;

Use our fast version of StrIComp(), to be used with PUTF8Char/PAnsiChar

function StringBufferToUtf8(Dest: PUTF8Char; Source: PChar; SourceChars: PtrInt): PUTF8Char; overload;

Convert any generic VCL Text buffer into an UTF-8 encoded buffer

- Dest must be able to receive at least SourceChars*3 bytes
- it will work as is with Delphi 2009+ (direct unicode conversion)
- under older version of Delphi (no unicode), it will use the current RTL codepage, as with WideString conversion (but without slow WideString usage)

procedure StringBufferToUtf8(Source: PChar; **out** result: RawUTF8); overload;

Convert any generic VCL 0-terminated Text buffer into an UTF-8 string

- it will work as is with Delphi 2009+ (direct unicode conversion)
- under older version of Delphi (no unicode), it will use the current RTL codepage, as with WideString conversion (but without slow WideString usage)

procedure StringDynArrayToRawUTF8DynArray(**const** Source: TStringDynArray; **var** Result: TRawUTF8DynArray);

Convert the string dynamic array into a dynamic array of UTF-8 strings

function StringFromFile(**const** FileName: TFileName; HasNoSize: boolean=false): RawByteString;

Read a File content into a String

- content can be binary or text
- returns "" if file was not found or any read error occurred
- wil use GetFileSize() API by default, unless HasNoSize is defined, and read will be done using a buffer (required e.g. for char files under Linux)
- uses RawByteString for byte storage, whatever the codepage is

procedure StringListToRawUTF8DynArray(Source: TStringList; **var** Result: TRawUTF8DynArray);

Convert the string list into a dynamic array of UTF-8 strings

function StringReplaceAll(**const** S: RawUTF8; **const** OldNewPatternPairs: **array of** RawUTF8): RawUTF8; overload;

Fast version of several cascaded StringReplaceAll()

function StringReplaceAll(**const** S, OldPattern, NewPattern: RawUTF8): RawUTF8; overload;

Fast version of StringReplace(S, OldPattern, NewPattern,[rfReplaceAll]);

function StringReplaceAllProcess(**const** S, OldPattern, NewPattern: RawUTF8; found: integer): RawUTF8;

Actual replacement function called by StringReplaceAll() on first match
- not to be called as such, but defined globally for proper inlining

function StringReplaceChars(**const** Source: RawUTF8; OldChar, NewChar: AnsiChar): RawUTF8;

Fast replace of a specified char by a given string

function StringReplaceTabs(**const** Source, TabText: RawUTF8): RawUTF8;

Fast replace of all #9 chars by a given string

function StringToAnsi7(**const** Text: string): RawByteString;

Convert any generic VCL Text into Ansi 7 bit encoded String
- the Text content must contain only 7 bit pure ASCII characters

function StringToGUID(**const** text: string): TGUID;

Convert some text into a TGUID
- expect e.g. '{3F2504E0-4F89-11D3-9A0C-0305E82C3301}' (with the {})
- return {00000000-0000-0000-0000-000000000000} if the supplied text buffer is not a valid TGUID

function StringToRawUnicode(**const** S: string): RawUnicode; overload;

Convert any generic VCL Text into a Raw Unicode encoded String
- it's preferred to use TLanguageFile.StringToUTF8() method in mORMoti18n, which will handle full i18n of your application
- it will work as is with Delphi 2009+ (direct unicode conversion)
- under older version of Delphi (no unicode), it will use the current RTL codepage, as with WideString conversion (but without slow WideString usage)

function StringToRawUnicode(P: PChar; L: integer): RawUnicode; overload;

Convert any generic VCL Text into a Raw Unicode encoded String
- it's preferred to use TLanguageFile.StringToUTF8() method in mORMoti18n, which will handle full i18n of your application
- it will work as is with Delphi 2009+ (direct unicode conversion)
- under older version of Delphi (no unicode), it will use the current RTL codepage, as with WideString conversion (but without slow WideString usage)

procedure StringToSynUnicode(**const** S: string; **var** result: SynUnicode); overload;

Convert any generic VCL Text into a SynUnicode encoded String
- overloaded to avoid a copy to a temporary result string of a function

function StringToSynUnicode(**const** S: string): SynUnicode; overload;

Convert any generic VCL Text into a SynUnicode encoded String
- it's preferred to use TLanguageFile.StringToUTF8() method in mORMoti18n, which will handle full i18n of your application
- it will work as is with Delphi 2009+ (direct unicode conversion)
- under older version of Delphi (no unicode), it will use the current RTL codepage, as with WideString conversion (but without slow WideString usage)

procedure StringToUTF8(**const** Text: string; **var** result: RawUTF8); overload;

Convert any generic VCL Text into an UTF-8 encoded String
- this overloaded function use a faster by-reference parameter for the result

function StringToUTF8(const Text: string): RawUTF8; overload;

Convert any generic VCL Text into an UTF-8 encoded String

- in the VCL context, it's preferred to use TLanguageFile.StringToUTF8() method from mORMoti18n, which will handle full i18n of your application
- it will work as is with Delphi 2009+ (direct unicode conversion)
- under older version of Delphi (no unicode), it will use the current RTL codepage, as with WideString conversion (but without slow WideString usage)

procedure StringToUTF8(Text: PChar; TextLen: PtrInt; var result: RawUTF8); overload;

Convert any generic VCL Text buffer into an UTF-8 encoded String

- it will work as is with Delphi 2009+ (direct unicode conversion)
- under older version of Delphi (no unicode), it will use the current RTL codepage, as with WideString conversion (but without slow WideString usage)

function StringToWinAnsi(const Text: string): WinAnsiString;

Convert any generic VCL Text into WinAnsi (Win-1252) 8 bit encoded String

function StrInt32(P: PAnsiChar; val: PtrInt): PAnsiChar;

Internal fast integer val to text conversion

- expect the last available temporary char position in P
- return the last written char position (write in reverse order in P^)
- typical use:

```
function Int32ToUTF8(Value: PtrInt): RawUTF8;
var tmp: array[0..23] of AnsiChar;
    P: PAnsiChar;
begin
  P := StrInt32(@tmp[23], Value);
  SetString(result, P, @tmp[23]-P);
end;
```

- convert the input value as PtrInt, so as Int64 on 64-bit CPUs
- not to be called directly: use IntToStr() or Int32ToUTF8() instead

function StrInt64(P: PAnsiChar; const val: Int64): PAnsiChar;

Internal fast Int64 val to text conversion

- same calling convention as with StrInt32() above

function StrLenPas(S: pointer): PtrInt;

Slower version of StrLen(), but which will never read beyond the string

- this version won't access the memory beyond the string, so may be preferred to StrLen(), when using e.g. memory mapped files or any memory protected buffer

function StrLenW(S: PWideChar): PtrInt;

Our fast version of StrLen(), to be used with PWideChar

function StrPosI(upper substr, str: PUTF8Char): PUTF8Char;

A non case-sensitive version of Pos()

- upper substr is expected to be already in upper case
- this version handle only 7 bit ASCII (no accentuated characters)

function strspnpas(s, accept: pointer): integer;

Pure pascal version of strspn(), to be used with PUTF8Char/PAnsiChar

- please note that this optimized version may read up to 3 bytes beyond accept but never after s end, so is safe e.g. over memory mapped files

function strspnsse42(s, accept: pointer): integer;

SSE 4.2 version of strspn(), to be used with PUTF8Char/PAnsiChar

- please note that this optimized version may read up to 15 bytes beyond the string; this is rarely a problem but it may generate protection violations, which could trigger fatal SIGABRT or SIGSEGV on Posix system
- could be used instead of strspn() when you are confident about your s/accept input buffers, checking if cfSSE42 in CpuFeatures

function StrToCurr64(P: PUTF8Char; NoDecimal: PBoolean=nil): Int64;

*Convert a string into its INTEGER Curr64 (value*10000) representation*

- this type is compatible with Delphi currency memory map with PInt64(@Curr)^
- fast conversion, using only integer operations
- if NoDecimal is defined, will be set to TRUE if there is no decimal, AND the returned value will be an Int64 (not a PInt64(@Curr)^)

function StrToCurrency(P: PUTF8Char): currency;

Convert a string into its currency representation

- will call StrToCurr64()

function StrUInt32(P: PAnsiChar; val: PtrUInt): PAnsiChar;

Internal fast unsigned integer val to text conversion

- expect the last available temporary char position in P
- return the last written char position (write in reverse order in P^)
- convert the input value as PtrUInt, so as QWord on 64-bit CPUs

function StrUInt64(P: PAnsiChar; const val: QWord): PAnsiChar;

Internal fast unsigned Int64 val to text conversion

- same calling convention as with StrInt32() above

function SumInteger(const Values: TIntegerDynArray; ValuesCount: PtrInt): Integer;

Sum all 32-bit integers in Values[]

procedure SymmetricEncrypt(key: cardinal; var data: RawByteString);

Naive symmetric encryption scheme using a 32-bit key

- fast, but not very secure, since uses crc32tab[] content as master cypher key: consider using SynCrypto proven AES-based algorithms instead

function SynchFolders(const Reference, Dest: TFileName; SubFolder: boolean=false; ByContent: boolean=false; WriteFileNameToConsole: boolean=false): integer;

Ensure all files in Dest folder(s) do match the one in Reference

- won't copy all files from Reference folders, but only update files already existing in Dest, which did change since last synchronization
- will also process recursively nested folders if SubFolder is true
- will use file content instead of file date check if ByContent is true
- can optionally write the synched file name to the console
- returns the number of files copied during the process

procedure SynLZCompress(P: PAnsiChar; PLen: integer; out Result: RawByteString; CompressionSizeTrigger: integer=100; CheckMagicForCompressed: boolean=false); overload;

Deprecated function - please call AlgoSynLZ.Compress() method

function SynLZCompress(P: PAnsiChar; PLen, DestLen: integer; CompressionSizeTrigger: integer=100; CheckMagicForCompressed: boolean=false): integer; overload;

Deprecated function - please call AlgoSynLZ.Compress() method

function SynLZCompress(const Data: RawByteString; CompressionSizeTrigger: integer=100; CheckMagicForCompressed: boolean=false): RawByteString; overload;

Deprecated function - please call AlgoSynLZ.Compress() method

function SynLZCompressToBytes(P: PAnsiChar; PLen: integer; CompressionSizeTrigger: integer=100): TByteDynArray; overload;

Deprecated function - please call AlgoSynLZ.CompressToBytes() method

function SynLZCompressToBytes(const Data: RawByteString; CompressionSizeTrigger: integer=100): TByteDynArray; overload;

Deprecated function - please call AlgoSynLZ.DecompressToBytes() method

function SynLZDecompress(const Data: RawByteString): RawByteString; overload;

Deprecated function - please call AlgoSynLZ.Decompress() method

function SynLZDecompress(const Data: TByteDynArray): RawByteString; overload;

Deprecated function - please call AlgoSynLZ.Decompress() method

function SynLZDecompress(const Data: RawByteString; out Len: integer; var tmp: RawByteString): pointer; overload;

Deprecated function - please call AlgoSynLZ.Decompress() method

procedure SynLZDecompress(P: PAnsiChar; PLen: integer; out Result: RawByteString; SafeDecompression: boolean=false); overload;

Deprecated function - please call AlgoSynLZ.Decompress() method

function SynLZDecompress(P: PAnsiChar; PLen: integer; out Len: integer; var tmp: RawByteString): pointer; overload;

Deprecated function - please call AlgoSynLZ.Decompress() method

function SynLZDecompressBody(P, Body: PAnsiChar; PLen, BodyLen: integer; SafeDecompression: boolean=false): boolean;

Deprecated function - please call AlgoSynLZ.DecompressBody() method

function SynLZDecompressHeader(P: PAnsiChar; PLen: integer): integer;

Deprecated function - please call AlgoSynLZ.DecompressHeader() method

function SynLZDecompressPartial(P, Partial: PAnsiChar; PLen, PartialLen: integer): integer;

Deprecated function - please call AlgoSynLZ.DecompressPartial() method

function SynRegisterCustomVariantType(aClass: TSynInvokeableVariantTypeClass): TSynInvokeableVariantType;

Register a custom variant type to handle properties

- this will implement an internal mechanism used to bypass the default _DispInvoke() implementation in Variant.pas, to use a faster version
- is called in case of TSynTableVariant, TDocVariant, TBSONVariant or TSQLDBRowVariant

function SynUnicodeToString(const U: SynUnicode): string;

Convert any SynUnicode encoded string into a generic VCL Text

function SynUnicodeToUtf8(**const** Unicode: SynUnicode): RawUTF8;

Convert a SynUnicode string into a UTF-8 string

function TemporaryFileName: TFileName;

Compute an unique temporary file name

- following 'exename_01234567.tmp' pattern, in the system temporary folder

function TextToGUID(P: PUTF8Char; guid: PByteArray): PUTF8Char;

Convert some text into its TGUID binary value

- expect e.g. '3F2504E0-4F89-11D3-9A0C-0305E82C3301' (without any {})

- return nil if the supplied text buffer is not a valid TGUID

- this will be the format used for JSON encoding, e.g.

{ "UID": "C9A646D3-9C61-4CB7-BFCD-EE2522C8F633" }

procedure TextToVariant(**const** aValue: RawUTF8; AllowVarDouble: boolean; **out** aDest: variant);

Convert an UTF-8 encoded text buffer into a variant number or RawUTF8 varString

- first try with GetNumericVariantFromJSON(), then fallback to RawUTF8ToVariant

function TextToVariantNumberType(JSON: PUTF8Char): cardinal;

Identify either varInt64, varDouble, varCurrency types following JSON format

- any non valid number is returned as varString

- is used e.g. by GetVariantFromJSON() to guess the destination variant type

- warning: supplied JSON is expected to be not nil

function TextToVariantNumberTypeNoDouble(JSON: PUTF8Char): cardinal;

Identify either varInt64 or varCurrency types following JSON format

- this version won't return varDouble, i.e. won't handle more than 4 exact decimals (as varCurrency), nor scientific notation with exponent (1.314e10)

- this will ensure that any incoming JSON will converted back with its exact textual representation, without digit truncation due to limited precision

- any non valid number is returned as varString

- is used e.g. by GetVariantFromJSON() to guess the destination variant type

- warning: supplied JSON is expected to be not nil

function TimeLogFromDateTime(**const** DateTime: TDateTime): TTimeLog;

Get TTimeLog value from a given Delphi date and time

- handle TTimeLog bit-encoded Int64 format

- just a wrapper around PTimeLogBits(@aTime)^.From()

- we defined such a function since TTimeLogBits(aTimeLog).From() won't change the aTimeLog variable content

function TimeLogFromFile(**const** FileName: TFileName): TTimeLog;

Get TTimeLog value from a file date and time

- handle TTimeLog bit-encoded Int64 format

function TimeLogFromUnixTime(**const** UnixTime: TUnixTime): TTimeLog;

Get TTimeLog value from a given Unix seconds since epoch timestamp

- handle TTimeLog bit-encoded Int64 format

- just a wrapper around PTimeLogBits(@aTime)^.FromUnixTime()

function TimeLogNow: TTimeLog;

Get TTimeLog value from current local system date and time
- handle TTimeLog bit-encoded Int64 format

function TimeLogNowUTC: TTimeLog;

Get TTimeLog value from current UTC system Date and Time
- handle TTimeLog bit-encoded Int64 format

function TimeLogToDateTime(const Timestamp: TTimeLog): TDateTime;

Date/Time conversion from a TTimeLog value
- handle TTimeLog bit-encoded Int64 format
- just a wrapper around PTimeLogBits(@Timestamp)^.ToDateTime
- we defined such a function since TTimeLogBits(aTimeLog).ToDateTime gives an internal compiler error on some Delphi IDE versions (e.g. Delphi 6)

function TimeLogToUnixTime(const Timestamp: TTimeLog): TUnixTime;

Unix seconds since epoch timestamp conversion from a TTimeLog value
- handle TTimeLog bit-encoded Int64 format
- just a wrapper around PTimeLogBits(@Timestamp)^.ToUnixTime

function TimeToIso8601(Time: TDateTime; Expanded: boolean; FirstChar: AnsiChar='T'; WithMS: boolean=false): RawUTF8;

Basic Time conversion into ISO-8601
- use 'Thhmmss' format if not Expanded
- use 'Thh:mm:ss' format if Expanded
- if WithMS is TRUE, will append '.sss' for milliseconds resolution

function TimeToIso8601PChar(P: PUTF8Char; Expanded: boolean; H,M,S,MS: PtrUInt; FirstChar: AnsiChar = 'T'; WithMS: boolean=false): PUTF8Char; overload;

Write a Time to P^ Ansi buffer
- if Expanded is false, 'Thhmmss' time format is used
- if Expanded is true, 'Thh:mm:ss' time format is used
- you can custom the first char in from of the resulting text time
- if WithMS is TRUE, will append MS as '.sss' for milliseconds resolution

function TimeToIso8601PChar(Time: TDateTime; P: PUTF8Char; Expanded: boolean; FirstChar: AnsiChar = 'T'; WithMS: boolean=false): PUTF8Char; overload;

Write a Time to P^ Ansi buffer
- if Expanded is false, 'Thhmmss' time format is used
- if Expanded is true, 'Thh:mm:ss' time format is used
- you can custom the first char in from of the resulting text time
- if WithMS is TRUE, will append '.sss' for milliseconds resolution

function TimeToString: RawUTF8;

Retrieve the current Time (without Date), in the ISO 8601 layout
- useful for direct on screen logging e.g.

function TInt64DynArrayFrom(const Values: TIntegerDynArray): TInt64DynArray;

Quick helper to initialize a dynamic array of 64-bit integers from 32-bit values
- see also FromI64() for 64-bit signed integer values input

function TIntegerDynArrayFrom(const Values: array of integer): TIntegerDynArray;

Quick helper to initialize a dynamic array of integer from some constants

- can be used e.g. as:

```
MyArray := TIntegerDynArrayFrom([1,2,3]);
```

- see also FromI32()

function TIntegerDynArrayFrom64(const Values: TInt64DynArray;
raiseExceptionOnOverflow: boolean=true): TIntegerDynArray;

Quick helper to initialize a dynamic array of integer from 64-bit integers

- will raise a ESynException if any Value[] can not fit into 32-bit, unless raiseExceptionOnOverflow is FALSE and the returned array slot is filled with maxInt/minInt

function ToCardinal(const text: RawUTF8; out value: cardinal; minimal: cardinal=0):
boolean;

Get the unsigned 32-bit cardinal value stored in a RawUTF8 string

- returns TRUE if the supplied text was successfully converted into a cardinal

function ToDouble(const text: RawUTF8; out value: double): boolean;

Get a 64-bit floating-point value stored in a RawUTF8 string

- returns TRUE if the supplied text was successfully converted into a double

function ToInt64(const text: RawUTF8; out value: Int64): boolean;

Get the signed 64-bit integer value stored in a RawUTF8 string

- returns TRUE if the supplied text was successfully converted into an Int64

function ToInteger(const text: RawUTF8; out value: integer): boolean;

Get the signed 32-bit integer value stored in a RawUTF8 string

- returns TRUE if the supplied text was successfully converted into an integer

function ToText(kind: TDocVariantKind): PShortString; overload;

Retrieve the text representation of a TDocVairmatKind

function ToText(const aIntelCPUFeatures: TIntelCpuFeatures; const Sep: RawUTF8=','): RawUTF8; overload;

Convert Intel CPU features as plain CSV text

function ToText(C: TClass): RawUTF8; overload;

Just a wrapper around vmtClassName to avoid a string/RawUTF8 conversion

procedure ToText(C: TClass; var result: RawUTF8); overload;

Just a wrapper around vmtClassName to avoid a string/RawUTF8 conversion

function ToUTF8(const V: Variant): RawUTF8; overload;

Convert any Variant into UTF-8 encoded String

- use VariantSaveJSON() instead if you need a conversion to JSON with custom parameters

- note: null will be returned as 'null'

function ToUTF8(const Text: string): RawUTF8; overload;

Convert any generic VCL Text into an UTF-8 encoded String

function ToUTF8(const Ansi7Text: ShortString): RawUTF8; overload;

Convert any UTF-8 encoded shortstring Text into an UTF-8 encoded String

- expects the supplied content to be already ASCII-7 or UTF-8 encoded, e.g. a RTTI type or property name: it won't work with Ansi-encoded strings

function ToUTF8(const GUID: TGUID): RawUTF8; overload;

Convert a TGUID into UTF-8 encoded text

- will return e.g. '3F2504E0-4F89-11D3-9A0C-0305E82C3301' (without the {})
- if you need the embracing { }, use GUIDToRawUTF8() function instead

function ToUTF8(Value: Int64): RawUTF8; overload;

Use our fast RawUTF8 version of IntToStr()

function ToUTF8(Value: PtrInt): RawUTF8; overload;

Use our fast RawUTF8 version of IntToStr()

function ToVarInt32(Value: PtrInt; Dest: PByte): PByte;

Convert an integer into a 32-bit variable-length integer buffer

- store negative values as cardinal two-complement, i.e. 0=0,1=1,2=-1,3=2,4=-2...

function ToVarInt64(Value: Int64; Dest: PByte): PByte;

Convert a Int64 into a 64-bit variable-length integer buffer

function ToVarString(const Value: RawUTF8; Dest: PByte): PByte;

Convert a RawUTF8 into an UTF-8 encoded variable-length buffer

function ToVarUInt32(Value: cardinal; Dest: PByte): PByte;

Convert a cardinal into a 32-bit variable-length integer buffer

function ToVarUInt32Length(Value: PtrUInt): PtrUInt;

Return the number of bytes necessary to store a 32-bit variable-length integer

- i.e. the ToVarUInt32() buffer size

function ToVarUInt32LengthWithData(Value: PtrUInt): PtrUInt;

Return the number of bytes necessary to store some data with a its 32-bit variable-length integer length

function ToVarUInt64(Value: QWord; Dest: PByte): PByte;

Convert a UInt64 into a 64-bit variable-length integer buffer

function TQWordDynArrayFrom(const Values: TCardinalDynArray): TQWordDynArray;

Quick helper to initialize a dynamic array of 64-bit integers from 32-bit values

- see also FromU64() for 64-bit unsigned integer values input

function TRawUTF8DynArrayFrom(const Values: array of RawUTF8): TRawUTF8DynArray;

Quick helper to initialize a dynamic array of RawUTF8 from some constants

- can be used e.g. as:

```
MyArray := TRawUTF8DynArrayFrom(['a','b','c']);
```

function Trim(const S: RawUTF8): RawUTF8;

Fast dedicated RawUTF8 version of Trim()

- implemented using x86 asm, if possible
- this Trim() is seldom used, but this RawUTF8 specific version is needed e.g. by Delphi 2009+, to avoid two unnecessary conversions into UnicodeString
- in the middle of VCL code, consider using TrimU() which won't have name collision ambiguity as with SysUtils' homonymous function

```
function TrimControlChars(const text: RawUTF8; const controls:
TSynAnsicharSet=[#0..' ']): RawUTF8;
```

Returns the supplied text content, without any control char
 - a control char has an ASCII code #0 .. #32, i.e. text[]<=' '
 - you can specify a custom char set to be excluded, if needed

```
procedure TrimCopy(const S: RawUTF8; start,count: PtrInt; var result: RawUTF8);
  Single-allocation (therefore faster) alternative to Trim(copy())
```

```
function TrimLeft(const S: RawUTF8): RawUTF8;
```

Trims leading whitespace characters from the string by removing new line, space, and tab characters

```
function TrimLeftLowerCase(const V: RawUTF8): PUTF8Char;
```

Trim first lowercase chars ('otDone' will return 'Done' e.g.)
 - return a PUTF8Char to avoid any memory allocation

```
function TrimLeftLowerCaseShort(V: PShortString): RawUTF8;
```

Trim first lowercase chars ('otDone' will return 'Done' e.g.)
 - return an RawUTF8 string: enumeration names are pure 7bit ANSI with Delphi 7 to 2007, and UTF-8 encoded with Delphi 2009+

```
procedure TrimLeftLowerCaseToShort(V: PShortString; out result: ShortString);
overload;
```

Trim first lowercase chars ('otDone' will return 'Done' e.g.)
 - return a shortstring: enumeration names are pure 7bit ANSI with Delphi 7 to 2007, and UTF-8 encoded with Delphi 2009+

```
function TrimLeftLowerCaseToShort(V: PShortString): ShortString; overload;
```

Trim first lowercase chars ('otDone' will return 'Done' e.g.)
 - return a shortstring: enumeration names are pure 7bit ANSI with Delphi 7 to 2007, and UTF-8 encoded with Delphi 2009+

```
function TrimRight(const S: RawUTF8): RawUTF8;
```

Trims trailing whitespace characters from the string by removing trailing newline, space, and tab characters

```
function TrimU(const S: RawUTF8): RawUTF8;
```

Fast dedicated RawUTF8 version of Trim()
 - could be used if overloaded Trim() from SysUtils.pas is ambiguous

```
function TruncTo2Digits(Value: Currency): Currency;
```

Truncate a Currency value to only 2 digits
 - implementation will use fast Int64 math to avoid any precision loss due to temporary floating-point conversion

```
function TruncTo2Digits64(Value: Int64): Int64;
```

Truncate a Currency value, stored as Int64, to only 2 digits
 - implementation will use fast Int64 math to avoid any precision loss due to temporary floating-point conversion

procedure TruncTo2DigitsCurr64(**var** Value: Int64);

Truncate a Currency value, stored as Int64, to only 2 digits

- implementation will use fast Int64 math to avoid any precision loss due to temporary floating-point conversion

function TryEncodeDate(Year, Month, Day: cardinal; **out** Date: TDateTime): Boolean;

Our own fast version of the corresponding low-level RTL function

function TypeInfoToHash(aTypeInfo: pointer): cardinal;

Compute a crc32c-based hash of the RTTI for a managed given type

- can be used to ensure that the RecordSave/TDynArray.SaveTo binary layout is compatible accross executables, even between FPC and Delphi
- will ignore the type names, but will check the RTTI type kind and any nested fields (for records or arrays) - for a record/object type, will use TTextWriter.RegisterCustomJSONSerializerFromText definition, if available

procedure TypeInfoToName(aTypeInfo: pointer; **var** result: RawUTF8; **const** default: RawUTF8=''); **overload**;

Retrieve the type name from its low-level RTTI

function TypeInfoToName(aTypeInfo: pointer): RawUTF8; **overload**;

Retrieve the type name from its low-level RTTI

procedure TypeInfoToQualifiedNames(aTypeInfo: pointer; **var** result: RawUTF8; **const** default: RawUTF8=''); **overload**;

Retrieve the unit name and type name from its low-level RTTI

function TypeInfoToRttiType(aTypeInfo: pointer): TJSONCustomParserRTTIType;

Recognize a simple type from a supplied type information

- first try by name via TJSONCustomParserRTTI.TypeNameToSimpleRTTIType, then from RTTI via TJSONCustomParserRTTI.TypeInfoToSimpleRTTIType
- will return ptCustom for any unknown type

function UCS4ToUTF8(ucs4: cardinal; Dest: PUTF8Char): integer;

UTF-8 encode one UCS4 character into Dest

- return the number of bytes written into Dest (i.e. from 1 up to 6)
- this method DOES handle UTF-16 surrogate pairs

function UInt2DigitsToShort(Value: byte): TShort4;

Creates a 2 digits short string from a 0..99 value

- using TShort4 as returned string would avoid a string allocation on heap
- could be used e.g. as parameter to FormatUTF8()

function UInt2DigitsToShortFast(Value: byte): TShort4;

Creates a 2 digits short string from a 0..99 value

- won't test Value>99 as UInt2DigitsToShort()

function UInt32ToUtf8(Value: PtrUInt): RawUTF8; **overload**;

Optimized conversion of a cardinal into RawUTF8

procedure UInt32ToUtf8(Value: PtrUInt; **var** result: RawUTF8); **overload**;

Optimized conversion of a cardinal into RawUTF8

function UInt3DigitsToShort(Value: Cardinal): TShort4;

Creates a 3 digits short string from a 0..999 value

- using TShort4 as returned string would avoid a string allocation on heap
- could be used e.g. as parameter to FormatUTF8()

function UInt3DigitsToUTF8(Value: Cardinal): RawUTF8;

Creates a 3 digits string from a 0..999 value as '000'..'999'

- consider using UInt3DigitsToShort() to avoid temporary memory allocation, e.g. when used as FormatUTF8() parameter

function UInt4DigitsToShort(Value: Cardinal): TShort4;

Creates a 4 digits short string from a 0..9999 value

- using TShort4 as returned string would avoid a string allocation on heap
- could be used e.g. as parameter to FormatUTF8()

function UInt4DigitsToUTF8(Value: Cardinal): RawUTF8;

Creates a 4 digits string from a 0..9999 value as '0000'..'9999'

- consider using UInt4DigitsToShort() to avoid temporary memory allocation, e.g. when used as FormatUTF8() parameter

procedure UInt64ToUtf8(Value: QWord; var result: RawUTF8);

Fast RawUTF8 version of IntToStr(), with proper QWord conversion

function UnCamelCase(const S: RawUTF8): RawUTF8; overload;

Convert a CamelCase string into a space separated one

- 'OnLine' will return 'On line' e.g., and 'OnMyLINE' will return 'On my LINE'
- will handle capital words at the beginning, middle or end of the text, e.g. 'KLMFlightNumber' will return 'KLM flight number' and 'GoodBBCProgram' will return 'Good BBC program'
- will handle a number at the beginning, middle or end of the text, e.g. 'Email12' will return 'Email 12'
- '_' char is transformed into ' - '
- '__' chars are transformed into ': '
- return an RawUTF8 string: enumeration names are pure 7bit ANSI with Delphi 7 to 2007, and UTF-8 encoded with Delphi 2009+

function UnCamelCase(D, P: PUTF8Char): integer; overload;

Convert a CamelCase string into a space separated one

- 'OnLine' will return 'On line' e.g., and 'OnMyLINE' will return 'On my LINE'
- will handle capital words at the beginning, middle or end of the text, e.g. 'KLMFlightNumber' will return 'KLM flight number' and 'GoodBBCProgram' will return 'Good BBC program'
- will handle a number at the beginning, middle or end of the text, e.g. 'Email12' will return 'Email 12'
- return the char count written into D^
- D^ and P^ are expected to be UTF-8 encoded: enumeration and property names are pure 7bit ANSI with Delphi 7 to 2007, and UTF-8 encoded with Delphi 2009+
- '_' char is transformed into ' - '
- '__' chars are transformed into ': '

function UnicodeBufferToString(source: PWideChar): string;

Convert an Unicode buffer into a generic VCL string

procedure UnicodeBufferToWinAnsi(source: PWideChar; out Dest: WinAnsiString);

Convert an Unicode buffer into a WinAnsi (code page 1252) string

function UniqueRawUTF8(var UTF8: RawUTF8): pointer;

Equivalence to @UTF8[1] expression to ensure a RawUTF8 variable is unique

- will ensure that the string refcount is 1, and return a pointer to the text
- under FPC, @UTF8[1] does not call UniqueString() as it does with Delphi
- if UTF8 is a constant (refcount=-1), will create a temporary copy in heap

procedure UniqueRawUTF8ZeroToTilde(var UTF8: RawUTF8; MaxSize: integer=maxInt);

Will fast replace all #0 chars as ~

- could be used after UniqueRawUTF8() on a in-placed modified JSON buffer, in which all values have been ended with #0
- you can optionally specify a maximum size, in bytes (this won't reallocate the string, but just add a #0 at some point in the UTF8 buffer)
- could allow logging of parsed input e.g. after an exception

function UnixMSTimePeriodToString(const UnixMSTime: TUnixMSTime; FirstTimeChar: AnsiChar='T'): RawUTF8;

Delphi 2007 is buggy as hell convert some millisecond-based c-encoded time to the ISO 8601 text layout, as time or date elapsed period

- this function won't add the Unix epoch 1/1/1970 offset to the timestamp
- returns 'Thh:mm:ss' or 'YYYY-MM-DD' format, depending on the supplied value

function UnixMSTimeToDateTime(const UnixMSTime: TUnixMSTime): TDateTime;

Convert a millisecond-based c-encoded time (from Unix epoch 1/1/1970) as TDateTime

function UnixMSTimeToFileShort(const UnixMSTime: TUnixMSTime): TShort16;

Convert some millisecond-based c-encoded time (from Unix epoch 1/1/1970) to a small text layout, trimming to the second resolution, perfect e.g. for naming a local file

- use 'YYMMDDHHMMSS' format so year is truncated to last 2 digits, expecting a date > 1999 (a current date would be fine)

function UnixMSTimeToString(const UnixMSTime: TUnixMSTime; Expanded: boolean=true; FirstTimeChar: AnsiChar='T'; const TZD: RawUTF8=''): RawUTF8;

Convert some millisecond-based c-encoded time (from Unix epoch 1/1/1970) to the ISO 8601 text layout, including milliseconds

- i.e. 'YYYY-MM-DDThh:mm:ss.sssZ' or 'YYYYMMDDThhmmss.sssZ' format
- TZD is the ending time zone designator ('', 'Z' or '+hh:mm' or '-hh:mm')

function UnixMSTimeUTC: TUnixMSTime;

Returns the current UTC date/time as a millisecond-based c-encoded time

- i.e. current number of milliseconds elapsed since Unix epoch 1/1/1970
- faster and more accurate than NowUTC or GetTickCount64, on Windows or Unix
- will use e.g. fast clock_gettime(CLOCK_REALTIME_COARSE) under Linux, or GetSystemTimeAsFileTime/GetSystemTimePreciseAsFileTime under Windows - the later being more accurate, but slightly slower than the former, so you may consider using UnixMSTimeUTCFast on Windows if its 10-16ms accuracy is enough

function UnixMSTimeUTCFast: TUnixMSTime;

Returns the current UTC date/time as a millisecond-based c-encoded time

- under Linux/POSIX, is the very same than UnixMSTimeUTC
- under Windows 8+, will call GetSystemTimeAsFileTime instead of GetSystemTimePreciseAsFileTime, which has higher precision, but is slower
- prefer it under Windows, if a dozen of ms resolution is enough for your task

function UnixTimePeriodToString(const UnixTime: TUnixTime; FirstTimeChar: AnsiChar='T'): RawUTF8;

Delphi 2007 is buggy as hell convert some second-based c-encoded time to the ISO 8601 text layout, either as time or date elapsed period

- this function won't add the Unix epoch 1/1/1970 offset to the timestamp
- returns 'Thh:mm:ss' or 'YYYY-MM-DD' format, depending on the supplied value

function UnixTimeToDateTime(const UnixTime: TUnixTime): TDateTime;

Convert a second-based c-encoded time as TDateTime

- i.e. number of seconds elapsed since Unix epoch 1/1/1970 into TDateTime

procedure UnixTimeToFileShort(const UnixTime: TUnixTime; out result: TShort16); overload;

Convert some second-based c-encoded time (from Unix epoch 1/1/1970) to a small text layout, perfect e.g. for naming a local file

- use 'YYMMDDHHMMSS' format so year is truncated to last 2 digits, expecting a date > 1999 (a current date would be fine)

function UnixTimeToFileShort(const UnixTime: TUnixTime): TShort16; overload;

Convert some second-based c-encoded time (from Unix epoch 1/1/1970) to a small text layout, perfect e.g. for naming a local file

- use 'YYMMDDHHMMSS' format so year is truncated to last 2 digits, expecting a date > 1999 (a current date would be fine)

function UnixTimeToString(const UnixTime: TUnixTime; Expanded: boolean=true; FirstTimeChar: AnsiChar='T'): RawUTF8;

Convert some second-based c-encoded time (from Unix epoch 1/1/1970) to the ISO 8601 text layout

- use 'YYYYMMDDThhmmss' format if not Expanded
- use 'YYYY-MM-DDThh:mm:ss' format if Expanded

function UnixTimeUTC: TUnixTime;

Returns the current UTC date/time as a second-based c-encoded time

- i.e. current number of seconds elapsed since Unix epoch 1/1/1970
- faster than NowUTC or GetTickCount64, on Windows or Unix platforms (will use e.g. fast clock_gettime(CLOCK_REALTIME_COARSE) under Linux, or GetSystemTimeAsFileTime under Windows)
- returns a 64-bit unsigned value, so is "Year2038bug" free

function UnQuotedSQLSymbolName(const ExternalDBSymbol: RawUTF8): RawUTF8;

Unquote a SQL-compatible symbol name

- e.g. '[symbol]' -> 'symbol' or '"symbol"' -> 'symbol'

function UnQuoteSQLString(const Value: RawUTF8): RawUTF8;

Unquote a SQL-compatible string

function UnQuoteSQLStringVar(P: PUTF8Char; **out** Value: RawUTF8): PUTF8Char;

Unquote a SQL-compatible string

- the first character in P^ must be either ' or " then internal double quotes are transformed into single quotes
- 'text " end' -> text ' end
- "text "" end" -> text " end
- returns nil if P doesn't contain a valid SQL string
- returns a pointer just after the quoted text otherwise

procedure UnSetBit(**var** Bits; aIndex: PtrInt);

Unset/clear a particular bit into a bit array

- this function can't be inlined, whereas UnSetBitPtr() function can

procedure UnSetBit64(**var** Bits: Int64; aIndex: PtrInt);

Unset/clear a particular bit into a 64-bit integer bits (max aIndex is 63)

procedure UnSetBitPtr(Bits: pointer; aIndex: PtrInt);

Unset/clear a particular bit into a bit array

- UnSetBit() can't be inlined, whereas this pointer-oriented function can

procedure UpdateIniEntry(**var** Content: RawUTF8; **const** Section, Name, Value: RawUTF8);

Update a Name= Value in a [Section] of a INI RawUTF8 Content

- this function scans and update the Content memory buffer, and is therefore very fast (no temporary TMemIniFile is created)
- if Section equals "", update the Name= value before any [Section]

procedure UpdateIniEntryFile(**const** FileName: TFileName; **const** Section, Name, Value: RawUTF8);

Update a Name= Value in a [Section] of a .INI file

- if Section equals "", update the Name= value before any [Section]
- use internally fast UpdateIniEntry() function above

function UpdateIniNameValue(**var** Content: RawUTF8; **const** Name, UpperName, NewValue: RawUTF8): boolean;

Replace a value from a given set of name=value lines

- expect UpperName as 'UPPERNAME=', otherwise returns false
- if no UPPERNAME= entry was found, then Name+NewValue is added to Content
- a typical use may be:
 UpdateIniNameValue(headers, HEADER_CONTENT_TYPE, HEADER_CONTENT_TYPE_UPPER, contenttype);

function UpperCase(**const** S: RawUTF8): RawUTF8;

Fast conversion of the supplied text into uppercase

- this will only convert 'a'..'z' into 'A'..'Z' (no NormToUpper use), and will therefore be correct with true UTF-8 content, but only for 7 bit

procedure UpperCaseCopy(Text: PUTF8Char; Len: PtrInt; **var** result: RawUTF8); overload;

Fast conversion of the supplied text into uppercase

- this will only convert 'a'..'z' into 'A'..'Z' (no NormToUpper use), and will therefore be correct with true UTF-8 content, but only for 7 bit

procedure UpperCaseCopy(**const** Source: RawUTF8; **var** Dest: RawUTF8); overload;

Fast conversion of the supplied text into uppercase

- this will only convert 'a'..'z' into 'A'..'Z' (no NormToUpper use), and will therefore be correct with true UTF-8 content, but only for 7 bit

procedure UpperCaseSelf(**var** S: RawUTF8);

Fast in-place conversion of the supplied variable text into uppercase

- this will only convert 'a'..'z' into 'A'..'Z' (no NormToUpper use), and will therefore be correct with true UTF-8 content, but only for 7 bit

function UpperCaseU(**const** S: RawUTF8): RawUTF8;

Fast conversion of the supplied text into 8 bit uppercase

- this will not only convert 'a'..'z' into 'A'..'Z', but also accentuated latin characters ('e' acute into 'E' e.g.), using NormToUpper[] array
- it will therefore decode the supplied UTF-8 content to handle more than 7 bit of ascii characters (so this function is dedicated to WinAnsi code page 1252 characters set)

function UpperCaseUnicode(**const** S: RawUTF8): RawUTF8;

Accurate conversion of the supplied UTF-8 content into the corresponding upper-case Unicode characters

- this version will use the Operating System API, and will therefore be much slower than UpperCase/UpperCaseU versions, but will handle all kind of unicode characters

function UpperCopy(dest: PAnsiChar; **const** source: RawUTF8): PAnsiChar;

Copy source into dest^ with 7 bits upper case conversion

- returns final dest pointer
- will copy up to the source buffer end: so Dest^ should be big enough - which will the case e.g. if Dest := pointer(source)

function UpperCopy255(dest: PAnsiChar; **const** source: RawUTF8): PAnsiChar; overload;

Copy source into a 256 chars dest^ buffer with 7 bits upper case conversion

- used internally for short keys match or case-insensitive hash
- returns final dest pointer
- will copy up to 255 AnsiChar (expect the dest buffer to be defined e.g. as array[byte] of AnsiChar on the caller stack)

function UpperCopy255BufPas(dest: PAnsiChar; source: PUTF8Char; sourceLen: PtrInt): PAnsiChar;

Copy source^ into a 256 chars dest^ buffer with 7 bits upper case conversion

- used internally for short keys match or case-insensitive hash
- this version is written in optimized pascal
- you should not have to call this function, but rely on UpperCopy255Buf()
- returns final dest pointer
- will copy up to 255 AnsiChar (expect the dest buffer to be defined e.g. as array[byte] of AnsiChar on the caller stack)

function UpperCopy255BufSSE42(dest: PAnsiChar; source: PUTF8Char; sourceLen: PtrInt): PAnsiChar;

SSE 4.2 version of UpperCopy255Buf()

- copy source^ into a 256 chars dest^ buffer with 7 bits upper case conversion
- please note that this optimized version may read up to 15 bytes beyond the string; this is rarely a problem but it may generate protection violations, which could trigger fatal SIGABRT or SIGSEGV on Posix system
- could be used instead of UpperCopy255Buf() when you are confident about your dest/source input buffers, checking if cfSSE42 in CpuFeatures

function UpperCopy255W(dest: PAnsiChar; source: PWideChar; L: integer): PAnsiChar; overload;

Copy WideChar source into dest^ with upper case conversion

- used internally for short keys match or case-insensitive hash
- returns final dest pointer
- will copy up to 255 AnsiChar (expect the dest buffer to be array[byte] of AnsiChar)

function UpperCopy255W(dest: PAnsiChar; **const** source: SynUnicode): PAnsiChar; overload;

Copy WideChar source into dest^ with upper case conversion

- used internally for short keys match or case-insensitive hash
- returns final dest pointer
- will copy up to 255 AnsiChar (expect the dest buffer to be array[byte] of AnsiChar)

function UpperCopyShort(dest: PAnsiChar; **const** source: shortstring): PAnsiChar;

Copy source into dest^ with 7 bits upper case conversion

- returns final dest pointer
- this special version expect source to be a shortstring

function UpperCopyWin255(dest: PWinAnsiChar; **const** source: RawUTF8): PWinAnsiChar;

Copy source into dest^ with WinAnsi 8 bits upper case conversion

- used internally for short keys match or case-insensitive hash
- returns final dest pointer
- will copy up to 255 AnsiChar (expect the dest buffer to be array[byte] of AnsiChar)

function UrlDecode(U: PUTF8Char): RawUTF8; overload;

Decode a string compatible with URI encoding into its original value

function UrlDecode(**const** s: RawUTF8; i: PtrInt=1; len: PtrInt=-1): RawUTF8; overload;

Decode a string compatible with URI encoding into its original value

- you can specify the decoding range (as in copy(s,i,len) function)

function UrlDecodeCardinal(U: PUTF8Char; **const** Upper: RawUTF8; **var** Value: Cardinal; Next: PPUTF8Char=nil): boolean;

Decode a specified parameter compatible with URI encoding into its original cardinal numerical value

-

UrlDecodeCardinal('offset=20&where=LastName%3D%27M%C3%B4net%27','OFFSET=',O,@Next) will return Next^='where=...' and O=20

- if Upper is not found, Value is not modified, and result is FALSE
- if Upper is found, Value is modified with the supplied content, and result is TRUE

function UrlDecodeDouble(U: PUTF8Char; **const** Upper: RawUTF8; **var** Value: double; Next: PPUTF8Char=**nil**): boolean;

- Decode a specified parameter compatible with URI encoding into its original floating-point value*
- UrlDecodeDouble('price=20.45&where=LastName%3D%27M%C3%B4net%27','PRICE=',P,@Next) will return Next^='where=...' and P=20.45
 - if Upper is not found, Value is not modified, and result is FALSE
 - if Upper is found, Value is modified with the supplied content, and result is TRUE

function UrlDecodeExtended(U: PUTF8Char; **const** Upper: RawUTF8; **var** Value: TSynExtended; Next: PPUTF8Char=**nil**): boolean;

- Decode a specified parameter compatible with URI encoding into its original floating-point value*
- - UrlDecodeExtended('price=20.45&where=LastName%3D%27M%C3%B4net%27','PRICE=',P,@Next) will return Next^='where=...' and P=20.45
 - if Upper is not found, Value is not modified, and result is FALSE
 - if Upper is found, Value is modified with the supplied content, and result is TRUE

function UrlDecodeInt64(U: PUTF8Char; **const** Upper: RawUTF8; **var** Value: Int64; Next: PPUTF8Char=**nil**): boolean;

- Decode a specified parameter compatible with URI encoding into its original Int64 numerical value*
- UrlDecodeInt64('offset=20&where=LastName%3D%27M%C3%B4net%27','OFFSET=',O,@Next) will return Next^='where=...' and O=20
 - if Upper is not found, Value is not modified, and result is FALSE
 - if Upper is found, Value is modified with the supplied content, and result is TRUE

function UrlDecodeInteger(U: PUTF8Char; **const** Upper: RawUTF8; **var** Value: integer; Next: PPUTF8Char=**nil**): boolean;

- Decode a specified parameter compatible with URI encoding into its original integer numerical value*
- UrlDecodeInteger('offset=20&where=LastName%3D%27M%C3%B4net%27','OFFSET=',O,@Next) will return Next^='where=...' and O=20
 - if Upper is not found, Value is not modified, and result is FALSE
 - if Upper is found, Value is modified with the supplied content, and result is TRUE

function UrlDecodeNeedParameters(U, CSVNames: PUTF8Char): boolean;

- Returns TRUE if all supplied parameters do exist in the URI encoded text*
- CSVNames parameter shall provide as a CSV list of names
 - e.g. UrlDecodeNeedParameters('price=20.45&where=LastName%3D','price,where') will return TRUE

function UrlDecodeNextName(U: PUTF8Char; **out** Name: RawUTF8): PUTF8Char;

- Decode a URI-encoded Name from an input buffer*
- decoded value is set in Name out variable
 - returns a pointer just after the decoded name, after the '='
 - returns nil if there was no name=... pattern in U

function UrlDecodeNextNameValue(U: PUTF8Char; **var** Name, Value: RawUTF8): PUTF8Char;

Decode the next Name=Value&.... pair from input URI

- Name is returned directly (should be plain ASCII 7 bit text)
- Value is returned after URI decoding (from %.. patterns)
- if a pair is decoded, return a PUTF8Char pointer to the next pair in the input buffer, or points to #0 if all content has been processed
- if a pair is not decoded, return nil

function UrlDecodeNextValue(U: PUTF8Char; **out** Value: RawUTF8): PUTF8Char;

Decode a URI-encoded Value from an input buffer

- decoded value is set in Value out variable
- returns a pointer just after the decoded value (may points e.g. to 0 or '&') - it is up to the caller to **continue** the process or not

function UrlDecodeValue(U: PUTF8Char; **const** Upper: RawUTF8; **var** Value: RawUTF8; Next: PPUTF8Char=nil): boolean;

Decode a specified parameter compatible with URI encoding into its original textual value

- UrlDecodeValue('select=%2A&where=LastName%3D%27M%C3%B4net%27','SELECT=',V,@Next) will return Next^='where=...' and V=''
- if Upper is not found, Value is not modified, and result is FALSE
- if Upper is found, Value is modified with the supplied content, and result is TRUE

function UrlEncode(**const** svar: RawUTF8): RawUTF8; overload;

Encode a string to be compatible with URI encoding

function UrlEncode(**const** NameValuePairs: **array of const**): RawUTF8; overload;

Encode supplied parameters to be compatible with URI encoding

- parameters must be supplied two by two, as Name, Value pairs, e.g.
`url := UrlEncode(['select', '*', 'where', 'ID=12', 'offset', 23, 'object', aObject]);`
- parameters names should be plain ASCII-7 RFC compatible identifiers (0..9a..zA..Z_~), otherwise their values are skipped
- parameters values can be either textual, integer or extended, or any TObject
- TObject serialization into UTF-8 will be processed by the ObjectToJSON() function

function UrlEncode(Text: PUTF8Char): RawUTF8; overload;

Encode a string to be compatible with URI encoding

function UrlEncodeJsonObject(**const** URName, ParametersJSON: RawUTF8; **const** PropNamesToIgnore: **array of** RawUTF8; IncludeQueryDelimiter: Boolean=true): RawUTF8; overload;

Encode a JSON object UTF-8 buffer into URI parameters

- you can specify property names to ignore during the object decoding
- you can omit the leading query delimiter ('?') by setting IncludeQueryDelimiter=false
- overloaded function which will make a copy of the input JSON before parsing

function UrlEncodeJsonObject(**const** URName: RawUTF8; ParametersJSON: PUTF8Char; **const** PropNamesToIgnore: **array of** RawUTF8; IncludeQueryDelimiter: Boolean=true): RawUTF8; overload;

Encode a JSON object UTF-8 buffer into URI parameters

- you can specify property names to ignore during the object decoding
- you can omit the leading query delimiter ('?') by setting IncludeQueryDelimiter=false
- warning: the ParametersJSON input buffer will be modified in-place

function UTF16CharToUtf8(Dest: PUTF8Char; var Source: PWord): integer;

UTF-8 encode one UTF-16 encoded UCS4 character into Dest

- return the number of bytes written into Dest (i.e. from 1 up to 6)
- Source will contain the next UTF-16 character
- this method DOES handle UTF-16 surrogate pairs

function Utf8DecodeToRawUnicode(const S: RawUTF8): RawUnicode; overload;

Convert a UTF-8 string into a RawUnicode string

function Utf8DecodeToRawUnicode(P: PUTF8Char; L: integer): RawUnicode; overload;

Convert a UTF-8 encoded buffer into a RawUnicode string

- if L is 0, L is computed from zero terminated P buffer
- RawUnicode is ended by a WideChar(#0)
- faster than System.UTF8Decode() which uses slow widestrings

function Utf8DecodeToRawUnicodeUI(const S: RawUTF8; DestLen: PInteger=nil): RawUnicode; overload;

Convert a UTF-8 string into a RawUnicode string

- this version doesn't resize the length of the result RawUnicode and is therefore useful before a Win32 Unicode API call (with nCount=-1)
- if DestLen is not nil, the resulting length (in bytes) will be stored within

function Utf8DecodeToRawUnicodeUI(const S: RawUTF8; var Dest: RawUnicode): integer; overload;

Convert a UTF-8 string into a RawUnicode string

- returns the resulting length (in bytes) will be stored within Dest

procedure UTF8DecodeToString(P: PUTF8Char; L: integer; var result: string); overload;

Convert any UTF-8 encoded buffer into a generic VCL Text

function UTF8DecodeToString(P: PUTF8Char; L: integer): string; overload;

Convert any UTF-8 encoded buffer into a generic VCL Text

- it's preferred to use TLanguageFile.UTF8ToString() in mORMoti18n, which will handle full i18n of your application
- it will work as is with Delphi 2009+ (direct unicode conversion)
- under older version of Delphi (no unicode), it will use the current RTL codepage, as with WideString conversion (but without slow WideString usage)

function Utf8FirstLineToUnicodeLength(source: PUTF8Char): PtrInt;

Calculate the UTF-16 Unicode characters count of the UTF-8 encoded first line

- count may not match the UCS4 glyphs number, in case of UTF-16 surrogates
- end the parsing at first #13 or #10 character

function UTF8IComp(u1, u2: PUTF8Char): PtrInt;

Fast UTF-8 comparison using the NormToUpper[] array for all 8 bits values

- this version expects u1 and u2 to be zero-terminated
- this version will decode each UTF-8 glyph before using NormToUpper[]
- current implementation handles UTF-16 surrogates

function UTF8ILComp(u1, u2: PUTF8Char; L1,L2: cardinal): PtrInt;

Fast UTF-8 comparison using the NormToUpper[] array for all 8 bits values

- this version expects u1 and u2 not to be necessary zero-terminated, but uses L1 and L2 as length for u1 and u2 respectively
- use this function for SQLite3 collation (TSQCollateFunc)
- this version will decode the UTF-8 content before using NormToUpper[]
- current implementation handles UTF-16 surrogates

function UTF8ToInt64(const text: RawUTF8; const default: Int64=0): Int64;

Get the signed 64-bit integer value stored in a RawUTF8 string

- returns the default value if the supplied text was not successfully converted into an Int64

function UTF8ToInteger(const value: RawUTF8; Default: PtrInt=0): PtrInt; overload;

Get the signed 32-bit integer value stored in a RawUTF8 string

- we use the PtrInt result type, even if expected to be 32-bit, to use native CPU register size (don't want any 32-bit overflow here)

function UTF8ToInteger(const value: RawUTF8; Min,max: PtrInt; Default: PtrInt=0): PtrInt; overload;

Get and check range of a signed 32-bit integer stored in a RawUTF8 string

- we use the PtrInt result type, even if expected to be 32-bit, to use native CPU register size (don't want any 32-bit overflow here)

procedure Utf8ToRawUTF8(P: PUTF8Char; var result: RawUTF8);

Direct conversion of a UTF-8 encoded zero terminated buffer into a RawUTF8 String

procedure UTF8ToShortString(var dest: shortstring; source: PUTF8Char);

Direct conversion of a UTF-8 encoded buffer into a WinAnsi shortstring buffer

function UTF8ToString(const Text: RawUTF8): string;

Convert any UTF-8 encoded String into a generic VCL Text

- it's preferred to use TLanguageFile.UTF8ToString() in mORMoti18n, which will handle full i18n of your application
- it will work as is with Delphi 2009+ (direct unicode conversion)
- under older version of Delphi (no unicode), it will use the current RTL codepage, as with WideString conversion (but without slow WideString usage)

procedure UTF8ToSynUnicode(Text: PUTF8Char; Len: PtrInt; var result: SynUnicode); overload;

Convert any UTF-8 encoded buffer into a generic SynUnicode Text

function UTF8ToSynUnicode(const Text: RawUTF8): SynUnicode; overload;

Convert any UTF-8 encoded String into a generic SynUnicode Text

procedure UTF8ToSynUnicode(const Text: RawUTF8; var result: SynUnicode); overload;

Convert any UTF-8 encoded String into a generic SynUnicode Text

function Utf8ToUnicodeLength(source: PUTF8Char): PtrUInt;

Calculate the UTF-16 Unicode characters count, UTF-8 encoded in source^

- count may not match the UCS4 glyphs number, in case of UTF-16 surrogates
- faster than System.UTF8ToUnicode with dest=nil

function UTF8ToWideChar(dest: PWideChar; source: PUTF8Char; MaxDestChars, sourceBytes: PtrInt; NoTrailingZero: boolean=false): PtrInt; overload;

Convert an UTF-8 encoded text into a WideChar (UTF-16) buffer

- faster than System.UTF8ToUnicode
- this overloaded function expect a MaxDestChars parameter
- sourceBytes can not be 0 for this function
- enough place must be available in dest buffer (guess is sourceBytes*3+2)
- a WideChar(#0) is added at the end (if something is written) unless NoTrailingZero is TRUE
- returns the BYTE COUNT (not WideChar count) written in dest, excluding the ending WideChar(#0)

function UTF8ToWideChar(dest: PWideChar; source: PUTF8Char; sourceBytes: PtrInt=0; NoTrailingZero: boolean=false): PtrInt; overload;

Convert an UTF-8 encoded text into a WideChar (UTF-16) buffer

- faster than System.UTF8ToUnicode
- sourceBytes can be 0, therefore length is computed from zero terminated source
- enough place must be available in dest buffer (guess is sourceBytes*3+2)
- a WideChar(#0) is added at the end (if something is written) unless NoTrailingZero is TRUE
- returns the BYTE count written in dest, excluding the ending WideChar(#0)

function UTF8ToWideString(const Text: RawUTF8): WideString; overload;

Convert any UTF-8 encoded String into a generic WideString Text

procedure UTF8ToWideString(const Text: RawUTF8; var result: WideString); overload;

Convert any UTF-8 encoded String into a generic WideString Text

procedure UTF8ToWideString(Text: PUTF8Char; Len: PtrInt; var result: WideString); overload;

Convert any UTF-8 encoded String into a generic WideString Text

function Utf8ToWinAnsi(P: PUTF8Char): WinAnsiString; overload;

Direct conversion of a UTF-8 encoded zero terminated buffer into a WinAnsi String

function Utf8ToWinAnsi(const S: RawUTF8): WinAnsiString; overload;

Direct conversion of a UTF-8 encoded string into a WinAnsi String

function UTF8ToWinPChar(dest: PAnsiChar; source: PUTF8Char; count: integer): integer;

Direct conversion of a UTF-8 encoded buffer into a WinAnsi PAnsiChar buffer

function Utf8TruncatedLength(const text: RawUTF8; maxBytes: PtrUInt): PtrInt; overload;

Compute the truncated length of the supplied UTF-8 value if it exceeds the specified bytes count

- this function will ensure that the returned content will contain only valid UTF-8 sequence, i.e. will trim the whole trailing UTF-8 sequence
- returns maxUTF8 if text was not truncated, or the number of fitting bytes

function Utf8TruncatedLength(text: PAnsiChar; textlen, maxBytes: PtrUInt): PtrInt; overload;

Compute the truncated length of the supplied UTF-8 value if it exceeds the specified bytes count

- this function will ensure that the returned content will contain only valid UTF-8 sequence, i.e. will trim the whole trailing UTF-8 sequence
- returns maxUTF8 if text was not truncated, or the number of fitting bytes

function Utf8TruncateToLength(**var** text: RawUTF8; maxBytes: PtrUInt): boolean;

Will truncate the supplied UTF-8 value if its length exceeds the specified bytes count

- this function will ensure that the returned content will contain only valid UTF-8 sequence, i.e. will trim the whole trailing UTF-8 sequence
- returns FALSE if text was not truncated, TRUE otherwise

function Utf8TruncateToUnicodeLength(**var** text: RawUTF8; maxUtf16: integer): boolean;

Will truncate the supplied UTF-8 value if its length exceeds the specified UTF-16 Unicode characters count

- count may not match the UCS4 glyphs number, in case of UTF-16 surrogates
- returns FALSE if text was not truncated, TRUE otherwise

function UTF8UpperCopy(Dest, Source: PUTF8Char; SourceChars: Cardinal): PUTF8Char;

Copy WideChar source into dest^ with upper case conversion, using the NormToUpper[] array for all 8 bits values, encoding the result as UTF-8

- returns final dest pointer
- current implementation handles UTF-16 surrogates

function UTF8UpperCopy255(dest: PAnsiChar; **const** source: RawUTF8): PUTF8Char;

Copy WideChar source into dest^ with upper case conversion, using the NormToUpper[] array for all 8 bits values, encoding the result as UTF-8

- returns final dest pointer
- will copy up to 255 AnsiChar (expect the dest buffer to be array[byte] of AnsiChar), with UTF-8 encoding

function ValuesToVariantDynArray(**const** items: **array of const**): TVariantDynArray;

Convert an open array list into a dynamic array of variants

- will use a TDocVariantData temporary storage

function VarDataIsEmptyOrNull(VarData: pointer): Boolean;

Same as VarIsEmpty(PVariant(V)^) or VarIsEmpty(PVariant(V)^), but faster

- we also discovered some issues with FPC's Variants unit, so this function may be used even in end-user cross-compiler code

function VariantCompare(**const** V1,V2: **variant**): PtrInt;

TVariantCompare-compatible case-sensitive comparison function

- just a wrapper around SortDynArrayVariantComp(caseInsensitive=false)

function VariantCompareI(**const** V1,V2: **variant**): PtrInt;

TVariantCompare-compatible case-insensitive comparison function

- just a wrapper around SortDynArrayVariantComp(caseInsensitive=true)

procedure VariantDynArrayClear(**var** Value: TVariantDynArray);

Faster alternative to Finalize(aVariantDynArray)

- this function will take account and optimize the release of a dynamic array of custom variant types values
- for instance, an array of TDocVariant will be optimized for speed

function VariantDynArrayToJSON(**const** V: TVariantDynArray): RawUTF8;

Convert a dynamic array of variants into its JSON serialization

- will use a TDocVariantData temporary storage

```
function VariantEquals(const V: Variant; const Str: RawUTF8; CaseSensitive: boolean=true): boolean; overload;
```

Fast comparison of a Variant and UTF-8 encoded String (or number)

- slightly faster than plain V=Str, which computes a temporary variant
- here Str="" equals unassigned, null or false
- if CaseSensitive is false, will use IdemPropNameU() for comparison

```
function VariantHash(const value: variant; CaseInsensitive: boolean; Hasher: THasher=nil): cardinal;
```

Crc32c-based hash of a variant value

- complex string types will make up to 255 uppercase characters conversion if CaseInsensitive is true
- you can specify your own hashing function if crc32c is not what you expect

```
function VariantHexDisplayToBin(const Hex: variant; Bin: PByte; BinBytes: integer): boolean;
```

Fast conversion from hexa chars, supplied as a variant string, into a binary buffer

```
function VariantLoad(var Value: variant; Source: PAnsiChar; CustomVariantOptions: PDocVariantOptions; SourceMax: PAnsiChar=nil): PAnsiChar; overload;
```

Retrieve a variant value from our optimized binary serialization format

- follow the data layout as used by RecordLoad() or VariantSave() function
- return nil if the Source buffer is incorrect
- in case of success, return the memory buffer pointer just after the read content
- how custom type variants are created can be defined via CustomVariantOptions

```
function VariantLoad(const Bin: RawByteString; CustomVariantOptions: PDocVariantOptions): variant; overload;
```

Retrieve a variant value from our optimized binary serialization format

- follow the data layout as used by RecordLoad() or VariantSave() function
- return varEmpty if the Source buffer is incorrect
- just a wrapper around VariantLoad()
- how custom type variants are created can be defined via CustomVariantOptions

```
function VariantLoadJSON(const JSON: RawUTF8; TryCustomVariants: PDocVariantOptions=nil; AllowDouble: boolean=false): variant; overload;
```

Retrieve a variant value from a JSON number or string

- follows TTextWriter.AddVariant() format (calls GetVariantFromJSON)
- will instantiate either an Integer, Int64, currency, double or string value (as RawUTF8), guessing the best numeric type according to the textual content, and string in all other cases, except TryCustomVariants points to some options (e.g. @JSON_OPTIONS[true] for fast instance) and input is a known object or array, either encoded as strict-JSON (i.e. {...} or [...]), or with some extended (e.g. BSON) syntax
- this overloaded procedure will make a temporary copy before JSON parsing and return the variant as result

```
function VariantLoadJSON(var Value: variant; JSON: PUTF8Char; EndOfObject:
PUTF8Char=nil; TryCustomVariants: PDocVariantOptions=nil; AllowDouble:
boolean=false): PUTF8Char; overload;
```

Retrieve a variant value from a JSON number or string

- follows TTextWriter.AddVariant() format (calls GetVariantFromJSON)
- will instantiate either an Integer, Int64, currency, double or string value (as RawUTF8), guessing the best numeric type according to the textual content, and string in all other cases, except TryCustomVariants points to some options (e.g. @JSON_OPTIONS[true] for fast instance) and input is a known object or array, either encoded as strict-JSON (i.e. {...} or [...]), or with some extended (e.g. BSON) syntax
- warning: the JSON buffer will be modified in-place during process - use a temporary copy or the overloaded functions with RawUTF8 parameter if you need to access it later

```
procedure VariantLoadJSON(var Value: Variant; const JSON: RawUTF8; TryCustomVariants:
PDocVariantOptions=nil; AllowDouble: boolean=false); overload;
```

Retrieve a variant value from a JSON number or string

- follows TTextWriter.AddVariant() format (calls GetVariantFromJSON)
- will instantiate either an Integer, Int64, currency, double or string value (as RawUTF8), guessing the best numeric type according to the textual content, and string in all other cases, except TryCustomVariants points to some options (e.g. @JSON_OPTIONS[true] for fast instance) and input is a known object or array, either encoded as strict-JSON (i.e. {...} or [...]), or with some extended (e.g. BSON) syntax
- this overloaded procedure will make a temporary copy before JSON parsing and return the variant as result

```
function VariantSave(const Value: variant): RawByteString; overload;
```

Save a Variant content into a binary buffer

- will handle standard Variant types and custom types (serialized as JSON)
- will return "" in case of an invalid (not handled) Variant type
- just a wrapper around VariantSaveLength()+VariantSave()
- warning: will encode generic string fields as within the variant type itself: using this function between UNICODE and NOT UNICODE versions of Delphi, will probably fail - you have been warned!

```
function VariantSave(const Value: variant; Dest: PAnsiChar): PAnsiChar; overload;
```

Save a Variant content into a destination memory buffer

- Dest must be at least VariantSaveLength() bytes long
- will handle standard Variant types and custom types (serialized as JSON)
- will return nil in case of an invalid (not handled) Variant type
- will use a proprietary binary format, with some variable-length encoding of the string length
- warning: will encode generic string fields as within the variant type itself: using this function between UNICODE and NOT UNICODE versions of Delphi, will probably fail - you have been warned!

```
procedure VariantSaveJSON(const Value: variant; Escape: TTextWriterKind; var result: RawUTF8); overload;
```

Save a variant value into a JSON content

- follows the TTextWriter.AddVariant() and VariantLoadJSON() format
- is able to handle simple and custom variant types, for instance:

```
VariantSaveJSON(1.5)='1.5'
VariantSaveJSON('test')='"test"'
o := _Json('{BSON: [ "test", 5.05, 1986 ] }');
VariantSaveJSON(o)='{ "BSON": [ "test", 5.05, 1986 ] }'
o := _Obj([ 'name', 'John', 'doc', _Obj([ 'one', 1, 'two', _Arr([ 'one', 2 ]) ]) ]);
VariantSaveJSON(o)='{ "name": "John", "doc": { "one": 1, "two": [ "one", 2 ] } }'
```

- note that before Delphi 2009, any varString value is expected to be a RawUTF8 instance - which does make sense in the mORMot area

```
function VariantSaveJSON(const Value: variant; Escape: TTextWriterKind=twJSONEscape): RawUTF8; overload;
```

Save a variant value into a JSON content

- follows the TTextWriter.AddVariant() and VariantLoadJSON() format
- is able to handle simple and custom variant types, for instance:

```
VariantSaveJSON(1.5)='1.5'
VariantSaveJSON('test')='"test"'
o := _Json('{ BSON: [ "test", 5.05, 1986 ] }');
VariantSaveJSON(o)='{ "BSON": [ "test", 5.05, 1986 ] }'
o := _Obj([ 'name', 'John', 'doc', _Obj([ 'one', 1, 'two', _Arr([ 'one', 2 ]) ]) ]);
VariantSaveJSON(o)='{ "name": "John", "doc": { "one": 1, "two": [ "one", 2 ] } }'
```

- note that before Delphi 2009, any varString value is expected to be a RawUTF8 instance - which does make sense in the mORMot area

```
function VariantSaveJSONLength(const Value: variant; Escape: TTextWriterKind=twJSONEscape): integer;
```

Compute the number of chars needed to save a variant value into a JSON content

- follows the TTextWriter.AddVariant() and VariantLoadJSON() format
- this will be much faster than length(VariantSaveJSON()) for huge content
- note that before Delphi 2009, any varString value is expected to be a RawUTF8 instance - which does make sense in the mORMot area

```
function VariantSaveLength(const Value: variant): integer;
```

Compute the number of bytes needed to save a Variant content using the VariantSave() function

- will return 0 in case of an invalid (not handled) Variant type

```
function VariantToBoolean(const V: Variant; var Value: Boolean): boolean;
```

Convert any numerical Variant into a boolean value

- text content will return true after case-insensitive 'true' comparison

```
function VariantToCurrency(const V: Variant; var Value: currency): boolean;
```

Convert any numerical Variant into a fixed decimals floating point value

```
function VariantToDateTime(const V: Variant; var Value: TDateTime): boolean;
```

Convert any date/time Variant into a TDateTime value

- would handle varDate kind of variant, or use a string conversion and ISO-8601 parsing if possible

```
function VariantToDouble(const V: Variant; var Value: double): boolean;
```

Convert any numerical Variant into a floating point value

function VariantToDoubleDef(**const** V: **Variant**; **const** default: double=0): double;
Convert any numerical Variant into a floating point value

procedure VariantToInlineValue(**const** V: **Variant**; **var** result: RawUTF8);
*Convert any Variant into a value encoded as with :(...) inlined parameters in
 FormatUTF8(Format,Args,Params)*

function VariantToInt64(**const** V: **Variant**; **var** Value: Int64): boolean;
Convert any numerical Variant into a 64-bit integer
 - it will expect true numerical Variant and won't convert any string nor floating-pointer Variant,
 which will return FALSE and won't change the Value variable content

function VariantToInt64Def(**const** V: **Variant**; DefaultValue: Int64): Int64;
Convert any numerical Variant into a 64-bit integer
 - it will expect true numerical Variant and won't convert any string nor floating-pointer Variant,
 which will return the supplied DefaultValue

function VariantToInteger(**const** V: **Variant**; **var** Value: integer): boolean;
Convert any numerical Variant into a 32-bit integer
 - it will expect true numerical Variant and won't convert any string nor floating-pointer Variant,
 which will return FALSE and won't change the Value variable content

function VariantToIntegerDef(**const** V: **Variant**; DefaultValue: integer): integer;
 overload;
Convert any numerical Variant into an integer
 - it will expect true numerical Variant and won't convert any string nor floating-pointer Variant,
 which will return the supplied DefaultValue

procedure VariantToRawByteString(**const** Value: **variant**; **var** Dest: RawByteString);
Convert back a RawByteString from a variant
 - the supplied variant should have been created via a RawByteStringToVariant() function call

function VariantToString(**const** V: **Variant**): string;
Convert any Variant into a VCL string type
 - expects any varString value to be stored as a RawUTF8
 - prior to Delphi 2009, use VariantToString(aVariant) instead of string(aVariant) to safely retrieve a
 string=AnsiString value from a variant generated by our framework units - otherwise, you may
 loose encoded characters
 - for Unicode versions of Delphi, there won't be any potential data loss, but this version may be
 slightly faster than a string(aVariant)

function VariantToUTF8(**const** V: **Variant**): RawUTF8; overload;
Convert any Variant into UTF-8 encoded String
 - use VariantSaveJSON() instead if you need a conversion to JSON with custom parameters
 - note: null will be returned as 'null'

procedure VariantToUTF8(**const** V: **Variant**; **var** result: RawUTF8; **var** wasString:
 boolean); overload;
Convert any Variant into UTF-8 encoded String
 - use VariantSaveJSON() instead if you need a conversion to JSON with custom parameters
 - wasString is set if the V value was a text
 - empty and null variants will be stored as 'null' text - as expected by JSON
 - custom variant types (e.g. TDocVariant) will be stored as JSON

function VariantToUTF8(**const** V: **Variant**; **var** Text: RawUTF8): boolean; overload;

Convert any Variant into UTF-8 encoded String

- use VariantSaveJSON() instead if you need a conversion to JSON with custom parameters
- returns TRUE if the V value was a text, FALSE if was not (e.g. a number)
- empty and null variants will be stored as 'null' text - as expected by JSON
- custom variant types (e.g. TDocVariant) will be stored as JSON

function VariantToVariantUTF8(**const** V: **Variant**): **variant**;

Convert any Variant into another Variant storing an RawUTF8 of the value

- e.g. VariantToVariantUTF8('toto')='toto' and VariantToVariantUTF8(12)='12'

procedure VariantToVarRec(**const** V: **variant**; **var** result: TVarRec);

Convert a variant to an open array (const Args: array of const) argument

- will always map to a vtVariant kind of argument

function VarIs(**const** V: **Variant**; **const** VTypes: TVarDataTypes): Boolean;

Allow to check for a specific set of TVarData.VType

function VarIsEmptyOrNull(**const** V: **Variant**): Boolean;

Same as VarIsEmpty(V) or VarIsNull(V), but faster

- we also discovered some issues with FPC's Variants unit, so this function may be used even in end-user cross-compiler code

function VarIsVoid(**const** V: **Variant**): boolean;

Fastcheck if a variant hold a value

- varEmpty, varNull or a "" string would be considered as void
- varBoolean=false or varDate=0 would be considered as void
- a TDocVariantData with Count=0 would be considered as void
- any other value (e.g. integer) would be considered as not void

function VarRecAsChar(**const** V: TVarRec): integer;

Get an open array (const Args: array of const) character argument

- only handle varChar and varWideChar kind of arguments

function VarRecToDouble(**const** V: TVarRec; **out** value: double): boolean;

Convert an open array (const Args: array of const) argument to a floating point value

- returns TRUE and set Value if the supplied argument is a number (e.g. vtInteger, vtInt64, vtCurrency or vtExtended)
- returns FALSE if the argument is not a number
- note that, due to a Delphi compiler limitation, cardinal values should be type-casted to Int64() (otherwise the integer mapped value will be converted)

procedure VarRecToInlineValue(**const** V: TVarRec; **var** result: RawUTF8);

Convert an open array (const Args: array of const) argument to a value encoded as with :(...): inlined parameters in FormatUTF8(Format,Args,Params)

- note that, due to a Delphi compiler limitation, cardinal values should be type-casted to Int64() (otherwise the integer mapped value will be converted)
- any supplied TObjet instance will be written as their class name

function VarRecToInt64(**const** V: TVarRec; **out** value: Int64): boolean;

Convert an open array (const Args: array of const) argument to an Int64

- returns TRUE and set Value if the supplied argument is a vtInteger, vtInt64 or vtBoolean
- returns FALSE if the argument is not an integer
- note that, due to a Delphi compiler limitation, cardinal values should be type-casted to Int64() (otherwise the integer mapped value will be converted)

function VarRecToTempUTF8(**const** V: TVarRec; **var** Res: TTempUTF8): integer;

Convert an open array (const Args: array of const) argument to an UTF-8 encoded text, using a specified temporary buffer

- this function would allocate a RawUTF8 in TempRawUTF8 only if needed, but use the supplied Res.Temp[] buffer for numbers to text conversion - caller should ensure to make RawUTF8(TempRawUTF8) := '' on the entry
- it would return the number of UTF-8 bytes, i.e. Res.Len
- note that, due to a Delphi compiler limitation, cardinal values should be type-casted to Int64() (otherwise the integer mapped value will be converted)
- any supplied TObject instance will be written as their class name

procedure VarRecToUTF8(**const** V: TVarRec; **var** result: RawUTF8; wasString: PBoolean=nil);

Convert an open array (const Args: array of const) argument to an UTF-8 encoded text

- note that, due to a Delphi compiler limitation, cardinal values should be type-casted to Int64() (otherwise the integer mapped value will be converted)
- any supplied TObject instance will be written as their class name

function VarRecToUTF8IsString(**const** V: TVarRec; **var** value: RawUTF8): boolean;

Convert an open array (const Args: array of const) argument to an UTF-8 encoded text, returning FALSE if the argument was not a string value

function VarRecToVariant(**const** V: TVarRec): variant; overload;

Convert an open array (const Args: array of const) argument to a variant

- note that, due to a Delphi compiler limitation, cardinal values should be type-casted to Int64() (otherwise the integer mapped value will be converted)

procedure VarRecToVariant(**const** V: TVarRec; **var** result: variant); overload;

Convert an open array (const Args: array of const) argument to a variant

- note that, due to a Delphi compiler limitation, cardinal values should be type-casted to Int64() (otherwise the integer mapped value will be converted)

function VarStringOrNull(**const** v: RawUTF8): variant;

Returns a supplied string as variant, or null if v is void ('')

function WideCharToUtf8(Dest: PUTF8Char; aWideChar: PtrUInt): integer;

UTF-8 encode one UTF-16 character into Dest

- return the number of bytes written into Dest (i.e. 1,2 or 3)
- this method does NOT handle UTF-16 surrogate pairs

function WideCharToWinAnsi(wc: cardinal): integer;

Conversion of a wide char into a WinAnsi (CodePage 1252) char index

- return -1 for an unknown WideChar in code page 1252

function WideCharToWinAnsiChar(wc: cardinal): AnsiChar;

Conversion of a wide char into a WinAnsi (CodePage 1252) char
 - return '?' for an unknown WideChar in code page 1252

function WideStringToUTF8(const aText: WideString): RawUTF8;

Convert a WideString into a UTF-8 string

function WideStringToWinAnsi(const Wide: WideString): WinAnsiString;

Convert a WideString into a WinAnsi (code page 1252) string

function WinAnsiBufferToUtf8(Dest: PUTF8Char; Source: PAnsiChar; SourceChars: Cardinal): PUTF8Char;

Direct conversion of a WinAnsi PAnsiChar buffer into a UTF-8 encoded buffer
 - Dest^ buffer must be reserved with at least SourceChars*3
 - call internally WinAnsiConvert fast conversion class

function WinAnsiToRawUnicode(const S: WinAnsiString): RawUnicode;

Direct conversion of a WinAnsi (CodePage 1252) string into a Unicode encoded String
 - very fast, by using a fixed pre-calculated array for individual chars conversion

procedure WinAnsiToUnicodeBuffer(const S: WinAnsiString; Dest: PWordArray; DestLen: PtrInt);

Direct conversion of a WinAnsi (CodePage 1252) string into a Unicode buffer
 - very fast, by using a fixed pre-calculated array for individual chars conversion
 - text will be truncated if necessary to avoid buffer overflow in Dest[]

function WinAnsiToUtf8(WinAnsi: PAnsiChar; WinAnsiLen: PtrInt): RawUTF8; overload;

Direct conversion of a WinAnsi (CodePage 1252) string into a UTF-8 encoded String
 - faster than SysUtils: don't use Utf8Encode(WideString) -> no Windows.Global(), and use a fixed pre-calculated array for individual chars conversion

function WinAnsiToUtf8(const S: WinAnsiString): RawUTF8; overload;

Direct conversion of a WinAnsi (CodePage 1252) string into a UTF-8 encoded String
 - faster than SysUtils: don't use Utf8Encode(WideString) -> no Windows.Global(), and use a fixed pre-calculated array for individual chars conversion

function WordScanIndex(P: PWordArray; Count: PtrInt; Value: word): PtrInt;

Fast search of an unsigned Word value position in a Word array
 - Count is the number of Word entries in P^
 - return index of P^[index]=Value
 - return -1 if Value was not found

function WriteStringToStream(S: TStream; const Text: RawUTF8): boolean;

Write an UTF-8 text into a TStream
 - format is Length(Integer):Text, i.e. the one used by ReadStringFromStream

procedure XorMemory(Dest, Source: PByteArray; size: PtrInt); overload;

Logical XOR of two memory buffers
 - will perform on all buffer bytes:
 Dest[i] := Dest[i] xor Source[i];

procedure XorMemory(Dest,Source1,Source2: PByteArray; size: PtrInt); overload;

Logical XOR of two memory buffers into a third

- will perform on all buffer bytes:

Dest[i] := Source1[i] xor Source2[i];

function xxHash32(crc: cardinal; P: PAnsiChar; len: integer): cardinal;

Perform very fast xxHash hashing in 32-bit mode

- will use optimized asm for x86/x64, or a pascal version on other CPUs

procedure YearToPChar(Y: PtrUInt; P: PUTF8Char);

Add the 4 digits of integer Y to P^ as '0000'..'9999'

procedure ZeroFill(Value: PVarData);

Same as FillChar(Value^,SizeOf(TVarData),0)

- so can be used for TVarData or Variant

- it will set V.VType := varEmpty, so Value will be Unassigned

- it won't call VarClear(variant(Value)): it should have been cleaned before

function _Arr(const Items: array of const; Options: TDocVariantOptions=[]): variant;

Initialize a variant instance to store some document-based array content

- array will be initialized with data supplied as parameters, e.g.

aVariant := _Arr(['one',2,3.0]);

- this global function is an alias to TDocVariant.NewArray()

- by default, every internal value will be copied, so access of nested properties can be slow - if you expect the data to be read-only or not propagated into another place, set

Options=[dvoValueCopiedByReference] or using _ArrFast() will increase the process speed a lot

function _ArrFast(const Items: array of const): variant; overload;

Initialize a variant instance to store some document-based array content

- this global function is a handy alias to:

_Array(Items,JSON_OPTIONS[true]);

- so all created objects and arrays will be handled by reference, for best speed - but you should better write on the resulting variant tree with caution

function _ByRef(const DocVariant: variant; Options: TDocVariantOptions): variant;
overload;

Copy a TDocVariant to another variable, changing the options on the fly

- note that the content (items or properties) is copied by reference, so consider using _Copy()

instead if you expect to safely modify its content

- will return null if the supplied variant is not a TDocVariant

procedure _ByRef(const DocVariant: variant; out Dest: variant; Options:
TDocVariantOptions); overload;

Copy a TDocVariant to another variable, changing the options on the fly

- note that the content (items or properties) is copied by reference, so consider using _Copy()

instead if you expect to safely modify its content

- will return null if the supplied variant is not a TDocVariant

function _Copy(const DocVariant: variant): variant;

Return a full nested copy of a document-based variant instance

- is just a wrapper around:

`TDocVariant.NewUnique(DocVariant, JSON_OPTIONS[false])`

- you can use this function to ensure that all internal properties of this variant will be copied per-value whatever options the nested objects or arrays were created with: to be used on a value returned as `varByRef` (e.g. by `_()` pseudo-method)
- for huge document with a big depth of nested objects or arrays, a full per-value copy may be time and resource consuming, but will be also safe - consider using `_ByRef()` instead if a fast copy-by-reference is enough
- will raise an `EDocVariant` if the supplied variant is not a `TDocVariant` or a `varByRef` pointing to a `TDocVariant`

function _CopyFast(const DocVariant: variant): variant;

Return a full nested copy of a document-based variant instance

- is just a wrapper around:

`TDocVariant.NewUnique(DocVariant, JSON_OPTIONS[true])`

- you can use this function to ensure that all internal properties of this variant will be copied per-value whatever options the nested objects or arrays were created with: to be used on a value returned as `varByRef` (e.g. by `_()` pseudo-method)
- for huge document with a big depth of nested objects or arrays, a full per-value copy may be time and resource consuming, but will be also safe - consider using `_ByRef()` instead if a fast copy-by-reference is enough
- will raise an `EDocVariant` if the supplied variant is not a `TDocVariant` or a `varByRef` pointing to a `TDocVariant`

function _CSV(const DocVariantOrString: variant): RawUTF8;

Convert a TDocVariantData array or a string value into a CSV

- will call either `TDocVariantData.ToCSV`, or return the string
- returns "" if the supplied value is neither a `TDocVariant` or a string
- could be used e.g. to store either a JSON CSV string or a JSON array of strings in a settings property

```
function _Json(const JSON: RawUTF8; Options:
TDocVariantOptions=[dvoReturnNullForUnknownProperty]): variant; overload;
```

Initialize a variant instance to store some document-based content from a supplied (extended) JSON content

- this global function is an alias to TDocVariant.NewJSON(), and will return an Unassigned variant if JSON content was not correctly converted

- warning: exclude dvoAllowDoubleValue so won't parse any float, just currency

- object or array will be initialized from the supplied JSON content, e.g.

```
aVariant := _Json('{"id":10,"doc":{"name":"John","birthyear":1972}}');
```

```
// now you can access to the properties via late binding
```

```
assert(aVariant.id=10);
```

```
assert(aVariant.doc.name='John');
```

```
assert(aVariant.doc.birthYear=1972);
```

```
// and also some pseudo-properties:
```

```
assert(aVariant._count=2);
```

```
assert(aVariant.doc._kind=ord(dvObject));
```

```
// or with a JSON array:
```

```
aVariant := _Json('["one",2,3]');
```

```
assert(aVariant._kind=ord(dvArray));
```

```
for i := 0 to aVariant._count-1 do
```

```
  writeln(aVariant._(i));
```

- in addition to the JSON RFC specification strict mode, this method will handle some BSON-like extensions, e.g. unquoted field names:

```
aVariant := _Json('{id:10,doc:{name:"John",birthyear:1972}}');
```

- if the SynMongoDB unit is used in the application, the MongoDB Shell syntax will also be recognized to create TBSONVariant, like

```
new Date() ObjectId() MinKey MaxKey /<jRegex>/<jOptions>
```

see @<http://docs.mongodb.org/manual/reference/mongodb-extended-json>

- by default, every internal value will be copied, so access of nested properties can be slow - if you expect the data to be read-only or not propagated into another place, add

dvoValueCopiedByReference in Options will increase the process speed a lot, or use _JsonFast()

```
function _Json(const JSON: RawUTF8; var Value: variant; Options:
TDocVariantOptions=[dvoReturnNullForUnknownProperty]): boolean; overload;
```

Initialize a variant instance to store some document-based content from a supplied (extended) JSON content

- this global function is an alias to TDocVariant.NewJSON(), and will return TRUE if JSON content was correctly converted into a variant

- warning: exclude dvoAllowDoubleValue so won't parse any float, just currency

- in addition to the JSON RFC specification strict mode, this method will handle some BSON-like extensions, e.g. unquoted field names or ObjectId()

- by default, every internal value will be copied, so access of nested properties can be slow - if you expect the data to be read-only or not propagated into another place, add

dvoValueCopiedByReference in Options will increase the process speed a lot, or use _JsonFast()

function _JsonFast(const JSON: RawUTF8): variant;

Initialize a variant instance to store some document-based content from a supplied (extended) JSON content

- warning: exclude dvoAllowDoubleValue so won't parse any float, just currency
- this global function is an handy alias to:
`_Json(JSON,JSON_OPTIONS[true]); or _Json(JSON,JSON_OPTIONS_FAST)`

so it will return an Unassigned variant if JSON content was not correct

- so all created objects and arrays will be handled by reference, for best speed - but you should better write on the resulting variant tree with caution
- in addition to the JSON RFC specification strict mode, this method will handle some BSON-like extensions, e.g. unquoted field names or ObjectID()

function _JsonFastExt(const JSON: RawUTF8): variant;

Initialize a variant instance to store some extended document-based content

- this global function is an handy alias to:
`_Json(JSON,JSON_OPTIONS_FAST_EXTENDED);`

function _JsonFastFloat(const JSON: RawUTF8): variant;

Initialize a variant instance to store some document-based content from a supplied (extended) JSON content, parsing any kind of float

- use JSON_OPTIONS_FAST_FLOAT including the dvoAllowDoubleValue option

function _JsonFastFmt(const Format: RawUTF8; const Args,Params: array of const): variant;

Initialize a variant instance to store some document-based content from a supplied (extended) JSON content, with parameters forming

- warning: exclude dvoAllowDoubleValue so won't parse any float, just currency
- this global function is an handy alias e.g. to:
`aVariant := _JSONFmt('{%:{$in:[?,?]}'}',['type'],['food','snack'],JSON_OPTIONS[true]);`
- so all created objects and arrays will be handled by reference, for best speed - but you should better write on the resulting variant tree with caution
- in addition to the JSON RFC specification strict mode, this method will handle some BSON-like extensions, e.g. unquoted field names or ObjectID():

procedure _JsonFmt(const Format: RawUTF8; const Args,Params: array of const; Options: TDocVariantOptions; out result: variant); overload;

Initialize a variant instance to store some document-based content from a supplied (extended) JSON content, with parameters forming

- this overload function will set directly a local variant variable, and would be used by inlined `_JsonFmt/_JsonFastFmt` functions

function _JsonFmt(const Format: RawUTF8; const Args,Params: array of const; Options: TDocVariantOptions=[dvoReturnNullForUnknownProperty]): variant; overload;

Initialize a variant instance to store some document-based content from a supplied (extended) JSON content, with parameters forming

- wrapper around the _Json(FormatUTF8(...,JSONFormat=true)) function, i.e. every Args[] will be inserted for each % and Params[] for each ?, with proper JSON escaping of string values, and writing nested _Obj() /

- warning: exclude dvoAllowDoubleValue so won't parse any float, just currency _Arr() instances as expected JSON objects / arrays

- typical use (in the context of SynMongoDB unit) could be:

```
aVariant := _JSONFmt('{%:{$in:[?,?]}'},['type'],['food','snack']);
aVariant := _JSONFmt('{type:{$in:[]}}',[],[_Arr(['food','snack'])]);
// which are the same as:
aVariant := _JSONFmt('{type:{$in:["food","snack"]}}');
// in this context:
u := VariantSaveJSON(aVariant);
assert(u='{ "type":{ "$in":["food","snack"] } }');
u := VariantSaveMongoJSON(aVariant,modMongoShell);
assert(u='{type:{$in:["food","snack"]}}');
```

- by default, every internal value will be copied, so access of nested properties can be slow - if you expect the data to be read-only or not propagated into another place, add dvoValueCopiedByReference in Options will increase the process speed a lot, or use _JsonFast()

function _Obj(const NameValuePairs: array of const; Options: TDocVariantOptions=[]): variant;

Initialize a variant instance to store some document-based object content

- object will be initialized with data supplied two by two, as Name,Value pairs, e.g.

```
aVariant := _Obj(['name','John','year',1972]);
```

or even with nested objects:

```
aVariant := _Obj(['name','John','doc',_Obj(['one',1,'two',2.0])]);
```

- this global function is an alias to TDocVariant.NewObject()

- by default, every internal value will be copied, so access of nested properties can be slow - if you expect the data to be read-only or not propagated into another place, set

Options=[dvoValueCopiedByReference] or using _ObjFast() will increase the process speed a lot

procedure _ObjAddProps(const Document: variant; var Obj: variant); overload;

Add the property values of a document to a document-based object content

- if Document is not a TDocVariant object, will do nothing

- if Obj is a TDocVariant object, will add Document fields to its content

- if Obj is not a TDocVariant object, Document will be copied to Obj

procedure _ObjAddProps(const NameValuePairs: array of const; var Obj: variant); overload;

Add some property values to a document-based object content

- if Obj is a TDocVariant object, will add the Name/Value pairs

- if Obj is not a TDocVariant, will create a new fast document, initialized with supplied the Name/Value pairs

- this function will also ensure that ensure Obj is not stored by reference, but as a true TDocVariantData

```
function _ObjFast(aObject: TObject; aOptions:
TTextWriterWriteObjectOptions=[woDontStoreDefault]): variant; overload;
```

Initialize a variant instance to store any object as a TDocVariant
 - is a wrapper around _JsonFast(ObjectToJson(aObject,aOptions))

```
function _ObjFast(const NameValuePairs: array of const): variant; overload;
```

Initialize a variant instance to store some document-based object content
 - this global function is an handy alias to:
 Obj(NameValuePairs,JSON_OPTIONS[true]);
 - so all created objects and arrays will be handled by reference, for best speed - but you should better write on the resulting variant tree with caution

```
function _Safe(const DocVariant: variant; ExpectedKind: TDocVariantKind):
PDocVariantData; overload;
```

Delphi has problems inlining this :(direct access to a TDocVariantData from a given variant instance
 - return a pointer to the TDocVariantData corresponding to the variant instance, which may be of kind varByRef (e.g. when retrieved by late binding)
 - will check the supplied document kind, i.e. either dvObject or dvArray and raise a EDocVariant exception if it does not match

```
function _Safe(const DocVariant: variant): PDocVariantData; overload;
```

Direct access to a TDocVariantData from a given variant instance
 - return a pointer to the TDocVariantData corresponding to the variant instance, which may be of kind varByRef (e.g. when retrieved by late binding)
 - will return a read-only fake TDocVariantData with Kind=dvUndefined if the supplied variant is not a TDocVariant instance, so could be safely used in a with block (use "with" moderation, of course):

```
with _Safe(aDocVariant)^ do
  for ndx := 0 to Count-1 do // here Count=0 for the "fake" result
    writeln(Names[ndx]);
```

or excluding the "with" statement, as more readable code:

```
var dv: PDocVariantData;
    ndx: PtrInt;
begin
  dv := _Safe(aDocVariant);
  for ndx := 0 to dv.Count-1 do // here Count=0 for the "fake" result
    writeln(dv.Names[ndx]);
```

```
procedure _Unique(var DocVariant: variant);
```

Ensure a document-based variant instance will have only per-value nested objects or array documents

- is just a wrapper around:
 TDocVariantData(DocVariant).InitCopy(DocVariant,JSON_OPTIONS[false])

- you can use this function to ensure that all internal properties of this variant will be copied per-value whatever options the nested objects or arrays were created with
 - for huge document with a big depth of nested objects or arrays, a full per-value copy may be time and resource consuming, but will be also safe
 - will raise an EDocVariant if the supplied variant is not a TDocVariant or a varByRef pointing to a TDocVariant

procedure _UniqueFast(**var** DocVariant: **variant**);

Ensure a document-based variant instance will have only per-value nested objects or array documents

- is just a wrapper around:

`TDocVariantData(DocVariant).InitCopy(DocVariant, JSON_OPTIONS[true])`

- you can use this function to ensure that all internal properties of this variant will be copied per-reference whatever options the nested objects or arrays were created with
- for huge document with a big depth of nested objects or arrays, it will first create a whole copy of the document nodes, but further assignments of the resulting value will be per-reference, so will be almost instant
- will raise an EDocVariant if the supplied variant is not a TDocVariant or a varByRef pointing to a TDocVariant

Variables implemented in the SynCommons unit

AlgoSynLZ: TAlgoCompress;

Access to our fast SynLZ compression as a TAlgoCompress class

- please use this global variable methods instead of the deprecated SynLZCompress/SynLZDecompress wrapper functions

BiosInfoText: RawUTF8;

Some textual information about the current computer hardware, from BIOS

BOOL_UTF8: **array**[**boolean**] **of** RawUTF8;

JSON compatible representation of a boolean value, i.e. 'false' and 'true'

- can be used when a RawUTF8 string is expected

CacheResCount: **integer** = -1;

Current LoadResString() cached entries count

- i.e. resourcestring caching for faster use
- used only if a default system.pas is used, not our Extended version
- defined here, but resourcestring caching itself is implemented in the mORMoti18n.pas unit, if the ENHANCEDRTL conditional is not defined

CompareMemFixed: **function**(P1, P2: **Pointer**; Length: **PtrInt**): **Boolean** = CompareMem;

A CompareMem()-like function designed for small and fixed-sized content

- here, Length is expected to be a constant value - typically from sizeof() - so that inlining has better performance than calling the CompareMem() function

ConvertHexToBin: TNormTableByte;

A conversion table from hexa chars into binary data

- returns 255 for any character out of 0..9,A..Z,a..z range
- used e.g. by HexToBin() function
- is defined globally, since may be used from an inlined function

CpuFeatures: TIntelCpuFeatures;

The available CPU features, as recognized at program startup

CpuInfoText: RawUTF8;

Some textual information about the current CPU

crc32c: THasher;

Compute CRC32C checksum on the supplied buffer

- result is not compatible with zlib's crc32() - Intel/SCSI CRC32C is not the same polynom - but will use the fastest mean available, e.g. SSE 4.2, to achieve up to 16GB/s with the optimized implementation from SynCrypto.pas
- you should use this function instead of crc32cfast() or crc32csse42()

crc32cBy4: TCrc32cBy4;

Compute CRC32C checksum on one 32-bit unsigned integer

- can be used instead of crc32c() for inlined process during data acquisition
- doesn't make "crc := not crc" before and after the computation: caller has to start with "crc := cardinal(not 0)" and make "crc := not crc" at the end, to compute the very same hash value than regular crc32c()
- this variable will use the fastest mean available, e.g. SSE 4.2

crc32ctab: TCrc32tab;

Tables used by crc32cfast() function

- created with a polynom diverse from zlib's crc32() algorithm, but compatible with SSE 4.2 crc32 instruction
- tables content is created from code in initialization section below
- will also be used internally by SymmetricEncrypt, FillRandom and TSynUniqueIdentifierGenerator as 1KB master/reference key tables

crcblock: procedure(crc128, data128: PBlock128) = crcblockNoSSE42;

Compute a proprietary 128-bit CRC of a 128-bit binary buffer

- apply four crc32c() calls on the 128-bit input chunk, into a 128-bit crc
- its output won't match crc128c() value, which works on 8-bit input
- will use SSE 4.2 hardware accelerated instruction, if available
- is used e.g. by SynCrypto's TAESCFBCRC to check for data integrity

crcblocks: procedure(crc128, data128: PBlock128; count: integer)=crcblocksfast;

Compute a proprietary 128-bit CRC of 128-bit binary buffers

- apply four crc32c() calls on the 128-bit input chunks, into a 128-bit crc
- its output won't match crc128c() value, which works on 8-bit input
- will use SSE 4.2 hardware accelerated instruction, if available
- is used e.g. by SynEcc's TECDHEProtocol.ComputeMAC for macCrc128c

CurrentAnsiConvert: TSynAnsiConvert;

Global TSynAnsiConvert instance to handle current system encoding

- this is the encoding as used by the AnsiString Delphi, so will be used before Delphi 2009 to speed-up VCL string handling (especially for UTF-8)
- this instance is global and instantiated during the whole program life time

DefaultHasher: THasher;

The default hasher used by TDynArrayHashed

- set to crc32csse42() if SSE4.2 instructions are available on this CPU, or fallback to xxHash32() which performs better than crc32cfast()

DefaultSynLogExceptionToStr: `TSynLogExceptionToStr = nil;`

Default exception logging callback - will be set by the SynLog unit

- will add the default Exception details, including any Exception.Message
- if the exception inherits from ESynException
- returns TRUE: caller will then append ' at EAddr' and the stack trace

DefaultTextWriterSerializer: `TTextWriterClass = TTextWriterWithEcho;`

Contains the default JSON serialization class for WriteObject

- if only SynCommons.pas is used, it will be TTextWriterWithEcho
- mORMot.pas will assign TJSONSerializer which uses RTTI to serialize TSQLRecord and any class published properties as JSON

DocVariantType: `TDocVariant = nil;`

The internal custom variant type used to register TDocVariant

DocVariantVType: `integer = -1;`

Copy of DocVariantType.VarType

- as used by inlined functions of TDocVariantData

DOUBLE_PRECISION: `integer = 15;`

Best possible precision when rendering a "double" kind of float

- can be used as parameter for ExtendedToShort/ExtendedToStr
- is defined as a var, so that you may be able to override the default settings, for the whole process

DynArrayIsObjArray: `function(aDynArrayTypeInfo: Pointer): TPointerClassHashed;`

*MORMot.pas will registry here its T*ObjArray serialization process*

- will be used by TDynArray.GetIsObjArray

DYNARRAY_HASHFIRSTFIELD: `array[boolean,TDynArrayKind] of TDynArrayHashOne = ((nil, HashByte, HashByte, HashWord, HashInteger, HashInteger, HashInteger, HashInt64, HashInt64, HashInt64, HashInt64, HashInt64, HashInt64, HashInt64, HashAnsiString, HashAnsiString, HashAnsiString, HashAnsiString, HashWideString, HashSynUnicode, Hash128, Hash256, Hash512, HashPointer, HashVariant, nil), (nil, HashByte, HashByte, HashWord, HashInteger, HashInteger, HashInteger, HashInt64, HashInt64, HashInt64, HashInt64, HashInt64, HashInt64, HashInt64, HashAnsiStringI, HashAnsiStringI, HashAnsiStringI, HashAnsiStringI, HashWideStringI, HashSynUnicodeI, Hash128, Hash256, Hash512, HashPointer, HashVariantI, nil));`

Helper array to get the hashing function corresponding to a given standard array type

- e.g. as DYNARRAY_HASHFIRSTFIELD[CaseInsensitive,djRawUTF8]
- not to be used as such, but e.g. when inlining TDynArray methods

```
DYNARRAY_SORTFIRSTFIELD: array[boolean,TDynArrayKind] of TDynArraySortCompare = (
  (nil, SortDynArrayBoolean, SortDynArrayByte, SortDynArrayWord, SortDynArrayInteger,
  SortDynArrayCardinal, SortDynArraySingle, SortDynArrayInt64, SortDynArrayQWord,
  SortDynArrayDouble, SortDynArrayInt64, SortDynArrayInt64, SortDynArrayDouble,
  SortDynArrayDouble, SortDynArrayAnsiString, SortDynArrayAnsiString,
  SortDynArrayString, SortDynArrayRawByteString, SortDynArrayUnicodeString,
  SortDynArrayUnicodeString, SortDynArray128, SortDynArray256, SortDynArray512,
  SortDynArrayPointer, SortDynArrayVariant, nil), (nil, SortDynArrayBoolean,
  SortDynArrayByte, SortDynArrayWord, SortDynArrayInteger, SortDynArrayCardinal,
  SortDynArraySingle, SortDynArrayInt64, SortDynArrayQWord, SortDynArrayDouble,
  SortDynArrayInt64, SortDynArrayInt64, SortDynArrayDouble, SortDynArrayDouble,
  SortDynArrayAnsiStringI, SortDynArrayAnsiStringI, SortDynArrayStringI,
  SortDynArrayRawByteString, SortDynArrayUnicodeStringI, SortDynArrayUnicodeStringI,
  SortDynArray128, SortDynArray256, SortDynArray512, SortDynArrayPointer,
  SortDynArrayVariantI, nil));
```

Helper array to get the comparison function corresponding to a given standard array type

- e.g. as DYNARRAY_SORTFIRSTFIELD[CaseInsensitive,djRawUTF8]
- not to be used as such, but e.g. when inlining TDynArray methods

```
ExeVersion: TExeVersion;
```

Global information about the current executable and computer

- this structure is initialized in this unit's initialization block below
- you can call SetExecutableVersion() with a custom version, if needed

```
EXTENDED_PRECISION: integer = 18;
```

Best possible precision when rendering a "extended" kind of float

- can be used as parameter for ExtendedToShort/ExtendedToStr
- is defined as a var, so that you may be able to override the default settings, for the whole process

```
FillCharFast: procedure(var Dest; count: PtrInt; Value: byte);
```

Our fast version of FillChar()

- on Intel i386/x86_64, will use fast SSE2/ERMS instructions (if available), or optimized X87 assembly implementation for older CPUs
- on non-Intel CPUs, it will fallback to the default RTL FillChar()
- note: Delphi x86_64 is far from efficient: even ERMS was wrongly introduced in latest updates

```
GarbageCollector: TSynObjectList;
```

A global "Garbage collector", for some classes instances which must live during whole main executable process

- used to avoid any memory leak with e.g. 'class var RecordProps', i.e. some singleton or static objects

- to be used, e.g. as:

```
Version := TFileVersion.Create(InstanceFileName,DefaultVersion32);
GarbageCollector.Add(Version);
```

- see also GarbageCollectorFreeAndNil() as an alternative

```
GarbageCollectorFreeing: boolean;
```

Set to TRUE when the global "Garbage collector" are being freed

GetBitsCountPtrInt: function(value: PtrInt): PtrInt = GetBitsCountPas;

Compute how many bits are set in a given pointer-sized integer

- the PopCnt() intrinsic under FPC doesn't have any fallback on older CPUs, and default implementation is 5 times slower than our GetBitsCountPas() on x64
- this redirected function will use fast SSE4.2 popcnt opcode, if available

GetSystemTimePreciseAsFileTime: procedure(var ft: TFILETIME); stdcall;

Returns the highest resolution possible UTC timestamp on this system

- detects newer API available since Windows 8, or fallback to good old GetSystemTimeAsFileTime() which may have the resolution of the HW timer, i.e. typically around 16 ms
- GetSystemTimeAsFileTime() is always faster, so is to be preferred if second resolution is enough (e.g. for UnixTimeUTC)
- see <http://www.windowstimestamp.com/description>

GetTickCount64: function: Int64; stdcall;

The number of milliseconds that have elapsed since the system was started

- compatibility function, to be implemented according to the running OS
- will use the corresponding native API function under Vista+, or will emulate it for older Windows versions (XP)
- warning: FPC's SysUtils.GetTickCount64 or TThread.GetTickCount64 don't handle properly 49 days wrapping under XP -> always use this safe version

i18nDateText: function(const Iso: TTimeLog): string = nil;

Custom TTimeLog date to ready to be displayed text function

- you can override this pointer in order to display the text according to your expected i18n settings
- this callback will therefore be set by the mORMoti18n.pas unit
- used e.g. by TTimeLogBits.i18nText and by TSQLTable.ExpandAsString() methods, i.e. TSQLTableToGrid.DrawCell()

i18nDateTimeText: function(const DateTime: TDateTime): string = nil;

Custom date to ready to be displayed text function

- you can override this pointer in order to display the text according to your expected i18n settings
- this callback will therefore be set by the mORMoti18n.pas unit
- used e.g. by TSQLTable.ExpandAsString() method, i.e. TSQLTableToGrid.DrawCell()

InterningHasher: THasher;

The hash function used by TRawUTF8Interning

- set to crc32csse42() if SSE4.2 instructions are available on this CPU, or fallback to xxHash32() which performs better than crc32cfast()

IsWow64: boolean;

Is set to TRUE if the current process is a 32-bit image running under WOW64

- WOW64 is the x86 emulator that allows 32-bit Windows-based applications to run seamlessly on 64-bit Windows
- equals always FALSE if the current executable is a 64-bit image

JSON_CHARS: TJsonCharSet;

Branch-less table used for JSON parsing

JSON_CONTENT_TYPE_HEADER_VAR: RawUTF8;

HTTP header for MIME content type used for plain JSON

- this global will be initialized with JSON_CONTENT_TYPE_HEADER constant, to avoid a memory allocation each time it is assigned to a variable

JSON_CONTENT_TYPE_VAR: RawUTF8;

MIME content type used for JSON communication

- i.e. 'application/json; charset=UTF-8'

- this global will be initialized with JSON_CONTENT_TYPE constant, to avoid a memory allocation each time it is assigned to a variable

LoadResStringTranslate: procedure(var Text: string) = nil;

These procedure type must be defined if a default system.pas is used

- mORMoti18n.pas unit will hack default LoadResString() procedure

- already defined in our Extended system.pas unit

- needed with FPC, Delphi 2009 and up, i.e. when ENHANCEDRTL is not defined

- expect generic "string" type, i.e. UnicodeString for Delphi 2009+

- not needed with the LVCL framework (we should be on server side)

MoveFast: procedure(const Source; var Dest; Count: PtrInt);

Our fast version of move()

- on Delphi Intel i386/x86_64, will use fast SSE2 instructions (if available), or optimized X87 assembly implementation for older CPUs

- on non-Intel CPUs, it will fallback to the default RTL Move()

NormToLower: TNormTable;

The NormToLower[] array is defined in our Enhanced RTL: define it now if it was not installed

- handle 8 bit upper chars as in WinAnsi / code page 1252 (e.g. accents)

NormToNorm: TNormTable;

Case sensitive NormToUpper[]/NormToLower[]-like table

- i.e. NormToNorm[c] = c

NormToUpper: TNormTable;

The NormToUpper[] array is defined in our Enhanced RTL: define it now if it was not installed

- handle 8 bit upper chars as in WinAnsi / code page 1252 (e.g. accents)

NormToUpperAnsi7: TNormTable;

This table will convert 'a'..'z' into 'A'..'Z'

- so it will work with UTF-8 without decoding, whereas NormToUpper[] expects WinAnsi encoding

Null: variant absolute NullVarData;

A slightly faster alternative to Variants.Null function

NULL_STR_VAR: RawUTF8;

Can be used to avoid a memory allocation for res := 'null'

OSVersion: TWindowsVersion;

The current Operating System version, as retrieved for the current process

OSVersion32: TOperatingSystemVersion;

The running Operating System

OSVersionInfo: TOSVersionInfoEx;

The current Operating System information, as retrieved for the current process

OSVersionInfoEx: RawUTF8;

Some addition system information as text, e.g. 'Wine 1.1.5'

- also always appended to OSVersionText high-level description

OSVersionText: RawUTF8;

The current Operating System version, as retrieved for the current process

- contains e.g. 'Windows Seven 64 SP1 (6.1.7601)' or 'Ubuntu 16.04.5 LTS - Linux 3.13.0 110 generic#157 Ubuntu SMP Mon Feb 20 11:55:25 UTC 2017'

OS_KIND: TOperatingSystem = osWindows;

The target Operating System used for compilation, as TOperatingSystem

- a specific Linux distribution may be detected instead of plain osLinux

PosExString: **function**(const SubStr, S: **string**; Offset: PtrUInt=1): PtrInt;

Our own PosEx() function dedicated to VCL string process

- Delphi XE or older don't support Pos() with an Offset

SetThreadNameInternal: **procedure**(ThreadID: TThreadID; **const** Name: RawUTF8) = SetThreadNameDefault;

Is overridden e.g. by mORMot.pas to log the thread name

SINGLE_PRECISION: integer = 8;

Best possible precision when rendering a "single" kind of float

- can be used as parameter for ExtendedToShort/ExtendedToStr

- is defined as a var, so that you may be able to override the default settings, for the whole process

SmallUInt32UTF8: **array**[0..999] **of** RawUTF8;

Naive but efficient cache to avoid string memory allocation for 0..999 small numbers by Int32ToUTF8/UInt32ToUTF8

- use around 16KB of heap (since each item consumes 16 bytes), but increase overall performance and reduce memory allocation (and fragmentation), especially during multi-threaded execution

- noticeable when strings are used as array indexes (e.g. in SynMongoDB BSON)

- is defined globally, since may be used from an inlined function

StrComp: **function**(Str1, Str2: **pointer**): PtrInt = StrCompFast;

Fastest available version of StrComp(), to be used with PUTF8Char/PAnsiChar

- won't use SSE4.2 instructions on supported CPUs by default, which may read some bytes beyond the s string, so should be avoided e.g. over memory mapped files - call explicitly StrCompSSE42() if you are confident on your input

strcspn: **function**(s, reject: **pointer**): integer = strcspnpas;

Fastest available version of strcspn(), to be used with PUTF8Char/PAnsiChar

- returns size of initial segment of s which doesn't appears in reject chars, e.g.

strcspn('1234,6789', ',')=4

- won't use SSE4.2 instructions on supported CPUs by default, which may read some bytes beyond the s string, so should be avoided e.g. over memory mapped files - call explicitly strcspnsse42() if you are confident on your input

StrLen: function(S: pointer): PtrInt = StrLenPas;

Our fast version of StrLen(), to be used with PUTF8Char/PAnsiChar

- if available, a fast SSE2 asm will be used on Intel/AMD CPUs
- won't use SSE4.2 instructions on supported CPUs by default, which may read some bytes beyond the string, so should be avoided e.g. over memory mapped files - call explicitly StrLenSSE42() if you are confident on your input

strspn: function(s,accept: pointer): integer = strspnpas;

Fastest available version of strspn(), to be used with PUTF8Char/PAnsiChar

- returns size of initial segment of s which appears in accept chars, e.g.
`strspn('abcdef', 'debca')=5`
- won't use SSE4.2 instructions on supported CPUs by default, which may read some bytes beyond the s string, so should be avoided e.g. over memory mapped files - call explicitly strspnsse42() if you are confident on your input

SystemInfo: TSystemInfo;

The current System information, as retrieved for the current process

- under a WOW64 process, it will use the GetNativeSystemInfo() new API to retrieve the real top-most system information
- note that the lpMinimumApplicationAddress field is replaced by a more optimistic/realistic value (\$100000 instead of default \$10000)
- under BSD/Linux, only contain dwPageSize and dwNumberOfProcessors fields

TEXT_CHARS: TTextCharSet;

Branch-less table used for text line/word/identifiers/uri parsing

TSynLogExceptionToStrCustom: TSynLogExceptionToStr = nil;

Allow to customize the ESynException logging message

TwoDigitByteLookupW: packed[0..99] of word;

Fast lookup table for converting any decimal number from 0 to 99 into their byte digits (0..9) equivalence

- used e.g. by DoubleToAscii() implementing Grisu algorithm

TwoDigitLookupW: packed[0..99] of word absolute TwoDigitLookup;

Fast lookup table for converting any decimal number from 0 to 99 into their ASCII ('0'..'9') equivalence

UpperCopy255Buf: function(dest: PAnsiChar; source: PUTF8Char; sourceLen: PtrInt): PAnsiChar;

Copy source^ into a 256 chars dest^ buffer with 7 bits upper case conversion

- used internally for short keys match or case-insensitive hash
- returns final dest pointer
- will copy up to 255 AnsiChar (expect the dest buffer to be defined e.g. as array[byte] of AnsiChar on the caller stack)
- won't use SSE4.2 instructions on supported CPUs by default, which may read some bytes beyond the s string, so should be avoided e.g. over memory mapped files - call explicitly UpperCopy255BufSSE42() if you are confident on your input

UTF8AnsiConvert: TSynAnsiUTF8;

Global TSynAnsiConvert instance to handle UTF-8 encoding (code page CP_UTF8)

- this instance is global and instantiated during the whole program life time

`WinAnsiConvert: TSynAnsiFixedWidth;`

Global TSynAnsiConvert instance to handle WinAnsi encoding (code page 1252)

- this instance is global and instantiated during the whole program life time
- it will be created from hard-coded values, and not using the system API, since it appeared that some systems (e.g. in Russia) did tweak the registry so that 1252 code page maps 1251 code page

27.6. SynCrtSock.pas unit

Purpose: Classes implementing TCP/UDP/HTTP client and server protocol

- this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

The *SynCrtSock* unit is quoted in the following items

SWRS #	Description	Page
DI-2.1.1.2.4	HTTP/1.1 protocol	2555

Units used in the *SynCrtSock* unit

Unit Name	Description	Page
<i>SynWinSock</i>	Low level access to network Sockets for the Win32 platform - this unit is a part of the freeware Synapse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1851

SynCrtSock class hierarchy

Objects implemented in the *SynCrtSock* unit

Objects	Description	Page
---------	-------------	------

Objects	Description	Page
ECrtSocket	Exception thrown by the classes of this unit	1088
EWinHTTP	WinHTTP exception type	1121
EWinINet	WinINet exception type	1121
TCrtSocket	Fast low-level Socket implementation	1089
THttpApiServer	HTTP server using fast http.sys kernel-mode server	1106
THttpApiWebSocketConnection	Structure representing a single WebSocket connection	1110
THttpApiWebSocketServer	HTTP & WebSocket server using fast http.sys kernel-mode server	1112
THttpApiWebSocketServerProtocol	Protocol Handler of websocket endpoints events	1110
THttpClientSocket	Socket API based REST and HTTP/1.1 compatible client class	1096
THttpRequest	To have existing RTTI for published properties abstract class to handle HTTP/1.1 request	1117
THttpRequestExtendedOptions	A record to set some extended options for HTTP clients	1117
THttpServer	Main HTTP server Thread using the standard Sockets API (e.g. WinSock)	1113
THttpServerGeneric	Abstract class to implement a HTTP server	1103
THttpServerRequest	A generic input/output structure used for HTTP server requests	1100
THttpServerResp	HTTP response Thread as used by THttpServer Socket API based class	1098
THttpServerSocket	Socket API based HTTP/1.1 server class used by THttpServer Threads	1096
THttpSocket	Parent of THttpClientSocket and THttpServerSocket classes	1094
THttpSocketCompressRec	Used to maintain a list of known compression algorithms	1094
TMacAddress	Interface name/address pairs as returned by GetMacAddresses	1123
TPollAsynchSockets	Read/write buffer-oriented process of multiple non-blocking connections	1128
TPollSocketAbstract	Abstract parent class for efficient socket polling	1124
TPollSocketPoll	Socket polling via poll/WSAPoll API	1125
TPollSocketResult	Modifications notified by TPollSocketAbstract.WaitForModified	1124
TPollSockets	Implements efficient polling of multiple sockets	1126
TPollSocketSelect	Socket polling via Windows' Select() API	1125
TPollSocketsSlot	Store information of one TPollAsynchSockets connection	1127

Objects	Description	Page
TServerGeneric	Abstract class to implement a server thread	1102
TSimpleHttpClient	Simple wrapper around THttpClientSocket/THttpRequest instances	1122
TSMTTPConnection	May be used to store a connection to a SMTP server	1123
TSynThread	A simple TThread with a "Terminate" event run in the thread context	1098
TSynThreadPool	A simple Thread Pool, used e.g. for fast handling HTTP requests	1099
TSynThreadPoolHttpApi WebSocketServer	A Thread Pool, used for fast handling WebSocket requests	1113
TSynThreadPoolTHttpSe rver	A simple Thread Pool, used for fast handling HTTP requests of a THttpServer	1100
TSynThreadPoolWorkThr ead	I/O completion ports API is the best option under Windows under Linux/POSIX, we fallback to a classical event-driven pool defines the sub-threads used by TSynThreadPool	1099
TSynWebSocketGuard	Thread for closing WebSocket connections which not response more than PingTimeout interval	1113
TURI	Structure used to parse an URI into its components	1116
TWinHTTP	A class to handle HTTP/1.1 request using the WinHTTP API	1121
TWinHttpAPI	A class to handle HTTP/1.1 request using either WinINet or WinHTTP API	1120
TWinHTTPUpgradeable	A class to establish a client connection to a WebSocket server using Windows API	1122
TWinHTTPWebSocketClie nt	WebSocket client implementation	1122
TWinINet	A class to handle HTTP/1.1 request using the WinINet API	1121

ECrtSocket = **class**(Exception)

Exception thrown by the classes of this unit

constructor Create(const Msg: string; Error: integer); overload;

Will concat the message with the supplied WSAGetLastError information

constructor Create(const Msg: string); overload;

Will concat the message with the WSAGetLastError information

constructor CreateFmt(const Msg: string; const Args: array of const; Error: integer); overload;

Will concat the message with the supplied WSAGetLastError information

property LastError: integer **read** fLastError;

The associated WSAGetLastError value

TCrtSocket = class(TObject)

Fast low-level Socket implementation

- direct access to the OS (Windows, Linux) network layer API
- use Open constructor to create a client to be connected to a server
- use Bind constructor to initialize a server
- use SockIn and SockOut (after CreateSock*) to read/readln or write/writeln as with standard Delphi text files (see SendEmail implementation)
- even if you do not use read(SockIn^), you may call CreateSockIn then read the (binary) content via SockInRead/SockInPending methods, which would benefit of the SockIn^ input buffer to maximize reading speed
- to write data, CreateSockOut and write(SockOut^) is not mandatory: you rather may use SockSend() overloaded methods, followed by a SockFlush call
- in fact, you can decide whatever to use none, one or both SockIn/SockOut
- since this class rely on its internal optimized buffering system, TCP_NODELAY is set to disable the Nagle algorithm
- our classes are (much) faster than the Indy or Synapse implementation

constructor Bind(**const** aAddr: SockString; aLayer: TCrtSocketLayer=cs1TCP; aTimeOut: integer=10000);

Bind to an address

- aAddr='1234' - bind to a port on all interfaces, the same as '0.0.0.0:1234'
- aAddr='IP:port' - bind to specified interface only, e.g. '1.2.3.4:1234'
- aAddr='unix:/path/to/file' - bind to unix domain socket, e.g. 'unix:/run/mormot.sock'
- aAddr='' - bind to systemd descriptor on linux. See <http://0pointer.de/blog/projects/socket-activation.html>

constructor Create(aTimeOut: PtrInt=10000); reintroduce; virtual;

Common initialization of all constructors

- do not call directly, but use Open / Bind constructors instead

constructor Open(**const** aServer, aPort: SockString; aLayer: TCrtSocketLayer=cs1TCP; aTimeOut: cardinal=10000; aTLS: boolean=false);

Connect to aServer:aPort

- you may ask for a TLS secured client connection (only available under Windows by now, using the SChannel API)

destructor Destroy; override;

Close the opened socket, and corresponding SockIn/SockOut

function AcceptIncoming(ResultClass: TCrtSocketClass=nil): TCrtSocket;

Direct accept an new incoming connection on a bound socket

- instance should have been setup as a server via a previous Bind() call
- returns nil on error or a ResultClass instance on success
- if ResultClass is nil, will return a plain TCrtSocket, but you may specify e.g. THttpServerSocket if you expect incoming HTTP requests

function LastLowSocketError: Integer;

Returns the low-level error number

- i.e. returns WSAGetLastError

function PeerAddress: SockString;

Remote IP address of the last packet received (SocketLayer=slUDP only)

function PeerPort: integer;

Remote IP port of the last packet received (SocketLayer=slUDP only)

function SockConnected: boolean;

Check the connection status of the socket

function SockInPending(aTimeOutMS: integer; aPendingAlsoInSocket: boolean=false): integer;

Returns the number of bytes in SockIn buffer or pending in Sock

- if SockIn is available, it first check from any data in SockIn^.Buffer, then call InputSock to try to receive any pending data if the buffer is void
- if aPendingAlsoInSocket is TRUE, returns the bytes available in both the buffer and the socket (sometimes needed, e.g. to process a whole block at once)
- will wait up to the specified aTimeOutMS value (in milliseconds) for incoming data - may wait a little less time on Windows due to a select bug
- returns -1 in case of a socket error (e.g. broken/closed connection); you can raise a ECrtSocket exception to propagate the error

function SockInRead(Content: PAnsiChar; Length: integer; UseOnlySockIn: boolean=false): integer;

Read Length bytes from SockIn buffer + Sock if necessary

- if SockIn is available, it first gets data from SockIn^.Buffer, then directly receive data from socket if UseOnlySockIn=false
- if UseOnlySockIn=true, it will return the data available in SockIn^, and returns the number of bytes
- can be used also without SockIn: it will call directly SockRecv() in such case (assuming UseOnlySockin=false)

function SockReceivePending(TimeOutMS: integer): TCrtSocketPending;

Check if there are some pending bytes in the input sockets API buffer

- returns cspSocketError if the connection is broken or closed
- warning: on Windows, may wait a little less than TimeOutMS (select bug)

function SockReceiveString: SockString;

Returns the socket input stream as a string

function SockSendRemainingSize: integer;

How many bytes could be added by SockSend() in the internal buffer

function TrySndLow(P: pointer; Len: integer): boolean;

Direct send data through network

- return false on any error, true on success
- bypass the SndBuf or SockOut^ buffers

function TrySockRecv(Buffer: pointer; var Length: integer; StopBeforeLength: boolean=false): boolean;

Fill the Buffer with Length bytes

- use Timeout milliseconds wait for incoming data
- bypass the SockIn^ buffers
- return false on any fatal socket error, true on success
- call Close if the socket is identified as shutdown from the other side
- you may optionally set StopBeforeLength=true, then the read bytes count are set in Length, even if not all expected data has been received - in this case, Close method won't be called

function TrySockSendFlush: boolean;

Flush all pending data to be sent

- returning true on success

procedure AcceptRequest(aClientSock: TSocket; aClientSin: PVarSin);

Initialize the instance with the supplied accepted socket

- is called from a bound TCP Server, just after Accept()

procedure Close;

Close and shutdown the connection (called from Destroy)

procedure CloseSockIn;

Finalize SockIn receiving buffer

- you may call this method when you are sure that you don't need the input buffering feature on this connection any more (e.g. after having parsed the HTTP header, then rely on direct socket communication)

procedure CloseSockOut;

Finalize SockOut receiving buffer

- you may call this method when you are sure that you don't need the output buffering feature on this connection any more (e.g. after having parsed the HTTP header, then rely on direct socket communication)

procedure CreateSockIn(LineBreak: TTextLineBreakStyle=tlbsCRLF; InputBufferSize: Integer=1024);

Initialize SockIn for receiving with read[ln](SockIn^,...)

- data is buffered, filled as the data is available
- read(char) or readln() is indeed very fast
- multithread applications would also use this SockIn pseudo-text file
- by default, expect CR+LF as line feed (i.e. the HTTP way)

procedure CreateSockOut(OutputBufferSize: Integer=1024);

Initialize SockOut for sending with write[ln](SockOut^,...)

- data is sent (flushed) after each writeln() - it's a compiler feature
- use rather SockSend() + SockSendFlush to send headers at once e.g. since writeln(SockOut^,...) flush buffer each time

procedure OpenBind(const aServer, aPort: SockString; doBind: boolean; aSock: integer=-1; aLayer: TCrtSocketLayer=cslTCP; aTLS: boolean=false);

Low-level internal method called by Open() and Bind() constructors

- raise an ECrtSocket exception on error
- you may ask for a TLS secured client connection (only available under Windows by now, using the SChannel API)

procedure SndLow(P: pointer; Len: integer);

Direct send data through network

- raise a ECrtSocket exception on any error
- bypass the SockSend() or SockOut^ buffers

procedure SockRecv(Buffer: pointer; Length: integer);

Fill the Buffer with Length bytes

- use Timeout milliseconds wait for incoming data
- bypass the SockIn^ buffers
- raise ECrtSocket exception on socket error

procedure SockRecvLn(out Line: SockString; CROnly: boolean=false); overload;

Call readln(SockIn^,Line) or simulate it with direct use of Recv(Sock, ..)

- char are read one by one if needed
- use Timeout milliseconds wait for incoming data
- raise ECrtSocket exception on socket error
- by default, will handle #10 or #13#10 as line delimiter (as normal text files), but you can delimit lines using #13 if CROnly is TRUE

procedure SockRecvLn; overload;

Call readln(SockIn^) or simulate it with direct use of Recv(Sock, ..)

- char are read one by one
- use Timeout milliseconds wait for incoming data
- raise ECrtSocket exception on socket error
- line content is ignored

procedure SockSend(const Line: SockString=''); overload;

Simulate writeln() with a single line - includes trailing #13#10

procedure SockSend(const Values: array of const); overload;

Simulate writeln() with direct use of Send(Sock, ..) - includes trailing #13#10

- useful on multi-treaded environnement (as in THttpServer.Process)
- no temp buffer is used
- handle SockString, ShortString, Char, Integer parameters
- raise ECrtSocket exception on socket error

procedure SockSend(P: pointer; Len: integer); overload;

Append P^ data into SndBuf (used by SockSend(), e.g.) - no trailing #13#10

- call SockSendFlush to send it through the network via SndLow()

procedure SockSendFlush(const aBody: SockString=''); virtual;

Flush all pending data to be sent, optionally with some body content

- raise ECrtSocket on error

procedure Write(const Data: SockString);

Direct send data through network

- raise a ECrtSocket exception on any error
- bypass the SndBuf or SockOut^ buffers
- raw Data is sent directly to OS: no LF/CRLF is appened to the block

property BytesIn: Int64 read fBytesIn;

Total bytes received

property BytesOut: Int64 read fBytesOut;

Total bytes sent

property KeepAlive: Integer index SO_KEEPAIVE write SetInt32OptionByIndex;

Set the SO_KEEPAIVE option for the connection

- 1 (true) will enable keep-alive packets for the connection
- see <http://msdn.microsoft.com/en-us/library/windows/desktop/ee470551>

property Linger: Integer index SO_LINGER write SetInt32OptionByIndex;

Set the SO_LINGER option for the connection, to control its shutdown

- by default (or Linger<0), Close will return immediately to the caller, and any pending data will be delivered if possible
- Linger > 0 represents the time in seconds for the timeout period to be applied at Close; under Linux, will also set SO_REUSEADDR; under Darwin, set SO_NOSIGPIPE
- Linger = 0 causes the connection to be aborted and any pending data is immediately discarded at Close

property Port: SockString read fPort;

IP port, initialized after Open() with port number

property ReceiveTimeout: Integer index SO_RCVTIMEO write SetInt32OptionByIndex;

Set the SO_RCVTIMEO option for the connection

- i.e. the timeout, in milliseconds, for blocking receive calls
- see <http://msdn.microsoft.com/en-us/library/windows/desktop/ms740476>

property RemoteIP: SockString read fRemoteIP write fRemoteIP;

Remote IP address after AcceptRequest() call over TCP

- is either the raw connection IP to the current server socket, or a custom header value set by a local proxy as retrieved by inherited THttpServerSocket.GetRequest, searching the header named in THttpServerGeneric.RemoteIPHeader (e.g. 'X-Real-IP' for nginx)

property SendTimeout: Integer index SO_SNDTIMEO write SetInt32OptionByIndex;

Set the SO_SNDTIMEO option for the connection

- i.e. the timeout, in milliseconds, for blocking send calls
- see <http://msdn.microsoft.com/en-us/library/windows/desktop/ms740476>

property Server: SockString read fServer;

IP address, initialized after Open() with Server name

property Sock: TSocket read fSock write fSock;

Low-level socket handle, initialized after Open() with socket

property SocketLayer: TCrtSocketLayer read fSocketLayer;

Low-level socket type, initialized after Open() with socket

property SockIn: PTextFile read fSockIn;

After CreateSockIn, use ReadLn(SockIn^,s) to read a line from the opened socket

property SockOut: PTextFile read fSockOut;

After CreateSockOut, use Writeln(SockOut^,s) to send a line to the opened socket

property TCPNoDelay: Integer **index** TCP_NODELAY **write** SetInt32OptionByIndex;

Set the TCP_NODELAY option for the connection

- default 1 (true) will disable the Nagle buffering algorithm; it should only be set for applications that send frequent small bursts of information without getting an immediate response, where timely delivery of data is required - so it expects buffering before calling Write() or SndLow()
- you can set 0 (false) here to enable the Nagle algorithm, if needed
- see <http://www.unixguide.net/network/socketfaq/2.16.shtml>

property TimeOut: PtrInt **read** fTimeOut;

If higher than 0, read loop will wait for incoming data till TimeOut milliseconds (default value is 10000) - used also in SockSend()

THttpSocketCompressRec = record

Used to maintain a list of known compression algorithms

CompressMinSize: integer;

The size in bytes after which compress will take place

- will be 1024 e.g. for 'zip' or 'deflate'
- could be 0 e.g. when encrypting the content, meaning "always compress"

Func: THttpSocketCompress;

The function handling compression and decompression

Name: SockString;

The compression name, as in ACCEPT-ENCODING: header (gzip,deflate,synlz)

THttpSocket = class(TCrtSocket)

Parent of THttpClientSocket and THttpServerSocket classes

- contain properties for implementing HTTP/1.1 using the Socket API
- handle chunking of body content
- can optionally compress and uncompress on the fly the data, with standard gzip/deflate or custom (synlzo/synlz) protocols

Command: SockString;

Will contain the first header line:

- 'GET /path HTTP/1.1' for a GET request with THttpServer, e.g.
- 'HTTP/1.0 200 OK' for a GET response after Get() e.g.

Content: SockString;

Will contain the data retrieved from the server, after the Request

ContentLength: integer;

Same as HeaderGetValue('CONTENT-LENGTH'), but retrieved during Request

- is overridden with real Content length during HTTP body retrieval

ContentType: SockString;

Same as HeaderGetValue('CONTENT-TYPE'), but retrieved during Request

HeaderFlags: set of (transferChuked, connectionClose, connectionUpgrade, connectionKeepAlive, hasRemoteIP);

Map the presence of some HTTP headers, but retrieved during Request

Headers: SockString;

Will contain all header lines after a Request

- use `HeaderGetValue()` to get one HTTP header item value by name

ServerInternalState: integer;

Same as `HeaderGetValue('SERVER-INTERNALSTATE')`, but retrieved during Request

- proprietary header, used with our RESTful ORM access

TCPPrefix: SockString;

TCP/IP prefix to mask HTTP protocol

- if not set, will create full HTTP/1.0 or HTTP/1.1 compliant content

- in order to make the TCP/IP stream not HTTP compliant, you can specify a prefix which will be put before the first header line: in this case, the TCP/IP stream won't be recognized as HTTP, and will be ignored by most AntiVirus programs, and increase security - but you won't be able to use an Internet Browser nor AJAX application for remote access any more

Upgrade: SockString;

Same as `HeaderGetValue('UPGRADE')`, but retrieved during Request

XPoweredBy: SockString;

Same as `HeaderGetValue('X-POWERED-BY')`, but retrieved during Request

function `HeaderGetText(const aRemoteIP: SockString=''): SockString;`

Get all Header values at once, as CRLF delimited text

- you can optionally specify a value to be added as 'RemoteIP: ' header

function `HeaderGetValue(const aUpperName: SockString): SockString;`

`HeaderGetValue('CONTENT-TYPE')`='text/html', e.g.

- supplied `aUpperName` should be already uppercased

function `RegisterCompress(aFunction: THttpSocketCompress; aCompressMinSize: integer=1024): boolean;`

Will register a compression algorithm

- used e.g. to compress on the fly the data, with standard gzip/deflate or custom (synlzo/synlz) protocols

- returns true on success, false if this function or this ACCEPT-ENCODING: header was already registered

- you can specify a minimal size (in bytes) before which the content won't be compressed (1024 by default, corresponding to a MTU of 1500 bytes)

- the first registered algorithm will be the preferred one for compression

procedure `GetBody;`

Retrieve the HTTP body (after uncompression if necessary) into Content

procedure `GetHeader(HeadersUnFiltered: boolean=false);`

Retrieve the HTTP headers into Headers[] and fill most properties below

- only relevant headers are retrieved, unless HeadersUnFiltered is set

procedure `HeaderAdd(const aValue: SockString);`

Add an header 'name: value' entry

procedure `HeaderSetText(const aText: SockString; const aForcedContentType: SockString='');`

Set all Header values at once, from CRLF delimited text

THttpServerSocket = class(THttpSocket)

Socket API based HTTP/1.1 server class used by THttpServer Threads

constructor Create(aServer: THttpServer); **reintroduce**;

Create the socket according to a server

- will register the THttpSocketCompress functions from the server
- once created, caller should call AcceptRequest() to accept the socket

function GetRequest(withBody: boolean; headerMaxTix: Int64):
THttpServerSocketGetRequestResult; **virtual**;

Main object function called after aClientSock := Accept + Create:

- get Command, Method, URL, Headers and Body (if withBody is TRUE)
- get sent data in Content (if withBody=true and ContentLength<>0)
- returned enumeration will indicates the processing state

property KeepAliveClient: boolean **read** fKeepAliveClient **write** fKeepAliveClient;

True if the client is HTTP/1.1 and 'Connection: Close' is not set

- default HTTP/1.1 behavior is "keep alive", unless 'Connection: Close' is specified, cf. RFC 2068 page 108: "HTTP/1.1 applications that do not support persistent connections MUST include the "close" connection option in every message"

property Method: SockString **read** fMethod;

Contains the method ('GET','POST'.. e.g.) after GetRequest()

property RemoteConnectionID: THttpServerConnectionID **read** fRemoteConnectionID;

The recognized connection ID, after a call to GetRequest()

- identifies either the raw connection on the current server, or is a custom header value set by a local proxy, e.g. THttpServerGeneric.RemoteConnIDHeader='X-Conn-ID' for nginx

property URL: SockString **read** fURL;

Contains the URL ('/' e.g.) after GetRequest()

THttpClientSocket = class(THttpSocket)

Socket API based REST and HTTP/1.1 compatible client class

- this component is HTTP/1.1 compatible, according to RFC 2068 document
- the REST commands (GET/POST/PUT/DELETE) are directly available
- open connection with the server with inherited Open(server,port) function
- if KeepAlive>0, the connection is not broken: a further request (within KeepAlive milliseconds) will use the existing connection if available, or recreate a new one if the former is outdated or reset by server (will retry only once); this is faster, uses less resources (especially under Windows), and is the recommended way to implement a HTTP/1.1 server
- on any error (timeout, connection closed) will retry once to get the value
- don't forget to use Free procedure when you are finished

constructor Create(aTimeOut: PtrInt=0); **override**;

Common initialization of all constructors

- this overridden method will set the UserAgent with some default value
- you can customize the default client timeouts by setting appropriate aTimeout parameters (in ms) if you left the 0 default parameters, it would use global HTTP_DEFAULT_RECEIVETIMEOUT variable values

function Delete(const url: SockString; KeepAlive: cardinal=0; const header: SockString=''): integer;

After an Open(server,port), return 200,202,204 if OK, http status error otherwise

function Get(const url: SockString; KeepAlive: cardinal=0; const header: SockString=''): integer;

- After an Open(server,port), return 200 if OK, http status error otherwise*
- get the page data in Content

function GetAuth(const url, AuthToken: SockString; KeepAlive: cardinal=0): integer;

- After an Open(server,port), return 200 if OK, http status error otherwise*
- get the page data in Content
 - if AuthToken<>'', will add an header with 'Authorization: Bearer '+AuthToken

function Head(const url: SockString; KeepAlive: cardinal=0; const header: SockString=''): integer;

After an Open(server,port), return 200 if OK, http status error otherwise - only header is read from server: Content is always "", but Headers are set

function Post(const url, Data, DataType: SockString; KeepAlive: cardinal=0; const header: SockString=''): integer;

After an Open(server,port), return 200,201,204 if OK, http status error otherwise

function Put(const url, Data, DataType: SockString; KeepAlive: cardinal=0; const header: SockString=''): integer;

After an Open(server,port), return 200,201,204 if OK, http status error otherwise

function Request(const url, method: SockString; KeepAlive: cardinal; const header, Data, DataType: SockString; retry: boolean): integer; **virtual**;

Low-level HTTP/1.1 request

- called by all Get/Head/Post/Put/Delete REST methods
- after an Open(server,port), return 200,202,204 if OK, http status error otherwise
- retry is false by caller, and will be recursively called with true to retry once

property ProcessName: SockString **read** fProcessName **write** fProcessName;

The associated process name

property UserAgent: SockString **read** fUserAgent **write** fUserAgent;

- By default, the client is identified as IE 5.5, which is very friendly welcome by most servers :(*
- you can specify a custom value here

TSynThread = class(TThread)

A simple TThread with a "Terminate" event run in the thread context

- the TThread.OnTerminate event is run within Synchronize() so did not match our expectations to be able to release the resources in the thread context which created them (e.g. for COM objects, or some DB drivers)
- used internally by THttpServerGeneric.NotifyThreadStart() - you should not have to use the protected fOnThreadTerminate event handler
- also define a Start method for compatibility with older versions of Delphi

constructor Create(CreateSuspended: boolean); **reintroduce**; **virtual**;

Initialize the server instance, in non suspended state

function SleepOrTerminated(MS: cardinal): boolean;

Safe version of Sleep() which won't break the thread process

- returns TRUE if the thread was Terminated
- returns FALSE if successfully waited up to MS milliseconds

procedure Start;

Method to be called when the thread was created as suspended

- Resume is deprecated in the newest RTL, since some OS - e.g. Linux - do not implement this pause/resume feature
- we define here this method for older versions of Delphi

property Terminated;

Defined as public since may be used to terminate the processing methods

THttpServerResp = class(TSynThread)

HTTP response Thread as used by THttpServer Socket API based class

- Execute procedure get the request and calculate the answer, using the thread for a single client connection, until it is closed
- you don't have to overload the protected THttpServerResp Execute method: override THttpServer.Request() function or, if you need a lower-level access (change the protocol, e.g.) THttpServer.Process() method itself

constructor Create(aServerSock: THttpServerSocket; aServer: THttpServer); **reintroduce**; **overload**; **virtual**;

Initialize the response thread for the corresponding incoming socket

- this version will handle KeepAlive, for such an incoming request

constructor Create(aSock: TSocket; **const** aSin: TVarSin; aServer: THttpServer); **reintroduce**; **overload**;

Initialize the response thread for the corresponding incoming socket

- this version will get the request directly from an incoming socket

property ConnectionID: THttpServerConnectionID **read** fConnectionID;

The unique identifier of this connection

property Server: THttpServer **read** fServer;

The associated main HTTP server instance

property ServerSock: THttpServerSocket **read** fServerSock;

The associated socket to communicate with the client

TSynThreadPoolWorkThread = class(TSynThread)

I/O completion ports API is the best option under Windows under Linux/POSIX, we fallback to a classical event-driven pool defines the sub-threads used by TSynThreadPool

constructor Create(Owner: TSynThreadPool); **reintroduce**;

Exception-safe call of fOwner.Task() initialize the thread

destructor Destroy; **override**;

Finalize the thread

procedure Execute; **override**;

Will loop for any pending task, and execute fOwner.Task()

TSynThreadPool = class(TObject)

A simple Thread Pool, used e.g. for fast handling HTTP requests

- implemented over I/O Completion Ports under Windows, or a classical Event-driven approach under Linux/POSIX

constructor Create(NumberOfThreads: Integer=32; aOverlapHandle: THandle=INVALID_HANDLE_VALUE);

Initialize a thread pool with the supplied number of threads

- abstract Task() virtual method will be called by one of the threads

- up to 256 threads can be associated to a Thread Pool

- can optionally accept aOverlapHandle - a handle previously opened for overlapped I/O (IOCP) under Windows

- aQueuePendingContext=true will store the pending context into an internal queue, so that Push() always returns true

destructor Destroy; **override**;

Shut down the Thread pool, releasing all associated threads

function Push(aContext: pointer; aWaitOnContention: boolean=false): boolean;

Let a task (specified as a pointer) be processed by the Thread Pool

- returns false if there is no idle thread available in the pool and

Create(aQueuePendingContext=false) was used (caller should retry later); if

aQueuePendingContext was true in Create, or IOCP is used, the supplied context will be added to an internal list and handled when possible

- if aWaitOnContention is default false, returns immediately when the queue is full; set

aWaitOnContention=true to wait up to ContentionAbortDelay ms and retry to queue the task

property ContentionAbortCount: cardinal **read** fContentionAbortCount;

How many tasks were rejected due to thread pool contention

- if this number is high, consider setting a higher number of threads, or profile and tune the Task method

property ContentionAbortDelay: integer **read** fContentionAbortDelay **write** fContentionAbortDelay;

Milliseconds delay to reject a connection due to contention

- default is 5000, i.e. 5 seconds wait for some room to be available in the IOCP or aQueuePendingContext internal list
- during this delay, no new connection is available (i.e. Accept is not called), so that a load balancer could detect the contention and switch to another instance in the pool, or a direct client may eventually have its connection rejected, so won't start sending data

property ContentionCount: cardinal **read** fContentionCount;

How many times the pool waited for an available slot in the queue

- contention won't fail immediately, but will retry until ContentionAbortDelay
- any high number here may better increase the threads count
- use this property and ContentionTime to compute the average contention time

property ContentionTime: Int64 **read** fContentionTime;

Total milliseconds spent waiting for an available slot in the queue

- contention won't fail immediately, but will retry until ContentionAbortDelay
- any high number here requires code refactoring of the Task method

property RunningThreads: integer **read** fRunningThreads;

How many threads are currently running in this thread pool

property WorkThread: TSynThreadPoolWorkThreads **read** fWorkThread;

Low-level access to the threads defined in this thread pool

property WorkThreadCount: integer **read** fWorkThreadCount;

How many threads have been defined in this thread pool

TSynThreadPoolTHttpServer = class(TSynThreadPool)

A simple Thread Pool, used for fast handling HTTP requests of a THttpServer

- will handle multi-connection with less overhead than creating a thread for each incoming request
- will create a THttpServerResp response thread, if the incoming request is identified as HTTP/1.1 keep alive, or HTTP body length is bigger than 1 MB

constructor Create(Server: THttpServer; NumberOfThreads: Integer=32); **reintroduce;**

Initialize a thread pool with the supplied number of threads

- Task() overridden method processs the HTTP request set by Push()
- up to 256 threads can be associated to a Thread Pool

THttpServerRequest = class(TObject)

A generic input/output structure used for HTTP server requests

- URL/Method/InHeaders/InContent properties are input parameters
- OutContent/OutContentType/OutCustomHeader are output parameters

Status: integer;

Low-level property which may be used during requests processing

constructor Create(aServer: THttpServerGeneric; aConnectionID: THttpServerConnectionID; aConnectionThread: TSynThread); **virtual**;

Initialize the context, associated to a HTTP server instance

procedure AddInHeader(additionalHeader: SockString);

Append some lines to the InHeaders input parameter

procedure Prepare(**const** aURL, aMethod, aInHeaders, aInContent, aInContentType, aRemoteIP: SockString; aUseSSL: boolean=false);

Prepare an incoming request

- will set input parameters URL/Method/InHeaders/InContent/InContentType
- will reset output parameters

property AuthenticatedUser: SockString **read** fAuthenticatedUser;

Contains the THttpServer-side authenticated user name, UTF-8 encoded

- e.g. when using http.sys authentication with HTTP API 2.0, the domain user name is retrieved from the supplied AccessToken
- could also be set by the THttpServerGeneric.Request() method, after proper authentication, so that it would be logged as expected

property AuthenticationStatus: THttpServerRequestAuthentication **read** fAuthenticationStatus;

Contains the THttpServer-side authentication status

- e.g. when using http.sys authentication with HTTP API 2.0

property ConnectionID: THttpServerConnectionID **read** fConnectionID;

The ID of the connection which called this execution context

- e.g. SynBidirSock's TWebSocketProcess.NotifyCallback method would use this property to specify the client connection to be notified
- is set as an Int64 to match http.sys ID type, but will be an increasing 31-bit integer sequence for (web)socket-based servers

property ConnectionThread: TSynThread **read** fConnectionThread;

The thread which owns the connection of this execution context

- depending on the HTTP server used, may not follow ConnectionID

property FullURL: SockUnicode **read** fFullURL;

Input parameter containing the caller Full URL

property HttpApiRequest: Pointer **read** fHttpApiRequest;

For THttpApiServer, points to a PHTTP_REQUEST structure

- not used by now for other servers

property InContent: SockString **read** fInContent **write** fInContent;

Input parameter containing the caller message body

- e.g. some GET/POST/PUT JSON data can be specified here

property InContentType: SockString **read** fInContentType **write** fInContentType;

Input parameter defining the caller message body content type

property InHeaders: SockString **read** fInHeaders **write** fInHeaders;

Input parameter containing the caller message headers

property Method: SockString read fMethod write fMethod;

Input parameter containing the caller method (GET/POST...)

property OutContent: SockString read fOutContent write fOutContent;

Output parameter to be set to the response message body

property OutContentType: SockString read fOutContentType write fOutContentType;

Output parameter to define the response message body content type

- if OutContentType is HTTP_RESP_STATICFILE (i.e. '!STATICFILE', defined as STATICFILE_CONTENT_TYPE in mORMot.pas), then OutContent is the UTF-8 file name of a file which must be sent to the client via http.sys or NGINX's X-Accel-Redirect header (faster than local buffering/sending)
- if OutContentType is HTTP_RESP_NORESPONSE (i.e. '!NORESPONSE', defined as NORESPONSE_CONTENT_TYPE in mORMot.pas), then the actual transmission protocol may not wait for any answer - used e.g. for WebSockets

property OutCustomHeaders: SockString read fOutCustomHeaders write fOutCustomHeaders;

Output parameter to be sent back as the response message header

- e.g. to set Content-Type/Location

property RemoteIP: SockString read fRemoteIP write fRemoteIP;

The client remote IP, as specified to Prepare()

property RequestID: integer read fRequestID;

A 31-bit sequential number identifying this instance on the server

property Server: THttpServerGeneric read fServer;

The associated server instance

- may be a THttpServer or a THttpApiServer class

property URL: SockString read fURL write fURL;

Input parameter containing the caller URI

property UseSSL: boolean read fUseSSL;

Is TRUE if the caller is connected via HTTPS

- only set for THttpApiServer class yet

TServerGeneric = class(TSynThread)

Abstract class to implement a server thread

- do not use this class, but rather the THttpServer, THttpApiServer or TAsynchFrameServer (as defined in SynBidirSock)

constructor Create(CreateSuspended: boolean; OnStart,OnStop: TNotifyThreadEvent;
const ProcessName: SockString); **reintroduce; virtual;**

Initialize the server instance, in non suspended state

THttpClientGeneric = class(TServerGeneric)

Abstract class to implement a HTTP server

- do not use this class, but rather the THttpClient or THttpClientApiServer

Used for DI-2.1.1.2.4 (page 2555).

constructor Create(CreateSuspended: boolean; OnStart, OnStop: TNotifyThreadEvent;
const ProcessName: SockString); **reintroduce; virtual;**

31-bit internal sequence initialize the server instance, in non suspended state

function Callback(Ctxt: THttpClientRequest; aNonBlocking: boolean): cardinal;
virtual;

Server can send a request back to the client, when the connection has been upgraded e.g. to WebSockets

- InURL/InMethod/InContent properties are input parameters (InContentType is ignored)
- OutContent/OutContentType/OutCustomHeader are output parameters
- CallingThread should be set to the client's Ctxt.CallingThread value, so that the method could know which connection is to be used - it will return STATUS_NOTFOUND (404) if the connection is unknown
- result of the function is the HTTP error code (200 if OK, e.g.)
- warning: this void implementation will raise an ECrtSocket exception - inherited classes should override it, e.g. as in TWebSocketServerRest

function Request(Ctxt: THttpClientRequest): cardinal; **virtual;**

Override this function to customize your http server

- InURL/InMethod/InContent properties are input parameters
- OutContent/OutContentType/OutCustomHeader are output parameters
- result of the function is the HTTP error code (200 if OK, e.g.),
- OutCustomHeader is available to handle Content-Type/Location
- if OutContentType is HTTP_RESP_STATICFILE (i.e. '!STATICFILE' or STATICFILE_CONTENT_TYPE defined in mORMot.pas), then OutContent is the UTF-8 file name of a file which must be sent to the client via http.sys or NGINX's X-Accel-Redirect (much faster than manual buffering/sending); the OutCustomHeader should contain the proper 'Content-type:'
- default implementation is to call the OnRequest event (if existing), and will return STATUS_NOTFOUND if OnRequest was not set
- warning: this process must be thread-safe (can be called by several threads simultaneously, but with a given Ctxt instance for each)

Used for DI-2.1.1.2.4 (page 2555).

procedure RegisterCompress(aFunction: THttpClientCompress; aCompressMinSize:
integer=1024); **virtual;**

Will register a compression algorithm

- used e.g. to compress on the fly the data, with standard gzip/deflate or custom (synlzo/synlz) protocols
- you can specify a minimal size (in bytes) before which the content won't be compressed (1024 by default, corresponding to a MTU of 1500 bytes)
- the first registered algorithm will be the preferred one for compression

procedure Shutdown;

You can call this method to prepare the HTTP server for shutting down

property APIVersion: **string read** GetAPIVersion;

Returns the API version used by the inherited implementation

property CanNotifyCallback: **boolean read** fCanNotifyCallback;

TRUE if the inherited class is able to handle callbacks

- only TWebSocketServer has this ability by now

property HTTPQueueLength: **cardinal read** GetHTTPQueueLength **write** SetHTTPQueueLength;

Defines request/response internal queue length

- default value is 1000, which sounds fine for most use cases

- for THttpApiServer, will return 0 if the system does not support HTTP API 2.0 (i.e. under Windows XP or Server 2003)

- for THttpServer, will shutdown any incoming accepted socket if the internal TSynThreadPool.PendingContextCount+ThreadCount exceeds this limit; each pending connection is a THttpServerSocket instance in the queue

- increase this value if you don't have any load-balancing in place, and in case of e.g. many 503 HTTP answers or if many "QueueFull" messages appear in HTTP.sys log files (normally in C:\Windows\System32\LogFiles\HTTPERR\httperr*.log) - may appear with thousands of concurrent clients accessing at once the same server - see

@<http://msdn.microsoft.com/en-us/library/windows/desktop/aa364501>

- you can use this property with a reverse-proxy as load balancer, e.g. with nginx configured as such:

```
location / {
    proxy_pass          http://balancing_upstream;
    proxy_next_upstream error timeout invalid_header http_500 http_503;
    proxy_connect_timeout 2;
    proxy_set_header    Host            $host;
    proxy_set_header     X-Real-IP      $remote_addr;
    proxy_set_header     X-Forwarded-For $proxy_add_x_forwarded_for;
    proxy_set_header     X-Conn-ID     $connection
}
```

see <https://synapse.info/forum/viewtopic.php?pid=28174#p28174>

property MaximumAllowedContentLength: **cardinal read** fMaximumAllowedContentLength **write** SetMaximumAllowedContentLength;

Reject any incoming request with a body size bigger than this value

- default to 0, meaning any input size is allowed

- returns STATUS_PAYLOADTOOLARGE = 413 error if "Content-Length" incoming header overflow the supplied number of bytes

property OnAfterRequest: TOnHttpServerRequest **read** fOnAfterRequest **write** SetOnAfterRequest;

Event handler called after request is processed but before response is sent back to client

- main purpose is to apply post-processor, not part of request logic

- if handler returns value > 0 it will override the OnProcess response code

- warning: this handler must be thread-safe (can be called by several threads simultaneously)

property OnAfterResponse: TOnHttpServerAfterResponse **read** fOnAfterResponse **write** SetOnAfterResponse;

Event handler called after response is sent back to client

- main purpose is to apply post-response analysis, logging, etc.

- warning: this handler must be thread-safe (can be called by several threads simultaneously)

property OnBeforeBody: TOnHttpServerBeforeBody **read** fOnBeforeBody **write** SetOnBeforeBody;

Event handler called just before the body is retrieved from the client

- should return STATUS_SUCCESS=200 to continue the process, or an HTTP error code to reject the request immediatly, and close the connection

property OnBeforeRequest: TOnHttpRequest **read** fOnBeforeRequest **write** SetOnBeforeRequest;

Event handler called after HTTP body has been retrieved, before OnProcess

- may be used e.g. to return a STATUS_ACCEPTED (202) status to client and continue a long-term job inside the OnProcess handler in the same thread; or to modify incoming information before passing it to main businnes logic, (header preprocessor, body encoding etc...)
 - if the handler returns > 0 server will send a response immediatly, unless return code is STATUS_ACCEPTED (202), then OnRequest will be called
 - warning: this handler must be thread-safe (can be called by several threads simultaneously)

property OnHttpThreadStart: TNotifyThreadEvent **read** fOnHttpThreadStart **write** fOnHttpThreadStart;

Event handler called after each working Thread is just initiated

- called in the thread context at first place in THttpServerGeneric.Execute

property OnHttpThreadTerminate: TNotifyThreadEvent **read** fOnThreadTerminate **write** SetOnTerminate;

Event handler called when a working Thread is terminating

- called in the corresponding thread context
 - the TThread.OnTerminate event will be called within a Synchronize() wrapper, so it won't fit our purpose
 - to be used e.g. to call CoUnInitialize from thread in which CoInitialize was made, for instance via a method defined as such:

```
procedure TMyServer.OnHttpThreadTerminate(Sender: TObject);  
begin // TSQLDBConnectionPropertiesThreadSafe  
    fMyConnectionProps.EndCurrentThread;  
end;
```

- is used e.g. by TSQLRest.EndCurrentThread for proper multi-threading

property OnRequest: TOnHttpRequest **read** fOnRequest **write** SetOnRequest;

Event handler called by the default implementation of the virtual Request method

- warning: this process must be thread-safe (can be called by several threads simultaneously)

Used for DI-2.1.1.2.4 (page 2555).

property ProcessName: SockString **read** fProcessName **write** fProcessName;

The associated process name

property RemoteConnIDHeader: SockString **read** fRemoteConnIDHeader **write** SetRemoteConnIDHeader;

The value of a custom HTTP header containing the real client connection ID

- by default, Ctxt.ConnectionID information will be retrieved from our socket layer - but if the server runs behind some proxy service, you should define here the HTTP header name which indicates the real remote connection, for example as 'X-Conn-ID', setting in nginx config:

```
proxy_set_header    X-Conn-ID    $connection
```

property RemoteIPHeader: SockString **read** fRemoteIPHeader **write** SetRemoteIPHeader;

The value of a custom HTTP header containing the real client IP

- by default, the RemoteIP information will be retrieved from the socket layer - but if the server runs behind some proxy service, you should define here the HTTP header name which indicates the true remote client IP value, mostly as 'X-Real-IP' or 'X-Forwarded-For'

property ServerName: SockString **read** fServerName **write** SetServerName;

The Server name, UTF-8 encoded, e.g. 'mORMot/1.18 (Linux)'

- will be served as "Server: ..." HTTP header
- for THttpApiServer, when called from the main instance, will propagate the change to all cloned instances, and included in any HTTP API 2.0 log

THttpApiServer = class(THttpServerGeneric)

HTTP server using fast http.sys kernel-mode server

- The HTTP Server API enables applications to communicate over HTTP without using Microsoft Internet Information Server (IIS). Applications can register to receive HTTP requests for particular URLs, receive HTTP requests, and send HTTP responses. The HTTP Server API includes SSL support so that applications can exchange data over secure HTTP connections without IIS. It is also designed to work with I/O completion ports.
- The HTTP Server API is supported on Windows Server 2003 operating systems and on Windows XP with Service Pack 2 (SP2). Be aware that Microsoft IIS 5 running on Windows XP with SP2 is not able to share port 80 with other HTTP applications running simultaneously.

Used for DI-2.1.1.2.4 (page 2555).

constructor Create(CreateSuspended: boolean; QueueName: SockUnicode=''; OnStart: TNotifyThreadEvent=nil; OnStop: TNotifyThreadEvent=nil; **const** ProcessName: SockString=''); **reintroduce**;

Initialize the HTTP Service

- will raise an exception if http.sys is not available e.g. before Windows XP SP2) or if the request queue creation failed
- if you override this constructor, put the AddUrl() methods within, and you can set CreateSuspended to FALSE
- if you will call AddUrl() methods later, set CreateSuspended to TRUE, then call explicitly the Resume method, after all AddUrl() calls, in order to start the server

Used for DI-2.1.1.2.4 (page 2555).

destructor Destroy; **override**;

Release all associated memory and handles

```
function AddUrl(const aRoot, aPort: SockString; Https: boolean=false; const
aDomainName: SockString='*'; aRegisterURI: boolean=false; aContext: Int64=0):
integer;
```

Register the URLs to Listen On

- e.g. AddUrl('root','888')
- aDomainName could be either a fully qualified case-insensitive domain name, an IPv4 or IPv6 literal string, or a wildcard ('+' will bound to all domain names for the specified port, '*' will accept the request when no other listening hostnames match the request for that port)
- return 0 (NO_ERROR) on success, an error code if failed: under Vista and Seven, you could have ERROR_ACCESS_DENIED if the process is not running with enough rights (by default, UAC requires administrator rights for adding an URL to http.sys registration list) - solution is to call the THttpApiServer.AddUrlAuthorize class method during program setup
- if this method is not used within an overridden constructor, default Create must have been called with CreateSuspended = TRUE and then call the Resume method after all Url have been added
- if aRegisterURI is TRUE, the URI will be registered (need administrator rights) - default is FALSE, as defined by Windows security policy

```
class function AddUrlAuthorize(const aRoot, aPort: SockString; Https:
boolean=false; const aDomainName: SockString='*'; OnlyDelete: boolean=false):
string;
```

Will authorize a specified URL prefix

- will allow to call AddUrl() later for any user on the computer
- if aRoot is left "", it will authorize any root for this port
- must be called with Administrator rights: this class function is to be used in a Setup program for instance, especially under Vista or Seven, to reserve the Url for the server
- add a new record to the http.sys URL reservation store
- return "" on success, an error message otherwise
- will first delete any matching rule for this URL prefix
- if OnlyDelete is true, will delete but won't add the new authorization; in this case, any error message at deletion will be returned

```
function HasAPI2: boolean;
```

Can be used to check if the HTTP API 2.0 is available

```
function RemoveUrl(const aRoot, aPort: SockString; Https: boolean=false; const
aDomainName: SockString='*'): integer;
```

Un-register the URLs to Listen On

- this method expect the same parameters as specified to AddUrl()
- return 0 (NO_ERROR) on success, an error code if failed (e.g.
- 1 if the corresponding parameters do not match any previous AddUrl)

```
procedure Clone(ChildThreadCount: integer);
```

Will clone this thread into multiple other threads

- could speed up the process on multi-core CPU
- will work only if the OnProcess property was set (this is the case e.g. in TSQLHttpServer.Create() constructor)
- maximum value is 256 - higher should not be worth it

```
procedure LogStart(const aLogFolder: TFileName; aType: THttpApiLoggingType=hltW3C;  
const aSoftwareName: TFileName=''; aRolloverType:  
THttpApiLoggingRollOver=hlrDaily; aRolloverSize: cardinal=0; aLogFields:  
THttpApiLogFields=[hlfDate..hlfSubStatus]; aFlags:  
THttpApiLoggingFlags=[hlfUseUTF8Conversion]);
```

Enable HTTP API 2.0 logging

- will raise an EHttpApiServer exception if the old HTTP API 1.x is used so you should better test the availability of the method first:

```
if aServer.HasAPI2 then  
  LogStart(...);
```

- this method won't do anything on the cloned instances, but the main instance logging state will be replicated to all cloned instances

- you can select the output folder and the expected logging layout

- aSoftwareName will set the optional W3C-only software name string

- aRolloverSize will be used only when aRolloverType is hlrSize

```
procedure LogStop;
```

Disable HTTP API 2.0 logging

- this method won't do anything on the cloned instances, but the main instance logging state will be replicated to all cloned instances

```
procedure RegisterCompress(aFunction: THttpSocketCompress; aCompressMinSize:  
integer=1024); override;
```

Will register a compression algorithm

- overridden method which will handle any cloned instances

```
procedure SetAuthenticationSchemes(schemes: THttpApiRequestAuthentications; const  
DomainName: SockUnicode=''; const Realm: SockUnicode='');
```

Enable HTTP API 2.0 server-side authentication

- once enabled, the client sends an unauthenticated request: it is up to the server application to generate the initial 401 challenge with proper WWW-Authenticate headers; any further authentication steps will be performed in kernel mode, until the authentication handshake is finalized; later on, the application can check the AuthenticationStatus property of

THttpRequest and its associated AuthenticatedUser value see

<https://msdn.microsoft.com/en-us/library/windows/desktop/aa364452>

- will raise an EHttpApiServer exception if the old HTTP API 1.x is used so you should better test the availability of the method first:

```
if aServer.HasAPI2 then  
  SetAuthenticationSchemes(...);
```

- this method will work on the current group, for all instances

- see HTTPAPI_AUTH_ENABLE_ALL constant to set all available schemes

- optional Realm parameters can be used when haBasic scheme is defined

- optional DomainName and Realm parameters can be used for haDigest

procedure SetTimeOutLimits(aEntityBody, aDrainEntityBody, aRequestQueue, aIdleConnection, aHeaderWait, aMinSendRate: cardinal);

Enable HTTP API 2.0 advanced timeout settings

- all those settings are set for the current URL group
- will raise an EHttpApiServer exception if the old HTTP API 1.x is used so you should better test the availability of the method first:

```
if aServer.HasAPI2 then
  SetTimeOutLimits(...);
```
- aEntityBody is the time, in seconds, allowed for the request entity body to arrive - default value is 2 minutes
- aDrainEntityBody is the time, in seconds, allowed for the HTTP Server API to drain the entity body on a Keep-Alive connection - default value is 2 minutes
- aRequestQueue is the time, in seconds, allowed for the request to remain in the request queue before the application picks it up - default value is 2 minutes
- aIdleConnection is the time, in seconds, allowed for an idle connection; is similar to THttpServer.ServerKeepAliveTimeOut - default value is 2 minutes
- aHeaderWait is the time, in seconds, allowed for the HTTP Server API to parse the request header - default value is 2 minutes
- aMinSendRate is the minimum send rate, in bytes-per-second, for the response - default value is 150 bytes-per-second
- any value set to 0 will set the HTTP Server API default value

property AuthenticationSchemes: THttpApiRequestAuthentications **read** fAuthenticationSchemes;

Read-only access to HTTP API 2.0 server-side enabled authentication schemes

property Cloned: boolean **read** GetCloned;

TRUE if this instance is in fact a cloned instance for the thread pool

property Clones: THttpApiServers **read** fClones;

Access to the internal THttpApiServer list cloned by this main instance
- as created by Clone() method

property Logging: boolean **read** GetLogging;

Read-only access to check if the HTTP API 2.0 logging is enabled
- use LogStart/LogStop methods to change this property value

property LoggingServiceName: SockString **read** fLoggingServiceName **write** SetLoggingServiceName;

The current HTTP API 2.0 logging Service name
- should be UTF-8 encoded, if LogStart(aFlags=[hlfUseUTF8Conversion])
- this value is dedicated to one instance, so the main instance won't propagate the change to all cloned instances

property MaxBandwidth: Cardinal **read** GetMaxBandwidth **write** SetMaxBandwidth;

The maximum allowed bandwidth rate in bytes per second (via HTTP API 2.0)
- Setting this value to 0 allows an unlimited bandwidth
- by default Windows not limit bandwidth (actually limited to 4 Gbit/sec).
- will return 0 if the system does not support HTTP API 2.0 (i.e. under Windows XP or Server 2003)

property MaxConnections: Cardinal **read** GetMaxConnections **write** SetMaxConnections;

The maximum number of HTTP connections allowed (via HTTP API 2.0)

- Setting this value to 0 allows an unlimited number of connections
- by default Windows does not limit number of allowed connections
- will return 0 if the system does not support HTTP API 2.0 (i.e. under Windows XP or Server 2003)

property ReceiveBufferSize: cardinal **read** fReceiveBufferSize **write** SetReceiveBufferSize;

How many bytes are retrieved in a single call to ReceiveRequestEntityBody

- set by default to 1048576, i.e. 1 MB - practical limit is around 20 MB
- you may customize this value if you encounter HTTP error STATUS_NOTACCEPTABLE (406) from client, corresponding to an ERROR_NO_SYSTEM_RESOURCES (1450) exception on server side, when uploading huge data content

property RegisteredUrl: SockUnicode **read** GetRegisteredUrl;

Return the list of registered URL on this server instance

property ServerSessionID: HTTP_SERVER_SESSION_ID **read** fServerSessionID;

Read-only access to the low-level HTTP API 2.0 Session ID

property UrlGroupID: HTTP_URL_GROUP_ID **read** fUrlGroupID;

Read-only access to the low-level HTTP API 2.0 URI Group ID

THttpApiWebSocketConnection = object(TObject)

Structure representing a single WebSocket connection

procedure Close(aStatus: WEB_SOCKET_CLOSE_STATUS; aBuffer: Pointer; aBufferSize: ULONG);

Close connection

procedure Send(aBufferType: WEB_SOCKET_BUFFER_TYPE; aBuffer: Pointer; aBufferSize: ULONG);

Send data to client

property Index: integer **read** fIndex;

Index of connection in protocol's connection list

property PrivateData: pointer **read** fPrivateData **write** fPrivateData;

Custom user data

property Protocol: THttpApiWebSocketServerProtocol **read** fProtocol;

Protocol of connection

property State: TWebSocketState **read** fState;

Access to the current state of this connection

THttpApiWebSocketServerProtocol = class(TObject)

Protocol Handler of websocket endpoints events

- maintains a list of all WebSockets clients for a given protocol

```
constructor Create(const aName: SockString; aManualFragmentManagement: Boolean;  
aServer: THttpApiWebSocketServer; aOnAccept:  
THttpApiWebSocketServerOnAcceptEvent; aOnMessage:  
THttpApiWebSocketServerOnMessageEvent; aOnConnect:  
THttpApiWebSocketServerOnConnectEvent; aOnDisconnect:  
THttpApiWebSocketServerOnDisconnectEvent; aOnFragment:  
THttpApiWebSocketServerOnMessageEvent=nil);
```

Initialize the WebSockets process

- if aManualFragmentManagement is true, onMessage will appear only for whole received messages, otherwise OnFragment handler must be passed (for video broadcast, for example)

```
destructor Destroy; override;
```

Finalize the process

```
function Broadcast(aBufferType: ULONG; aBuffer: Pointer; aBufferSize: ULONG):  
boolean;
```

Send message to all connections of this protocol

```
function Close(index: Integer; aStatus: WEB_SOCKET_CLOSE_STATUS; aBuffer: Pointer;  
aBufferSize: ULONG): boolean;
```

Close WebSocket connection identified by its index

```
function Send(index: Integer; aBufferType: ULONG; aBuffer: Pointer; aBufferSize:  
ULONG): boolean;
```

Send message to the WebSocket connection identified by its index

```
property Index: integer read fIndex;
```

Identify the endpoint instance

```
property ManualFragmentManagement: Boolean read fManualFragmentManagement;
```

OnFragment event will be called for each fragment

```
property Name: SockString read fName;
```

Text identifier

```
property OnAccept: THttpApiWebSocketServerOnAcceptEvent read fOnAccept;
```

Event triggered when a WebSockets client is initiated

```
property OnConnect: THttpApiWebSocketServerOnConnectEvent read fOnConnect;
```

Event triggered when a WebSockets client is connected

```
property OnDisconnect: THttpApiWebSocketServerOnDisconnectEvent read  
fOnDisconnect;
```

Event triggered when a WebSockets client is gracefully disconnected

```
property OnFragment: THttpApiWebSocketServerOnMessageEvent read fOnFragment;
```

Event triggered when a non complete frame is received

- required if ManualFragmentManagement is true

```
property OnMessage: THttpApiWebSocketServerOnMessageEvent read fOnMessage;
```

Event triggered when a WebSockets message is received

THttpApiWebSocketServer = class(THttpApiServer)

HTTP & WebSocket server using fast http.sys kernel-mode server

- can be used like simple THttpApiServer
- when AddUrlWebSocket is called WebSocket support are added in this case WebSocket will receiving the frames in asynchronous

constructor Create(CreateSuspended: Boolean; aSocketThreadsCount: integer=1; aPingTimeout: integer=0; QueueName: SockUnicode=''; aOnWSThreadStart: TNotifyThreadEvent=nil; aOnWSThreadTerminate: TNotifyThreadEvent=nil);
reintroduce;

Initialize the HTTPAPI based Server with WebSocket support

- will raise an exception if http.sys or websocket.dll is not available (e.g. before Windows 8) or if the request queue creation failed
- for aPingTimeout explanation see PingTimeout property documentation

function AddUrlWebSocket(const aRoot, aPort: SockString; Https: boolean=false; const aDomainName: SockString='*'; aRegisterURI: boolean=false): integer;

Register the URLs to Listen on using WebSocket

- aProtocols is an array of a record with callbacks, server call during WebSocket activity

procedure RegisterProtocol(const aName: SockString; aManualFragmentManagement: Boolean; aOnAccept: THttpApiWebSocketServerOnAcceptEvent; aOnMessage: THttpApiWebSocketServerOnMessageEvent; aOnConnect: THttpApiWebSocketServerOnConnectEvent; aOnDisconnect: THttpApiWebSocketServerOnDisconnectEvent; aOnFragment: THttpApiWebSocketServerOnMessageEvent=nil);

Prepare the process for a given THttpApiWebSocketServerProtocol

procedure SendServiceMessage;

Can be called from any thread

- will send a "service" message to a WebSocketServer to wake up a WebSocket thread
- When a websocket thread receives such a message it will call onServiceMessage in the thread context

property OnServiceMessage: TThreadMethod read fOnServiceMessage write fOnServiceMessage;

Event called when a service message is raised

property OnWSThreadStart: TNotifyThreadEvent read FOnWSThreadStart write SetOnWSThreadStart;

Event called when the processing thread starts

property OnWSThreadTerminate: TNotifyThreadEvent read FOnWSThreadTerminate write SetOnWSThreadTerminate;

Event called when the processing thread terminates

property PingTimeout: integer read fPingTimeout;

Ping timeout in seconds. 0 mean no ping.

- if connection not receive messages longer than this timeout TSynWebSocketGuard will send ping frame
- if connection not receive any messages longer than double of this timeout it will be closed

```
property Protocols[index: integer]: THttpApiWebSocketServerProtocol read  
GetProtocol;
```

Access to the associated endpoints

```
property ProtocolsCount: Integer read getProtocolsCount;
```

Access to the associated endpoints count

```
TSynThreadPoolHttpApiWebSocketServer = class(TSynThreadPool)
```

A Thread Pool, used for fast handling WebSocket requests

```
constructor Create(Server: THttpApiWebSocketServer; NumberOfThreads: Integer=1);  
reintroduce;
```

Initialize the thread pool

```
TSynWebSocketGuard = class(TThread)
```

Thread for closing WebSocket connections which not response more than PingTimeout interval

```
constructor Create(Server: THttpApiWebSocketServer); reintroduce;
```

Initialize the thread

```
THttpServer = class(THttpServerGeneric)
```

Main HTTP server Thread using the standard Sockets API (e.g. WinSock)

- bind to a port and listen to incoming requests
- assign this requests to THttpServerResp threads from a ThreadPool
- it implements a HTTP/1.1 compatible server, according to RFC 2068 specifications
- if the client is also HTTP/1.1 compatible, KeepAlive connection is handled: multiple requests will use the existing connection and thread; this is faster and uses less resources, especially under Windows
- a Thread Pool is used internally to speed up HTTP/1.0 connections - a typical use, under Linux, is to run this class behind a NGINX frontend, configured as https reverse proxy, leaving default "proxy_http_version 1.0" and "proxy_request_buffering on" options for best performance, and setting KeepAliveTimeOut=0 in the THttpServer.Create constructor
- under windows, will trigger the firewall UAC popup at first run
- don't forget to use Free method when you are finished

Used for DI-2.1.1.2.4 (page 2555).

```
constructor Create(const aPort: SockString; OnStart,OnStop: TNotifyThreadEvent;  
const ProcessName: SockString; ServerThreadPoolCount: integer=32;  
KeepAliveTimeOut: integer=30000; HeadersUnFiltered: boolean=false;  
CreateSuspended: boolean = false); reintroduce; virtual;
```

Create a Server Thread, ready to be bound and listening on a port

- this constructor will raise a EHttpServer exception if binding failed
- expects the port to be specified as string, e.g. '1234'; you can optionally specify a server address to bind to, e.g. '1.2.3.4:1234'
- can listed on UDS in case port is specified with 'unix:' prefix, e.g. 'unix:/run/myapp.sock'
- on Linux in case aPort is empty string will check if external fd is passed by systemd and use it (so called systemd socked activation)
- you can specify a number of threads to be initialized to handle incoming connections. Default is 32, which may be sufficient for most cases, maximum is 256. If you set 0, the thread pool will be disabled and one thread will be created for any incoming connection
- you can also tune (or disable with 0) HTTP/1.1 keep alive delay and how incoming request Headers[] are pushed to the processing method
- this constructor won't actually do the port binding, which occurs in the background thread: caller should therefore call WaitStarted after THttpServer.Create()

Used for DI-2.1.1.2.4 (page 2555).

```
destructor Destroy; override;
```

Release all memory and handlers

```
procedure NginxSendFileFrom(const FileNameLeftTrim: TFileName);
```

Enable NGINX X-Accel internal redirection for HTTP_RESP_STATICFILE

- will define internally a matching OnSendFile event handler
- generating "X-Accel-Redirect: " header, trimming any supplied left case-sensitive file name prefix, e.g. with NginxSendFileFrom('/var/www'):

```
# Will serve /var/www/protected_files/myfile.tar.gz  
# When passed URI /protected_files/myfile.tar.gz  
location /protected_files {  
    internal;  
    root /var/www;  
}
```

- call this method several times to register several folders

```
procedure WaitStarted(Seconds: integer = 30); virtual;
```

Ensure the HTTP server thread is actually bound to the specified port

- TCrtSocket.Bind() occurs in the background in the Execute method: you should call and check this method result just after THttpServer.Create
- initial THttpServer design was to call Bind() within Create, which works fine on Delphi + Windows, but fails with a EThreadError on FPC/Linux
- raise a ECrtSocket if binding failed within the specified period (if port is free, it would be almost immediate)
- calling this method is optional, but if the background thread didn't actually bind the port, the server will be stopped and unresponsive with no explicit error message, until it is terminated

```
property HeaderRetrieveAbortDelay: integer read fHeaderRetrieveAbortDelay write fHeaderRetrieveAbortDelay;
```

Milliseconds delay to reject a connection due to too long header retrieval

- default is 0, i.e. not checked (typically not needed behind a reverse proxy)

property HeadersNotFiltered: boolean **read** fHeadersNotFiltered;

By default, only relevant headers are added to internal headers list

- for instance, Content-Length, Content-Type and Content-Encoding are stored as fields in this THttpSocket, but not included in its Headers[]
- set this property to true to include all incoming headers

property OnSendFile: TOnHttpServerSendFile **read** fOnSendFile **write** fOnSendFile;

Custom event handler used to send a local file for HTTP_RESP_STATICFILE

- see also NgInxSendFileFrom() method

property ServerConnectionActive: integer **read** fServerConnectionActive **write** fServerConnectionActive;

Will contain the current number of connections to the server

property ServerConnectionCount: integer **read** fServerConnectionCount **write** fServerConnectionCount;

Will contain the total number of connections to the server

- it's the global count since the server started

property ServerKeepAliveTimeOut: cardinal **read** fServerKeepAliveTimeOut **write** fServerKeepAliveTimeOut;

Time, in milliseconds, for the HTTP/1.1 connections to be kept alive

- default is 30000 ms, i.e. 30 seconds
- setting 0 here (or in KeepAliveTimeOut constructor parameter) will disable keep-alive, and fallback to HTTP.1/0 for all incoming requests (may be a good idea e.g. behind a NGINX reverse proxy)
- see THttpApiServer.SetTimeOutLimits(aIdleConnection) parameter

property Sock: TCrtSocket **read** fSock;

Access to the main server low-level Socket

- it's a raw TCrtSocket, which only need a socket to be bound, listening and accept incoming request
- THttpServerSocket are created on the fly for every request, then a THttpServerResp thread is created for handling this THttpServerSocket

property SockPort: SockString **read** fSockPort;

The bound TCP port, as specified to Create() constructor

- TCrtSocket.Bind() occurs in the Execute method

property StatBodyProcessed: integer **index** grBodyReceived **read** GetStat;

How many HTTP bodies have been processed

property StatHeaderErrors: integer **index** grError **read** GetStat;

How many invalid HTTP headers have been rejected

property StatHeaderException: integer **index** grException **read** GetStat;

How many invalid HTTP headers raised an exception

property StatHeaderProcessed: integer **index** grHeaderReceived **read** GetStat;

How many HTTP headers have been processed

property StatHeaderTimeout: integer **index** grTimeout **read** GetStat;

How many HTTP requests were rejected after HeaderRetrieveAbortDelay timeout

property StatOversizedPayloads: integer **index** grOversizedPayload **read** GetStat;

How many HTTP requests pushed more than MaximumAllowedContentLength bytes

property StatOwnedConnections: integer **index** grOwned **read** GetStat;

How many HTTP connections were passed to an asynchronous handler

- e.g. for background WebSockets processing after proper upgrade

property StatRejected: integer **index** grRejected **read** GetStat;

How many HTTP requests were rejected by the OnBeforeBody event handler

property TCPPrefix: SockString **read** fTCPPrefix **write** fTCPPrefix;

TCP/IP prefix to mask HTTP protocol

- if not set, will create full HTTP/1.0 or HTTP/1.1 compliant content

- in order to make the TCP/IP stream not HTTP compliant, you can specify a prefix which will be put before the first header line: in this case, the TCP/IP stream won't be recognized as HTTP, and will be ignored by most AntiVirus programs, and increase security - but you won't be able to use an Internet Browser nor AJAX application for remote access any more

property ThreadPool: TSynThreadPoolTHttpServer **read** fThreadPool;

The associated thread pool

- may be nil if ServerThreadPoolCount was 0 on constructor

TURI = object(TObject)

Structure used to parse an URI into its components

- ready to be supplied e.g. to a THttpRequest sub-class

- used e.g. by class function THttpRequest.Get()

- will decode standard HTTP/HTTPS urls or Unix sockets URI like

'http://unix:/path/to/socket.sock:/url/path'

Address: SockString;

The resource address, including optional parameters

- e.g. '/category/name/10?param=1'

Https: boolean;

If the server is accessible via https:// and not plain http://

Layer: TCrtSocketLayer;

Either cslTcp for HTTP/HTTPS or cslUnix for Unix socket URI

Port: SockString;

The server port

- e.g. '80'

Scheme: SockString;

If the server is accessible via something else than http:// or https://

- e.g. 'ws' or 'wss' for ws:// or wss://

Server: SockString;

The server name

- e.g. 'www.somewebsite.com' or 'path/to/socket.sock' Unix socket URI

function From(aURI: SockString; const DefaultPort: SockString=''): boolean;

Fill the members from a supplied URI

- recognize e.g. 'http://Server:Port/Address', 'https://Server/Address', 'Server/Address' (as http), or 'http://unix:/Server:/Address'
- returns TRUE is at least the Server has been extracted, FALSE on error

function PortInt: integer;

The server port, as integer value

function Root: SockString;

Compute the root resource Address, without any URI-encoded parameter

- e.g. '/category/name/10'

function URI: SockString;

Compute the whole normalized URI

- e.g. 'https://Server:Port/Address' or 'http://unix:/Server:/Address'

procedure Clear;

Reset all stored information

THttpRequestExtendedOptions = record

A record to set some extended options for HTTP clients

- allow easy propagation e.g. from a TSQLHttpClient* wrapper class to the actual SynCrtSock's THttpRequest implementation class

Auth: record

Allow HTTP authentication to take place at connection

- Auth.Scheme and Username/Password properties are handled by the TWinHttp class only by now

IgnoreSSLCertificateErrors: boolean;

Let HTTPS be less paranoid about SSL certificates

- IgnoreSSLCertificateErrors is handled by TWinHttp and TCurlHTTP

UserAgent: SockString;

Allow to customize the User-Agent header

THttpRequest = class(TObject)

To have existing RTTI for published properties abstract class to handle HTTP/1.1 request

- never instantiate this class, but inherited TWinHTTP, TWinINet or TCurlHTTP

constructor Create(const aURI: SockString; const aProxyName: SockString=''; const aProxyByPass: SockString=''; ConnectionTimeout: DWORD=0; SendTimeout: DWORD=0; ReceiveTimeout: DWORD=0; aIgnoreSSLCertificateErrors: boolean=false); overload;

Connect to the supplied URI

- is just a wrapper around TURI and the overloaded Create() constructor

```
constructor Create(const aServer, aPort: SockString; aHttps: boolean; const
aProxyName: SockString=''; const aProxyByPass: SockString=''; ConnectionTimeOut:
DWORD=0; SendTimeout: DWORD=0; ReceiveTimeout: DWORD=0; aLayer:
TCrtSocketLayer=cs1TCP); overload; virtual;
```

Connect to http://aServer:aPort or https://aServer:aPort

- optional aProxyName may contain the name of the proxy server to use, and aProxyByPass an optional semicolon delimited list of host names or IP addresses, or both, that should not be routed through the proxy: aProxyName/aProxyByPass will be recognized by TWinHTTP and TWinINet, and aProxyName will set the CURLOPT_PROXY option to TCurlHttp (see https://curl.haxx.se/libcurl/c/CURLOPT_PROXY.html as reference)
- you can customize the default client timeouts by setting appropriate SendTimeout and ReceiveTimeout parameters (in ms) - note that after creation of this instance, the connection is tied to the initial parameters, so we won't publish any properties to change those initial values once created - if you left the 0 default parameters, it would use global HTTP_DEFAULT_CONNECTTIMEOUT, HTTP_DEFAULT_SENDBTIMEOUT and HTTP_DEFAULT_RECEIVETIMEOUT variable values
- *TimeOut parameters are currently ignored by TCurlHttp

```
class function Delete(const aURI: SockString; const aHeader: SockString='';
aIgnoreSSLCertificateErrors: boolean=true; outHeaders: PSockString=nil; outStatus:
PInteger=nil): SockString;
```

Wrapper method to delete a resource via an HTTP DELETE

- will parse the supplied URI to check for the http protocol (HTTP/HTTPS), server name and port, and resource name
- aIgnoreSSLCertificateErrors will ignore the error when using untrusted certificates
- it will internally create a THttpRequest inherited instance: do not use THttpRequest.Delete() but either TWinHTTP.Delete(), TWinINet.Delete() or TCurlHTTP.Delete() methods

```
class function Get(const aURI: SockString; const aHeader: SockString='';
aIgnoreSSLCertificateErrors: boolean=true; outHeaders: PSockString=nil; outStatus:
PInteger=nil): SockString;
```

Wrapper method to retrieve a resource via an HTTP GET

- will parse the supplied URI to check for the http protocol (HTTP/HTTPS), server name and port, and resource name
- aIgnoreSSLCertificateErrors will ignore the error when using untrusted certificates
- it will internally create a THttpRequest inherited instance: do not use THttpRequest.Get() but either TWinHTTP.Get(), TWinINet.Get() or TCurlHTTP.Get() methods

```
class function IsAvailable: boolean; virtual; abstract;
```

Returns TRUE if the class is actually supported on this system

```
class function Post(const aURI, aData: SockString; const aHeader: SockString='';
aIgnoreSSLCertificateErrors: boolean=true; outHeaders: PSockString=nil; outStatus:
PInteger=nil): SockString;
```

Wrapper method to create a resource via an HTTP POST

- will parse the supplied URI to check for the http protocol (HTTP/HTTPS), server name and port, and resource name
- aIgnoreSSLCertificateErrors will ignore the error when using untrusted certificates
- the supplied aData content is POSTed to the server, with an optional aHeader content
- it will internally create a THttpRequest inherited instance: do not use THttpRequest.Post() but either TWinHTTP.Post(), TWinINet.Post() or TCurlHTTP.Post() methods

```
class function Put(const aURI, aData: SockString; const aHeader: SockString='';  
aIgnoreSSLCertificateErrors: boolean=true; outHeaders: PSockString=nil; outStatus:  
PInteger=nil): SockString;
```

Wrapper method to update a resource via an HTTP PUT

- will parse the supplied URI to check for the http protocol (HTTP/HTTPS), server name and port, and resource name
- aIgnoreSSLCertificateErrors will ignore the error when using untrusted certificates
- the supplied aData content is PUT to the server, with an optional aHeader content
- it will internally create a THttpRequest inherited instance: do not use THttpRequest.Put() but either TWinHTTP.Put(), TWInINet.Put() or TCurlHTTP.Put() methods

```
function RegisterCompress(aFunction: THttpSocketCompress; aCompressMinSize:  
integer=1024): boolean;
```

Will register a compression algorithm

- used e.g. to compress on the fly the data, with standard gzip/deflate or custom (synlzo/synlz) protocols
- returns true on success, false if this function or this ACCEPT-ENCODING: header was already registered
- you can specify a minimal size (in bytes) before which the content won't be compressed (1024 by default, corresponding to a MTU of 1500 bytes)
- the first registered algorithm will be the preferred one for compression

```
function Request(const url, method: SockString; KeepAlive: cardinal; const InHeader,  
InData, InDataType: SockString; out OutHeader, OutData: SockString): integer;  
virtual;
```

Low-level HTTP/1.1 request

- after an Create(server,port), return 200,202,204 if OK, http status error otherwise
- KeepAlive is in milliseconds, 0 for "Connection: Close" HTTP/1.0 requests

```
property AuthPassword: SockUnicode read fExtendedOptions.Auth.Password write  
fExtendedOptions.Auth.Password;
```

Optional Password for Authentication

```
property AuthScheme: THttpRequestAuthentication read fExtendedOptions.Auth.Scheme  
write fExtendedOptions.Auth.Scheme;
```

Optional Authentication Scheme

```
property AuthUserName: SockUnicode read fExtendedOptions.Auth.UserName write  
fExtendedOptions.Auth.UserName;
```

Optional User Name for Authentication

```
property ExtendedOptions: THttpRequestExtendedOptions read fExtendedOptions write  
fExtendedOptions;
```

Internal structure used to store extended options

- will be replicated by IgnoreSSLCertificateErrors and Auth* properties

```
property Https: boolean read fHttps;
```

If the remote server uses HTTPS, as specified to the class constructor

```
property IgnoreSSLCertificateErrors: boolean read  
fExtendedOptions.IgnoreSSLCertificateErrors write  
fExtendedOptions.IgnoreSSLCertificateErrors;
```

Allows to ignore untrusted SSL certificates

- similar to adding a security exception for a domain in the browser

property Port: cardinal read fPort;

The remote server port number, as specified to the class constructor

property ProxyByPass: SockString read fProxyByPass;

The remote server optional proxy by-pass list, as specified to the class constructor

property ProxyName: SockString read fProxyName;

The remote server optional proxy, as specified to the class constructor

property Server: SockString read fServer;

The remote server host name, as stated specified to the class constructor

property Tag: PtrInt read fTag write fTag;

Some internal field, which may be used by end-user code

property UserAgent: SockString read fExtendedOptions.UserAgent write fExtendedOptions.UserAgent;

Custom HTTP "User Agent:" header value

TwinHttpAPI = class(THttpRequest)

A class to handle HTTP/1.1 request using either WinINet or WinHTTP API

- both APIs have a common logic, which is encapsulated by this parent class
- this abstract class defined some abstract methods which will be implemented by TWinINet or TWinHttp with the proper API calls

class function IsAvailable: boolean; **override**;

Returns TRUE if the class is actually supported on this system

property NoAllAccept: boolean read fNoAllAccept write fNoAllAccept;

*Do not add "Accept: */*" HTTP header by default*

property OnDownload: TwinHttpDownload read fOnDownload write fOnDownload;

Download would call this method instead of filling Data: SockString value

- may be used e.g. when downloading huge content, and saving directly the incoming data on disk or database
- if this property is set, raw TCP/IP incoming data would be supplied: compression and encoding won't be handled by the class

property OnDownloadChunkSize: cardinal read fOnDownloadChunkSize write fOnDownloadChunkSize;

How many bytes should be retrieved for each OnDownload event chunk

- if default 0 value is left, would use 65536, i.e. 64KB

property OnProgress: TwinHttpProgress read fOnProgress write fOnProgress;

Download would call this method to notify progress of incoming data

property OnUpload : TwinHttpUpload read fOnUpload write fOnUpload;

Upload would call this method to notify progress of outgoing data

- and optionally abort sending the data by returning FALSE

```
TwinINet = class(TWinHttpAPI)
```

A class to handle HTTP/1.1 request using the WinINet API

- The Microsoft Windows Internet (WinINet) application programming interface (API) enables applications to access standard Internet protocols, such as FTP and HTTP/HTTPS, similar to what IE offers
- by design, the WinINet API should not be used from a service, since this API may require end-user GUI interaction
- note: WinINet is MUCH slower than THttpClientSocket or TWinHttp: do not use this, only if you find some configuration benefit on some old networks (e.g. to display the dialup popup window for a GUI client application)

```
destructor Destroy; override;
```

Relase the connection

```
EWinINet = class(ECrtSocket)
```

WinINet exception type

```
constructor Create;
```

Create a WinINet exception, with the error message as text

```
TwinHTTP = class(TWinHttpAPI)
```

A class to handle HTTP/1.1 request using the WinHTTP API

- has a common behavior as THttpClientSocket() but seems to be faster over a network and is able to retrieve the current proxy settings (if available) and handle secure https connection - so it seems to be the class to use in your client programs
- WinHTTP does not share any proxy settings with Internet Explorer. The WinHTTP proxy configuration is set by either
proxycfg.exe
on Windows XP and Windows Server 2003 or earlier, either
netsh.exe
on Windows Vista and Windows Server 2008 or later; for instance, you can run either:
proxycfg -u
netsh winhttp import proxy source=ie
to use the current user's proxy settings for Internet Explorer (under 64-bit Vista/Seven, to configure applications using the 32 bit WinHttp settings, call netsh or proxycfg bits from %SystemRoot%\SysWOW64 folder explicetely)
- Microsoft Windows HTTP Services (WinHTTP) is targeted at middle-tier and back-end server applications that require access to an HTTP client stack

```
destructor Destroy; override;
```

Relase the connection

```
EWinHTTP = class(Exception)
```

WinHTTP exception type

TwinHTTPUpgradeable = class(TwinHTTP)

A class to establish a client connection to a WebSocket server using Windows API

- used by TwinWebSocketClient class

constructor Create(**const** aServer, aPort: SockString; aHttps: boolean; **const** aProxyName: SockString=''; **const** aProxyByPass: SockString=''; ConnectionTimeout: DWORD=0; SendTimeout: DWORD=0; ReceiveTimeout: DWORD=0; aLayer: TCrtSocketLayer=cslTCP); **override**;

Initialize the instance

TwinHTTPWebSocketClient = class(TObject)

WebSocket client implementation

constructor Create(**const** aServer, aPort: SockString; aHttps: boolean; **const** url: SockString; **const** aSubProtocol: SockString = ''; **const** aProxyName: SockString=''; **const** aProxyByPass: SockString=''; ConnectionTimeout: DWORD=0; SendTimeout: DWORD=0; ReceiveTimeout: DWORD=0);

Initialize the instance

- all parameters do match TWinHTTP.Create except url: address of WebSocketServer for sending upgrade request

function CloseConnection(**const** aCloseReason: SockString): DWORD;

Close current connection

function Receive(aBuffer: pointer; aBufferLength: DWORD; **out** aBytesRead: DWORD; **out** aBufferType: WINHTTP_WEB_SOCKET_BUFFER_TYPE): DWORD;

Receive buffer

function Send(aBufferType: WINHTTP_WEB_SOCKET_BUFFER_TYPE; aBuffer: pointer; aBufferLength: DWORD): DWORD;

Send buffer

TSimpleHttpClient = class(TObject)

Simple wrapper around THttpClientSocket/THttpRequest instances

- this class will reuse the previous connection if possible, and select the best connection class available on this platform for a given URI

constructor Create(aOnlyUseClientSocket: boolean=false); **reintroduce**;

Initialize the instance

destructor Destroy; **override**;

Finalize the connection

function RawRequest(**const** Uri: TURI; **const** Method, Header, Data, DataType: SockString; KeepAlive: cardinal): integer; overload;

Low-level entry point of this instance

```
function Request(const uri: SockString; const method: SockString='GET'; const header: SockString = ''; const data: SockString = ''; const datatype: SockString = ''; const keepalive: cardinal=10000): integer; overload;
```

Simple-to-use entry point of this instance

- use Body and Headers properties to retrieve the HTTP body and headers

```
property Body: SockString read fBody;
```

Returns the HTTP body as returned by a previous call to Request()

```
property Headers: SockString read fHeaders;
```

Returns the HTTP headers as returned by a previous call to Request()

```
property IgnoreSSLCertificateErrors: boolean read fIgnoreSSLCertificateErrors  
write fIgnoreSSLCertificateErrors;
```

Allows to customize HTTPS connection and allow weak certificates

```
property Proxy: SockString read fProxy write fProxy;
```

Allows to customize the connection using a proxy

```
property UserAgent: SockString read fUserAgent write fUserAgent;
```

Allows to customize the user-agent header

```
TSMTPConnection = object(TObject)
```

May be used to store a connection to a SMTP server

- see SendEmail() overloaded function

```
Host: SockString;
```

The SMTP server IP or host name

```
Pass: SockString;
```

The SMTP user password (if any)

```
Port: SockString;
```

The SMTP server port (25 by default)

```
User: SockString;
```

The SMTP user login (if any)

```
function FromText(const aText: SockString): boolean;
```

Fill the SMTP server information from a single text field

- expects 'user:password@smtpserver:port' format

- if aText equals SMTP_DEFAULT ('user:password@smtpserver:port'), does nothing

```
TMacAddress = record
```

Interface name/address pairs as returned by GetMacAddresses

```
address: SockString;
```

Contains e.g. '12:50:b6:1e:c6:aa' from /sys/class/net/eth0/address

```
name: SockString;
```

Contains e.g. 'eth0' on Linux

TPollSocketResult = record

Modifications notified by TPollSocketAbstract.WaitForModified

events: TPollSocketEvents;

The events which are notified

tag: TPollSocketTag;

Opaque value as defined by TPollSocketAbstract.Subscribe

TPollSocketAbstract = class(TObject)

Abstract parent class for efficient socket polling

- works like Linux epoll API in level-triggered (LT) mode
- implements libevent-like cross-platform features
- use PollSockClass global function to retrieve the best class depending on the running Operating System

constructor Create; **virtual**;

Initialize the polling

class function New: TPollSocketAbstract;

Class function factory, returning a socket polling instance matching at best the current operating system

- returns a TPollSocketSelect/TPollSocketPoll instance under Windows, a TPollSocketEpoll instance under Linux, or a TPollSocketPoll on BSD
- just a wrapper around PollSockClass.Create

function Subscribe(socket: TSocket; events: TPollSocketEvents; tag: TPollSocketTag): boolean; **virtual**; **abstract**;

Track status modifications on one specified TSocket

- you can specify which events are monitored - pseError and pseClosed will always be notified
- tag parameter will be returned as TPollSocketResult - you may set here the socket file descriptor value, or a transtyped class instance
- similar to epoll's EPOLL_CTL_ADD control interface

function Unsubscribe(socket: TSocket): boolean; **virtual**; **abstract**;

Stop status modifications tracking on one specified TSocket

- the socket should have been monitored by a previous call to Subscribe()
- on success, returns true and fill tag with the associated opaque value
- similar to epoll's EPOLL_CTL_DEL control interface

function WaitForModified(out results: TPollSocketResults; timeoutMS: integer): integer; **virtual**; **abstract**;

Waits for status modifications of all tracked TSocket

- will wait up to timeoutMS milliseconds, 0 meaning immediate return and -1 for infinite blocking
- returns -1 on error (e.g. no TSocket currently registered), or the number of modifications stored in results[] (may be 0 if none)

property Count: integer **read** fCount;

How many TSocket instances are currently tracked

property MaxSockets: integer read fMaxSockets;

How many TSocket instances could be tracked, at most
- depends on the API used

TPollSocketSelect = **class**(TPollSocketAbstract)

Socket polling via Windows' Select() API

- under Windows, Select() handles up to 64 TSocket, and is available in Windows XP, whereas WSAPoll() is available only since Vista
- under Linux, select() is very limited, so poll/epoll APIs are to be used
- in practice, TPollSocketSelect is slightly FASTER than TPollSocketPoll when tracking a lot of connections (at least under Windows): WSAPoll() seems to be just an emulation API - very disappointing :(

constructor Create; **override**;

Initialize the polling via creating an epoll file descriptor

function Subscribe(socket: TSocket; events: TPollSocketEvents; tag: TPollSocketTag): boolean; **override**;

Track status modifications on one specified TSocket

- you can specify which events are monitored - pseError and pseClosed will always be notified

function Unsubscribe(socket: TSocket): boolean; **override**;

Stop status modifications tracking on one specified TSocket

- the socket should have been monitored by a previous call to Subscribe()

function WaitForModified(out results: TPollSocketResults; timeoutMS: integer): integer; **override**;

Waits for status modifications of all tracked TSocket

- will wait up to timeoutMS milliseconds, 0 meaning immediate return and -1 for infinite blocking

- returns -1 on error (e.g. no TSocket currently registered), or the number of modifications stored in results[] (may be 0 if none)

TPollSocketPoll = **class**(TPollSocketAbstract)

Socket polling via poll/WSAPoll API

- direct call of the Linux/POSIX poll() API, or Windows WSAPoll() API

constructor Create; **override**;

Initialize the polling using poll/WSAPoll API

function Subscribe(socket: TSocket; events: TPollSocketEvents; tag: TPollSocketTag): boolean; **override**;

Track status modifications on one specified TSocket

- you can specify which events are monitored - pseError and pseClosed will always be notified

function Unsubscribe(socket: TSocket): boolean; **override**;

Stop status modifications tracking on one specified TSocket

- the socket should have been monitored by a previous call to Subscribe()

```
function WaitForModified(out results: TPollSocketResults; timeoutMS: integer):  
integer; override;
```

Waits for status modifications of all tracked TSocket

- will wait up to timeoutMS milliseconds, 0 meaning immediate return and -1 for infinite blocking
- returns -1 on error (e.g. no TSocket currently registered), or the number of modifications stored in results[] (may be 0 if none)

```
TPollSockets = class(TObject)
```

Implements efficient polling of multiple sockets

- will maintain a pool of TPollSocketAbstract instances, to monitor incoming data or outgoing availability for a set of active connections
- call Subscribe/Unsubscribe to setup the monitored sockets
- call GetOne from any consuming threads to process new events

```
constructor Create(aPollClass: TPollSocketClass=nil);
```

Initialize the sockets polling

- you can specify the TPollSocketAbstract class to be used, if the default is not the one expected
- under Linux/POSIX, will set the open files maximum number for the current process to match the system hard limit: if your system has a low "ulimit -H -n" value, you may add the following line in your /etc/limits.conf or /etc/security/limits.conf file:
* hard nfile 65535

```
destructor Destroy; override;
```

Finalize the sockets polling, and release all used memory

```
function GetOne(timeoutMS: integer; out notif: TPollSocketResult): boolean;  
virtual;
```

Retrieve the next pending notification, or let the poll wait for new

- if there is no pending notification, will poll and wait up to timeoutMS milliseconds for pending data
- returns true and set notif.events/tag with the corresponding notification
- returns false if no pending event was handled within the timeoutMS period
- this method is thread-safe, and could be called from several threads

```
function GetOneWithinPending(out notif: TPollSocketResult): boolean;
```

Retrieve the next pending notification

- returns true and set notif.events/tag with the corresponding notification
- returns false if no pending event is available
- this method is thread-safe, and could be called from several threads

```
function Subscribe(socket: TSocket; tag: TPollSocketTag; events:  
TPollSocketEvents): boolean; virtual;
```

Track modifications on one specified TSocket and tag

- the supplied tag value - maybe a PtrInt(aObject) - will be part of GetOne method results
- will create as many TPollSocketAbstract instances as needed, depending on the MaxSockets capability of the actual implementation class
- this method is thread-safe

function Unsubscribe(socket: TSocket; tag: TPollSocketTag): boolean; **virtual**;

Stop status modifications tracking on one specified TSocket and tag

- the socket should have been monitored by a previous call to Subscribe()
- this method is thread-safe

procedure Terminate;

Notify any GetOne waiting method to stop its polling loop

property Count: integer **read** fCount;

How many sockets are currently tracked

property PollClass: TPollSocketClass **read** fPollClass;

The actual polling class used to track socket state changes

property Terminated: boolean **read** fTerminated;

Set to true by the Terminate method

TPollSocketsSlot = **object**(TObject)

Store information of one TPollAsynchSockets connection

lastWSAError: integer;

The last error reported by WSAGetLastError before the connection ends

lockcounter: **array**[boolean] **of** integer;

Lock/Unlock R/W thread acquisition (lighter than a TRTLCriticalSection)

readbuf: SockString;

The current read data buffer of this slot

socket: TSocket;

The associated TCP connection

- equals 0 after TPollAsynchSockets.Stop

writebuf: SockString;

The current write data buffer of this slot

function Lock(writer: boolean): boolean;

Acquire an exclusive R/W access to this connection

- returns true if slot has been acquired
- returns false if it is used by another thread
- warning: this method is not re-entrant

function TryLock(writer: boolean; timeoutMS: cardinal): boolean;

Try to acquire an exclusive R/W access to this connection

- returns true if slot has been acquired
- returns false if it is used by another thread, after the timeoutMS period
- warning: this method is not re-entrant

procedure UnLock(writer: boolean);

Release exclusive R/W access to this connection

TPollAsynchSockets = class(TObject)

Read/write buffer-oriented process of multiple non-blocking connections

- to be used e.g. for stream protocols (e.g. WebSockets or IoT communication)
- assigned sockets will be set in non-blocking mode, so that polling will work as expected: you should then never use directly the socket (e.g. via blocking TCrtSocket), but rely on this class for asynchronous process: OnRead() overridden method will receive all incoming data from input buffer, and Write() should be called to add some data to asynchronous output buffer
- connections are identified as TObject instances, which should hold a TPollSocketsSlot record as private values for the polling process
- ProcessRead/ProcessWrite methods are to be run for actual communication: either you call those methods from multiple threads, or you run them in loop from a single thread, then define a TSynThreadPool for running any blocking process (e.g. computing requests answers) from OnRead callbacks
- inherited classes should override abstract OnRead, OnClose, OnError and SlotFromConnection methods according to the actual connection class

constructor Create; virtual;

Initialize the read/write sockets polling

- fRead and fWrite TPollSocketsBuffer instances will track pseRead or pseWrite events, and maintain input and output data buffers

destructor Destroy; override;

Finalize buffer-oriented sockets polling, and release all used memory

function Start(connection: TObject): boolean; virtual;

Assign a new connection to the internal poll

- the TSocket handle will be retrieved via SlotFromConnection, and set in non-blocking mode from now on - it is not recommended to access it directly any more, but use Write() and handle OnRead() callback
- fRead will poll incoming packets, then call OnRead to handle them, or Unsubscribe and delete the socket when pseClosed is notified
- fWrite will poll for outgoing packets as specified by Write(), then send any pending data once the socket is ready

function Stop(connection: TObject): boolean; virtual;

Remove a connection from the internal poll, and shutdown its socket

- most of the time, the connection is released by OnClose when the other end shutdown the socket; but you can explicitly call this method when the connection (and its socket) is to be shutdown
- this method won't call OnClose, since it is initiated by the class

function Write(connection: TObject; const data; datalen: integer; timeout: integer=5000): boolean; virtual;

Add some data to the asynchronous output buffer of a given connection

- this method may block if the connection is currently writing from another thread (which is not possible from TPollAsynchSockets.Write), up to timeout milliseconds

function WriteString(connection: TObject; const data: SockString): boolean;

Add some data to the asynchronous output buffer of a given connection

procedure ProcessRead(timeoutMS: integer);

One or several threads should execute this method

- thread-safe handle of any incoming packets
- if this method is called from a single thread, you should use a TSynThreadPool for any blocking process of OnRead events
- otherwise, this method is thread-safe, and incoming packets may be consumed from a set of threads, and call OnRead with newly received data

procedure ProcessWrite(timeoutMS: integer);

One or several threads should execute this method

- thread-safe handle of any outgoing packets

procedure Terminate(waitforMS: integer);

Notify internal socket polls to stop their polling loop ASAP

property Count: integer **read** GetCount;

How many connections are currently managed by this instance

property Options: TPollAsynchSocketsOptions **read** fOptions **write** fOptions;

Some processing options

property PollRead: TPollSockets **read** fRead;

Low-level access to the polling class used for incoming data

property PollWrite: TPollSockets **write** fWrite;

Low-level access to the polling class used for outgoing data

property ReadBytes: Int64 **read** fReadBytes;

How many data bytes have been received by this instance

property ReadCount: integer **read** fReadCount;

How many times data has been received by this instance

property WriteBytes: Int64 **read** fWriteBytes;

How many data bytes have been sent by this instance

property WriteCount: integer **read** fWriteCount;

How many times data has been sent by this instance

Types implemented in the SynCrtSock unit

PPollSocketsSlot = ^TPollSocketsSlot;

Points to thread-safe information of one TPollAsynchSockets connection

PSockString = ^SockString;

Points to a 8-bit raw storage variable, used for data buffer management

PtrInt = integer;

FPC 64-bit compatibility integer type

SockString = **type** AnsiString;

Define a 8-bit raw storage string type, used for data buffer management

SockUnicode = WideString;

Define the fastest 16-bit Unicode string type of the compiler

```
TCrtSocketLayer = ( cslTCP, cslUDP, cslUNIX );
```

The available available network transport layer
- either TCP/IP, UDP/IP or Unix sockets

```
TCrtSocketPending = ( cspSocketError, cspNoData, cspDataAvailable );
```

Identify the incoming data availability in TCrtSocket.SockReceivePending

```
THttpApiLogFields = set of ( hlfDate, hlfTime, hlfClientIP, hlfUserName, hlfSiteName,
hlfComputerName, hlfServerIP, hlfMethod, hlfURISem, hlfURIQuery, hlfStatus,
hlfWIN32Status, hlfBytesSent, hlfBytesRecv, hlfTimeTaken, hlfServerPort, hlfUserAgent,
hlfCookie, hlfReferer, hlfVersion, hlfHost, hlfSubStatus);
```

Http.sys API 2.0 fields used for W3C logging
- match low-level HTTP_LOG_FIELD_* constants as defined in HTTP 2.0 API

```
THttpApiLoggingFlags = set of ( hlfLocalTimeRollover, hlfUseUTF8Conversion,
hlfLogErrorsOnly, hlfLogSuccessOnly);
```

Http.sys API 2.0 logging option flags
- used to alter the default logging behavior
- hlfLocalTimeRollover would force the log file rollovers by local time, instead of the default GMT time
- hlfUseUTF8Conversion will use UTF-8 instead of default local code page
- only one of hlfLogErrorsOnly and hlfLogSuccessOnly flag could be set at a time: if neither of them are present, both errors and success will be logged, otherwise mutually exclusive flags could be set to force only errors or success logging
- match low-level HTTP_LOGGING_FLAG_* constants as defined in HTTP 2.0 API

```
THttpApiLoggingRollOver = ( hlrSize, hlrDaily, hlrWeekly, hlrMonthly, hlrHourly );
```

Http.sys API 2.0 logging file rollover types
- match low-level HTTP_LOGGING_ROLLOVER_TYPE as defined in HTTP 2.0 API

```
THttpApiLoggingType = ( hltW3C, hltIIS, hltNCSA, hltRaw );
```

Http.sys API 2.0 logging file supported layouts
- match low-level HTTP_LOGGING_TYPE as defined in HTTP 2.0 API

```
THttpApiRequestAuthentications = set of ( haBasic, haDigest, haNtlm, haNegotiate,
haKerberos);
```

Http.sys API 2.0 fields used for server-side authentication
- as used by THttpApiServer.SetAuthenticationSchemes/AuthenticationSchemes
- match low-level HTTP_AUTH_ENABLE_* constants as defined in HTTP 2.0 API

```
THttpApiWebsocketServerOnAcceptEvent = function(Ctxt: THttpServerRequest; var Conn:
THttpApiWebsocketConnection): Boolean of object;
```

Event handler on THttpApiWebsocketServerProtocol Accept

```
THttpApiWebsocketServerOnConnectEvent = procedure(var Conn:
THttpApiWebsocketConnection) of object;
```

Event handler on THttpApiWebsocketServerProtocol connection

```
THttpApiWebsocketServerOnDisconnectEvent = procedure(var Conn:
THttpApiWebsocketConnection; aStatus: WEB_SOCKET_CLOSE_STATUS; aBuffer: Pointer;
aBufferSize: ULONG) of object;
```

Event handler on THttpApiWebsocketServerProtocol disconnection

```
THttpApiWebsocketServerOnMessageEvent = procedure(var Conn:
THttpApiWebsocketConnection; aBufferType: WEB_SOCKET_BUFFER_TYPE; aBuffer: Pointer;
```

aBufferSize: ULONG) of object;

Event handler on THttpApiWebSocketServerProtocol Message received

THttpClientSocketClass = class of THttpClientSocket;

Class-reference type (metaclass) of a HTTP client socket access

- may be either THttpClientSocket or THttpClientWebSockets (from SynBidirSock unit)

THttpRequestAuthentication = (wraNone, wraBasic, wraDigest, wraNegotiate);

The supported authentication schemes which may be used by HTTP clients

- supported only by TWinHTTP class yet

THttpRequestClass = class of THttpRequest;

Store the actual class of a HTTP/1.1 client instance

- may be used to define at runtime which API to be used (e.g. WinHTTP, WinINet or LibCurl), following the Liskov substitution principle

THttpServerConnectionID = Int64;

A genuine identifier for a given client connection on server side

- maps http.sys ID, or is a genuine 31-bit value from increasing sequence

THttpServerConnectionIDDynArray = array of THttpServerConnectionID;

A dynamic array of client connection identifiers, e.g. for broadcasting

THttpServerRequestAuthentication = (hraNone, hraFailed, hraBasic, hraDigest, hraNtlm, hraNegotiate, hraKerberos);

The server-side available authentication schemes

- as used by THttpServerRequest.AuthenticationStatus

- hraNone..hraKerberos will match low-level HTTP_REQUEST_AUTH_TYPE enum as defined in HTTP 2.0 API and

THttpServerRespClass = class of THttpServerResp;

Metaclass of HTTP response Thread

THttpServerSocketClass = class of THttpServerSocket;

Meta-class of the THttpServerSocket process

- used to override THttpServerSocket.GetRequest for instance

THttpServerSocketGetRequestResult = (grError, grException, grOversizedPayload, grRejected, grTimeout, grHeaderReceived, grBodyReceived, grOwned);

Results of THttpServerSocket.GetRequest virtual method

- return grError if the socket was not connected any more, or grException if any exception occurred during the process

- grOversizedPayload is returned when MaximumAllowedContentLength is reached

- grRejected is returned when OnBeforeBody returned not 200

- grTimeout is returned when HeaderRetrieveAbortDelay is reached

- grHeaderReceived is returned for GetRequest({withbody=}false)

- grBodyReceived is returned for GetRequest({withbody=}true)

- grOwned indicates that this connection is now handled by another thread, e.g. asynchronous WebSockets

THttpSocketCompress = function(var DataRawByteString; Compress: boolean): AnsiString;

Event used to compress or uncompress some data during HTTP protocol

- should always return the protocol name for ACCEPT-ENCODING: header e.g. 'gzip' or 'deflate' for standard HTTP format, but you can add your own (like 'synlzo' or 'synlz')

- the data is compressed (if Compress=TRUE) or uncompressed (if Compress=FALSE) in the Data variable (i.e. it is modified in-place)
- to be used with THttpSocket.RegisterCompress method
- DataRawByteStringtype should be a generic AnsiString/RawByteString, which should be in practice a SockString or a RawByteString

THttpSocketCompressRecDynArray = array of THttpSocketCompressRec;
List of known compression algorithms

THttpSocketCompressSet = set of 0..31;
Identify some items in a list of known compression algorithms
- filled from ACCEPT-ENCODING: header value

TNotifyThreadEvent = procedure(Sender: TThread) of object;
Event prototype used e.g. by THttpServerGeneric.OnHttpThreadStart

TOnHttpServerAfterResponse = procedure(Ctxt: THttpServerRequest; const Code: cardinal) of object;
Event handler used by THttpServerGeneric.OnAfterResponse property
- Ctxt defines both input and output parameters
- Code defines the HTTP response code the (200 if OK, e.g.)

TOnHttpServerBeforeBody = function(const aURL,aMethod,aInHeaders, aInContentType,aRemoteIP: SockString; aContentLength: integer; aUseSSL: boolean): cardinal of object;
Event handler used by THttpServerGeneric.OnBeforeBody property
- if defined, is called just before the body is retrieved from the client
- supplied parameters reflect the current input state
- should return STATUS_SUCCESS=200 to continue the process, or an HTTP error code (e.g. STATUS_FORBIDDEN or STATUS_PAYLOADTOOLARGE) to reject the request

TOnHttpServerRequest = function(Ctxt: THttpServerRequest): cardinal of object;
Event handler used by THttpServerGeneric.OnRequest property
- Ctxt defines both input and output parameters
- result of the function is the HTTP error code (200 if OK, e.g.)
- OutCustomHeader will handle Content-Type/Location
- if OutContentType is HTTP_RESP_STATICFILE (i.e. 'STATICFILE' aka STATICFILE_CONTENT_TYPE in mORMot.pas), then OutContent is the UTF-8 file name of a file which must be sent directly to the client via http.sys or NGINX's X-Accel-Redirect; the OutCustomHeader should contain the proper 'Content-type:' value

TOnHttpServerSendFile = function(Context: THttpServerRequest; const LocalFileName: TFileName): boolean of object;
Event handler used by THttpServer.Process to send a local file when HTTP_RESP_STATICFILE content-type is returned by the service
- can be defined e.g. to use NGINX X-Accel-Redirect header
- should return true if the Context has been modified to serve the file, or false so that the file will be manually read and sent from memory
- any exception during process will be returned as a STATUS_NOTFOUND page

TPollAsynchSocketOnRead = (sorContinue, sorClose);
Let TPollAsynchSockets.OnRead shutdown the socket if needed

TPollAsynchSocketsOptions = set of (paoWritePollOnly);

Possible options for TPollAsynchSockets process

- by default, TPollAsynchSockets.Write will first try to send the data using Send() in non-blocking mode, unless paoWritePollOnly is defined, and fWrite will be used to poll output state and send it asynchronously

TPollSocketClass = class of TPollSocketAbstract;

Meta-class of TPollSocketAbstract socket polling classes

- since TPollSocketAbstract.Create is declared as virtual, could be used to specify the proper polling class to add
- see PollSockClass function and TPollSocketAbstract.New method

TPollSocketEvent = (pseRead, pseWrite, pseError, pseClosed);

The events monitored by TPollSocketAbstract classes

- we don't make any difference between urgent or normal read/write events

TPollSocketEvents = set of TPollSocketEvent;

Set of events monitored by TPollSocketAbstract classes

TPollSocketResults = array of TPollSocketResult;

All modifications returned by TPollSocketAbstract.WaitForModified

TPollSocketTag = type PtrInt;

Some opaque value (which may be a pointer) associated with a polling event

TSockStringDynArray = array of SockString;

Defines a dynamic array of SockString

TWebSocketState = (wsConnecting, wsOpen, wsClosing, wsClosedByClient, wsClosedByServer, wsClosedByGuard, wsClosedByShutdown);

Current state of a THttpApiWebSocketConnection

TWinHttpDownload = function(Sender: TWinHttpAPI; CurrentSize, ContentLength, ChunkSize: DWORD; const ChunkData): boolean of object;

Event callback to process the download by chunks, not in memory

- used in TWinHttpAPI.OnDownload property
- CurrentSize is the current total number of downloaded bytes
- ContentLength is retrieved from HTTP headers, but may be 0 if not set
- ChunkSize is the size of the latest downloaded chunk, available in the untyped ChunkData memory buffer
- implementation should return TRUE to continue the download, or FALSE to abort the download process

TWinHttpProgress = procedure(Sender: TWinHttpAPI; CurrentSize, ContentLength: DWORD) of object;

Event callback to track download progress, e.g. in the UI

- used in TWinHttpAPI.OnProgress property
- CurrentSize is the current total number of downloaded bytes
- ContentLength is retrieved from HTTP headers, but may be 0 if not set

TWinHttpUpload = function(Sender: TWinHttpAPI; CurrentSize, ContentLength: DWORD): boolean of object;

Event callback to track upload progress, e.g. in the UI

- used in TWinHttpAPI.OnUpload property
- CurrentSize is the current total number of uploaded bytes

- ContentLength is the size of content
- implementation should return TRUE to continue the upload, or FALSE to abort the upload process

WEB_SOCKET_BUFFER_TYPE = ULONG;

The bit values used to construct the WebSocket frame header for httpapi.dll

- not equals to WINHTTP_WEB_SOCKET_BUFFER_TYPE from winhttp.dll

WEB_SOCKET_CLOSE_STATUS = Word;

WebSocket close status as defined by <http://tools.ietf.org/html/rfc6455#section-7.4>

WEB_SOCKET_HANDLE = Pointer;

Low-level API reference to a WebSocket session

WINHTTP_WEB_SOCKET_BUFFER_TYPE = ULONG;

Types of WebSocket buffers for winhttp.dll it is the different thing than WEB_SOCKET_BUFFER_TYPE for httpapi.dll

Constants implemented in the SynCrtSock unit

HTTPAPI_AUTH_ENABLE_ALL = [hraBasic..hraKerberos];

Can be used with THttpApiServer.AuthenticationSchemes to enable all schemes

HTTP_RESP_NORESPONSE = '!NORESPONSE';

Used to notify e.g. the THttpServerRequest not to wait for any response from the client

- is not to be used in normal HTTP process, but may be used e.g. by TWebSocketProtocolRest.ProcessFrame() to avoid to wait for an incoming response from the other endpoint
- should match NORESPONSE_CONTENT_TYPE constant defined in mORMot.pas unit

HTTP_RESP_STATICFILE = '!STATICFILE';

Internal HTTP content-type for efficient static file sending

- detected e.g. by http.sys' THttpApiServer.Request or via the NGINX X-Accel-Redirect header's THttpServer.Process (see THttpServer.NginxSendFileFrom) for direct sending with no local buffering
- the OutCustomHeader should contain the proper 'Content-type:' corresponding to the file (e.g. by calling GetMimeContentType() function from SynCommons supplying the file name)
- should match HTML_CONTENT_STATICFILE constant defined in mORMot.pas unit

SMTP_DEFAULT = 'user:password@smtpserver:port';

The layout of TSMTPConnection.FromText method

STATUS_ACCEPTED = 202;

HTTP Status Code for "Accepted"

STATUS_BADREQUEST = 400;

HTTP Status Code for "Bad Request"

STATUS_CREATED = 201;

HTTP Status Code for "Created"

STATUS_FORBIDDEN = 403;

HTTP Status Code for "Forbidden"

STATUS_HTTPVERSIONNOTSUPPORTED = 505;

HTTP Status Code for "HTTP Version Not Supported"

STATUS_NOCONTENT = 204;

HTTP Status Code for "No Content"

STATUS_NOTACCEPTABLE = 406;

HTTP Status Code for "Not Acceptable"

STATUS_NOTFOUND = 404;

HTTP Status Code for "Not Found"

STATUS_NOTIMPLEMENTED = 501;

HTTP Status Code for "Not Implemented"

STATUS_NOTMODIFIED = 304;

HTTP Status Code for "Not Modified"

STATUS_PARTIALCONTENT = 206;

HTTP Status Code for "Partial Content"

STATUS_PAYLOADTOOLARGE = 413;

HTTP Status Code for "Payload Too Large"

STATUS_SERVERERROR = 500;

HTTP Status Code for "Internal Server Error"

STATUS_SUCCESS = 200;

HTTP Status Code for "Success"

STATUS_UNAUTHORIZED = 401;

HTTP Status Code for "Unauthorized"

WEB_SOCKET_ABORTED_CLOSE_STATUS : WEB_SOCKET_CLOSE_STATUS = 1006;

The connection was closed without sending or receiving a close frame

WEB_SOCKET_BINARY_FRAGMENT_BUFFER_TYPE: WEB_SOCKET_BUFFER_TYPE = \$80000003;

The buffer contains part of a binary message

WEB_SOCKET_BINARY_MESSAGE_BUFFER_TYPE: WEB_SOCKET_BUFFER_TYPE = \$80000002;

The buffer contains the last, and possibly only, part of a binary message

WEB_SOCKET_CLOSE_BUFFER_TYPE: WEB_SOCKET_BUFFER_TYPE = \$80000004;

The buffer contains a close message

WEB_SOCKET_EMPTY_CLOSE_STATUS : WEB_SOCKET_CLOSE_STATUS = 1005;

No close status code was provided

WEB_SOCKET_ENDPOINT_UNAVAILABLE_CLOSE_STATUS : WEB_SOCKET_CLOSE_STATUS = 1001;

The endpoint is going away and thus closing the connection

WEB_SOCKET_INVALID_DATA_TYPE_CLOSE_STATUS : WEB_SOCKET_CLOSE_STATUS = 1003;

The endpoint cannot receive this type of data

WEB_SOCKET_INVALID_PAYLOAD_CLOSE_STATUS : WEB_SOCKET_CLOSE_STATUS = 1007;

Data within a message is not consistent with the type of the message

WEB_SOCKET_MAX_CLOSE_REASON_LENGTH = 123;

<https://msdn.microsoft.com/en-us/library/windows/desktop/hh449347>

WEB_SOCKET_MESSAGE_TOO_BIG_CLOSE_STATUS : WEB_SOCKET_CLOSE_STATUS = 1009;

The message sent was too large to process

WEB_SOCKET_PING_PONG_BUFFER_TYPE: WEB_SOCKET_BUFFER_TYPE = \$80000005;

The buffer contains a ping or pong message

- when sending, this value means 'ping'
- when processing received data, this value means 'pong'

WEB_SOCKET_POLICY_VIOLATION_CLOSE_STATUS : WEB_SOCKET_CLOSE_STATUS = 1008;

The message violates an endpoint's policy

WEB_SOCKET_PROTOCOL_ERROR_CLOSE_STATUS : WEB_SOCKET_CLOSE_STATUS = 1002;

Peer detected protocol error and it is closing the connection

WEB_SOCKET_SECURE_HANDSHAKE_ERROR_CLOSE_STATUS : WEB_SOCKET_CLOSE_STATUS = 1015;

The TLS handshake could not be completed

WEB_SOCKET_SERVER_ERROR_CLOSE_STATUS : WEB_SOCKET_CLOSE_STATUS = 1011;

An unexpected condition prevented the server from fulfilling the request

WEB_SOCKET_SUCCESS_CLOSE_STATUS : WEB_SOCKET_CLOSE_STATUS = 1000;

Close completed successfully

WEB_SOCKET_UNSOLICITED_PONG_BUFFER_TYPE: WEB_SOCKET_BUFFER_TYPE = \$80000006;

The buffer contains an unsolicited pong message

WEB_SOCKET_UNSUPPORTED_EXTENSIONS_CLOSE_STATUS : WEB_SOCKET_CLOSE_STATUS = 1010;

A client endpoint expected the server to negotiate one or more extensions, but the server didn't return them in the response message of the WebSocket handshake

WEB_SOCKET_UTF8_FRAGMENT_BUFFER_TYPE: WEB_SOCKET_BUFFER_TYPE = \$80000001;

The buffer contains part of a UTF8 message

WEB_SOCKET_UTF8_MESSAGE_BUFFER_TYPE: WEB_SOCKET_BUFFER_TYPE = \$80000000;

The buffer contains the last, and possibly only, part of a UTF8 message

XPOWEREDOS = 'Windows' ;

The running Operating System

XPOWEREDPROGRAM = 'mORMot 1.18';

The full text of the current Synopse mORMot framework version

- match the value defined in SynCommons.pas and SynopseCommit.inc
- we don't supply full version number with build revision, to reduce potential attack surface

Functions or procedures implemented in the SynCrtSock unit

Functions or procedures	Description	Page
AsynchRecv	Low-level direct call of the socket recv() function	1138
AsynchSend	Low-level direct call of the socket send() function	1138
AsynchSocket	Low-level change of a socket to be in non-blocking mode	1138

Functions or procedures	Description	Page
AuthorizationBearer	Compute the 'Authorization: Bearer ####' HTTP header of a given token value	1138
CallServer	Low-level direct creation of a TSocket handle for TCP, UDP or UNIX layers	1138
DirectShutdown	Low-level direct shutdown of a given socket	1138
GetIPAddresses	Enumerate all IP addresses of the current computer	1139
GetIPAddressesText	Returns all IP addresses of the current computer as a single CSV text	1139
GetMacAddresses	Enumerate all Mac addresses of the current computer	1139
GetMacAddressesText	Enumerate all Mac addresses of the current computer as 'name1=addr1 name2=addr2'	1139
GetRemoteIP	Retrieve the text-converted remote IP address of a client socket	1139
GetRemoteMacAddress	Remotely get the MAC address of a computer, from its IP Address	1139
HtmlEncode	Escaping of HTML codes like < > & "	1139
HttpChunkToHex32	Decode a HTTP chunk length	1139
HttpGet	Retrieve the content of a web page, using the HTTP/1.1 protocol and GET method	1139
HttpGet	Retrieve the content of a web page, using the HTTP/1.1 protocol and GET method	1139
HttpGet	Retrieve the content of a web page, using the HTTP/1.1 protocol and GET method	1139
HttpGetAuth	Retrieve the content of a web page, using HTTP/1.1 GET method and a token	1139
HttpPost	Send some data to a remote web server, using the HTTP/1.1 protocol and POST method	1140
HttpPut	Send some data to a remote web server, using the HTTP/1.1 protocol and PUT method	1140
IP4Text	Compute the '1.2.3.4' text representation of a raw IP4 binary	1140
IPText	Compute the text representation of a IP4/IP6 low-level connection	1140
MainHttpClass	Returns the best THttpRequest class, depending on the system it runs on	1140
Open	Create a TCrtSocket, returning nil on error (useful to easily catch socket error exception ECrtSocket)	1140
OpenHttp	Create a THttpClientSocket, returning nil on error	1140
OpenHttp	Create a THttpClientSocket, returning nil on error	1140

Functions or procedures	Description	Page
PollSocketClass	Returns the TPollSocketAbstract class best fitting with the current Operating System	1140
ReplaceMainHttpClass	Low-level forcing of another THttpRequest class	1140
ResolveName	Retrieve the IP address from a computer name	1140
SendEmail	Send an email using the SMTP protocol	1141
SendEmail	Send an email using the SMTP protocol	1141
SendEmailSubject	Convert a supplied subject text into an Unicode encoding	1141
SockBase64Decode	Base64 decoding of a string	1141
SockBase64Encode	Base64 encoding of a string	1141
SocketErrorMessage	Low-level text description of Socket error code	1141
StatusCodeToReason	Retrieve the HTTP reason text from a code	1141
WinHTTP_WebSocketEnabled	Is HTTP.SYS web socket API available on the target system Windows 8 and UP	1141

function AsynchRecv(sock: TSocket; buf: pointer; buflen: integer): integer;

Low-level direct call of the socket recv() function

- by-pass overridden blocking recv() e.g. in SynFPCSock, so will work if the socket is in non-blocking mode, as with AsynchSocket/TPollAsynchSockets

function AsynchSend(sock: TSocket; buf: pointer; buflen: integer): integer;

Low-level direct call of the socket send() function

- by-pass overridden blocking send() e.g. in SynFPCSock, so will work if the socket is in non-blocking mode, as with AsynchSocket/TPollAsynchSockets

function AsynchSocket(sock: TSocket): boolean;

Low-level change of a socket to be in non-blocking mode

- used e.g. by TPollAsynchSockets.Start

function AuthorizationBearer(const AuthToken: SockString): SockString;

Compute the 'Authorization: Bearer #####' HTTP header of a given token value

function CallServer(const Server, Port: SockString; doBind: boolean; aLayer: TCrtSocketLayer; ConnectTimeout: DWORD): TSocket;

Low-level direct creation of a TSocket handle for TCP, UDP or UNIX layers

- doBind=true will call Bind() to create a server socket instance

- doBind=false will call Connect() to create a client socket instance

procedure DirectShutdown(sock: TSocket; rdwr: boolean=false);

Low-level direct shutdown of a given socket

function GetIPAddresses(Kind: TIPAddress = tiaAny): TSockStringDynArray;

Enumerate all IP addresses of the current computer
- may be used to enumerate all adapters

function GetIPAddressesText(const Sep: SockString = ' '; PublicOnly: boolean = false): SockString;

Returns all IP addresses of the current computer as a single CSV text
- may be used to enumerate all adapters

function GetMacAddresses: TMacAddressDynArray;

Enumerate all Mac addresses of the current computer

function GetMacAddressesText: SockString;

Enumerate all Mac addresses of the current computer as 'name1=addr1 name2=addr2'

function GetRemoteIP(aClientSock: TSocket): SockString;

Retrieve the text-converted remote IP address of a client socket

function GetRemoteMacAddress(const IP: SockString): SockString;

Remotely get the MAC address of a computer, from its IP Address
- only works under Win2K and later
- return the MAC address as a 12 hexa chars ('0050C204C80A' e.g.)

function HtmlEncode(const s: SockString): SockString;

Escaping of HTML codes like < > & "

function HttpChunkToHex32(p: PAnsiChar): integer;

Decode a HTTP chunk length

function HttpGet(const aURI: SockString; const inHeaders: SockString; outHeaders: PSockString=nil; forceNotSocket: boolean=false; outStatus: PInteger=nil): SockString; overload;

Retrieve the content of a web page, using the HTTP/1.1 protocol and GET method
- this method will use a low-level THttpClientSock socket for plain http URI, or TWinHTTP/TCurlHTTP for any https URI

function HttpGet(const server, port: SockString; const url: SockString; const inHeaders: SockString; outHeaders: PSockString=nil; aLayer: TCrtSocketLayer = cslTCP): SockString; overload;

Retrieve the content of a web page, using the HTTP/1.1 protocol and GET method
- this method will use a low-level THttpClientSock socket: if you want something able to use your computer proxy, take a look at TWinINet.Get() or the overloaded HttpGet() methods

function HttpGet(const aURI: SockString; outHeaders: PSockString=nil; forceNotSocket: boolean=false; outStatus: PInteger=nil): SockString; overload;

Retrieve the content of a web page, using the HTTP/1.1 protocol and GET method
- this method will use a low-level THttpClientSock socket for plain http URI, or TWinHTTP/TCurlHTTP for any https URI, or if forceNotSocket is set to true

function HttpGetAuth(const aURI, aAuthToken: SockString; outHeaders: PSockString=nil; forceNotSocket: boolean=false; outStatus: PInteger=nil): SockString;

Retrieve the content of a web page, using HTTP/1.1 GET method and a token
- this method will use a low-level THttpClientSock socket and its GetAuth method
- if AuthToken<>'', will add an header with 'Authorization: Bearer '+AuthToken

function HttpPost(const server, port: SockString; const url, Data, DataType: SockString; outData: PSockString=nil; const auth: SockString=''): boolean;

Send some data to a remote web server, using the HTTP/1.1 protocol and POST method

function HttpPut(const server, port: SockString; const url, Data, DataType: SockString; outData: PSockString=nil; const auth: SockString=''): boolean;

Send some data to a remote web server, using the HTTP/1.1 protocol and PUT method

procedure IP4Text(const ip4addr; var result: SockString); overload;

Compute the '1.2.3.4' text representation of a raw IP4 binary

procedure IPText(const sin: TVarSin; var result: SockString; localasvoid: boolean=false);

Compute the text representation of a IP4/IP6 low-level connection

function MainHttpClass: THttpRequestClass;

Returns the best THttpRequest class, depending on the system it runs on

- e.g. TWinHTTP or TCurlHTTP

- consider using TSimpleHttpClient if you just need a simple connection

function Open(const aServer, aPort: SockString; aTLS: boolean=false): TCrtSocket;

Create a TCrtSocket, returning nil on error (useful to easily catch socket error exception ECrtSocket)

function OpenHttp(const aServer, aPort: SockString; aTLS: boolean=false; aLayer: TCrtSocketLayer = cs1TCP): THttpClientSocket; overload;

Create a THttpClientSocket, returning nil on error

- useful to easily catch socket error exception ECrtSocket

function OpenHttp(const aURI: SockString; aAddress: PSockString=nil): THttpClientSocket; overload;

Create a THttpClientSocket, returning nil on error

- useful to easily catch socket error exception ECrtSocket

function PollSocketClass: TPollSocketClass;

Returns the TPollSocketAbstract class best fitting with the current Operating System

- as used by TPollSocketAbstract.New method

procedure ReplaceMainHttpClass(aClass: THttpRequestClass);

Low-level forcing of another THttpRequest class

- could be used if we found out that the current MainHttpClass failed (which could easily happen with TCurlHTTP if the library is missing or deprecated)

function ResolveName(const Name: SockString; Family: Integer=AF_INET; SocketProtocol: Integer=IPPROTO_TCP; SocketType: integer=SOCK_STREAM): SockString;

Retrieve the IP address from a computer name

function SendEmail(const Server: TSMTPConnection; const From, CSVDest, Subject, Text: SockString; const Headers: SockString=''; const TextCharSet: SockString = 'ISO-8859-1'; aTLS: boolean=false): boolean; overload;

Send an email using the SMTP protocol

- retry true on success

- the Subject is expected to be in plain 7 bit ASCII, so you could use SendEmailSubject() to encode it as Unicode, if needed

- you can optionally set the encoding charset to be used for the Text body, or even TextCharSet='JSON' to force application/json

```
function SendEmail(const Server, From, CSVDest, Subject, Text: SockString; const Headers: SockString=''; const User: SockString=''; const Pass: SockString=''; const Port: SockString='25'; const TextCharSet: SockString = 'ISO-8859-1'; aTLS: boolean=false): boolean; overload;
```

Send an email using the SMTP protocol

- retry true on success
- the Subject is expected to be in plain 7 bit ASCII, so you could use SendEmailSubject() to encode it as Unicode, if needed
- you can optionally set the encoding charset to be used for the Text body

```
function SendEmailSubject(const Text: string): SockString;
```

Convert a supplied subject text into an Unicode encoding

- will convert the text into UTF-8 and append '?UTF-8?B?'
- for pre-Unicode versions of Delphi, Text is expected to be already UTF-8 encoded - since Delphi 2010, it will be converted from UnicodeString

```
function SockBase64Decode(const s: SockString): SockString;
```

Base64 decoding of a string

- consider using more efficient Base64ToBin() from SynCommons.pas instead

```
function SockBase64Encode(const s: SockString): SockString;
```

Base64 encoding of a string

- used internally for STMP email sending
- consider using more efficient BinToBase64() from SynCommons.pas instead

```
function SocketErrorMessage(Error: integer=-1): string;
```

Low-level text description of Socket error code

- if Error is -1, will call WSAGetLastError to retrieve the last error code

```
function StatusCodeToReason(Code: cardinal): SockString;
```

Retrieve the HTTP reason text from a code

- e.g. StatusCodeToReason(200)='OK'
- see <http://www.w3.org/Protocols/rfc2616/rfc2616-sec10.html>
- mORMot.StatusCodeToErrorMsg() will call this function

```
function WinHTTP_WebSocketEnabled: boolean;
```

Is HTTP.SYS web socket API available on the target system Windows 8 and UP

Variables implemented in the SynCrtSock unit

```
DefaultListenBacklog: integer = SOMAXCONN;
```

Queue length for completely established sockets waiting to be accepted, a backlog parameter for listen() function. If queue overflows client got ECONNREFUSED error for connect() call

- for windows default is taken from SynWinSock (\$7fffffff) and should not be modified. Actual limit is 200;
- for Unix default is taken from SynFPCSock (128 as in linux kernel >2.2), but actual value is min(DefaultListenBacklog, /proc/sys/net/core/somaxconn)

```
HTTP_DEFAULT_CONNECTTIMEOUT: integer = 60000;
```

THttpRequest timeout default value for remote connection

- default is 60 seconds
- used e.g. by THttpRequest, TSQLHttpRequest and TSQLHttpClientGeneric

`HTTP_DEFAULT_RECEIVETIMEOUT: integer = 30000;`

THttpRequest timeout default value for data receiving

- default is 30 seconds
- used e.g. by THttpRequest, TSQLHttpClientRequest and TSQLHttpClientGeneric
- you can override this value by setting the corresponding parameter in THttpRequest.Create() constructor

`HTTP_DEFAULT_RESOLVETIMEOUT: integer = 0;`

THttpRequest timeout default value for DNS resolution

- leaving to 0 will let system default value be used

`HTTP_DEFAULT_SENDTIMEOUT: integer = 30000;`

THttpRequest timeout default value for data sending

- default is 30 seconds
- used e.g. by THttpRequest, TSQLHttpClientRequest and TSQLHttpClientGeneric
- you can override this value by setting the corresponding parameter in THttpRequest.Create() constructor

`RemoteIPLocalHostAsVoidInServers: boolean = true;`

Defines if a connection from the loopback should be reported as '' (no Remote-IP - which is the default) or as '127.0.0.1' (force to false)

- used by both TCrtSock.AcceptRequest and THttpApiServer.Execute servers

27.7. SynCrypto.pas unit

Purpose: Fast cryptographic routines (hashing and cypher)

- implements AES,XOR,ADLER32,MD5,RC4,SHA1,SHA256,SHA384,SHA512,SHA3 and JWT
- optimized for speed (tuned assembler and SSE3/SSE4/AES-NI/PADLOCK support)
- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the *SynCrypto* unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynLZ</i>	SynLZ Compression routines - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1399
<i>SynTable</i>	Filter/database/cache/buffer/security/search/multithread/OS features - as a complement to SynCommons, which tended to increase too much - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1728

SynCrypto class hierarchy

Objects implemented in the *SynCrypto* unit

Objects	Description	Page
EJWTException	Exception raised when running JSON Web Tokens	1180
ESynCrypto	Class of Exceptions raised by this unit	1147
IProtocol	Perform safe communication after unilateral or mutual authentication	1179
TAES	Handle AES cypher/uncypher	1148
TAESAbstract	Handle AES cypher/uncypher with chaining	1150
TAESAbstractAEAD	AEAD (authenticated-encryption with associated-data) abstract class	1159
TAESAbstractEncryptOnly	Abstract parent class for chaining modes using only AES encryption	1157
TAESAbstractSyn	Handle AES cypher/uncypher with chaining with out own optimized code	1156
TAESAbstract_API	Handle AES cypher/uncypher using Windows CryptoAPI and the official Microsoft AES Cryptographic Provider (PROV_RSA_AES)	1161
TAESCBC	Handle AES cypher/uncypher with Cipher-block chaining (CBC)	1157
TAESCBC_API	Handle AES cypher/uncypher Cipher-block chaining (CBC) using Windows CryptoAPI	1162
TAESCFB	Handle AES cypher/uncypher with Cipher feedback (CFB)	1157
TAESCFBCRC	AEAD combination of AES with Cipher feedback (CFB) and 256-bit MAC	1159
TAESCFB_API	Handle AES cypher/uncypher Cipher feedback (CFB) using Windows CryptoAPI	1162
TAESCTR	Handle AES cypher/uncypher with 64-bit Counter mode (CTR)	1158
TAESECB	Handle AES cypher/uncypher without chaining (ECB)	1156
TAESECB_API	Handle AES cypher/uncypher without chaining (ECB) using Windows CryptoAPI	1161
TAESFull	AES and XOR encryption object for easy direct memory or stream access	1172
TAESFullHeader	Internal header for storing our AES data with salt and CRC	1172
TAESGCM	Handle AES-GCM cypher/uncypher with built-in authentication	1160
TAESGCMEngine	Low-level AES-GCM processing	1149
TAESIVCTR	Used internally by TAESAbstract to detect replay attacks	1150
TAESLocked	Thread-safe class containing a TAES encryption/decryption engine	1162

Objects	Description	Page
TAESMAC256	Internal 256-bit structure used for TAESAbstractAEAD MAC storage	1158
TAESOFB	Handle AES cypher/uncypher with Output feedback (OFB)	1157
TAESOFBCRC	AEAD combination of AES with Output feedback (OFB) and 256-bit MAC	1160
TAESOFB_API	Handle AES cypher/uncypher Output feedback (OFB) using Windows CryptoAPI	1162
TAESPRNG	Cryptographic pseudorandom number generator (CSPRNG) based on AES-256	1162
TAESPRNGSystem	TAESPRNG-compatible class using Operating System pseudorandom source	1165
TAESWriteStream	AES encryption stream	1173
THash128History	Stores an array of THash128 to check for their unicity	1147
THMAC_CRC32C	Compute the HMAC message authentication code using crc32c as hash function	1178
THMAC_SHA1	Compute the HMAC message authentication code using SHA-1 as hash function	1174
THMAC_SHA256	Compute the HMAC message authentication code using SHA-256 as hash function	1175
THMAC_SHA384	Compute the HMAC message authentication code using SHA-384 as hash function	1174
THMAC_SHA512	Compute the HMAC message authentication code using SHA-512 as hash function	1175
TJWTAbstract	Abstract parent class for implementing JSON Web Tokens	1181
TJWTContent	JWT decoded content, as processed by TJWTAbstract	1180
TJWTSH256	Implements JSON Web Tokens using 'HS256' (HMAC SHA-256) algorithm	1185
TJWTSH384	Implements JSON Web Tokens using 'HS384' (HMAC SHA-384) algorithm	1185
TJWTSH512	Implements JSON Web Tokens using 'HS512' (HMAC SHA-512) algorithm	1185
TJWTNone	Implements JSON Web Tokens using 'none' algorithm	1184
TJWT3224	Experimental JSON Web Tokens using SHA3-224 algorithm	1185
TJWT3256	Experimental JSON Web Tokens using SHA3-256 algorithm	1185
TJWT3384	Experimental JSON Web Tokens using SHA3-384 algorithm	1185
TJWT3512	Experimental JSON Web Tokens using SHA3-512 algorithm	1185
TJWT3S128	Experimental JSON Web Tokens using SHA3-SHAKE128 algorithm	1186

Objects	Description	Page
TJWT3S256	Experimental JSON Web Tokens using SHA3-SHAKE256 algorithm	1186
TJWTSynSignerAbstract	Abstract parent of JSON Web Tokens using HMAC-SHA2 or SHA-3 algorithms	1184
TMD5	Handle MD5 hashing	1171
TProtocolAES	Implements a secure protocol using AES encryption	1180
TProtocolNone	Implements a fake no-encryption protocol	1179
TRC4	Handle RC4 encryption/decryption	1171
TSHA1	Handle SHA-1 hashing	1166
TSHA256	Handle SHA-256 hashing	1166
TSHA3	Handle SHA-3 (Keccak) hashing	1168
TSHA384	Handle SHA-384 hashing	1167
TSHA512	Handle SHA-512 hashing	1168
TSynHasher	Convenient multi-algorithm hashing wrapper	1178
TSynSigner	A generic wrapper object to handle digital HMAC-SHA-2/SHA-3 signatures	1176
TSynSignerParams	JSON-serialization ready object as used by TSynSigner.PBKDF2 overloaded methods	1176

ESynCrypto = class(ESynException)

Class of Exceptions raised by this unit

THash128History = object(TObject)

Stores an array of THash128 to check for their unicity

- used e.g. to implement TAESAbstract.IVHistoryDepth property, but may be also used to efficiently store a list of 128-bit IPv6 addresses

Count: integer;

How many THash128 values are currently stored

Depth: integer;

How many THash128 values can be stored

function Add(const hash: THash128): boolean;

Add a hash value to the stored entries, checking for duplicates

- returns true if the hash was added, or false if it did already appear

function Exists(const hash: THash128): boolean;

O(n) fast search of a hash value in the stored entries

- returns true if the hash was found, or false if it did not appear

procedure Init(size, maxsize: integer);

Initialize the storage for a given history depth

- if Count reaches Depth, then older items will be removed

TAES = object(TObject)

Handle AES cypher/uncypher

- this is the default Electronic codebook (ECB) mode

- this class will use AES-NI hardware instructions, if available

- we defined a record instead of a class, to allow stack allocation and thread-safe reuse of one initialized instance (warning: not for Padlock)

function DecryptInit(const Key; KeySize: cardinal): boolean;

Initialize AES contexts for uncypher

- first method to call before using this object for decryption

- KeySize is in bits, i.e. 128,192,256

function DecryptInitFrom(const Encryption: TAES; const Key; KeySize: cardinal): boolean;

Initialize AES contexts for uncypher, from another TAES.EncryptInit

function DoInit(const Key; KeySize: cardinal; doEncrypt: boolean): boolean;

Generic initialization method for AES contexts

- call either EncryptInit() either DecryptInit() method

function EncryptInit(const Key; KeySize: cardinal): boolean;

Initialize AES contexts for cypher

- first method to call before using this object for encryption

- KeySize is in bits, i.e. 128,192,256

function Initialized: boolean;

TRUE if the context was initialized via EncryptInit/DecryptInit

function KeyBits: integer;

Returns the key size in bits (128/192/256)

function UsesAESNI: boolean;

Return TRUE if the AES-NI instruction sets are available on this CPU

procedure Decrypt(var B: TAESBlock); overload;

Decrypt an AES data block

procedure Decrypt(const BI: TAESBlock; var B0: TAESBlock); overload;

Decrypt an AES data block into another data block

procedure DoBlocks(pIn, pOut: PAESBlock; Count: integer; doEncrypt: boolean); overload;

Perform the AES cypher or uncypher to continuous memory blocks

- call either Encrypt() either Decrypt() method

procedure DoBlocks(pIn, pOut: PAESBlock; out oIn, oOut: PAESBlock; Count: integer; doEncrypt: boolean); overload;

Perform the AES cypher or uncypher to continuous memory blocks

- call either Encrypt() either Decrypt() method

procedure DoBlocksOFB(**const** iv: TAESBlock; src, dst: pointer; blockcount: PtrUInt);

Performs AES-OFB encryption and decryption on whole blocks

- may be called instead of TAESOFB when only a raw TAES is available
- this method is thread-safe (except if padlock is used)

procedure DoBlocksThread(**var** bIn, bOut: PAESBlock; Count: integer; doEncrypt: boolean);

Perform the AES cypher or uncypher to continuous memory blocks

- this special method will use Threads for bigs blocks (>512KB) if multi-CPU
- call either Encrypt() either Decrypt() method

procedure Done;

Finalize AES contexts for both cypher and uncypher

- would fill the TAES instance with zeros, for safety
- is only mandatoy when padlock is used

procedure Encrypt(**const** BI: TAESBlock; **var** B0: TAESBlock); overload;

Encrypt an AES data block into another data block

procedure Encrypt(**var** B: TAESBlock); overload;

Encrypt an AES data block

TAESGCMEngine = **object**(TObject)

Low-level AES-GCM processing

- implements standard AEAD (authenticated-encryption with associated-data) algorithm, as defined by NIST and

function Add_AAD(pAAD: pointer; aLen: PtrInt): boolean;

Append some data to be authenticated, but not encrypted

function Decrypt(ctp, ptp: Pointer; ILen: PtrInt; ptag: pointer=nil; tlen: PtrInt=0): boolean;

Decrypt a buffer with AES-GCM, updating the associated authentication data

- also validate the GMAC with the supplied ptag/tlen if ptag<>nil, and skip the AES-CTR phase if the authentication doesn't match

function Encrypt(ptp, ctp: Pointer; ILen: PtrInt): boolean;

Encrypt a buffer with AES-GCM, updating the associated authentication data

function Final(**out** tag: TAESBlock; andDone: boolean=true): boolean;

Finalize the AES-GCM encryption, returning the authentication tag

- will also flush the AES context to avoid forensic issues, unless andDone is forced to false

function FullDecryptAndVerify(**const** Key; KeyBits: PtrInt; pIV: pointer; IV_len: PtrInt; pAAD: pointer; aLen: PtrInt; ctp, ptp: Pointer; pLen: PtrInt; ptag: pointer; tLen: PtrInt): boolean;

Single call AES-GCM decryption and verification process

function FullEncryptAndAuthenticate(**const** Key; KeyBits: PtrInt; pIV: pointer; IV_len: PtrInt; pAAD: pointer; aLen: PtrInt; ptp, ctp: Pointer; pLen: PtrInt; **out** tag: TAESBlock): boolean;

Single call AES-GCM encryption and authentication process

function Init(const Key; KeyBits: PtrInt): boolean;

Initialize the AES-GCM structure for the supplied Key

function Reset(pIV: pointer; IV_len: PtrInt): boolean;

Start AES-GCM encryption with a given Initialization Vector

- IV_len is in bytes use 12 for exact IV setting, otherwise the supplied buffer will be hashed using gf_mul_h()

procedure Done;

Flush the AES context to avoid forensic issues

- do nothing if Final() has been already called

TAESIVCTR = packed record

Used internally by TAESAbstract to detect replay attacks

- when EncryptPKCS7/DecryptPKCS7 are used with IVAtBeginning=true, and IVReplayAttackCheck property contains repCheckedIfAvailable or repMandatory
 - EncryptPKCS7 will encrypt this record (using the global shared AESIVCTR_KEY over AES-128) to create a random IV, as a secure cryptographic pseudorandom number generator (CSPRNG), nonce and ctr ensuring 96 bits of entropy
 - DecryptPKCS7 will decode and ensure that the IV has an increasing CTR
 - memory size matches an TAESBlock on purpose, for direct encryption

ctr: cardinal;

An increasing counter, used to detect replay attacks

- is set to a 32-bit random value at initialization
 - is increased by one for every EncryptPKCS7, so can be checked against replay attack in DecryptPKCS7, and implement a safe CSPRNG for stored IV

magic: cardinal;

Contains the crc32c hash of the block cipher mode (e.g. 'AESCFB')

- when magic won't match (i.e. in case of mORMot revision < 3063), the check won't be applied in DecryptPKCS7: this security feature is backward compatible if IVReplayAttackCheck is repCheckedIfAvailable, but will fail for repMandatory

nonce: QWord;

8 bytes of random value

TAESAbstract = class(TSynPersistent)

Handle AES cypher/uncypher with chaining

- use any of the inherited implementation, corresponding to the chaining mode required -
 TAES ECB, TAES CBC, TAES CFB, TAES OFB and TAES CTR classes to handle in ECB, CBC, CFB, OFB and CTR mode (including PKCS7-like padding)

constructor Create(const aKey: THash256); reintroduce; overload;

Initialize AES context for AES-256 cypher

- first method to call before using this class
 - just a wrapper around Create(aKey,256);

constructor Create(const aKey: THash128); reintroduce; overload;

Initialize AES context for AES-128 cypher

- first method to call before using this class
- just a wrapper around Create(aKey,128);

constructor Create(const aKey; aKeySize: cardinal); reintroduce; overload; virtual;

Initialize AES context for cypher

- first method to call before using this class
- KeySize is in bits, i.e. 128,192,256

constructor CreateFromPBKDF2(const aKey: RawUTF8; const aSalt: RawByteString; aRounds: Integer);

Initialize AES context for cypher, from PBKDF2_HMAC_SHA256 derivation

- here the Key is supplied as a string, and will be hashed using PBKDF2_HMAC_SHA256 with the specified salt and rounds

constructor CreateFromSha256(const aKey: RawUTF8);

Initialize AES context for cypher, from SHA-256 hash

- here the Key is supplied as a string, and will be hashed using SHA-256 via the SHA256Weak proprietary algorithm - to be used only for backward compatibility of existing code
- consider using more secure (and more standard) CreateFromPBKDF2 instead

constructor CreateTemp(aKeySize: cardinal);

Initialize AES context for cypher, from some TAESPRNG random bytes

- may be used to hide some sensitive information from memory, like CryptDataForCurrentUser but with a temporary key

destructor Destroy; override;

Release the used instance memory and resources

- also fill the secret fKey buffer with zeros, for safety

function AlgoName: TShort16;

/ returns e.g. 'aes128cfb' or '' if nil

function Clone: TAESAbstract; virtual;

Compute a class instance similar to this one

- could be used to have a thread-safe re-use of a given encryption key

function CloneEncryptDecrypt: TAESAbstract; virtual;

Compute a class instance similar to this one, for performing the reverse encryption/decryption process

- this default implementation calls Clone, but CFB/OFB/CTR chaining modes using only AES encryption (i.e. inheriting from TAESAbstractEncryptOnly) will return self to avoid creating two instances
- warning: to be used only with IVAtBeginning=false

```
function DecryptPKCS7(const Input: RawByteString; IVAtBeginning: boolean=false;  
RaiseESynCryptoOnError: boolean=true): RawByteString; overload;
```

Decrypt a memory buffer using a PKCS7 padding pattern

- PKCS7 padding is described in RFC 5652 - it will trim up to 16 bytes from the input buffer; note this method uses the padding only, not the whole PKCS#7 Cryptographic Message Syntax
- if IVAtBeginning is TRUE, the Initialization Vector will be taken from the beginning of the input binary buffer - if IVReplayAttackCheck is set, this IV will be validated to contain an increasing encrypted CTR, and raise an ESynCrypto when a replay attack attempt is detected
- if RaiseESynCryptoOnError=false, returns "" on any decryption error

```
function DecryptPKCS7(const Input: TBytes; IVAtBeginning: boolean=false;  
RaiseESynCryptoOnError: boolean=true): TBytes; overload;
```

Decrypt a memory buffer using a PKCS7 padding pattern

- PKCS7 padding is described in RFC 5652 - it will trim up to 16 bytes from the input buffer; note this method uses the padding only, not the whole PKCS#7 Cryptographic Message Syntax
- if IVAtBeginning is TRUE, the Initialization Vector will be taken from the beginning of the input binary buffer - if IVReplayAttackCheck is set, this IV will be validated to contain an increasing encrypted CTR, and raise an ESynCrypto when a replay attack attempt is detected
- if RaiseESynCryptoOnError=false, returns [] on any decryption error

```
function DecryptPKCS7Buffer(Input: Pointer; InputLen: integer; IVAtBeginning:  
boolean; RaiseESynCryptoOnError: boolean=true): RawByteString;
```

Decrypt a memory buffer using a PKCS7 padding pattern

- PKCS7 padding is described in RFC 5652 - it will trim up to 16 bytes from the input buffer; note this method uses the padding only, not the whole PKCS#7 Cryptographic Message Syntax
- if IVAtBeginning is TRUE, the Initialization Vector will be taken from the beginning of the input binary buffer - this IV will in fact contain an internal encrypted CTR, to detect any replay attack attempt
- if RaiseESynCryptoOnError=false, returns "" on any decryption error

```
function EncryptPKCS7(const Input: TBytes; IVAtBeginning: boolean=false): TBytes;  
overload;
```

Encrypt a memory buffer using a PKCS7 padding pattern

- PKCS7 padding is described in RFC 5652 - it will add up to 16 bytes to the input buffer; note this method uses the padding only, not the whole PKCS#7 Cryptographic Message Syntax
- if IVAtBeginning is TRUE, a random Initialization Vector will be computed, and stored at the beginning of the output binary buffer - this IV may contain an internal encrypted CTR, to detect any replay attack attempt, if IVReplayAttackCheck is set to repCheckedIfAvailable or repMandatory

```
function EncryptPKCS7(const Input: RawByteString; IVAtBeginning: boolean=false):  
RawByteString; overload;
```

Encrypt a memory buffer using a PKCS7 padding pattern

- PKCS7 padding is described in RFC 5652 - it will add up to 16 bytes to the input buffer; note this method uses the padding only, not the whole PKCS#7 Cryptographic Message Syntax
- if IVAtBeginning is TRUE, a random Initialization Vector will be computed, and stored at the beginning of the output binary buffer - this IV may contain an internal encrypted CTR, to detect any replay attack attempt, if IVReplayAttackCheck is set to repCheckedIfAvailable or repMandatory

function EncryptPKCS7Buffer(Input,Output: Pointer; InputLen,OutputLen: cardinal; IVAtBeginning: boolean): boolean;

Encrypt a memory buffer using a PKCS7 padding pattern

- PKCS7 padding is described in RFC 5652 - it will add up to 16 bytes to the input buffer; note this method uses the padding only, not the whole PKCS#7 Cryptographic Message Syntax
- use EncryptPKCS7Length() function to compute the actual needed length
- if IVAtBeginning is TRUE, a random Initialization Vector will be computed, and stored at the beginning of the output binary buffer - this IV will in fact contain an internal encrypted CTR, to detect any replay attack attempt
- returns TRUE on success, FALSE if OutputLen is not correct - you should use EncryptPKCS7Length() to compute the exact needed number of bytes

function EncryptPKCS7Length(InputLen: cardinal; IVAtBeginning: boolean): cardinal;

Compute how many bytes would be needed in the output buffer, when encrypt using a PKCS7 padding pattern

- could be used to pre-compute the OutputLength for EncryptPKCS7Buffer()
- PKCS7 padding is described in RFC 5652 - it will add up to 16 bytes to the input buffer; note this method uses the padding only, not the whole PKCS#7 Cryptographic Message Syntax

function MACAndCrypt(const Data: RawByteString; Encrypt: boolean): RawByteString;

Perform one step PKCS7 encryption/decryption and authentication with the current AES instance

- returns "" on any (MAC) issue during decryption (Encrypt=false) or if this class does not support AEAD MAC
- as used e.g. by CryptDataForCurrentUser()
- do not use this abstract class method, but inherited TAESCFBCRC/TAESOFBCRC
- will store a header with its own CRC, so detection of most invalid formats (e.g. from fuzzing input) will occur before any AES/MAC process

function MACCheckError(aEncrypted: pointer; Count: cardinal): boolean; **virtual;**

Validate if an encrypted buffer matches the stored AEAD MAC

- expects the 256-bit MAC, as returned by MACGetLast, to be stored after the encrypted data
- default implementation, for a non AEAD protocol, returns false

class function MACEncrypt(const Data: RawByteString; const Key: THash256; Encrypt: boolean): RawByteString; **overload;**

Perform one step PKCS7 encryption/decryption and authentication from a given 256-bit key

- returns "" on any (MAC) issue during decryption (Encrypt=false) or if this class does not support AEAD MAC
- as used e.g. by CryptDataForCurrentUser()
- do not use this abstract class method, but inherited TAESCFBCRC/TAESOFBCRC
- will store a header with its own CRC, so detection of most invalid formats (e.g. from fuzzing input) will occur before any AES/MAC process

class function MACEncrypt(const Data: RawByteString; const Key: THash128; Encrypt: boolean): RawByteString; **overload;**

Perform one step PKCS7 encryption/decryption and authentication from a given 128-bit key

- returns "" on any (MAC) issue during decryption (Encrypt=false) or if this class does not support AEAD MAC
- do not use this abstract class method, but inherited TAESCFBCRC/TAESOFBCRC
- will store a header with its own CRC, so detection of most invalid formats (e.g. from fuzzing input) will occur before any AES/MAC process

function MACEquals(const aCRC: THash256): boolean; virtual;

Validate if the computed AEAD MAC matches the expected supplied value
 - is just a wrapper around MACGetLast() and IsEqual() functions

function MACGetLast(out aCRC: THash256): boolean; virtual;

Returns AEAD (authenticated-encryption with associated-data) MAC
 - i.e. optional 256-bit MAC computation during last Encrypt/Decrypt call
 - may be used e.g. for AES-GCM or our custom AES-CTR modes
 - default implementation, for a non AEAD protocol, returns false

function MACSetNonce(const aKey: THash256; aAssociated: pointer=nil;
 aAssociatedLen: integer=0): boolean; virtual;

Initialize AEAD (authenticated-encryption with associated-data) nonce
 - i.e. setup 256-bit MAC computation during next Encrypt/Decrypt call
 - may be used e.g. for AES-GCM or our custom AES-CTR modes
 - default implementation, for a non AEAD protocol, returns false

class function SimpleEncrypt(const Input: RawByteString; const Key; KeySize:
 integer; Encrypt: boolean; IVAtBeginning: boolean=false; RaiseESynCryptoOnError:
 boolean=true): RawByteString; overload;

Simple wrapper able to cypher/decypher any in-memory content
 - here data variables could be text or binary
 - you could use e.g. THMAC_SHA256 to safely compute the Key/KeySize value
 - if IVAtBeginning is TRUE, a random Initialization Vector will be computed, and stored at the beginning of the output binary buffer
 - will use SHA256Weak() and PKCS7 padding with the current class mode

class function SimpleEncrypt(const Input,Key: RawByteString; Encrypt: boolean;
 IVAtBeginning: boolean=false; RaiseESynCryptoOnError: boolean=true):
 RawByteString; overload;

Simple wrapper able to cypher/decypher any in-memory content
 - here data variables could be text or binary
 - use StringToUTF8() to define the Key parameter from a VCL string
 - if IVAtBeginning is TRUE, a random Initialization Vector will be computed, and stored at the beginning of the output binary buffer
 - will use SHA256Weak() and PKCS7 padding with the current class mode

class function SimpleEncryptFile(const InputFile, Outputfile: TFileName; const Key;
 KeySize: integer; Encrypt: boolean; IVAtBeginning: boolean=false;
 RaiseESynCryptoOnError: boolean=true): boolean; overload;

Simple wrapper able to cypher/decypher any file content
 - just a wrapper around SimpleEncrypt() and StringFromFile/FileFromString
 - you could use e.g. THMAC_SHA256 to safely compute the Key/KeySize value
 - if IVAtBeginning is TRUE, a random Initialization Vector will be computed, and stored at the beginning of the output binary buffer
 - will use SHA256Weak() and PKCS7 padding with the current class mode

```
class function SimpleEncryptFile(const InputFile, OutputFile: TFileName; const Key: RawByteString; Encrypt: boolean; IVAtBeginning: boolean=false; RaiseESynCryptoOnError: boolean=true): boolean; overload;
```

Simple wrapper able to cypher/decypher any file content

- just a wrapper around SimpleEncrypt() and StringFromFile/FileFromString
- use StringToUTF8() to define the Key parameter from a VCL string
- if IVAtBeginning is TRUE, a random Initialization Vector will be computed, and stored at the beginning of the output binary buffer
- will use SHA256Weak() and PKCS7 padding with the current class mode

```
procedure Decrypt(BufIn, BufOut: pointer; Count: cardinal); virtual; abstract;
```

Perform the AES un-cypher in the corresponding mode

- when used in block chaining mode, you should have set the IV property

```
procedure Encrypt(BufIn, BufOut: pointer; Count: cardinal); virtual; abstract;
```

Perform the AES cypher in the corresponding mode

- when used in block chaining mode, you should have set the IV property

```
property IV: TAESBlock read fIV write fIV;
```

Associated Initialization Vector

- all modes (except ECB) do expect an IV to be supplied for chaining, before any encryption or decryption is performed
- you could also use PKCS7 encoding with IVAtBeginning=true option

```
property IVHistoryDepth: integer read fIVHistoryDec.Depth write SetIVHistory;
```

Maintains an history of previous IV, to avoid re-play attacks

- only useful when EncryptPKCS7/DecryptPKCS7 are used with IVAtBeginning=true, and IVReplayAttackCheck is left to repNoCheck

```
property IVReplayAttackCheck: TAESIVReplayAttackCheck read fIVReplayAttackCheck write fIVReplayAttackCheck;
```

Let IV detect replay attack for EncryptPKCS7 and DecryptPKCS7

- if IVAtBeginning=true and this property is set, EncryptPKCS7 will store a random IV from an internal CTR, and DecryptPKCS7 will check this incoming IV CTR consistency, and raise an ESynCrypto exception on failure
- leave it to its default repNoCheck if the very same TAESAbstract instance is expected to be used with several sources, by which the IV CTR will be unsynchronized
- security warning: by design, this is NOT cautious with CBC chaining: you should use it only with CFB, OFB or CTR mode, since the IV sequence will be predictable if you know the fixed AES private key of this unit, but the IV sequence features uniqueness as it is generated by a good PRNG - see <http://crypto.stackexchange.com/q/3515>

```
property KeySize: cardinal read fKeySize;
```

Associated Key Size, in bits (i.e. 128,192,256)

TAESAbstractSyn = class(TAESAbstract)

Handle AES cypher/uncypher with chaining with out own optimized code

- use any of the inherited implementation, corresponding to the chaining mode required - TAESECB, TAESCBC, TAESCFB, TAESOFB and TAESCTR classes to handle in ECB, CBC, CFB, OFB and CTR mode (including PKCS7-like padding)
- this class will use AES-NI hardware instructions, if available
- those classes are re-entrant, i.e. that you can call the Encrypt* or Decrypt* methods on the same instance several times

destructor Destroy; override;

Release the used instance memory and resources

- also fill the TAES instance with zeros, for safety

function Clone: TAESAbstract; override;

Creates a new instance with the very same values

- by design, our classes will use TAES stateless context, so this method will just copy the current fields to a new instance, by-passing the key creation step

procedure Decrypt(BufIn, BufOut: pointer; Count: cardinal); override;

Perform the AES un-cypher in the corresponding mode

- this abstract method will set CV from fIV property, and fln/fOut from BufIn/BufOut

procedure Encrypt(BufIn, BufOut: pointer; Count: cardinal); override;

Perform the AES cypher in the corresponding mode, over Count bytes

- this abstract method will set CV from fIV property, and fln/fOut from BufIn/BufOut

property CV: TAESBlock read fCV;

Read-only access to the internal CV block, which may be have just been used by Encrypt/Decrypt methods

TAESECB = class(TAESAbstractSyn)

Handle AES cypher/uncypher without chaining (ECB)

- this mode is known to be less secure than the others
- IV property should be set to a fixed value to encode the trailing bytes of the buffer by a simple XOR - but you should better use the PKC7 pattern
- this class will use AES-NI hardware instructions, if available, e.g.
ECB128: 19.70ms in x86 optimized code, 6.97ms with AES-NI

procedure Decrypt(BufIn, BufOut: pointer; Count: cardinal); override;

Perform the AES un-cypher in the ECB mode

procedure Encrypt(BufIn, BufOut: pointer; Count: cardinal); override;

Perform the AES cypher in the ECB mode

TAESCBC = class(TAESAbstractSyn)

Handle AES cypher/uncypher with Cipher-block chaining (CBC)

- this class will use AES-NI hardware instructions, if available, e.g.
CBC192: 24.91ms in x86 optimized code, 9.75ms with AES-NI

- expect IV to be set before process, or IVAtBeginning=true

procedure Decrypt(BufIn, BufOut: pointer; Count: cardinal); **override;**

Perform the AES un-cypher in the CBC mode

procedure Encrypt(BufIn, BufOut: pointer; Count: cardinal); **override;**

Perform the AES cypher in the CBC mode

TAESAbstractEncryptOnly = class(TAESAbstractSyn)

Abstract parent class for chaining modes using only AES encryption

constructor Create(const aKey; aKeySize: cardinal); **override;**

Initialize AES context for cypher

- will pre-generate the encryption key (aKeySize in bits, i.e. 128,192,256)

function CloneEncryptDecrypt: TAESAbstract; **override;**

Compute a class instance similar to this one, for performing the reverse encryption/decryption process

- will return self to avoid creating two instances

- warning: to be used only with IVAtBeginning=false

TAESCFB = class(TAESAbstractEncryptOnly)

Handle AES cypher/uncypher with Cipher feedback (CFB)

- this class will use AES-NI hardware instructions, if available, e.g.
CFB128: 22.25ms in x86 optimized code, 9.29ms with AES-NI

- expect IV to be set before process, or IVAtBeginning=true

procedure Decrypt(BufIn, BufOut: pointer; Count: cardinal); **override;**

Perform the AES un-cypher in the CFB mode

procedure Encrypt(BufIn, BufOut: pointer; Count: cardinal); **override;**

Perform the AES cypher in the CFB mode

TAESOFB = class(TAESAbstractEncryptOnly)

Handle AES cypher/uncypher with Output feedback (OFB)

- this class will use AES-NI hardware instructions, if available, e.g.
OFB256: 27.69ms in x86 optimized code, 9.94ms with AES-NI

- expect IV to be set before process, or IVAtBeginning=true

- TAESOFB 128/256 have an optimized asm version under x86_64 + AES_NI

procedure Decrypt(BufIn, BufOut: pointer; Count: cardinal); **override;**

Perform the AES un-cypher in the OFB mode

procedure Encrypt(BufIn, BufOut: pointer; Count: cardinal); **override;**

Perform the AES cypher in the OFB mode

TAESCTR = class(TAESAbstractEncryptOnly)

Handle AES cypher/uncypher with 64-bit Counter mode (CTR)

- the CTR will use a counter in bytes 7..0 by default - which is safe but not standard - call

ComposeIV() to change e.g. to NIST behavior

- this class will use AES-NI hardware instructions, e.g.

CTR256: 28.13ms in x86 optimized code, 10.63ms with AES-NI

- expect IV to be set before process, or IVAtBeginning=true

constructor Create(const aKey; aKeySize: cardinal); **override;**

Initialize AES context for cypher

- will pre-generate the encryption key (aKeySize in bits, i.e. 128,192,256)

function ComposeIV(const Nonce, Counter: TByteDynArray; LSBCounter: boolean): boolean; **overload;**

Defines how the IV is set and updated in CTR mode

- you can specify startup Nonce and Counter, and the Counter position

- Nonce + Counter lengths should add to 16 - otherwise returns false

function ComposeIV(Nonce, Counter: PAESBlock; NonceLen, CounterLen: integer; LSBCounter: boolean): boolean; **overload;**

Defines how the IV is set and updated in CTR mode

- default (if you don't call this method) uses a Counter in bytes 7..0

- you can specify startup Nonce and Counter, and the Counter position

- NonceLen + CounterLen should be 16 - otherwise it fails and returns false

procedure Decrypt(BufIn, BufOut: pointer; Count: cardinal); **override;**

Perform the AES un-cypher in the CTR mode

procedure Encrypt(BufIn, BufOut: pointer; Count: cardinal); **override;**

Perform the AES cypher in the CTR mode

TAESMAC256 = record

Internal 256-bit structure used for TAESAbstractAEAD MAC storage

encrypted: THash128;

The plain MAC of the encrypted content

- encrypted text digital signature, to check for errors, with no compromission of the plain content

plain: THash128;

The AES-encrypted MAC of the plain content

- plain text digital signature, to perform message authentication and integrity

TAESAbstractAEAD = class(TAESAbstractEncryptOnly)

AEAD (authenticated-encryption with associated-data) abstract class

- perform AES encryption and on-the-fly MAC computation, i.e. computes a proprietary 256-bit MAC during AES cyphering, as 128-bit CRC of the encrypted data and 128-bit CRC of the plain data, seeded from a Key
- the 128-bit CRC of the plain text is then encrypted using the current AES engine, so returned 256-bit MAC value has cryptographic level, and ensure data integrity, authenticity, and check against transmission errors

destructor Destroy; **override;**

Release the used instance memory and resources

- also fill the internal internal MAC hashes with zeros, for safety

function MACCheckError(aEncrypted: pointer; Count: cardinal): boolean; **override;**

Validate if an encrypted buffer matches the stored MAC

- expects the 256-bit MAC, as returned by MACGetLast, to be stored after the encrypted data
- returns true if the 128-bit CRC of the encrypted text matches the supplied buffer, ignoring the 128-bit CRC of the plain data
- since it is easy to forge such 128-bit CRC, it will only indicate that no transmission error occurred, but won't be an integrity or authentication proof (which will need full Decrypt + MACGetLast)
- may use any MACSetNonce() aAssociated value

function MACGetLast(out aCRC: THash256): boolean; **override;**

Returns 256-bit MAC computed during last Encrypt/Decrypt call

- encrypt the internal fMAC property value using the current AES cypher on the plain content and returns true; only the plain content CRC-128 is AES encrypted, to avoid reverse attacks against the known encrypted data

function MACSetNonce(const aKey: THash256; aAssociated: pointer=nil; aAssociatedLen: integer=0): boolean; **override;**

Initialize 256-bit MAC computation for next Encrypt/Decrypt call

- initialize the internal fMACKey property, and returns true
- only the plain text crc is seeded from aKey - encrypted message crc will use -1 as fixed seed, to avoid aKey compromission
- should be set with a new MAC key value before each message, to avoid replay attacks (as called from TECDHEProtocol.SetKey)

TAESCFBCRC = class(TAESAbstractAEAD)

AEAD combination of AES with Cipher feedback (CFB) and 256-bit MAC

- this class will use AES-NI and CRC32C hardware instructions, if available
- expect IV to be set before process, or IVAtBeginning=true

procedure Decrypt(BufIn, BufOut: pointer; Count: cardinal); **override;**

Perform the AES un-cypher in the CFB mode, and compute 256-bit MAC

procedure Encrypt(BufIn, BufOut: pointer; Count: cardinal); **override;**

Perform the AES cypher in the CFB mode, and compute a 256-bit MAC

TAESOFBCRC = class(TAESAbstractAEAD)

AEAD combination of AES with Output feedback (OFB) and 256-bit MAC

- this class will use AES-NI and CRC32C hardware instructions, if available
- expect IV to be set before process, or IVAtBeginning=true

procedure Decrypt(BufIn, BufOut: pointer; Count: cardinal); override;

Perform the AES un-cypher in the OFB mode, and compute a 256-bit MAC

procedure Encrypt(BufIn, BufOut: pointer; Count: cardinal); override;

Perform the AES cypher in the OFB mode, and compute a 256-bit MAC

TAESGCM = class(TAESAbstract)

Handle AES-GCM cypher/uncypher with built-in authentication

- implements AEAD (authenticated-encryption with associated-data) methods like MACEncrypt/MACCheckError
- this class will use AES-NI hardware instructions, if available

constructor Create(const aKey: THash256; aKeySize: cardinal); override;

Used to call AES.Reset() Initialize the AES-GCM context for cypher

- first method to call before using this class
- KeySize is in bits, i.e. 128,192,256

destructor Destroy; override;

Release the used instance memory and resources

- also fill the internal AES instance with zeros, for safety

function Clone: TAESAbstract; override;

Creates a new instance with the very same values

- by design, our classes will use TAESGCMEngine stateless context, so this method will just copy the current fields to a new instance, by-passing the key creation step

function MACCheckError(aEncrypted: pointer; Count: cardinal): boolean; override;

Validate if an encrypted buffer matches the stored AEAD MAC

- since AES-GCM is a one pass process, always assume the content is fine and returns true - we don't know the IV at this time

function MACGetLast(out aCRC: THash256): boolean; override;

Returns AEAD (authenticated-encryption with associated-data) MAC

- only the lower 128-bit (THash256.Lo) of aCRC is filled with the GMAC

function MACSetNonce(const aKey: THash256; aAssociated: pointer=nil; aAssociatedLen: integer=0): boolean; override;

Prepare the AES-GCM process before Encrypt/Decrypt is called

- aKey is not used: AES-GCM has its own nonce setting algorithm, and the IV will be set from random value by EncryptPKCS7()
- will just include any supplied associated data to the GMAC tag

procedure Decrypt(BufIn, BufOut: pointer; Count: cardinal); override;

Perform the AES un-cypher and authentication

procedure Encrypt(BufIn, BufOut: pointer; Count: cardinal); **override;**

Perform the AES-GCM cypher and authentication

TAESAbstract_API = class(TAESAbstract)

Handle AES cypher/uncypher using Windows CryptoAPI and the official Microsoft AES Cryptographic Provider (PROV_RSA_AES)

- see @<http://msdn.microsoft.com/en-us/library/windows/desktop/aa386979>

- timing of our optimized asm versions, for small (<=8KB) block processing (similar to standard web pages or most typical JSON/XML content), benchmarked on a Core i7 notebook and compiled as Win32 platform:

AES128 - ECB:79.33ms CBC:83.37ms CFB:80.75ms OFB:78.98ms CTR:80.45ms

AES192 - ECB:91.16ms CBC:96.06ms CFB:96.45ms OFB:92.12ms CTR:93.38ms

AES256 - ECB:103.22ms CBC:119.14ms CFB:111.59ms OFB:107.00ms CTR:110.13ms

- timing of the same process, using CryptoAPI official PROV_RSA_AES provider:

AES128 - ECB_API:102.88ms CBC_API:124.91ms

AES192 - ECB_API:115.75ms CBC_API:129.95ms

AES256 - ECB_API:139.50ms CBC_API:154.02ms

- but the CryptoAPI does not supports AES-NI, whereas our classes handle it, with a huge speed benefit

- under Win64, the official CryptoAPI is faster than our PUREPASCAL version, and the Win32 version of CryptoAPI itself, but slower than our AES-NI code

AES128 - ECB:107.95ms CBC:112.65ms CFB:109.62ms OFB:107.23ms CTR:109.42ms

AES192 - ECB:130.30ms CBC:133.04ms CFB:128.78ms OFB:127.25ms CTR:130.22ms

AES256 - ECB:145.33ms CBC:147.01ms CFB:148.36ms OFB:145.96ms CTR:149.67ms

AES128 - ECB_API:89.64ms CBC_API:100.84ms

AES192 - ECB_API:99.05ms CBC_API:105.85ms

AES256 - ECB_API:107.11ms CBC_API:118.04ms

- in practice, you could forget about using the CryptoAPI, unless you are required to do so, for legal/corporate reasons

constructor Create(const aKey; aKeySize: cardinal); **override;**

Initialize AES context for cypher

- first method to call before using this class

- KeySize is in bits, i.e. 128,192,256

destructor Destroy; **override;**

Release the AES execution context

procedure Decrypt(BufIn, BufOut: pointer; Count: cardinal); **override;**

Perform the AES un-cypher in the ECB mode

- if Count is not a multiple of a 16 bytes block, the IV will be used to XOR the trailing bytes - so it won't be compatible with our TAESAbstractSyn classes: you should better use PKC7 padding instead

procedure Encrypt(BufIn, BufOut: pointer; Count: cardinal); **override;**

Perform the AES cypher in the ECB mode

- if Count is not a multiple of a 16 bytes block, the IV will be used to XOR the trailing bytes - so it won't be compatible with our TAESAbstractSyn classes: you should better use PKC7 padding instead

TAESECB_API = class(TAESAbstract_API)

Handle AES cypher/uncypher without chaining (ECB) using Windows CryptoAPI

TAESCBC_API = class(TAESAbstract_API)

Handle AES cypher/uncypher Cipher-block chaining (CBC) using Windows CryptoAPI

TAESCFB_API = class(TAESAbstract_API)

Handle AES cypher/uncypher Cipher feedback (CFB) using Windows CryptoAPI

- NOT TO BE USED: the current PROV_RSA_AES provider does not return expected values for CFB

TAESOFB_API = class(TAESAbstract_API)

Handle AES cypher/uncypher Output feedback (OFB) using Windows CryptoAPI

- NOT TO BE USED: the current PROV_RSA_AES provider does not implement this mode, and returns a NTE_BAD_ALGID error

TAESLocked = class(TSynPersistentLock)

Thread-safe class containing a TAES encryption/decryption engine

destructor Destroy; **override;**

Finalize all used memory and resources

TAESPRNG = class(TAESLocked)

Cryptographic pseudorandom number generator (CSPRNG) based on AES-256

- use as a shared instance via TAESPRNG.Fill() overloaded class methods

- this class is able to generate some random output by encrypting successive values of a counter with AES-256 and a secret key

- this internal secret key is generated from PBKDF2 derivation of OS-supplied entropy using HMAC over SHA-512

- by design, such a PRNG is as good as the cypher used - for reference, see

https://en.wikipedia.org/wiki/Cryptographically_secure_pseudorandom_number_generator

- it would use fast hardware AES-NI or Padlock opcodes, if available

constructor Create(PBKDF2Rounds: integer = 16; ReseedAfterBytes: integer = 1024*1024; AESKeySize: integer = 256); **reintroduce;** **virtual;**

Initialize the internal secret key, using Operating System entropy

- entropy is gathered from the OS, using GetEntropy() method

- you can specify how many PBKDF2_HMAC_SHA512 rounds are applied to the OS-gathered entropy - the higher, the better, but also the slower

- internal private key would be re-seeded after ReseedAfterBytes bytes (1MB by default) are generated, using GetEntropy()

- by default, AES-256 will be used, unless AESKeySize is set to 128, which may be slightly faster (especially if AES-NI is not available)

function AFSplit(const Buffer: RawByteString; StripesCount: integer): RawByteString; **overload;**

Create an anti-forensic representation of a key for safe storage

- a binary buffer will be split into StripesCount items, ready to be saved on disk; returned length is BufferBytes*(StripesCount+1) bytes

- jsut a wrapper around the other overloaded AFSplit() funtion

function AFSplit(**const** Buffer; BufferBytes, StripesCount: integer): RawByteString;
overload;

Create an anti-forensic representation of a key for safe storage

- a binary buffer will be split into StripesCount items, ready to be saved on disk; returned length is BufferBytes*(StripesCount+1) bytes
- AFSplit supports secure data destruction crucial for secure on-disk key management. The key idea is to bloat information and therefore improve the chance of destroying a single bit of it. The information is bloated in such a way, that a single missing bit causes the original information become unrecoverable.
- this implementation uses SHA-256 as diffusion element, and the current TAESPRNG instance to gather randomness
- for reference, see TKS1 as used for LUKS and defined in
@<https://gitlab.com/cryptsetup/cryptsetup/wikis/TKS1-draft.pdf>

class function AFUnsplit(**const** Split: RawByteString; StripesCount: integer):
RawByteString; overload;

Retrieve a key from its anti-forensic representation

- is the reverse function of AFSplit() method
- returns the un-splitting binary content
- returns "" if StripesCount is incorrect

class function AFUnsplit(**const** Split: RawByteString; **out** Buffer; BufferBytes:
integer): boolean; overload;

Retrieve a key from its anti-forensic representation

- is the reverse function of AFSplit() method
- returns TRUE if the input buffer matches BufferBytes value

class function Bytes(Len: integer): TBytes;

Just a wrapper around TAESPRNG.Main.FillRandomBytes() function

- this method is thread-safe, but you may use your own TAESPRNG instance if you need some custom entropy level

class function Fill(Len: integer): RawByteString; overload;

Just a wrapper around TAESPRNG.Main.FillRandom() function

- this method is thread-safe, but you may use your own TAESPRNG instance if you need some custom entropy level

function FillRandom(Len: integer): RawByteString; overload;

Returns a binary buffer filled with some pseudorandom data

- this method is thread-safe

function FillRandomBytes(Len: integer): TBytes;

Returns a binary buffer filled with some pseudorandom data

- this method is thread-safe

function FillRandomHex(Len: integer): RawUTF8;

Returns a hexa-encoded binary buffer filled with some pseudorandom data

- this method is thread-safe

class function GetEntropy(Len: integer; SystemOnly: boolean=false): RawByteString;
virtual;

Retrieve some entropy bytes from the Operating System

- entropy comes from CryptGenRandom API on Windows, and /dev/urandom or /dev/random on Linux/POSIX
- this system-supplied entropy is then XORed with the output of a SHA-3 cryptographic SHAKE-256 generator in XOF mode, of several entropy sources (timestamp, thread and system information, SynCommons.Random32 function) unless SystemOnly is TRUE
- depending on the system, entropy may not be true randomness: if you need some truly random values, use TAESPRNG.Main.FillRandom() or TAESPRNG.Fill() methods, NOT this class function (which will be much slower, BTW)

class function Main: TAESPRNG;

Returns a shared instance of a TAESPRNG instance

- if you need to generate some random content, just call the TAESPRNG.Main.FillRandom() overloaded methods, or directly TAESPRNG.Fill()

function Random32(max: cardinal): cardinal; overload;

Returns a 32-bit unsigned random number, with a maximum value

function Random32: cardinal; overload;

Returns a 32-bit unsigned random number

function Random64: QWord;

Returns a 64-bit unsigned random number

function RandomDouble: double;

Returns a 64-bit floating-point random number in range [0..1]

function RandomExt: TSynExtended;

Returns a floating-point random number in range [0..1]

function RandomPassword(Len: integer): RawUTF8;

Computes a random ASCII password

- will contain uppercase/lower letters, digits and \$.:()?!+*/@# excluding ;,= to allow direct use in CSV content

class procedure Fill(Buffer: pointer; Len: integer); overload;

Just a wrapper around TAESPRNG.Main.FillRandom() function

- this method is thread-safe, but you may use your own TAESPRNG instance if you need some custom entropy level

class procedure Fill(out Block: TAESBlock); overload;

Just a wrapper around TAESPRNG.Main.FillRandom() function

- this method is thread-safe, but you may use your own TAESPRNG instance if you need some custom entropy level

class procedure Fill(out Block: THash256); overload;

Just a wrapper around TAESPRNG.Main.FillRandom() function

- this method is thread-safe, but you may use your own TAESPRNG instance if you need some custom entropy level

procedure FillRandom(out Buffer: THash256); overload;

Fill a 256-bit buffer with some pseudorandom data
 - this method is thread-safe

procedure FillRandom(Buffer: pointer; Len: integer); overload; **virtual**;

Fill a binary buffer with some pseudorandom data
 - this method is thread-safe

procedure FillRandom(out Block: TAESBlock); overload; **virtual**;

Fill a TAESBlock with some pseudorandom data
 - could be used e.g. to compute an AES Initialization Vector (IV)
 - this method is thread-safe

procedure Seed; **virtual**;

Would force the internal generator to re-seed its private key
 - avoid potential attacks on backward or forward security
 - would be called by FillRandom() methods, according to SeedAfterBytes
 - this method is thread-safe

property AESKeySize: integer **read** fAESKeySize;

How many bits (128 or 256 - which is the default) are used for the AES

property SeedAfterBytes: integer **read** fSeedAfterBytes;

After how many generated bytes Seed method would be called
 - default is 1 MB

property SeedPBKDF2Rounds: cardinal **read** fSeedPBKDF2Rounds;

How many PBKDF2_HMAC_SHA512 count is applied by Seed to the entropy
 - default is 16 rounds, which is more than enough for entropy gathering, since GetEntropy output comes from a SHAKE-256 generator in XOF mode

property TotalBytes: QWord **read** fTotalBytes;

How many bytes this generator did compute

TAESPRNGSystem = class(TAESPRNG)

TAESPRNG-compatible class using Operating System pseudorandom source
 - may be used instead of TAESPRNG if a "standard" generator is required - you could override MainAESPRNG global variable
 - will call /dev/urandom under POSIX, and CryptGenRandom API on Windows
 - warning: may block on some BSD flavors, depending on /dev/urandom
 - from the cryptographic point of view, our TAESPRNG class doesn't suffer from the "black-box" approach of Windows, give consistent randomness over all supported cross-platform, and is indubitably faster

constructor Create; **reintroduce**; **virtual**;

Initialize the Operating System PRNG

procedure FillRandom(Buffer: pointer; Len: integer); **override**;

Fill a binary buffer with some pseudorandom data
 - this method is thread-safe

procedure FillRandom(**out** Block: TAESBlock); **override**;

Fill a TAESBlock with some pseudorandom data
- this method is thread-safe

procedure Seed; **override**;

Called to force the internal generator to re-seed its private key
- won't do anything for the Operating System pseudorandom source

TSHA1 = object(TObject)

Handle SHA-1 hashing

- we defined a record instead of a class, to allow stack allocation and thread-safe reuse of one initialized instance, e.g. for THMAC_SHA1
- see TSynHasher if you expect to support more than one algorithm at runtime

function Final(NoInit: boolean=false): TSHA1Digest; **overload**;

Finalize and compute the resulting SHA-1 hash Digest of all data affected to Update() method
- will also call Init to reset all internal temporary context, for safety

procedure Final(**out** Digest: TSHA1Digest; NoInit: boolean=false); **overload**;

Finalize and compute the resulting SHA-1 hash Digest of all data affected to Update() method
- will also call Init to reset all internal temporary context, for safety

procedure Full(Buffer: pointer; Len: integer; **out** Digest: TSHA1Digest);

One method to rule them all
- call Init, then Update(), then Final()
- only Full() is Padlock-implemented - use this rather than Update()

procedure Init;

Initialize SHA-1 context for hashing

procedure Update(Buffer: pointer; Len: integer); **overload**;

Update the SHA-1 context with some data

procedure Update(**const** Buffer: RawByteString); **overload**;

Update the SHA-1 context with some data

TSHA256 = object(TObject)

Handle SHA-256 hashing

- we defined a record instead of a class, to allow stack allocation and thread-safe reuse of one initialized instance, e.g. for THMAC_SHA256
- see TSynHasher if you expect to support more than one algorithm at runtime

function Final(NoInit: boolean=false): TSHA256Digest; **overload**;

Finalize and compute the resulting SHA-256 hash Digest of all data affected to Update() method

procedure Final(**out** Digest: TSHA256Digest; NoInit: boolean=false); **overload**;

Finalize and compute the resulting SHA-256 hash Digest of all data affected to Update() method

procedure Full(Buffer: pointer; Len: integer; **out** Digest: TSHA256Digest);

One method to rule them all

- call Init, then Update(), then Final()
- only Full() is Padlock-implemented - use this rather than Update()

procedure Init;

Initialize SHA-256 context for hashing

procedure Update(Buffer: pointer; Len: integer); overload;

Update the SHA-256 context with some data

procedure Update(**const** Buffer: RawByteString); overload;

Update the SHA-256 context with some data

TSHA384 = object(TObject)

Handle SHA-384 hashing

- it is in fact a TSHA512 truncated hash, with other initial hash values
- we defined a record instead of a class, to allow stack allocation and thread-safe reuse of one initialized instance, e.g. for THMAC_SHA384
- see TSynHasher if you expect to support more than one algorithm at runtime

function Final(NoInit: boolean=false): TSHA384Digest; overload;

Finalize and compute the resulting SHA-384 hash Digest of all data affected to Update() method

procedure Final(**out** Digest: TSHA384Digest; NoInit: boolean=false); overload;

Finalize and compute the resulting SHA-384 hash Digest of all data affected to Update() method

- will also call Init to reset all internal temporary context, for safety

procedure Full(Buffer: pointer; Len: integer; **out** Digest: TSHA384Digest);

One method to rule them all

- call Init, then Update(), then Final()

procedure Init;

Initialize SHA-384 context for hashing

procedure Update(Buffer: pointer; Len: integer); overload;

Update the SHA-384 context with some data

procedure Update(**const** Buffer: RawByteString); overload;

Update the SHA-384 context with some data

TSHA512 = **object**(TObject)

Handle SHA-512 hashing

- by design, this algorithm is expected to be much faster on 64-bit CPU, since all internal process involves QWord - but we included a SSE3 asm optimized version on 32-bit CPU under Windows and Linux, which is almost as fast as on plain x64, and even faster than SHA-256 and SHA-3
- under x86/Delphi, plain pascal is 40MB/s, SSE3 asm 180MB/s
- on x64, pascal Delphi is 150MB/s, and FPC is 190MB/s (thanks to native RorQWord intrinsic compiler function) - we also included a SSE4 asm version which outperforms other cryptographic hashes to more than 380MB/s
- we defined a record instead of a class, to allow stack allocation and thread-safe reuse of one initialized instance, e.g. for THMAC_SHA512
- see TSynHasher if you expect to support more than one algorithm at runtime

function Final(NoInit: boolean=false): TSHA512Digest; overload;

Finalize and compute the resulting SHA-512 hash Digest of all data affected to Update() method

procedure Final(out Digest: TSHA512Digest; NoInit: boolean=false); overload;

Finalize and compute the resulting SHA-512 hash Digest of all data affected to Update() method

- will also call Init to reset all internal temporary context, for safety

procedure Full(Buffer: pointer; Len: integer; out Digest: TSHA512Digest);

One method to rule them all

- call Init, then Update(), then Final()

procedure Init;

Initialize SHA-512 context for hashing

procedure Update(Buffer: pointer; Len: integer); overload;

Update the SHA-512 context with some data

procedure Update(const Buffer: RawByteString); overload;

Update the SHA-512 context with some data

TSHA3 = **object**(TObject)

Handle SHA-3 (Keccak) hashing

- Keccak was the winner of the NIST hashing competition for a new hashing algorithm to provide an alternative to SHA-256. It became SHA-3 and was named by NIST a FIPS 180-4, then FIPS 202 hashing standard in 2015
- by design, SHA-3 doesn't need to be encapsulated into a HMAC algorithm, since it already includes proper padding, so keys could be concatenated
- this implementation is based on Wolfgang Ehrhardt's and Eric Grange's, with our own manually optimized x64 assembly
- we defined a record instead of a class, to allow stack allocation and thread-safe reuse of one initialized instance, e.g. after InitCypher
- see TSynHasher if you expect to support more than one algorithm at runtime

function Algorithm: TSHA3Algo;

Returns the algorithm specified at Init()

function Cypher(const Source: RawByteString): RawByteString; overload;

Uses SHA-3 in "Extendable-Output Function" (XOF) to cypher some content

- this overloaded function expects the instance to have been prepared by previous InitCypher call
- resulting string will have the very same size than the Source
- XOF is implemented as a symmetrical algorithm: use this Cypher() method for both encryption and decryption of any buffer
- you can call this method several times, to work with a stream buffer; but for safety, you should eventually call Done

function Cypher(const Key, Source: RawByteString; Algo: TSHA3Algo = SHAKE_256): RawByteString; overload;

Uses SHA-3 in "Extendable-Output Function" (XOF) to cypher some content

- this overloaded function works with RawByteString content
- resulting string will have the very same size than the Source
- XOF is implemented as a symmetrical algorithm: use this Cypher() method for both encryption and decryption of any buffer

function Final256(NoInit: boolean=false): THash256;

Finalize and compute the resulting SHA-3 hash 256-bit Digest

function Final512(NoInit: boolean=false): THash512;

Finalize and compute the resulting SHA-3 hash 512-bit Digest

function FullStr(Algo: TSHA3Algo; Buffer: pointer; Len: integer; DigestBits: integer=0): RawUTF8;

Compute a SHA-3 hash hexadecimal Digest from a buffer, in one call

- call Init, then Update(), then Final() using the supplied algorithm
- default DigestBits=0 will write the default number of bits to Digest output memory buffer, according to the specified TSHA3Algo

procedure Cypher(Source, Dest: pointer; DataLen: integer); overload;

Uses SHA-3 in "Extendable-Output Function" (XOF) to cypher some content

- this overloaded function expects the instance to have been prepared by previous InitCypher call
- resulting Dest buffer will have the very same size than the Source
- XOF is implemented as a symmetrical algorithm: use this Cypher() method for both encryption and decryption of any buffer
- you can call this method several times, to work with a stream buffer; but for safety, you should eventually call Done

procedure Cypher(Key, Source, Dest: pointer; KeyLen, DataLen: integer; Algo: TSHA3Algo = SHAKE_256); overload;

Uses SHA-3 in "Extendable-Output Function" (XOF) to cypher some content

- there is no MAC stored in the resulting binary
- Source and Dest will have the very same DataLen size in bytes, and Dest will be Source XORed with the XOF output, so encryption and decryption are just obtained by the same symmetric call
- in this implementation, Source and Dest should point to two diverse buffers
- for safety, the Key should be a secret value, pre-pended with a random salt/IV or a resource-specific identifier (e.g. a record ID or a S/N), to avoid reverse composition of the cypher from known content - note that concatenating keys with SHA-3 is as safe as computing a HMAC for SHA-2

procedure Done;

Fill all used memory context with zeros, for safety

- is necessary only when NoInit is set to true (e.g. after InitCypher)

procedure Final(out Digest: THash512; NoInit: boolean=false); overload;

Finalize and compute the resulting SHA-3 hash 512-bit Digest

procedure Final(out Digest: THash256; NoInit: boolean=false); overload;

Finalize and compute the resulting SHA-3 hash 256-bit Digest

procedure Final(Digest: pointer; DigestBits: integer=0; NoInit: boolean=false); overload;

Finalize and compute the resulting SHA-3 hash Digest

- Digest destination buffer must contain enough bytes
- default DigestBits=0 will write the default number of bits to Digest output memory buffer, according to the current TSHA3Algo
- you can call this method several times, to use this SHA-3 hasher as "Extendable-Output Function" (XOF), e.g. for stream encryption (ensure NoInit is set to true, to enable recall)

procedure Full(Buffer: pointer; Len: integer; out Digest: THash256); overload;

Compute a SHA-3 hash 256-bit Digest from a buffer, in one call

- call Init, then Update(), then Final() using SHA3_256 into a THash256

procedure Full(Buffer: pointer; Len: integer; out Digest: THash512); overload;

Compute a SHA-3 hash 512-bit Digest from a buffer, in one call

- call Init, then Update(), then Final() using SHA3_512 into a THash512

procedure Full(Algo: TSHA3Algo; Buffer: pointer; Len: integer; Digest: pointer; DigestBits: integer=0); overload;

Compute a SHA-3 hash Digest from a buffer, in one call

- call Init, then Update(), then Final() using the supplied algorithm
- default DigestBits=0 will write the default number of bits to Digest output memory buffer, according to the specified TSHA3Algo

procedure Init(Algo: TSHA3Algo);

Initialize SHA-3 context for hashing

- in practice, you may use SHA3_256 or SHA3_512 to return THash256 or THash512 digests

procedure InitCypher(Key: pointer; KeyLen: integer; Algo: TSHA3Algo = SHAKE_256); overload;

Uses SHA-3 in "Extendable-Output Function" (XOF) to cypher some content

- prepare the instance to further Cypher() calls
- you may reuse the very same TSHA3 instance by copying it to a local variable before calling this method (this copy is thread-safe)
- works with RawByteString content

procedure InitCypher(const Key: RawByteString; Algo: TSHA3Algo = SHAKE_256); overload;

Uses SHA-3 in "Extendable-Output Function" (XOF) to cypher some content

- prepare the instance to further Cypher() calls
- you may reuse the very same TSHA3 instance by copying it to a local variable before calling this method (this copy is thread-safe)
- works with RawByteString content

```
procedure Update(Buffer: pointer; Len: integer); overload;
```

Update the SHA-3 context with some data

```
procedure Update(const Buffer: RawByteString); overload;
```

Update the SHA-3 context with some data

```
TMD5 = object(TObject)
```

Handle MD5 hashing

- we defined a record instead of a class, to allow stack allocation and thread-safe reuse of one initialized instance
- see TSynHasher if you expect to support more than one algorithm at runtime
- even if MD5 is now seldom used, it is still faster than SHA alternatives, when you need a 128-bit cryptographic hash, but can afford some collisions
- this implementation has optimized x86 and x64 assembly, for processing around 500MB/s, and a pure-pascal fallback code on other platforms

```
function Final: TMD5Digest; overload;
```

Finalize and compute the resulting MD5 hash Digest of all data affected to Update() method

```
procedure Final(out result: TMD5Digest); overload;
```

Finalize and compute the resulting MD5 hash Digest of all data affected to Update() method

```
procedure Finalize;
```

Finalize the MD5 hash process

- the resulting hash digest would be stored in buf public variable

```
procedure Full(Buffer: pointer; Len: integer; out Digest: TMD5Digest);
```

One method to rule them all

- call Init, then Update(), then Final()

```
procedure Init;
```

Initialize MD5 context for hashing

```
procedure Update(const Buffer: RawByteString); overload;
```

Update the MD5 context with some data

```
procedure Update(const buffer; Len: cardinal); overload;
```

Update the MD5 context with some data

```
TRC4 = object(TObject)
```

Handle RC4 encryption/decryption

- we defined a record instead of a class, to allow stack allocation and thread-safe reuse of one initialized instance
- you can also restore and backup any previous state of the RC4 encryption by copying the whole TRC4 variable into another (stack-allocated) variable

```
procedure Drop(Count: cardinal);
```

Drop the next Count bytes from the RC4 cypher state

- may be used in Stream mode, or to initialize in RC4-drop[n] mode

procedure Encrypt(**const** BufIn; **var** BufOut; Count: cardinal);

Perform the RC4 cypher encryption/decryption on a buffer

- each call to this method shall be preceeded with an Init() call
- RC4 is a symmetrical algorithm: use this Encrypt() method for both encryption and decryption of any buffer

procedure EncryptBuffer(BufIn, BufOut: PByte; Count: cardinal);

Perform the RC4 cypher encryption/decryption on a buffer

- each call to this method shall be preceeded with an Init() call
- RC4 is a symmetrical algorithm: use this EncryptBuffer() method for both encryption and decryption of any buffer

procedure Init(**const** aKey; aKeyLen: integer);

Initialize the RC4 encryption/decryption

- KeyLen is in bytes, and should be within 1..255 range

procedure InitSHA3(**const** aKey; aKeyLen: integer);

Initialize RC4-drop[3072] encryption/decryption after SHA-3 hashing

- will use SHAKE-128 generator in XOF mode to generate a 256 bytes key, then drop the first 3072 bytes from the RC4 stream
- this initializer is much safer than plain Init, so should be considered for any use on RC4 for new projects - even if AES-NI is 2 times faster, and safer SHAKE-128 operates in XOF mode at a similar speed range

TAESFullHeader = **object**(TObject)

Internal header for storing our AES data with salt and CRC

- memory size matches an TAESBlock on purpose, for direct encryption

HeaderCheck: cardinal;

CRC from header

OriginalLen: cardinal;

Len before compression (if any)

SomeSalt: cardinal;

Random Salt for better encryption

SourceLen: cardinal;

Len before AES encoding

function Calc(**const** Key; KeySize: cardinal): cardinal;

Computes the Key checksum, using Adler32 algorithm

TAESFull = **object**(TObject)

AES and XOR encryption object for easy direct memory or stream access

- calls internaly TAES objet methods, and handle memory and streams for best speed
- a TAESFullHeader is encrypted at the begining, allowing fast Key validation, but the resulting stream is not compatible with raw TAES object

Head: TAESFullHeader;

Header, stored at the beginning of struct -> 16-byte aligned

outStreamCreated: TMemoryStream;

This memory stream is used in case of EncodeDecode(outStream=bOut=nil) method call

function EncodeDecode(**const** Key; KeySize, inLen: cardinal; Encrypt: boolean;
inStream, outStream: TStream; bIn, bOut: pointer; OriginalLen: cardinal=0): integer;

Main method of AES or XOR cypher/uncypher

- return out size, -1 if error on decoding (Key not correct)
- valid KeySize: 0=nothing, 32=xor, 128,192,256=AES
- if outStream is TMemoryStream -> auto-reserve space (no Realloc:)
- for normal usage, you just have to Assign one In and one Out
- if outStream AND bOut are both nil, an outStream is created via THeapMemoryStream.Create
- if Padlock is used, 16-byte alignment is forced (via tmp buffer if necessary)
- if Encrypt -> OriginalLen can be used to store unCompressed Len

TAESWriteStream = class(TStream)

AES encryption stream

- encrypt the Data on the fly, in a compatible way with AES() - last bytes are coded with XOR (not compatible with TAESFull format)
- not optimized for small blocks -> ok if used AFTER TBZCompressor/TZipCompressor
- warning: Write() will crypt Buffer memory in place -> use AFTER T*Compressor

DestSize: cardinal;

CRC from unencrypted compressed data - for Key check

constructor Create(outStream: TStream; **const** Key; KeySize: cardinal);

If KeySize=0 initialize the AES encryption stream for an output stream (e.g. a TMemoryStream or a TFileStream)

destructor Destroy; **override;**

- Finalize the AES encryption stream*
- internaly call the Finish method

function Read(**var** Buffer; Count: Longint): Longint; **override;**

Read some data is not allowed -> this method will raise an exception on call

function Seek(Offset: Longint; Origin: Word): Longint; **override;**

Read some data is not allowed -> this method will raise an exception on call

function Write(**const** Buffer; Count: Longint): Longint; **override;**

Append some data to the outStream, after encryption

procedure Finish;

- Write pending data*
- should always be called before closing the outStream (some data may still be in the internal buffers)

THMAC_SHA1 = object(TObject)

Compute the HMAC message authentication code using SHA-1 as hash function

- you may use HMAC_SHA1() overloaded functions for one-step process
- we defined a record instead of a class, to allow stack allocation and thread-safe reuse of one initialized instance via Compute(), e.g. for fast PBKDF2

procedure Compute(msg: pointer; msglen: integer; **out** result: TSHA1Digest);

Computes the HMAC of the supplied message according to the key

- expects a previous call on Init() to setup the shared key
- similar to a single Update(msg,msglen) followed by Done, but re-usable
- this method is thread-safe on any shared THMAC_SHA1 instance

procedure Done(**out** result: RawUTF8; NoInit: boolean=false); overload;

Computes the HMAC of all supplied message according to the key

procedure Done(**out** result: TSHA1Digest; NoInit: boolean=false); overload;

Computes the HMAC of all supplied message according to the key

procedure Init(key: pointer; keylen: integer);

Prepare the HMAC authentication with the supplied key

- content of this record is stateless, so you can prepare a HMAC for a key using Init, then copy this THMAC_SHA1 instance to a local variable, and use this local thread-safe copy for actual HMAC computing

procedure Update(msg: pointer; msglen: integer);

Call this method for each continuous message block

- iterate over all message blocks, then call Done to retrieve the HMAC

THMAC_SHA384 = object(TObject)

Compute the HMAC message authentication code using SHA-384 as hash function

- you may use HMAC_SHA384() overloaded functions for one-step process
- we defined a record instead of a class, to allow stack allocation and thread-safe reuse of one initialized instance via Compute(), e.g. for fast PBKDF2

procedure Compute(msg: pointer; msglen: integer; **out** result: TSHA384Digest);

Computes the HMAC of the supplied message according to the key

- expects a previous call on Init() to setup the shared key
- similar to a single Update(msg,msglen) followed by Done, but re-usable
- this method is thread-safe on any shared THMAC_SHA384 instance

procedure Done(**out** result: RawUTF8; NoInit: boolean=false); overload;

Computes the HMAC of all supplied message according to the key

procedure Done(**out** result: TSHA384Digest; NoInit: boolean=false); overload;

Computes the HMAC of all supplied message according to the key

procedure Init(key: pointer; keylen: integer);

Prepare the HMAC authentication with the supplied key

- content of this record is stateless, so you can prepare a HMAC for a key using Init, then copy this THMAC_SHA384 instance to a local variable, and use this local thread-safe copy for actual HMAC computing

procedure Update(msg: pointer; msglen: integer);

Call this method for each continuous message block

- iterate over all message blocks, then call Done to retrieve the HMAC

THMAC_SHA512 = **object**(TObject)

Compute the HMAC message authentication code using SHA-512 as hash function

- you may use HMAC_SHA512() overloaded functions for one-step process
- we defined a record instead of a class, to allow stack allocation and thread-safe reuse of one initialized instance via Compute(), e.g. for fast PBKDF2

procedure Compute(msg: pointer; msglen: integer; **out** result: TSHA512Digest);

Computes the HMAC of the supplied message according to the key

- expects a previous call on Init() to setup the shared key
- similar to a single Update(msg,msglen) followed by Done, but re-usable
- this method is thread-safe on any shared THMAC_SHA512 instance

procedure Done(**out** result: RawUTF8; NoInit: boolean=false); overload;

Computes the HMAC of all supplied message according to the key

procedure Done(**out** result: TSHA512Digest; NoInit: boolean=false); overload;

Computes the HMAC of all supplied message according to the key

procedure Init(key: pointer; keylen: integer);

Prepare the HMAC authentication with the supplied key

- content of this record is stateless, so you can prepare a HMAC for a key using Init, then copy this THMAC_SHA512 instance to a local variable, and use this local thread-safe copy for actual HMAC computing

procedure Update(msg: pointer; msglen: integer);

Call this method for each continuous message block

- iterate over all message blocks, then call Done to retrieve the HMAC

THMAC_SHA256 = **object**(TObject)

Compute the HMAC message authentication code using SHA-256 as hash function

- you may use HMAC_SHA256() overloaded functions for one-step process
- we defined a record instead of a class, to allow stack allocation and thread-safe reuse of one initialized instance via Compute(), e.g. for fast PBKDF2

procedure Compute(msg: pointer; msglen: integer; **out** result: TSHA256Digest);

Computes the HMAC of the supplied message according to the key

- expects a previous call on Init() to setup the shared key
- similar to a single Update(msg,msglen) followed by Done, but re-usable
- this method is thread-safe on any shared THMAC_SHA256 instance

procedure Done(**out** result: TSHA256Digest; NoInit: boolean=false); overload;

Computes the HMAC of all supplied message according to the key

procedure Done(**out** result: RawUTF8; NoInit: boolean=false); overload;

Computes the HMAC of all supplied message according to the key

procedure Init(key: pointer; keylen: integer);

Prepare the HMAC authentication with the supplied key

- content of this record is stateless, so you can prepare a HMAC for a key using Init, then copy this THMAC_SHA256 instance to a local variable, and use this local thread-safe copy for actual HMAC computing

procedure Update(**const** msg: RawByteString); overload;

Call this method for each continuous message block

- iterate over all message blocks, then call Done to retrieve the HMAC

procedure Update(msg: pointer; msglen: integer); overload;

Call this method for each continuous message block

- iterate over all message blocks, then call Done to retrieve the HMAC

procedure Update(**const** msg: THash128); overload;

Call this method for each continuous message block

- iterate over all message blocks, then call Done to retrieve the HMAC

procedure Update(**const** msg: THash256); overload;

Call this method for each continuous message block

- iterate over all message blocks, then call Done to retrieve the HMAC

TSynSignerParams = **packed record**

JSON-serialization ready object as used by TSynSigner.PBKDF2 overloaded methods

- default value for unspecified parameters will be SHAKE_128 with rounds=1000 and a fixed salt

TSynSigner = **object**(TObject)

A generic wrapper object to handle digital HMAC-SHA-2/SHA-3 signatures

- used e.g. to implement TJWTSynSignerAbstract

function Final: RawUTF8; overload;

Returns the computed digital signature as lowercase hexadecimal text

function Full(aAlgo: TSignAlgo; **const** aSecret: RawUTF8; aBuffer: Pointer; aLen: integer): RawUTF8; overload;

One-step digital signature of a buffer as lowercase hexadecimal string

function Full(aAlgo: TSignAlgo; **const** aSecret, aSalt: RawUTF8; aSecretPBKDF2Rounds: integer; aBuffer: Pointer; aLen: integer): RawUTF8; overload;

One-step digital signature of a buffer with PBKDF2 derivation

procedure AssignTo(**var** aDerivedKey: THash512Rec; **out** aAES: TAES; aEncrypt: boolean);

Prepare a TAES object with the key derived via a PBKDF2() call

- aDerivedKey is defined as "var", since it will be zeroed after use

procedure Done;

Fill the internal context with zeros, for security

procedure Final(out aSignature: THash512Rec; aNoInit: boolean=false); overload;

Returns the raw computed digital signature

- SignatureSize bytes will be written: use Signature.Lo/h0/b3/b accessors

procedure Init(aAlgo: TSignAlgo; const aSecret: RawUTF8); overload;

Initialize the digital HMAC/SHA-3 signing context with some secret text

procedure Init(aAlgo: TSignAlgo; aSecret: pointer; aSecretLen: integer); overload;

Initialize the digital HMAC/SHA-3 signing context with some secret binary

procedure Init(aAlgo: TSignAlgo; const aSecret, aSalt: RawUTF8;
aSecretPBKDF2Rounds: integer; aPBKDF2Secret: PHash512Rec=nil); overload;

Initialize the digital HMAC/SHA-3 signing context with PBKDF2 safe iterative key derivation of a secret salted text

procedure PBKDF2(aParamsJSON: PUTF8Char; aParamsJSONLen: integer; out
aDerivedKey: THash512Rec; const aDefaultSalt: RawUTF8='I6sWioAidNnhX09BK';
aDefaultAlgo: TSignAlgo=saSha3S128); overload;

Convenient wrapper to perform PBKDF2 safe iterative key derivation

- accept as input a TSynSignerParams serialized as JSON object

procedure PBKDF2(const aParamsJSON: RawUTF8; out aDerivedKey: THash512Rec; const
aDefaultSalt: RawUTF8='I6sWioAidNnhX09BK'; aDefaultAlgo: TSignAlgo=saSha3S128);
overload;

Convenient wrapper to perform PBKDF2 safe iterative key derivation

- accept as input a TSynSignerParams serialized as JSON object

procedure PBKDF2(aAlgo: TSignAlgo; const aSecret, aSalt: RawUTF8;
aSecretPBKDF2Rounds: integer; out aDerivedKey: THash512Rec); overload;

Convenient wrapper to perform PBKDF2 safe iterative key derivation

procedure PBKDF2(const aParams: TSynSignerParams; out aDerivedKey: THash512Rec);
overload;

Convenient wrapper to perform PBKDF2 safe iterative key derivation

procedure Update(aBuffer: pointer; aLen: integer); overload;

Process some message content supplied as memory buffer

procedure Update(const aBuffer: RawByteString); overload;

Process some message content supplied as string

property Algo: TSignAlgo read fAlgo;

The algorithm used for digital signature

property SignatureSize: integer read fSignatureSize;

The size, in bytes, of the digital signature of this algorithm

- potential values are 20, 28, 32, 48 and 64

TSynHasher = object(TObject)

Convenient multi-algorithm hashing wrapper

- as used e.g. by HashFile/HashFull functions
- we defined a record instead of a class, to allow stack allocation and thread-safe reuse of one initialized instance

function Final: RawUTF8;

Returns the resulting hash as lowercase hexadecimal string

function Full(aAlgo: THashAlgo; aBuffer: Pointer; aLen: integer): RawUTF8;

One-step hash computation of a buffer as lowercase hexadecimal string

function Init(aAlgo: THashAlgo): boolean;

Enough space for all algorithms initialize the internal hashing structure for a specific algorithm
- returns false on unknown/unsupported algorithm

procedure Update(aBuffer: Pointer; aLen: integer); overload;

Hash the supplied memory buffer

procedure Update(const aBuffer: RawByteString); overload;

Hash the supplied string content

property Algo: THashAlgo read fAlgo;

The hash algorithm used by this instance

THMAC_CRC32C = object(TObject)

Compute the HMAC message authentication code using crc32c as hash function

- HMAC over a non cryptographic hash function like crc32c is known to be a safe enough MAC, if the supplied key comes e.g. from cryptographic HMAC_SHA256
- SSE 4.2 will let MAC be computed at 4 GB/s on a Core i7
- you may use HMAC_CRC32C() overloaded functions for one-step process
- we defined a record instead of a class, to allow stack allocation and thread-safe reuse of one initialized instance via Compute()

function Compute(msg: pointer; msglen: integer): cardinal;

Computes the HMAC of the supplied message according to the key

- expects a previous call on Init() to setup the shared key
- similar to a single Update(msg,msglen) followed by Done, but re-usable
- this method is thread-safe

function Done(NoInit: boolean=false): cardinal;

Computes the HMAC of all supplied message according to the key

procedure Init(key: pointer; keylen: integer); overload;

Prepare the HMAC authentication with the supplied key

- consider using Compute to re-use a prepared HMAC instance

procedure Init(const key: RawByteString); overload;

Prepare the HMAC authentication with the supplied key

- consider using Compute to re-use a prepared HMAC instance

procedure Update(msg: pointer; msglen: integer); overload;

Call this method for each continuous message block

- iterate over all message blocks, then call Done to retrieve the HMAC

procedure Update(const msg: RawByteString); overload;

Call this method for each continuous message block

- iterate over all message blocks, then call Done to retrieve the HMAC

IProtocol = **interface**(IInterface)

Perform safe communication after unilateral or mutual authentication

- see e.g. TProtocolNone or SynEcc's TECDHEProtocolClient and TECDHEProtocolServer implementation classes

function Clone: IProtocol;

Will create another instance of this communication protocol

function Decrypt(const aEncrypted: RawByteString; out aPlain: RawByteString): TProtocolResult;

Decrypt a message on one side, as transmitted from the other side

- should return sprSuccess if the

- should return sprInvalidMAC in case of wrong aEncrypted input (e.g. packet corruption, MiM or Replay attacks attempts)

- this method should be thread-safe in the implementation class

function ProcessHandshake(const MsgIn: RawUTF8; out MsgOut: RawUTF8): TProtocolResult;

Initialize the communication by exchanging some client/server information

- expects the handshaking messages to be supplied as UTF-8 text, may be as base64-encoded binary - see e.g. TWebSocketProtocolBinary.ProcessHandshake

- should return sprUnsupported if the implemented protocol does not expect any handshaking mechanism

- returns sprSuccess and set something into OutData, depending on the current step of the handshake

- returns an error code otherwise

procedure Encrypt(const aPlain: RawByteString; out aEncrypted: RawByteString);

Encrypt a message on one side, ready to be transmitted to the other side

- this method should be thread-safe in the implementation class

TProtocolNone = **class**(TInterfacedObject)

Implements a fake no-encryption protocol

- may be used for debugging purposes, or when encryption is not needed

function Clone: IProtocol;

Will create another instance of this communication protocol

function Decrypt(const aEncrypted: RawByteString; out aPlain: RawByteString): TProtocolResult;

Decrypt a message on one side, as transmitted from the other side

- this method will return the encrypted text with no actual decryption

function ProcessHandshake(**const** MsgIn: RawUTF8; **out** MsgOut: RawUTF8):
 TProtocolResult;

Initialize the communication by exchanging some client/server information
 - this method will return sprUnsupported

procedure Encrypt(**const** aPlain: RawByteString; **out** aEncrypted: RawByteString);

Encrypt a message on one side, ready to be transmitted to the other side
 - this method will return the plain text with no actual encryption

TProtocolAES = class(TInterfacedObjectLocked)

Implements a secure protocol using AES encryption

- as used e.g. by 'synapsebinary' WebSockets protocol
 - this class will maintain two TAESAbstract instances, one for encryption and another one for decryption, with PKCS7 padding and no MAC validation

constructor Create(aClass: TAESAbstractClass; **const** aKey; aKeySize: cardinal;
 aIVReplayAttackCheck: TAESIVReplayAttackCheck=repCheckedIfAvailable);
reintroduce; virtual;

[false]=decrypt [true]=encrypt initialize this encryption protocol with the given AES settings

constructor CreateFrom(aAnother: TProtocolAES); **reintroduce; virtual;**

Will create another instance of this communication protocol

destructor Destroy; **override;**

Finalize the encryption

function Clone: IProtocol;

Will create another instance of this communication protocol

function Decrypt(**const** aEncrypted: RawByteString; **out** aPlain: RawByteString):
 TProtocolResult;

Decrypt a message on one side, as transmitted from the other side
 - this method uses AES decryption and PKCS7 padding

function ProcessHandshake(**const** MsgIn: RawUTF8; **out** MsgOut: RawUTF8):
 TProtocolResult;

Initialize the communication by exchanging some client/server information
 - this method will return sprUnsupported, since no key negotiation is involved

procedure Encrypt(**const** aPlain: RawByteString; **out** aEncrypted: RawByteString);

Encrypt a message on one side, ready to be transmitted to the other side
 - this method uses AES encryption and PKCS7 padding

EJWTException = class(ESynException)

Exception raised when running JSON Web Tokens

TJWTContent = record

JWT decoded content, as processed by TJWTAbstract
 - optionally cached in memory

audience: set of 0..15;

Match TJWTAbstract.Audience[] indexes for reg[jrcAudience]

claims: TJWTClaims;

Set of known/registered claims, as stored in the JWT payload

data: TDocVariantData;

Custom/unregistered claim values, as stored in the JWT payload

- registered claims will be available from reg[], not in this field

- e.g. data.U['name']='John Doe' and data.B['admin']=true for

{ "sub": "1234567890", "name": "John Doe", "admin": true }

but data.U['sub'] if not defined, and reg[jrcSubject]='1234567890'

reg: array[TJWTClaim] of RawUTF8;

Known/registered claims UTF-8 values, as stored in the JWT payload

- e.g. reg[jrcSubject]='1234567890' and reg[jrcIssuer]='' for

{ "sub": "1234567890", "name": "John Doe", "admin": true }

result: TJWTResult;

Store latest Verify() result

TJWTAbstract = class(TSynPersistent)

Abstract parent class for implementing JSON Web Tokens

- to represent claims securely between two parties, as defined in industry standard

@<http://tools.ietf.org/html/rfc7519>

- you should never use this abstract class directly, but e.g. TJWTHS256, TJWTHS384, TJWTHS512 or TJWTES256 (as defined in SynEcc.pas) inherited classes

- for security reasons, one inherited class is implementing a single algorithm, as is very likely to be the case on production: you pickup one "alg", then you stick to it; if your server needs more than one algorithm for compatibility reasons, use a separate key and URI - this design will reduce attack surface, and fully avoid weaknesses as described in

@<https://auth0.com/blog/critical-vulnerabilities-in-json-web-token-libraries> and

@<http://tools.ietf.org/html/rfc7518#section-8.5>

constructor Create(const aAlgorithm: RawUTF8; aClaims: TJWTClaims; const aAudience: array of RawUTF8; aExpirationMinutes: integer; aIDIdentifier: TSynUniqueIdentifierProcess; aIDObfuscationKey: RawUTF8); **reintroduce;**

Initialize the JWT processing instance

- the supplied set of claims are expected to be defined in the JWT payload

- aAudience are the allowed values for the jrcAudience claim

- aExpirationMinutes is the deprecation time for the jrcExpirationTime claim

- aIDIdentifier and aIDObfuscationKey are passed to a TSynUniqueIdentifierGenerator instance used for jrcJwtID claim

destructor Destroy; **override;**

Finalize the instance

```
function Compute(const DataNameValue: array of const; const Issuer: RawUTF8='';  

const Subject: RawUTF8=''; const Audience: RawUTF8=''; NotBefore: TDateTime=0;  

ExpirationMinutes: integer=0; Signature: PRawUTF8=nil): RawUTF8;
```

Compute a new JWT for a given payload

- here the data payload is supplied as Name,Value pairs - by convention, some registered Names (see TJWTClaim) should not be used here, and private claims names are expected to be short (typically 3 chars), or an URI
- depending on the instance Claims, you should also specify associated Issuer, Subject, Audience and NotBefore values; expected 'exp', 'nbf', 'iat', 'jti' claims will also be generated and included, if needed
- you can override the aExpirationMinutes value as defined in Create()
- Audience is usually a single text, serialized as a JSON string, but if the value supplied starts with '[', it is expected to be an array of text values, already serialized as a JSON array of strings
- this method is thread-safe

```
function ComputeAuthorizationHeader(const DataNameValue: array of const; const  

Issuer: RawUTF8=''; const Subject: RawUTF8=''; const Audience: RawUTF8='';  

NotBefore: TDateTime=0; ExpirationMinutes: integer=0): RawUTF8;
```

Compute a HTTP Authorization header containing a JWT for a given payload

- just a wrapper around Compute(), returned the HTTP header value:
 Authorization: <HttpAuthorizationHeader>

following the expected pattern:

Authorization: Bearer <Token>

- this method is thread-safe

```
function Verify(const Token: RawUTF8): TJWTResult; overload;
```

Check a JWT value, and its signature

- will validate all expected Claims, and the associated signature
- verification state is returned as function result
- supplied JWT is transmitted e.g. in HTTP header:
 Authorization: Bearer <Token>
- this method is thread-safe

```
function VerifyAuthorizationHeader(const HttpAuthorizationHeader: RawUTF8; out  

JWT: TJWTContent): boolean; overload;
```

Check a HTTP Authorization header value as JWT, and its signature

- will validate all expected Claims, and the associated signature
- verification state is returned in JWT.result (jwtValid for a valid JWT), together with all parsed payload information
- expect supplied HttpAuthorizationHeader as transmitted in HTTP header:
 Authorization: <HttpAuthorizationHeader>
- this method is thread-safe

```
class function VerifyPayload(const Token, ExpectedSubject, ExpectedIssuer,  
ExpectedAudience: RawUTF8; Expiration: PUnixTime=nil; Signature: PRawUTF8=nil;  
Payload: PVariant=nil; IgnoreTime: boolean=false; NotBeforeDelta: TUnixTime=15):  
TJWTResult;
```

In-place decoding and quick check of the JWT payload

- it won't check the signature, but the header's algorithm against the class name (use TJWTAbstract class to allow any algorithm)
- it will decode the JWT payload and check for its expiration, and some mandatory field values - you can optionally retrieve the Expiration time, the ending Signature, and/or the Payload decoded as TDocVariant
- NotBeforeDelta allows to define some time frame for the "nbf" field
- may be used on client side to quickly validate a JWT received from server, without knowing the exact algorithm or secret keys

```
procedure Verify(const Token: RawUTF8; out JWT: TJWTContent; ExcludedClaims:  
TJWTClaims=[]); overload;
```

Check a JWT value, and its signature

- will validate all expected Claims (minus ExcludedClaims optional parameter), and the associated signature
- verification state is returned in JWT.result (jwtValid for a valid JWT), together with all parsed payload information
- supplied JWT is transmitted e.g. in HTTP header:
Authorization: Bearer <Token>
- this method is thread-safe

```
property Algorithm: RawUTF8 read fAlgorithm;
```

The name of the algorithm used by this instance (e.g. 'HS256')

```
property Audience: TRawUTF8DynArray read fAudience;
```

The audience string values associated with this instance

- will be checked by Verify() method, and set in TJWTContent.audience

```
property CacheResults: TJWTResults read fCacheResults write fCacheResults;
```

Which TJWTContent.result should be stored in in-memory cache

- default is [jwtValid] but you may also include jwtInvalidSignature if signature checking uses a lot of resources
- only used if CacheTimeoutSeconds>0

```
property CacheTimeoutSeconds: integer read fCacheTimeoutSeconds write  
SetCacheTimeoutSeconds;
```

Delay of optional in-memory cache of Verify() TJWTContent

- equals 0 by default, i.e. cache is disabled
- may be useful if the signature process is very resource consuming (e.g. for TJWTES256 or even HMAC-SHA-256) - see also CacheResults
- each time this property is assigned, internal cache content is flushed

```
property Claims: TJWTClaims read fClaims;
```

The JWT Registered Claims, as implemented by this instance

- Verify() method will ensure all claims are defined in the payload, then fill TJWTContent.reg[] with all corresponding values

```
property ExpirationSeconds: integer read fExpirationSeconds;
```

The period, in seconds, for the "exp" claim

property Options: TJWTOptions read fOptions write fOptions;

Allow to tune the Verify and Compute method process

TJWTNone = class(TJWTAbstract)

Implements JSON Web Tokens using 'none' algorithm

- as defined in @<http://tools.ietf.org/html/rfc7518> paragraph 3.6
- you should never use this weak algorithm in production, unless your communication is already secured by other means, and use JWT as cookies

constructor Create(aClaims: TJWTClaims; const aAudience: array of RawUTF8; aExpirationMinutes: integer=0; aIDIdentifier: TSynUniqueIdentifierProcess=0; aIDObfuscationKey: RawUTF8=''); reintroduce;

Initialize the JWT processing using the 'none' algorithm

- the supplied set of claims are expected to be defined in the JWT payload
- aAudience are the allowed values for the jrcAudience claim
- aExpirationMinutes is the deprecation time for the jrcExpirationTime claim
- aIDIdentifier and aIDObfuscationKey are passed to a TSynUniqueIdentifierGenerator instance used for jrcJwtID claim

TJWTSynSignerAbstract = class(TJWTAbstract)

Abstract parent of JSON Web Tokens using HMAC-SHA2 or SHA-3 algorithms

- SHA-3 is not yet officially defined in @<http://tools.ietf.org/html/rfc7518> but could be used as a safer (and sometimes faster) alternative to HMAC-SHA2
- digital signature will be processed by an internal TSynSigner instance
- never use this abstract class, but any inherited class, or JWT_CLASS[].Create to instantiate a JWT process from a given algorithm

constructor Create(const aSecret: RawUTF8; aSecretPBKDF2Rounds: integer; aClaims: TJWTClaims; const aAudience: array of RawUTF8; aExpirationMinutes: integer=0; aIDIdentifier: TSynUniqueIdentifierProcess=0; aIDObfuscationKey: RawUTF8=''; aPBKDF2Secret: PHash512Rec=nil); reintroduce;

Initialize the JWT processing using SHA3 algorithm

- the supplied set of claims are expected to be defined in the JWT payload
- the supplied secret text will be used to compute the digital signature, directly if aSecretPBKDF2Rounds=0, or via PBKDF2 iterative key derivation if some number of rounds were specified
- aAudience are the allowed values for the jrcAudience claim
- aExpirationMinutes is the deprecation time for the jrcExpirationTime claim
- aIDIdentifier and aIDObfuscationKey are passed to a TSynUniqueIdentifierGenerator instance used for jrcJwtID claim
- optionally return the PBKDF2 derivated key for aSecretPBKDF2Rounds>0

destructor Destroy; override;

Finalize the instance

property SignatureAlgo: TSignAlgo read fSignPrepared.fAlgo;

The TSynSigner raw algorithm used for digital signature

property SignatureSize: integer read fSignPrepared.fSignatureSize;

The digital signature size, in byte

property SignPrepared: TSynSigner read fSignPrepared;

Low-level read access to the internal signature structure

TJWTHS256 = class(TJWTSynSignerAbstract)

Implements JSON Web Tokens using 'HS256' (HMAC SHA-256) algorithm

- as defined in @<http://tools.ietf.org/html/rfc7518> paragraph 3.2
- our HMAC SHA-256 implementation used is thread safe, and very fast (x86: 3us, x64: 2.5us) so cache is not needed
- resulting signature size will be of 256 bits

TJWTHS384 = class(TJWTSynSignerAbstract)

Implements JSON Web Tokens using 'HS384' (HMAC SHA-384) algorithm

- as defined in @<http://tools.ietf.org/html/rfc7518> paragraph 3.2
- our HMAC SHA-384 implementation used is thread safe, and very fast even on x86 (if the CPU supports SSE3 opcodes)
- resulting signature size will be of 384 bits

TJWTHS512 = class(TJWTSynSignerAbstract)

Implements JSON Web Tokens using 'HS512' (HMAC SHA-512) algorithm

- as defined in @<http://tools.ietf.org/html/rfc7518> paragraph 3.2
- our HMAC SHA-512 implementation used is thread safe, and very fast even on x86 (if the CPU supports SSE3 opcodes)
- resulting signature size will be of 512 bits

TJWTS3224 = class(TJWTSynSignerAbstract)

Experimental JSON Web Tokens using SHA3-224 algorithm

- SHA-3 is not yet officially defined in @<http://tools.ietf.org/html/rfc7518> but could be used as a safer (and sometimes faster) alternative to HMAC-SHA2
- resulting signature size will be of 224 bits

TJWTS3256 = class(TJWTSynSignerAbstract)

Experimental JSON Web Tokens using SHA3-256 algorithm

- SHA-3 is not yet officially defined in @<http://tools.ietf.org/html/rfc7518> but could be used as a safer (and sometimes faster) alternative to HMAC-SHA2
- resulting signature size will be of 256 bits

TJWTS3384 = class(TJWTSynSignerAbstract)

Experimental JSON Web Tokens using SHA3-384 algorithm

- SHA-3 is not yet officially defined in @<http://tools.ietf.org/html/rfc7518> but could be used as a safer (and sometimes faster) alternative to HMAC-SHA2
- resulting signature size will be of 384 bits

TJWTS3512 = class(TJWTSynSignerAbstract)

Experimental JSON Web Tokens using SHA3-512 algorithm

- SHA-3 is not yet officially defined in @<http://tools.ietf.org/html/rfc7518> but could be used as a safer (and sometimes faster) alternative to HMAC-SHA2
- resulting signature size will be of 512 bits

TJWTS3S128 = class(TJWTSynSignerAbstract)

Experimental JSON Web Tokens using SHA3-SHAKE128 algorithm

- SHA-3 is not yet officially defined in @<http://tools.ietf.org/html/rfc7518> but could be used as a safer (and sometimes faster) alternative to HMAC-SHA2
- resulting signature size will be of 256 bits

TJWTS3S256 = class(TJWTSynSignerAbstract)

Experimental JSON Web Tokens using SHA3-SHAKE256 algorithm

- SHA-3 is not yet officially defined in @<http://tools.ietf.org/html/rfc7518> but could be used as a safer (and sometimes faster) alternative to HMAC-SHA2
- resulting signature size will be of 512 bits

Types implemented in the *SynCrypto* unit

IProtocolDynArray = array of IProtocol;

Stores a list of IProtocol instances

PAESBlock = ^TAESBlock;

Points to a 128 bits memory block, as used for AES data cypher/uncypher

PHMAC_CRC32C= ^THMAC_CRC32C;

Points to HMAC message authentication code using crc32c as hash function

PHMAC_SHA1 = ^THMAC_SHA1;

Points to a HMAC message authentication context using SHA-1

PHMAC_SHA256 = ^THMAC_SHA256;

Points to a HMAC message authentication context using SHA-256

PHMAC_SHA384 = ^THMAC_SHA384;

Points to a HMAC message authentication context using SHA-384

PHMAC_SHA512 = ^THMAC_SHA512;

Points to a HMAC message authentication context using SHA-512

PJWTContent = ^TJWTContent;

Pointer to a JWT decoded content, as processed by TJWTAbstract

PSHA384 = ^TSHA384;

Points to SHA-384 hashing instance

PSHA512 = ^TSHA512;

Points to SHA-512 hashing instance

PSynSigner = ^TSynSigner;

Reference to TSynSigner wrapper object

Short32 = string[32];

32-characters ASCII string, e.g. as returned by AESBlockToShortString()

TAESAbstractClass = class of TAESAbstract;

Class-reference type (metaclass) of an AES cypher/uncypher

TAESBlock = THash128;

128 bits memory block for AES data cypher/uncypher

```
TAESIVReplayAttackCheck = ( repNoCheck, repCheckedIfAvailable, repMandatory );
```

How TAESAbstract.DecryptPKCS7 should detect replay attack

- repNoCheck and repCheckedIfAvailable will be compatible with older versions of the protocol, but repMandatory will reject any encryption without the TAESIVCTR algorithm

```
TAESKey = THash256;
```

256 bits memory block for maximum AES key storage

```
THashAlgo = ( hfMD5, hfSHA1, hfSHA256, hfSHA384, hfSHA512, hfSHA3_256, hfSHA3_512 );
```

Hash algorithms available for HashFile/HashFull functions and TSynHasher object

```
THashAlgos = set of THashAlgo;
```

Set of algorithms available for HashFile/HashFull functions and TSynHasher object

```
TJWTAbstractClass = class of TJWTAbstract;
```

Class-reference type (metaclass) of a JWT algorithm process

```
TJWTClaim = ( jrcIssuer, jrcSubject, jrcAudience, jrcExpirationTime, jrcNotBefore, jrcIssuedAt, jrcJwtID );
```

JWT Registered Claims, as defined in RFC 7519

- known registered claims have a specific name and behavior, and will be handled automatically by TJWTAbstract

- corresponding field names are iss,sub,aud,exp,nbf,iat,jti - as defined in JWT_CLAIMS_TEXT constant
- jrcIssuer identifies the server which originated the token, e.g. "iss":"https://example.auth0.com/" when the token comes from Auth0 servers

- jrcSubject is the application-specific extent which is protected by this JWT, e.g. an User or Resource ID, e.g. "sub":"auth0|57fe9f1bad961aa242870e"

- jrcAudience claims that the token is valid only for one or several resource servers (may be a JSON string or a JSON array of strings), e.g. "aud":["https://myshinyfileserver.sometld"] - TJWTAbstract will check that the supplied "aud" field does match an expected list of identifiers

- jrcExpirationTime contains the Unix timestamp in seconds after which the token must not be granted access, e.g. "exp":1477474667

- jrcNotBefore contains the Unix timestamp in seconds before which the token must not be granted access, e.g. "nbf":147745438

- jrcIssuedAt contains the Unix timestamp in seconds when the token was generated, e.g. "iat":1477438667

- jrcJwtID provides a unique identifier for the JWT, to prevent any replay; TJWTAbstract.Compute will set an obfuscated TSynUniqueIdentifierGenerator hexadecimal value

```
TJWTClaims = set of TJWTClaim;
```

Set of JWT Registered Claims, as in TJWTAbstract.Claims

```
TJWTContentDynArray = array of TJWTContent;
```

Used to store a list of JWT decoded content

- as used e.g. by TJWTAbstract cache

```
TJWTOption = ( joHeaderParse, joAllowUnexpectedClaims, joAllowUnexpectedAudience, joNoJwtIDGenerate, joNoJwtIDCheck, joDoubleInData );
```

Available options for TJWTAbstract process

```
TJWTOptions = set of TJWTOption;
```

Store options for TJWTAbstract process

```
TJWTResult = ( jwtValid, jwtNoToken, jwtWrongFormat, jwtInvalidAlgorithm,
```

```
jwtInvalidPayload, jwtUnexpectedClaim, jwtMissingClaim, jwtUnknownAudience,
jwtExpired, jwtNotBeforeFailed, jwtInvalidIssuedAt, jwtInvalidID, jwtInvalidSignature
);
```

TJWTContent.result codes after TJWTAbstract.Verify method call

```
TJWTResults = set of TJWTResult;
/ set of TJWTContent.result codes
```

```
TJWTSynSignerAbstractClass = class of TJWTSynSignerAbstract;
Meta-class for TJWTSynSignerAbstract creations
```

```
TMD5Digest = THash128;
128 bits memory block for MD5 hash digest storage
```

```
TProtocolAESCClass = class of TProtocolAES;
Class-reference type (metaclass) of an AES secure protocol
```

```
TProtocolResult = ( sprSuccess, sprBadRequest, sprUnsupported, sprUnexpectedAlgorithm,
sprInvalidCertificate, sprInvalidSignature, sprInvalidEphemeralKey,
sprInvalidPublicKey, sprInvalidPrivateKey, sprInvalidMAC );
Possible return codes by IProtocol classes
```

```
TSHA1Digest = THash160;
160 bits memory block for SHA-1 hash digest storage
```

```
TSHA256Digest = THash256;
256 bits (32 bytes) memory block for SHA-256 hash digest storage
```

```
TSHA384Digest = THash384;
384 bits (64 bytes) memory block for SHA-384 hash digest storage
```

```
TSHA3Algo = ( SHA3_224, SHA3_256, SHA3_384, SHA3_512, SHAKE_128, SHAKE_256 );
SHA-3 instances, as defined by NIST Standard for Keccak sponge construction
```

```
TSHA512Digest = THash512;
512 bits (64 bytes) memory block for SHA-512 hash digest storage
```

```
TSignAlgo = ( saSha1, saSha256, saSha384, saSha512, saSha3224, saSha3256, saSha3384,
saSha3512, saSha3S128, saSha3S256 );
The HMAC/SHA-3 algorithms known by TSynSigner
```

Constants implemented in the SynCrypto unit

```
AESBlockMod = 15;
Bit mask for fast modulo of AES block size
```

```
AESBlockShift = 4;
Power of two for a standard AES block size during cypher/uncypher
- to be used as 1 shl AESBlockShift or 1 shr AESBlockShift for fast div/mod
```

```
AESContextSize = 276+sizeof(pointer) +sizeof(pointer);
Hide all AES Context complex code
```

```
AESKeySize = 256 div 8;
Maximum AES key size (in bytes)
```

```
JWT_CLAIMS_TEXT: array[TJWTClaim] of RawUTF8 = (
```

```
'iss', 'sub', 'aud', 'exp', 'nbf', 'iat', 'jti');
```

The text field names of the registered claims, as defined by RFC 7519

- see TJWTClaim enumeration and TJWTClaims set
- RFC standard expects those to be case-sensitive

```
JWT_CLASS: array[TSignAlgo] of TJWTSynSignerAbstractClass = ( TJWTHS256, TJWTHS256,  
TJWTHS384, TJWTHS512, TJWTS3224, TJWTS3256, TJWTS3384, TJWTS3512, TJWTS3S128,  
TJWTS3S256);
```

Able to instantiate any of the TJWTSynSignerAbstract instance expected

- SHA-1 will fallback to TJWTHS256 (since SHA-1 will never be supported)
- SHA-3 is not yet officially defined in @<http://tools.ietf.org/html/rfc7518>
- typical use is the following:

```
result := JWT_CLASS[algo].Create(master, round, claims, [], expirationMinutes);
```

```
JWT_TEXT: array[TSignAlgo] of RawUTF8 = (  
'HS256', 'HS256', 'HS384', 'HS512', 'S3224', 'S3256', 'S3384', 'S3512', 'S3S128', 'S3S256');
```

How TJWTSynSignerAbstract algorithms are identified in the JWT

- SHA-1 will fallback to HS256 (since there will never be SHA-1 support)
- SHA-3 is not yet officially defined in @<http://tools.ietf.org/html/rfc7518>

```
SHA3ContextSize = 412;
```

Hide all SHA-3 complex code by storing the Keccak Sponge as buffer

```
SHAContextSize = 108;
```

Hide all SHA-1/SHA-2 complex code by storing the context as buffer

Functions or procedures implemented in the SynCrypto unit

Functions or procedures	Description	Page
Adler32Asm	Fast Adler32 implementation	1193
Adler32Pas	Simple Adler32 implementation	1193
Adler32SelfTest	Self test of Adler32 routines	1193
AES	Direct Encrypt/Decrypt of data using the TAES class	1194
AES	Direct Encrypt/Decrypt of data using the TAES class	1194
AES	Direct Encrypt/Decrypt of data using the TAES class	1194
AES	Direct Encrypt/Decrypt of data using the TAES class	1194
AESBlockToShortString	Compute the hexadecimal representation of an AES 16-byte block	1194
AESBlockToShortString	Compute the hexadecimal representation of an AES 16-byte block	1194
AESBlockToString	Compute the hexadecimal representation of an AES 16-byte block	1194
AESFull	AES and XOR encryption using the TAESFull format	1194
AESFull	AES and XOR encryption using the TAESFull format	1194

Functions or procedures	Description	Page
AESFullKeyOK	AES and XOR decryption check using the TAESFull format	1194
AESIVCtrEncryptDecrypt	Global shared function which may encrypt or decrypt any 128-bit block using AES-128 and the global AESIVCTR_KEY	1194
AESSelfTest	Self test of AES routines	1194
AESSHA256	AES encryption using the TAES format with a supplied SHA-256 password	1195
AESSHA256	AES encryption using the TAES format with a supplied SHA-256 password	1195
AESSHA256	AES encryption using the TAES format with a supplied SHA-256 password	1195
AESSHA256Full	AES encryption using the TAESFull format with a supplied SHA-256 password	1195
AFDiffusion	Low-level anti-forensic diffusion of a memory buffer using SHA-256	1195
bswap160	Little endian fast conversion	1195
bswap256	Little endian fast conversion	1195
CompressShaAes	Encrypt data content using the AES-256/CFB algorithm, after SynLZ compression	1195
CompressShaAesSetKey	Set an text-based encryption key for CompressShaAes() global function	1195
CryptDataForCurrentUser	Protect some data via AES-256-CFB and a secret known by the current user only	1196
CryptDataForCurrentUserDPAPI	Protect some data for the current user, using Windows DPAPI	1196
FillSystemRandom	Low-level function returning some random binary using standard API	1196
Hash128ToDouble	Low-level function able to derivate a 0..1 64-bit floating-point from 128-bit of data	1197
Hash128ToExt	Low-level function able to derivate a 0..1 floating-point from 128-bit of data	1197
Hash128ToSingle	Low-level function able to derivate a 0..1 32-bit floating-point from 128-bit of data	1197
HashFile	Compute the hexadecimal hash of any (big) file	1197
HashFile	Compute the hexadecimal hashe(s) of one file, as external .md5/.sha256/.. files	1197
HashFull	One-step hash computation of a buffer as lowercase hexadecimal string	1197
HMAC_CRC256C	Compute the HMAC message authentication code using crc256c as hash function	1197

Functions or procedures	Description	Page
HMAC_CRC256C	Compute the HMAC message authentication code using crc256c as hash function	1197
HMAC_CRC256C	Compute the HMAC message authentication code using crc256c as hash function	1197
HMAC_CRC32C	Compute the HMAC message authentication code using crc32c as hash function	1198
HMAC_CRC32C	Compute the HMAC message authentication code using crc32c as hash function	1198
HMAC_CRC32C	Compute the HMAC message authentication code using crc32c as hash function	1198
HMAC_SHA1	Compute the HMAC message authentication code using SHA-1 as hash function	1198
HMAC_SHA1	Compute the HMAC message authentication code using SHA-1 as hash function	1198
HMAC_SHA1	Compute the HMAC message authentication code using SHA-1 as hash function	1198
HMAC_SHA256	Compute the HMAC message authentication code using SHA-256 as hash function	1198
HMAC_SHA256	Compute the HMAC message authentication code using SHA-256 as hash function	1198
HMAC_SHA256	Compute the HMAC message authentication code using SHA-256 as hash function	1198
HMAC_SHA384	Compute the HMAC message authentication code using SHA-384 as hash function	1198
HMAC_SHA384	Compute the HMAC message authentication code using SHA-384 as hash function	1198
HMAC_SHA384	Compute the HMAC message authentication code using SHA-384 as hash function	1198
HMAC_SHA512	Compute the HMAC message authentication code using SHA-512 as hash function	1199
HMAC_SHA512	Compute the HMAC message authentication code using SHA-512 as hash function	1199
HMAC_SHA512	Compute the HMAC message authentication code using SHA-512 as hash function	1199
htdigest	Compute the HTDigest for a user and a realm, according to a supplied password	1199
MD5	Direct MD5 hash calculation of some data (string-encoded)	1199

Functions or procedures	Description	Page
MD5Buf	Direct MD5 hash calculation of some data	1199
MD5DigestToString	Compute the hexadecimal representation of a MD5 digest	1199
MD5SelfTest	Self test of MD5 routines	1199
MD5StringToDigest	Compute the MD5 digest from its hexadecimal representation	1199
PBKDF2_HMAC_SHA1	Compute the PBKDF2 derivation of a password using HMAC over SHA-1	1199
PBKDF2_HMAC_SHA256	Compute the PBKDF2 derivation of a password using HMAC over SHA-256	1199
PBKDF2_HMAC_SHA256	Compute the PBKDF2 derivation of a password using HMAC over SHA-256, into several 256-bit items, so can be used to return any size of output key	1199
PBKDF2_HMAC_SHA384	Compute the PBKDF2 derivation of a password using HMAC over SHA-384	1199
PBKDF2_HMAC_SHA512	Compute the PBKDF2 derivation of a password using HMAC over SHA-512	1199
PBKDF2_SHA3	Safe key derivation using iterated SHA-3 hashing	1200
PBKDF2_SHA3_Crypt	Encryption/decryption of any data using iterated SHA-3 hashing key derivation	1200
RawMd5Compress	Entry point of the raw MD5 transform function - may be used for low-level use	1200
RawSha1Compress	Entry point of the raw SHA-1 transform function - may be used for low-level use	1200
RawSha256Compress	Entry point of the raw SHA-256 transform function - may be used for low-level use	1200
RawSha512Compress	Entry point of the raw SHA-512 transform function - may be used for low-level use	1200
RC4SelfTest	Self test of RC4 routines	1200
SHA1	Direct SHA-1 hash calculation of some data (string-encoded)	1200
SHA1DigestToString	Compute the hexadecimal representation of a SHA-1 digest	1200
SHA1SelfTest	Self test of SHA-1 routines	1200
SHA1StringToDigest	Compute the SHA-1 digest from its hexadecimal representation	1200
SHA256	Direct SHA-256 hash calculation of some data (string-encoded)	1200
SHA256	Direct SHA-256 hash calculation of some binary data	1200
SHA256Digest	Direct SHA-256 hash calculation of some binary data	1201

Functions or procedures	Description	Page
SHA256Digest	Direct SHA-256 hash calculation of some binary data	1201
SHA256DigestToString	Compute the hexadecimal representation of a SHA-256 digest	1201
SHA256SelfTest	Self test of SHA-256 routines	1201
SHA256StringToDigest	Compute the SHA-256 digest from its hexadecimal representation	1201
SHA256Weak	Direct SHA-256 hash calculation of some data (string-encoded)	1201
SHA3	Direct SHA-3 hash calculation of some binary buffer	1201
SHA3	Direct SHA-3 hash calculation of some data (string-encoded)	1201
SHA384	Direct SHA-384 hash calculation of some data (string-encoded)	1201
SHA384DigestToString	Compute the hexadecimal representation of a SHA-384 digest	1202
SHA512	Direct SHA-512 hash calculation of some data (string-encoded)	1202
SHA512DigestToString	Compute the hexadecimal representation of a SHA-512 digest	1202
XorBlock		1202
XorBlock16	Apply the XOR operation to the supplied binary buffers of 16 bytes	1202
XorBlock16	Apply the XOR operation to the supplied binary buffers of 16 bytes	1202
XorConst	Fast XOR Cypher changing by Count value	1202
XorOffset	Fast and simple XOR Cypher using Index (=Position in Dest Stream)	1202

function Adler32Asm(Adler: cardinal; p: pointer; Count: Integer): cardinal;

Fast Adler32 implementation

- 16-bytes-chunck unrolled asm version

function Adler32Pas(Adler: cardinal; p: pointer; Count: Integer): cardinal;

Simple Adler32 implementation

- a bit slower than Adler32Asm() version below, but shorter code size

function Adler32SelfTest: boolean;

Self test of Adler32 routines

function AES(const Key; KeySize: cardinal; const s: RawByteString; Encrypt: boolean): RawByteString; overload;

Direct Encrypt/Decrypt of data using the TAES class

- last bytes (not part of 16 bytes blocks) are not crypted by AES, but with XOR

function AES(const Key; KeySize: cardinal; buffer: pointer; Len: cardinal; Stream: TStream; Encrypt: boolean): boolean; overload;

Direct Encrypt/Decrypt of data using the TAES class

- last bytes (not part of 16 bytes blocks) are not crypted by AES, but with XOR

procedure AES(const Key; KeySize: cardinal; buffer: pointer; Len: Integer; Encrypt: boolean); overload;

Direct Encrypt/Decrypt of data using the TAES class

- last bytes (not part of 16 bytes blocks) are not crypted by AES, but with XOR

procedure AES(const Key; KeySize: cardinal; bIn, bOut: pointer; Len: Integer; Encrypt: boolean); overload;

Direct Encrypt/Decrypt of data using the TAES class

- last bytes (not part of 16 bytes blocks) are not crypted by AES, but with XOR

function AESBlockToShortString(const block: TAESBlock): short32; overload;

Compute the hexadecial representation of an AES 16-byte block

- returns a stack-allocated short string

procedure AESBlockToShortString(const block: TAESBlock; out result: short32); overload;

Compute the hexadecial representation of an AES 16-byte block

- fill a stack-allocated short string

function AESBlockToString(const block: TAESBlock): RawUTF8;

Compute the hexadecial representation of an AES 16-byte block

function AESFull(const Key; KeySize: cardinal; bIn: pointer; Len: Integer; outStream: TStream; Encrypt: boolean; OriginalLen: Cardinal=0): boolean; overload;

AES and XOR encryption using the TAESFull format

- outStream will be larger/smaller than Len (full AES encrypted)

- returns true if OK

function AESFull(const Key; KeySize: cardinal; bIn, bOut: pointer; Len: Integer; Encrypt: boolean; OriginalLen: Cardinal=0): integer; overload;

AES and XOR encryption using the TAESFull format

- bOut must be at least bIn+32/Encrypt bIn-16/Decrypt

- returns outLength, -1 if error

function AESFullKeyOK(const Key; KeySize: cardinal; buff: pointer): boolean;

AES and XOR decryption check using the TAESFull format

- return true if begining of buff contains true AESFull encrypted data with this Key

- if not KeySize in [128,192,256] -> use fast and efficient Xor Cypher

procedure AESIVCtrEncryptDecrypt(const BI; var BO; DoEncrypt: boolean);

Global shared function which may encrypt or decrypt any 128-bit block using AES-128 and the global AESIVCTR_KEY

function AESSelfTest(onlytables: Boolean): boolean;

Self test of AES routines

procedure AESSHA256(Buffer: pointer; Len: integer; const Password: RawByteString; Encrypt: boolean); overload;

AES encryption using the TAES format with a supplied SHA-256 password

- last bytes (not part of 16 bytes blocks) are not crypted by AES, but with XOR

procedure AESSHA256(bIn, bOut: pointer; Len: integer; **const** Password: RawByteString; Encrypt: boolean); overload;

AES encryption using the TAES format with a supplied SHA-256 password
- last bytes (not part of 16 bytes blocks) are not crypted by AES, but with XOR

function AESSHA256(**const** s, Password: RawByteString; Encrypt: boolean): RawByteString; overload;

AES encryption using the TAES format with a supplied SHA-256 password
- last bytes (not part of 16 bytes blocks) are not crypted by AES, but with XOR

procedure AESSHA256Full(bIn: pointer; Len: Integer; outStream: TStream; **const** Password: RawByteString; Encrypt: boolean); overload;

AES encryption using the TAESFull format with a supplied SHA-256 password
- outStream will be larger/smaller than Len: this is a full AES version with a trimming TAESFullHeader at the beginning

procedure AFDiffusion(buf,rnd: pointer; size: cardinal);

Low-level anti-forensic diffusion of a memory buffer using SHA-256
- as used by TAESPRNG.AFSplit and TAESPRNG.AFUnSplit

procedure bswap160(s,d: PIntegerArray);

Little endian fast conversion
- 160 bits = 5 integers
- use fast bswap asm in x86/x64 mode

procedure bswap256(s,d: PIntegerArray);

Little endian fast conversion
- 256 bits = 8 integers
- use fast bswap asm in x86/x64 mode

function CompressShaAes(**var** DataRawByteString; Compress: boolean): AnsiString;

Encrypt data content using the AES-256/CFB algorithm, after SynLZ compression
- as expected by THttpSocket.RegisterCompress()
- will return 'synshaaes' as ACCEPT-ENCODING: header parameter
- will use global CompressShaAesKey / CompressShaAesClass variables to be set according to the expected algorithm and Key e.g. via a call to CompressShaAesSetKey()
- if you want to change the chaining mode, you can customize the global CompressShaAesClass variable to the expected TAES* class name
- will store a hash of both cyphered and clear stream: if the data is corrupted during transmission, will instantly return ""

procedure CompressShaAesSetKey(**const** Key: RawByteString; AesClass: TAESAbstractClass=**nil**);

Set an text-based encryption key for CompressShaAes() global function
- will compute the key via SHA256Weak() and set CompressShaAesKey
- the key is global to the whole process

function CryptDataForCurrentUser(**const** Data, AppSecret: RawByteString; Encrypt: boolean): RawByteString;

Protect some data via AES-256-CFB and a secret known by the current user only

- the application can specify a secret salt text, which should reflect the current execution context, to ensure nobody could decrypt the data without knowing this application-specific AppSecret value

- here data is cyphered using a random secret key, stored in a file located in
 GetSystemPath(spUserData)+sep+PBKDF2_HMAC_SHA256(CryptProtectDataEntropy, User)

with sep='_' under Windows, and sep='.syn-' under Linux/Posix

- under Windows, it will encode the secret file via CryptProtectData DPAPI, so has the same security level than plain CryptDataForCurrentUserDPAPI()

- under Linux/POSIX, access to the \$HOME user's .xxxxxxxxxx secret file with chmod 400 is considered to be a safe enough approach

- this function is up to 100 times faster than CryptDataForCurrentUserDPAPI, generates smaller results, and is consistent on all Operating Systems

- you can use this function over a specified variable, to cypher it in place, with try ... finally block to protect memory access of the plain data:

```
constructor TMyClass.Create;
...
  fSecret := CryptDataForCurrentUser('Some Secret Value', 'appsalt', true);
...
procedure TMyClass.DoSomething;
var plain: RawByteString;
begin
  plain := CryptDataForCurrentUser(fSecret, 'appsalt', false);
  try
    // here plain = 'Some Secret Value'
  finally
    FillZero(plain); // safely erase uncyphered content from heap
  end;
end;
```

function CryptDataForCurrentUserDPAPI(**const** Data, AppSecret: RawByteString; Encrypt: boolean): RawByteString;

Protect some data for the current user, using Windows DPAPI

- the application can specify a secret salt text, which should reflect the current execution context, to ensure nobody could decrypt the data without knowing this application-specific AppSecret value

- will use CryptProtectData DPAPI function call under Windows

- see <https://msdn.microsoft.com/en-us/library/ms995355>

- this function is Windows-only, could be slow, and you don't know which algorithm is really used on your system, so using CryptDataForCurrentUser() may be a better (and cross-platform) alternative

- also note that DPAPI has been closely reverse engineered - see e.g.

<https://www.passcape.com/index.php?section=docsys&cmd=details&id=28>

procedure FillSystemRandom(Buffer: PByteArray; Len: integer; AllowBlocking: boolean);

Low-level function returning some random binary using standard API

- will call /dev/urandom or /dev/random under POSIX, and CryptGenRandom API on Windows, and fallback to SynCommons.FillRandom if the system API failed or for padding if more than 32 bytes is retrieved from /dev/urandom

- you should not have to call this procedure, but faster and safer TAESPRNG

function Hash128ToDouble(const r: THash128): double;

Low-level function able to derivate a 0..1 64-bit floating-point from 128-bit of data
- used e.g. by TAESPRNG.RandomDouble

function Hash128ToExt(const r: THash128): TSynExtended;

Low-level function able to derivate a 0..1 floating-point from 128-bit of data
- used e.g. by TAESPRNG.RandomExt

function Hash128ToSingle(const r: THash128): double;

Low-level function able to derivate a 0..1 32-bit floating-point from 128-bit of data

procedure HashFile(const aFileName: TFileName; aAlgos: THashAlgos); overload;

Compute the hexadecimal hashe(s) of one file, as external .md5/.sha256/.. files
- reading the file once in memory, then apply all algorithms on it and generate the text hash files in the very same folder

function HashFile(const aFileName: TFileName; aAlgo: THashAlgo): RawUTF8; overload;

Compute the hexadecimal hash of any (big) file
- using a temporary buffer of 1MB for the sequential reading

function HashFull(aAlgo: THashAlgo; aBuffer: Pointer; aLen: integer): RawUTF8;

One-step hash computation of a buffer as lowercase hexadecimal string

procedure HMAC_CRC256C(const key, msg: RawByteString; out result: THash256); overload;

Compute the HMAC message authentication code using crc256c as hash function
- HMAC over a non cryptographic hash function like crc256c is known to be safe as MAC, if the supplied key comes e.g. from cryptographic HMAC_SHA256
- performs two crc32c hashes, so SSE 4.2 gives more than 2.2 GB/s on a Core i7

procedure HMAC_CRC256C(const key: THash256; const msg: RawByteString; out result: THash256); overload;

Compute the HMAC message authentication code using crc256c as hash function
- HMAC over a non cryptographic hash function like crc256c is known to be safe as MAC, if the supplied key comes e.g. from cryptographic HMAC_SHA256
- performs two crc32c hashes, so SSE 4.2 gives more than 2.2 GB/s on a Core i7

procedure HMAC_CRC256C(key, msg: pointer; keylen, msglen: integer; out result: THash256); overload;

Compute the HMAC message authentication code using crc256c as hash function
- HMAC over a non cryptographic hash function like crc256c is known to be safe as MAC, if the supplied key comes e.g. from cryptographic HMAC_SHA256
- performs two crc32c hashes, so SSE 4.2 gives more than 2.2 GB/s on a Core i7

function HMAC_CRC32C(const key, msg: RawByteString): cardinal; overload;

Compute the HMAC message authentication code using crc32c as hash function
- HMAC over a non cryptographic hash function like crc32c is known to be a safe enough MAC, if the supplied key comes e.g. from cryptographic HMAC_SHA256
- SSE 4.2 will let MAC be computed at 4 GB/s on a Core i7

```
function HMAC_CRC32C(const key: THash256; const msg: RawByteString): cardinal;  
overload;
```

Compute the HMAC message authentication code using crc32c as hash function

- HMAC over a non cryptographic hash function like crc32c is known to be a safe enough MAC, if the supplied key comes e.g. from cryptographic HMAC_SHA256
- SSE 4.2 will let MAC be computed at 4 GB/s on a Core i7

```
function HMAC_CRC32C(key,msg: pointer; keylen,msglen: integer): cardinal; overload;
```

Compute the HMAC message authentication code using crc32c as hash function

- HMAC over a non cryptographic hash function like crc32c is known to be a safe enough MAC, if the supplied key comes e.g. from cryptographic HMAC_SHA256
- SSE 4.2 will let MAC be computed at 4 GB/s on a Core i7

```
procedure HMAC_SHA1(const key: TSHA1Digest; const msg: RawByteString; out result:  
TSHA1Digest); overload;
```

Compute the HMAC message authentication code using SHA-1 as hash function

```
procedure HMAC_SHA1(const key,msg: RawByteString; out result: TSHA1Digest); overload;
```

Compute the HMAC message authentication code using SHA-1 as hash function

```
procedure HMAC_SHA1(key,msg: pointer; keylen,msglen: integer; out result:  
TSHA1Digest); overload;
```

Compute the HMAC message authentication code using SHA-1 as hash function

```
procedure HMAC_SHA256(key,msg: pointer; keylen,msglen: integer; out result:  
TSHA256Digest); overload;
```

Compute the HMAC message authentication code using SHA-256 as hash function

```
procedure HMAC_SHA256(const key: TSHA256Digest; const msg: RawByteString; out result:  
TSHA256Digest); overload;
```

Compute the HMAC message authentication code using SHA-256 as hash function

```
procedure HMAC_SHA256(const key,msg: RawByteString; out result: TSHA256Digest);  
overload;
```

Compute the HMAC message authentication code using SHA-256 as hash function

```
procedure HMAC_SHA384(const key,msg: RawByteString; out result: TSHA384Digest);  
overload;
```

Compute the HMAC message authentication code using SHA-384 as hash function

```
procedure HMAC_SHA384(const key: TSHA384Digest; const msg: RawByteString; out result:  
TSHA384Digest); overload;
```

Compute the HMAC message authentication code using SHA-384 as hash function

```
procedure HMAC_SHA384(key,msg: pointer; keylen,msglen: integer; out result:  
TSHA384Digest); overload;
```

Compute the HMAC message authentication code using SHA-384 as hash function

```
procedure HMAC_SHA512(const key,msg: RawByteString; out result: TSHA512Digest);  
overload;
```

Compute the HMAC message authentication code using SHA-512 as hash function

```
procedure HMAC_SHA512(key,msg: pointer; keylen,msglen: integer; out result:  
TSHA512Digest); overload;
```

Compute the HMAC message authentication code using SHA-512 as hash function

```
procedure HMAC_SHA512(const key: TSHA512Digest; const msg: RawByteString; out result: TSHA512Digest); overload;
```

Compute the HMAC message authentication code using SHA-512 as hash function

```
function htldigest(const user, realm, pass: RawByteString): RawUTF8;
```

Compute the HTLDigest for a user and a realm, according to a supplied password

- apache-compatible: 'agent007:download area:8364d0044ef57b3defcfa141e8f77b65'

```
function MD5(const s: RawByteString): RawUTF8;
```

Direct MD5 hash calculation of some data (string-encoded)

- result is returned in hexadecimal format

```
function MD5Buf(const Buffer; Len: Cardinal): TMD5Digest;
```

Direct MD5 hash calculation of some data

```
function MD5DigestToString(const D: TMD5Digest): RawUTF8;
```

Compute the hexadecimal representation of a MD5 digest

```
function MD5SelfTest: boolean;
```

Self test of MD5 routines

```
function MD5StringToDigest(const Source: RawUTF8; out Dest: TMD5Digest): boolean;
```

Compute the MD5 digest from its hexadecimal representation

- returns true on success (i.e. Source has the expected size and characters)

- just a wrapper around SynCommons.HexToBin()

```
procedure PBKDF2_HMAC_SHA1(const password,salt: RawByteString; count: Integer; out result: TSHA1Digest);
```

Compute the PBKDF2 derivation of a password using HMAC over SHA-1

- this function expect the resulting key length to match SHA-1 digest size

```
procedure PBKDF2_HMAC_SHA256(const password,salt: RawByteString; count: Integer; var result: THash256DynArray; const saltdefault: RawByteString=''); overload;
```

Compute the PBKDF2 derivation of a password using HMAC over SHA-256, into several 256-bit items, so can be used to return any size of output key

- this function expect the result array to have the expected output length

- allows resulting key length to be more than one SHA-256 digest size, e.g. to be used for both Encryption and MAC

```
procedure PBKDF2_HMAC_SHA256(const password,salt: RawByteString; count: Integer; out result: TSHA256Digest; const saltdefault: RawByteString=''); overload;
```

Compute the PBKDF2 derivation of a password using HMAC over SHA-256

- this function expect the resulting key length to match SHA-256 digest size

```
procedure PBKDF2_HMAC_SHA384(const password,salt: RawByteString; count: Integer; out result: TSHA384Digest);
```

Compute the PBKDF2 derivation of a password using HMAC over SHA-384

- this function expect the resulting key length to match SHA-384 digest size

```
procedure PBKDF2_HMAC_SHA512(const password,salt: RawByteString; count: Integer; out result: TSHA512Digest);
```

Compute the PBKDF2 derivation of a password using HMAC over SHA-512

- this function expect the resulting key length to match SHA-512 digest size

```
procedure PBKDF2_SHA3(algo: TSHA3Algo; const password,salt: RawByteString; count: Integer; result: PByte; resultbytes: integer=0);
```

Safe key derivation using iterated SHA-3 hashing

- you can use SHA3_224, SHA3_256, SHA3_384, SHA3_512 algorithm to fill the result buffer with the default sized derivated key of 224,256,384 or 512 bits (leaving resultbytes = 0)
- or you may select SHAKE_128 or SHAKE_256, and specify any custom key size in resultbytes (used e.g. by PBKDF2_SHA3_Crypt)

```
procedure PBKDF2_SHA3_Crypt(algo: TSHA3Algo; const password,salt: RawByteString; count: Integer; var data: RawByteString);
```

Encryption/decryption of any data using iterated SHA-3 hashing key derivation

- specified algo is expected to be SHAKE_128 or SHAKE_256
- expected the supplied data buffer to be small - for bigger content, consider using TSHA.Cypher after 256-bit PBKDF2_SHA3 key derivation

```
procedure RawMd5Compress(var Hash; Data: pointer);
```

Entry point of the raw MD5 transform function - may be used for low-level use

```
procedure RawSha1Compress(var Hash; Data: pointer);
```

Entry point of the raw SHA-1 transform function - may be used for low-level use

```
procedure RawSha256Compress(var Hash; Data: pointer);
```

Entry point of the raw SHA-256 transform function - may be used for low-level use

```
procedure RawSha512Compress(var Hash; Data: pointer);
```

Entry point of the raw SHA-512 transform function - may be used for low-level use

```
function RC4SelfTest: boolean;
```

Self test of RC4 routines

```
function SHA1(const s: RawByteString): RawUTF8;
```

Direct SHA-1 hash calculation of some data (string-encoded)
- result is returned in hexadecimal format

```
function SHA1DigestToString(const D: TSHA1Digest): RawUTF8;
```

Compute the hexadecimal representation of a SHA-1 digest

```
function SHA1SelfTest: boolean;
```

Self test of SHA-1 routines

```
function SHA1StringToDigest(const Source: RawUTF8; out Dest: TSHA1Digest): boolean;
```

Compute the SHA-1 digest from its hexadecimal representation
- returns true on success (i.e. Source has the expected size and characters)
- just a wrapper around SynCommons.HexToBin()

```
function SHA256(Data: pointer; Len: integer): RawUTF8; overload;
```

Direct SHA-256 hash calculation of some binary data
- result is returned in hexadecimal format

```
function SHA256(const s: RawByteString): RawUTF8; overload;
```

Direct SHA-256 hash calculation of some data (string-encoded)
- result is returned in hexadecimal format

function SHA256Digest(Data: pointer; Len: integer): TSHA256Digest; overload;

Direct SHA-256 hash calculation of some binary data

- result is returned in TSHA256Digest binary format
- since the result would be stored temporarily in the stack, it may be safer to use an explicit TSHA256Digest variable, which would be filled with zeros by a ... finally FillZero()

function SHA256Digest(const Data: RawByteString): TSHA256Digest; overload;

Direct SHA-256 hash calculation of some binary data

- result is returned in TSHA256Digest binary format
- since the result would be stored temporarily in the stack, it may be safer to use an explicit TSHA256Digest variable, which would be filled with zeros by a ... finally FillZero()

function SHA256DigestToString(const D: TSHA256Digest): RawUTF8;

Compute the hexadecimal representation of a SHA-256 digest

function SHA256SelfTest: boolean;

Self test of SHA-256 routines

function SHA256StringToDigest(const Source: RawUTF8; out Dest: TSHA256Digest): boolean;

Compute the SHA-256 digest from its hexadecimal representation

- returns true on success (i.e. Source has the expected size and characters)
- just a wrapper around SynCommons.HexToBin()

procedure SHA256Weak(const s: RawByteString; out Digest: TSHA256Digest);

Direct SHA-256 hash calculation of some data (string-encoded)

- result is returned in hexadecimal format
- this procedure has a weak password protection: small incoming data is append to some salt, in order to have at least a 256 bytes long hash: such a feature improve security for small passwords, e.g.
- note that this algorithm is proprietary, and less secure (and standard) than the PBKDF2 algorithm, so is there only for backward compatibility of existing code: use PBKDF2_HMAC_SHA256 or similar functions for password derivation

function SHA3(Algo: TSHA3Algo; const s: RawByteString; DigestBits: integer=0): RawUTF8; overload;

Direct SHA-3 hash calculation of some data (string-encoded)

- result is returned in hexadecimal format
- default DigestBits=0 will write the default number of bits to Digest output memory buffer, according to the specified TSHA3Algo

function SHA3(Algo: TSHA3Algo; Buffer: pointer; Len: integer; DigestBits: integer=0): RawUTF8; overload;

Direct SHA-3 hash calculation of some binary buffer

- result is returned in hexadecimal format
- default DigestBits=0 will write the default number of bits to Digest output memory buffer, according to the specified TSHA3Algo

function SHA384(const s: RawByteString): RawUTF8;

Direct SHA-384 hash calculation of some data (string-encoded)

- result is returned in hexadecimal format

function SHA384DigestToString(const D: TSHA384Digest): RawUTF8;

Compute the hexadecimal representation of a SHA-384 digest

function SHA512(const s: RawByteString): RawUTF8;

Direct SHA-512 hash calculation of some data (string-encoded)
 - result is returned in hexadecimal format

function SHA512DigestToString(const D: TSHA512Digest): RawUTF8;

Compute the hexadecimal representation of a SHA-512 digest

procedure XorBlock(p: PIntegerArray; Count, Cod: integer);

- very fast XOR according to Cod - not Compression or Stream compatible
 - used in AESFull() for KeySize=32

procedure XorBlock16(A,B,C: PCardinalArray); overload;

Apply the XOR operation to the supplied binary buffers of 16 bytes

procedure XorBlock16(A,B: PCardinalArray); overload;

Apply the XOR operation to the supplied binary buffers of 16 bytes

procedure XorConst(p: PIntegerArray; Count: integer);

Fast XOR Cypher changing by Count value
 - Compression compatible, since the XOR value is always the same, the compression rate will not change a lot

procedure XorOffset(P: PByteArray; Index,Count: integer);

Fast and simple XOR Cypher using Index (=Position in Dest Stream)
 - Compression not compatible with this function: should be applied after compress (e.g. as outStream for TAESWriteStream)
 - Stream compatible (with updated Index)
 - used in AES() and TAESWriteStream

Variables implemented in the SynCrypto unit

AESIVCTR_KEY: TBlock128 = (\$ce5d5e3e, \$26506c65, \$568e0092, \$12cce480);

128-bit random AES-128 entropy key for TAESAbstract.IVReplayAttackCheck
 - as used internally by AESIVCtrEncryptDecrypt() function
 - you may customize this secret for your own project, but be aware that it will affect all TAESAbstract instances, so should match on all ends

CompressShaAesClass: TAESAbstractClass = TAESCFB;

The AES-256 encoding class used by CompressShaAes() global function
 - use any of the implementation classes, corresponding to the chaining mode required - TAESECB, TAESCBC, TAESCFB, TAESOFB and TAESCTR classes to handle in ECB, CBC, CFB, OFB and CTR mode (including PKCS7-like padding)
 - set to the secure and efficient CFB mode by default

CompressShaAesKey: TSHA256Digest;

The encryption key used by CompressShaAes() global function
 - the key is global to the whole process
 - use CompressShaAesSetKey() procedure to set this Key from text

```
CryptProtectDataEntropy: THash256 = (  
$19,$8E,$BA,$52,$FA,$D6,$56,$99,$7B,$73,$1B,$D0,$8B,$3A,$95,$AB,  
$94,$63,$C2,$C0,$78,$05,$9C,$8B,$85,$B7,$A1,$E3,$ED,$93,$27,$18);
```

Salt for CryptDataForCurrentUser function

- is filled with some random bytes by default, but you may override it for a set of custom processes calling CryptDataForCurrentUser

```
MainAESPRNG: TAESPRNG;
```

The shared TAESPRNG instance returned by TAESPRNG.Main class function

- you may override this to a customized instance, e.g. if you expect a specific random generator to be used, like TAESPRNGSystem

- all TAESPRNG.Fill() class functions will use this instance

27.8. SynCurl.pas unit

Purpose: Curl library direct access classes

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the *SynCurl* unit

Unit Name	Description	Page
<i>SynWinSock</i>	Low level access to network Sockets for the Win32 platform - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1851

SynCurl class hierarchy

Objects implemented in the *SynCurl* unit

Objects	Description	Page
ECurl	Low-level exception raised during libcurl library access	1204
TCurlCertInfo	Low-level certificate information for libcurl library API	1204
TCurlMsgRec	Low-level message information for libcurl library API	1204
TCurlVersionInfo	Low-level version information for libcurl library	1204
TCurlWaitFD	Low-level file description event handler for libcurl library API	1204

ECurl = class(Exception)

Low-level exception raised during libcurl library access

TCurlVersionInfo = record

Low-level version information for libcurl library

TCurlCertInfo = packed record

Low-level certificate information for libcurl library API

TCurlMsgRec = packed record

Low-level message information for libcurl library API

TCurlWaitFD = packed record

Low-level file description event handler for libcurl library API

Types implemented in the *SynCurl* unit

CURLSHOOption = (CURLSHOPT_NONE, CURLSHOPT_SHARE, CURLSHOPT_UNSHARE, CURLSHOPT_LOCKFUNC, CURLSHOPT_UNLOCKFUNC, CURLSHOPT_USERDATA, CURLSHOPT_LAST);

Never use

```
curl_lock_function = procedure (handle: TCurl; data: curl_lock_data; locktype:
curl_lock_access; userptr: pointer); cdecl;
```

Lock function signature for CURLSHOPT_LOCKFUNC

```
curl_read_callback = function (buffer: PAnsiChar; size,nitems: integer; instream:
pointer): integer; cdecl;
```

Low-level read callback function signature for libcurl library API

```
curl_unlock_function = procedure (handle: TCurl; data: curl_lock_data; userptr:
pointer); cdecl;
```

Unlock function signature for CURLSHOPT_UNLOCKFUNC

```
curl_write_callback = function (buffer: PAnsiChar; size,nitems: integer; outstream:
pointer): integer; cdecl;
```

Low-level write callback function signature for libcurl library API

```
TCurl = type pointer;
```

Low-level access to the libcurl library instance

```
TCurlGlobalInit = set of (giNone,giSSL,giWin32,giAll);
```

Low-level initialization option for libcurl library API

- currently, only giSSL is set, since giWin32 is redundant with WinHTTP

```
TCurlInfo = ( ciNone, ciLastOne, ciEffectiveURL, ciContentType, ciPrivate,
ciRedirectURL, ciPrimaryIP, ciLocalIP, ciResponseCode, ciHeaderSize, ciRequestSize,
ciSSLVerifyResult, ciFileTime, ciRedirectCount, ciHTTPConnectCode, ciHTTPAuthAvail,
ciProxyAuthAvail, ciOS_Errno, ciNumConnects, ciPrimaryPort, ciLocalPort, ciTotalTime,
ciNameLookupTime, ciConnectTime, ciPreTransferTime, ciSizeUpload, ciSizeDownload,
ciSpeedDownload, ciSpeedUpload, ciContentLengthDownload, ciContentLengthUpload,
ciStartTransferTime, ciRedirectTime, ciAppConnectTime, ciSSLEngines, ciCookielist,
ciCertInfo, ciSizeDownloadT, ciTotalTimeT, ciNameLookupTimeT, ciConnectTimeT,
ciPreTransferTimeT, ciStartTransferTimeT, ciAppConnectTimeT );
```

Low-level information enumeration for libcurl library API calls

```
TCurlMsg = ( cmNone, cmDone );
```

Low-level message state for libcurl library API

```
TCurlMulti = type pointer;
```

Low-level access to the libcurl library instance in "multi" mode

```
TCurlOption = ( coPort, coTimeout, coInFileSize, coLowSpeedLimit, coLowSpeedTime,
coResumeFrom, coCRLF, coSSLVersion, coTimeCondition, coTimeValue, coVerbose, coHeader,
coNoProgress, coNoBody, coFailOnError, coUpload, coPost, coFTPListOnly, coFTPAppend,
coNetRC, coFollowLocation, coTransferText, coPut, coAutoReferer, coProxyPort,
coPostFieldSize, coHTTPProxyTunnel, coSSLVerifyPeer, coMaxRedirs, coFileTime,
coMaxConnects, coClosePolicy, coFreshConnect, coForbidResue, coConnectTimeout,
coHTTPGet, coSSLVerifyHost, coHTTPVersion, coFTPUseEPSV, coSSLEngineDefault,
coDNSUseGlobalCache, coDNSCacheTimeout, coCookieSession, coBufferSize, coNoSignal,
coProxyType, coUnrestrictedAuth, coFTPUseEPRT, coHTTPAuth, coFTPCreateMissingDirs,
coProxyAuth, coFTPResponseTimeout, coIPResolve, coMaxFileSize, coFTPSSL, coTCPNoDelay,
coFTPSSLAAuth, coIgnoreContentLength, coFTPSkipPasvIp, coTimeoutMs,
coConnectTimeoutMs, coFile, coWriteData, coURL, coProxy, coUserPwd, coProxyUserPwd,
coRange, coInFile, coErrorBuffer, coPostFields, coReferer, coFTPPort, coUserAgent,
coCookie, coHTTPHeader, coHTTPPost, coSSLCert, coSSLCertPasswd, coQuote,
coWriteHeader, coCookieFile, coCustomRequest, coStdErr, coPostQuote, coWriteInfo,
coProgressData, coXferInfoData, coInterface, coKRB4Level, coCAInfo, coTelnetOptions,
coRandomFile, coEGDSocket, coCookieJar, coSSLCipherList, coSSLCertType, coSSLKey,
```

```
coSSLKeyType, coSSLEngine, coPreQuote, coDebugData, coCAPath, coShare, coEncoding,
coAcceptEncoding, coPrivate, coHTTP200Aliases, coSSLCTXData, coNetRCFile,
coSourceUserPwd, coSourcePreQuote, coSourcePostQuote, coIOCTLDData, coSourceURL,
coSourceQuote, coFTPAccount, coCookieList, coUnixSocketPath, coWriteFunction,
coReadFunction, coProgressFunction, coHeaderFunction, coDebugFunction,
coSSLCTXtFunction, coIOCTLFunction, coXferInfoFunction, coInFileSizeLarge,
coResumeFromLarge, coMaxFileSizeLarge, coPostFieldSizeLarge );
```

Low-level options for libcurl library API calls

```
TCurlResult = ( crOK, crUnsupportedProtocol, crFailedInit, crURLMformat,
crURLMformatUser, crCouldNotResolveProxy, crCouldNotResolveHost, crCouldNotConnect,
crFTPWeirdServerReply, crFTPAccessDenied, crFTPUserPasswordIncorrect,

crSSLEngineInitFailed, crLoginDenied, crTFTPNotFound, crTFTPPerm, crTFTPDiskFull,
crTFTPIllegal, crTFTPUnknownID, crTFTPExists, crTFTPNoSuchUser );
```

Low-level result codes for libcurl library API calls

```
TCurlSList = type pointer;
```

Low-level string list type for libcurl library API

```
TCurlSocket = type TSocket;
```

Low-level access to one libcurl library socket instance

```
TCurlVersion = ( cvFirst, cvSecond, cvThird, cvFour, cvLast );
```

(3) SSL handshake low-level version identifier of the libcurl library

Constants implemented in the *SynCurl* unit

```
LIBCURL_DLL = 'libcurl.dll' ;
```

Low-level libcurl library file name, depending on the running OS

Functions or procedures implemented in the *SynCurl* unit

Functions or procedures	Description	Page
CurlDisableGlobalShare	Disable a global share for libcurl	1207
CurlEnableGlobalShare	Enable libcurl multiple easy handles to share data	1207
CurlIsAvailable	Return TRUE if a curl library is available	1207

Functions or procedures	Description	Page
<code>CurlWriteRawByteString</code>	Callback used by libcurl to write data; Usage: <code>curl.easy_setopt(fHandle,coWriteFunction,@CurlWriteRawByteString);</code> <code>curl.easy_setopt(curlHandle,coFile,@curlRespBody);</code> where <code>curlRespBody</code> should be a generic <code>AnsiString/RawByteString</code> , i.e. in practice a <code>SockString</code> or a <code>RawByteString</code>	1207
<code>LibCurlInitialize</code>	Initialize the libcurl API, accessible via the curl global variable	1207

function `CurlDisableGlobalShare`: `CURLSHcode`;

Disable a global share for libcurl

- is called automatically in finalization section
- can be called on purpose, to ensure there is no active HTTP requests and prevent `CURLSHE_IN_USE` error
- you can re-enable the libcurl global share by `CurlEnableGlobalShare`

function `CurlEnableGlobalShare`: `boolean`;

Enable libcurl multiple easy handles to share data

- is called automatically during libcurl initialization
- shared objects are: DNS cache, TLS session cache and connection cache
- this way, each single transfer can take advantage of the context of the other transfer(s)
- do nothing if the global share has already been enabled
- see <https://curl.se/libcurl/c/libcurl-share.html> for details

function `CurlIsAvailable`: `boolean`;

Return TRUE if a curl library is available

- will load and initialize it, calling `LibCurlInitialize` if necessary, catching any exception during the process

function `CurlWriteRawByteString`(`buffer`: `PAnsiChar`; `size,nitems`: `integer`; `opaque`: `pointer`): `integer`; **cdecl**;

Callback used by libcurl to write data; Usage:

`curl.easy_setopt(fHandle,coWriteFunction,@CurlWriteRawByteString);`

`curl.easy_setopt(curlHandle,coFile,@curlRespBody);` where `curlRespBody` should be a generic `AnsiString/RawByteString`, i.e. in practice a `SockString` or a `RawByteString`

procedure `LibCurlInitialize`(`engines`: `TCurlGlobalInit=[giAll]`; **const** `dllname`: `TFileName= LIBCURL_DLL`);

Initialize the libcurl API, accessible via the curl global variable

- do nothing if the library has already been loaded
- will raise `ECurl` exception on any loading issue

Variables implemented in the *SynCurl* unit

curl: **packed**

Low-level late binding functions access to the libcurl library API

- ensure you called `LibCurlInitialize` or `CurlIsAvailable` functions to setup this global instance before using any of its internal functions
- see also <https://curl.haxx.se/libcurl/c/libcurl-multi.html> interface

Objects	Description	Page
TSQldbColumnDefine	Used to define a field/column layout in a table schema	1210
TSQldbColumnProperty	Used to define a field/column layout	1212
TSQldbConnection	Abstract connection created from TSQldbConnectionProperties	1234
TSQldbConnectionProperties	Abstract class used to set Database-related properties	1223
TSQldbConnectionPropertiesThreadSafe	Connection properties which will implement an internal Thread-Safe connection pool	1247
TSQldbConnectionThreadSafe	Abstract connection created from TSQldbConnectionProperties	1247
TSQldbDefinitionLimitClause	Defines the LIMIT clause to be inserted for a given SQL syntax	1223
TSQldbIndexDefine	Used to describe extended Index definition of a table schema	1210
TSQldbLib	Access to a native library	1258
TSQldbParam	A structure used to store a standard binding parameter	1248
TSQldbProcColumnDefine	Used to define a parameter/column layout in a stored procedure schema	1211
TSQldbProxyConnection	Implements an abstract proxy-like virtual connection to a DB engine	1254
TSQldbProxyConnectionCommandExecute	Structure to embed all needed parameters to execute a SQL statement	1253
TSQldbProxyConnectionPropertiesAbstract	Implements a proxy-like virtual connection statement to a DB engine	1254
TSQldbProxyConnectionProtocol	Server-side implementation of a proxy connection to any SynDB engine	1233
TSQldbProxyStatement	Implements a proxy-like virtual connection statement to a DB engine	1256
TSQldbProxyStatementAbstract	Implements a proxy-like virtual connection statement to a DB engine	1255
TSQldbProxyStatementRandomAccess	Implements a virtual statement with direct data access	1258
TSQldbRemoteConnectionPropertiesAbstract	Client-side implementation of a remote connection to any SynDB engine	1257
TSQldbRemoteConnectionPropertiesTest	Fake proxy class for testing the remote connection to any SynDB engine	1257
TSQldbRemoteConnectionProtocol	Server-side implementation of a remote connection to any SynDB engine	1234
TSQldbRowVariantType	A custom variant type used to have direct access to a result row content	1214
TSQldbStatement	Generic abstract class to implement a prepared SQL query	1236

Objects	Description	Page
TSQldbStatementWithParams	Generic abstract class handling prepared statements with binding	1249
TSQldbStatementWithParamsAndColumns	Generic abstract class handling prepared statements with binding and column description	1252

TSQldbColumnDefine = **packed record**

Used to define a field/column layout in a table schema

- for TSQldbConnectionProperties.SQLCreate to describe the new table
- for TSQldbConnectionProperties.GetFields to retrieve the table layout

ColumnIndexed: boolean;

Specify if column is indexed

ColumnLength: PtrInt;

The Column default width (in chars or bytes) of ftUTF8 or ftBlob

- can be set to value <0 for CLOB or BLOB column type, i.e. for a value without any maximal length

ColumnName: RawUTF8;

The Column name

ColumnPrecision: PtrInt;

The Column data precision

- used e.g. for numerical values

ColumnScale: PtrInt;

The Column data scale

- used e.g. for numerical values
- may be -1 if the metadata SQL statement returned NULL

ColumnType: TSQldbFieldType;

The Column type, as recognized by our SynDB classes

- should not be ftUnknown nor ftNull

ColumnTypeNative: RawUTF8;

The Column type, as retrieved from the database provider

- returned as plain text by GetFields method, to be used e.g. by TSQldbConnectionProperties.GetFieldDefinitions method
- SQLCreate will check for this value to override the default type

TSQldbIndexDefine = **packed record**

Used to describe extended Index definition of a table schema

Filter: RawUTF8;

Expression for the subset of rows included in the filtered index

- only set for MS SQL - not retrieved for other DB types yet

IncludedColumns: RawUTF8;

Comma separated list of a nonkey column added to the index by using the CREATE INDEX INCLUDE clause

- only set for MS SQL - not retrieved for other DB types yet

IndexName: RawUTF8;

Name of the index

IsPrimaryKey: boolean;

If Index is part of a PRIMARY KEY constraint

- only set for MS SQL - not retrieved for other DB types yet

IsUnique: boolean;

If Index is unique

IsUniqueConstraint: boolean;

If Index is part of a UNIQUE constraint

- only set for MS SQL - not retrieved for other DB types yet

KeyColumns: RawUTF8;

Comma separated list of indexed column names, in order of their definition

TypeDesc: RawUTF8;

Description of the index type

- for MS SQL possible values are:

HEAP | CLUSTERED | NONCLUSTERED | XML | SPATIAL

- for Oracle:

NORMAL | BITMAP | FUNCTION-BASED NORMAL | FUNCTION-BASED BITMAP | DOMAIN

see @http://docs.oracle.com/cd/B19306_01/server.102/b14237/statviews_1069.htm

TSQLDBProcColumnDefine = packed record

Used to define a parameter/column layout in a stored procedure schema

- for TSQLDBConnectionProperties.GetProcedureParameters to retrieve the stored procedure parameters

- can be extended according to

[https://msdn.microsoft.com/en-us/library/ms711701\(v=vs.85\).aspx](https://msdn.microsoft.com/en-us/library/ms711701(v=vs.85).aspx)

ColumnLength: PtrInt;

The Column default width (in chars or bytes) of ftUTF8 or ftBlob

- can be set to value <0 for CLOB or BLOB column type, i.e. for a value without any maximal length

ColumnName: RawUTF8;

The Column name

ColumnParamType: TSQLDBParamInOutType;

Defines the procedure column as a parameter or a result set column

ColumnPrecision: PtrInt;

The Column data precision

- used e.g. for numerical values

ColumnScale: PtrInt;

The Column data scale

- used e.g. for numerical values
- may be -1 if the metadata SQL statement returned NULL

ColumnType: TSQldbFieldType;

The Column type, as recognized by our SynDB classes

- should not be ftUnknown nor ftNull

ColumnTypeNative: RawUTF8;

The Column type, as retrieved from the database provider

- used e.g. by TSQldbConnectionProperties.GetProcedureParameters method

TSQldbColumnProperty = packed record

Used to define a field/column layout

- for TSQldbConnectionProperties.SQLCreate to describe the table
- for T*Statement.Execute/Column*() methods to map the IRowSet content

ColumnAttr: PtrUInt;

A general purpose integer value

- for SQLCreate: default width (in WideChars or Bytes) of ftUTF8 or ftBlob; if set to 0, a CLOB or BLOB column type will be created - note that UTF-8 encoding is expected when calculating the maximum column byte size for the CREATE TABLE statement (e.g. for Oracle $1333=4000/3$ is used)
- for ToleDBStatement: the offset of this column in the IRowSet data, starting with a DBSTATUSENUM, the data, then its length (for inlined sftUTF8 and sftBlob only)
- for TSQldbOracleStatement: contains an offset to this column values inside fRowBuffer[] internal buffer
- for TSQldbDatasetStatement: maps TField pointer value
- for TSQldbPostgresStatement: contains the column type OID

ColumnDataSize: integer;

May contain the current column size for not FIXEDLENGTH_SQldbFIELDTYPE

- for SynDBODBC: size (in bytes) in corresponding fColData[]
- TSQldbProxyStatement: the actual maximum column size

ColumnDataState: TSQldbStatementGetCol;

May contain the current status of the column value

- for SynDBODBC: state of the latest SQLGetData() call

ColumnName: RawUTF8;

The Column name

ColumnNonNullable: boolean;

Set if the Column must exists (i.e. should not be null)

ColumnType: TSQldbFieldType;

The Column type, used for storage

- for SQLCreate: should not be ftUnknown nor ftNull
- for ToleDBStatement: should not be ftUnknown
- for SynDBOracle: never ftUnknown, may be ftNull (for SQLT_RSET)

ColumnUnique: boolean;

Set if the Column shall have unique value (add the corresponding constraint)

ColumnValueDBCharSet: integer;

Optional character set encoding for ftUTF8 columns

- for SQLT_STR/SQLT_CLOB (SynDBOracle): equals to the OCI char set

ColumnValueDBForm: byte;

Driver-specific encoding information

- for SynDBOracle: used to store the ftUTF8 column encoding, i.e. for SQLT_CLOB, equals either to SQLCS_NCHAR or SQLCS_IMPLICIT

ColumnValueDBSize: cardinal;

Expected column data size

- for TSQldbOracleStatement/TOLdbStatement/TODBCStatement: used to store one column size (in bytes)

ColumnValueDBType: smallint;

Internal DB column data type

- for TSQldbOracleStatement: used to store the DefineByPos() TypeCode, can be SQLT_STR/SQLT_CLOB, SQLT_FLT, SQLT_INT, SQLT_DAT, SQLT_BLOB, SQLT_BIN and SQLT_RSET
- for TSQldbODBCStatement: used to store the DataType as returned by ODBC.DescribeColW() - use private ODBC_TYPE_TO[ColumnType] to retrieve the marshalled type used during column retrieval
- for TSQldbFirebirdStatement: used to store XSQLVAR.sqltype
- for TSQldbDatasetStatement: indicates the TField class type, i.e. 0=TField, 1=TLargeIntField, 2=TWideStringField

ColumnValueInlined: boolean;

Set if the Column data is inlined within the main rows buffer

- for TOLdbStatement: set if column was NOT defined as DBTYPE_BYREF which is the most common case, when column data < 4 KB
- for TSQldbOracleStatement: FALSE if column is an array of POCILobLocator (SQLT_CLOB/SQLT_BLOB) or POCISmt (SQLT_RSET)
- for TSQldbODBCStatement: FALSE if bigger than 255 WideChar (ftUTF8) or 255 bytes (ftBlob)

TSQldbColumnCreate = record

Used to define how a column to be created

DBType: TSQldbFieldType;

The data type

- here, ftUnknown is used for Int32 values, ftInt64 for Int64 values, as expected by TSQldbFieldTypeDefinition

Name: RawUTF8;

The column name

NonNullable: boolean;

If the column should be non null

PrimaryKey: boolean;

If the column is the ID primary key

Unique: boolean;

If the column should be unique

Width: cardinal;

The width, e.g. for VARCHAR() types

TSQLDBRowVariantType = class(TSynInvokeableVariantType)

A custom variant type used to have direct access to a result row content

- use ISQLDBRows.RowData method to retrieve such a Variant

ISQLDBRows = interface(IInterface)

Generic interface to access a SQL query result rows

- not all TSQLDBStatement methods are available, but only those to retrieve data from a statement result: the purpose of this interface is to make easy access to result rows, not provide all available features - therefore you only have access to the Step() and Column*() methods

function ColumnBlob(Col: integer): RawByteString; overload;

Return a Column as a blob value of the current Row, first Col is 0

function ColumnBlob(const ColName: RawUTF8): RawByteString; overload;

Return a Column as a blob value of the current Row, from a supplied column name

function ColumnBlobBytes(Col: integer): TBytes; overload;

Return a Column as a blob value of the current Row, first Col is 0

function ColumnBlobBytes(const ColName: RawUTF8): TBytes; overload;

Return a Column as a blob value of the current Row, from a supplied column name

function ColumnCount: integer;

The column/field count of the current Row

function ColumnCurrency(Col: integer): currency; overload;

Return a Column currency value of the current Row, first Col is 0

function ColumnCurrency(const ColName: RawUTF8): currency; overload;

Return a Column currency value of the current Row, from a supplied column name

function ColumnCursor(const ColName: RawUTF8): ISQLDBRows; overload;

Return a special CURSOR Column content as a SynDB result set

- Cursors are not handled internally by mORMot, but some databases (e.g. Oracle) usually use such structures to get data from stored procedures
- such columns are mapped as ftNull internally - so this method is the only one giving access to the data rows

function ColumnCursor(Col: integer): ISQLDBRows; overload;

Return a special CURSOR Column content as a SynDB result set

- Cursors are not handled internally by mORMot, but some databases (e.g. Oracle) usually use such structures to get data from stored procedures
- such columns are mapped as ftNull internally - so this method is the only one giving access to the data rows
- see also BoundCursor() if you want to access a CURSOR out parameter

```
function ColumnDateTime(const ColName: RawUTF8): TDateTime; overload;
  Return a Column floating point value of the current Row, from a supplied column name
```

```
function ColumnDateTime(Col: integer): TDateTime; overload;
  Return a Column floating point value of the current Row, first Col is 0
```

```
function ColumnDouble(const ColName: RawUTF8): double; overload;
  Return a Column floating point value of the current Row, from a supplied column name
```

```
function ColumnDouble(Col: integer): double; overload;
  Return a Column floating point value of the current Row, first Col is 0
```

```
function ColumnIndex(const aColumnName: RawUTF8): integer;
  Returns the Column index of a given Column name
  - Columns numeration (i.e. Col value) starts with 0
  - returns -1 if the Column name is not found (via case insensitive search)
```

```
function ColumnInt(const ColName: RawUTF8): Int64; overload;
  Return a Column integer value of the current Row, from a supplied column name
```

```
function ColumnInt(Col: integer): Int64; overload;
  Return a Column integer value of the current Row, first Col is 0
```

```
function ColumnName(Col: integer): RawUTF8;
  The Column name of the current Row
  - Columns numeration (i.e. Col value) starts with 0
  - it's up to the implementation to ensure than all column names are unique
```

```
function ColumnNull(Col: integer): boolean;
  Returns TRUE if the column contains NULL
```

```
function ColumnString(const ColName: RawUTF8): string; overload;
  Return a Column text value as generic VCL string of the current Row, from a supplied column name
```

```
function ColumnString(Col: integer): string; overload;
  Return a Column text value as generic VCL string of the current Row, first Col is 0
```

```
function ColumnTimestamp(Col: integer): TTimeLog; overload;
  Return a column date and time value of the current Row, first Col is 0
```

```
function ColumnTimestamp(const ColName: RawUTF8): TTimeLog; overload;
  Return a column date and time value of the current Row, from a supplied column name
```

```
function ColumnToVariant(Col: integer; var Value: Variant): TSQLDBFieldType;
overload;
  Return a Column as a variant, first Col is 0
  - this default implementation will call Column*() method above
  - a ftUTF8 TEXT content will be mapped into a generic WideString variant for pre-Unicode
    version of Delphi, and a generic UnicodeString (=string) since Delphi 2009: you may not loose
    any data during charset conversion
  - a ftBlob BLOB content will be mapped into a TBlobData AnsiString variant
```

function ColumnType(Col: integer; FieldSize: PInteger=nil): TSQldbFieldType;

The Column type of the current Row

- FieldSize can be set to store the size in chars of a ftUTF8 column (0 means BLOB kind of TEXT column)

function ColumnUTF8(const ColName: RawUTF8): RawUTF8; overload;

Return a Column UTF-8 encoded text value of the current Row, from a supplied column name

function ColumnUTF8(Col: integer): RawUTF8; overload;

Return a Column UTF-8 encoded text value of the current Row, first Col is 0

function ColumnVariant(Col: integer): Variant; overload;

Return a Column as a variant

- a ftUTF8 TEXT content will be mapped into a generic WideString variant for pre-Unicode version of Delphi, and a generic UnicodeString (=string) since Delphi 2009: you may not loose any data during charset conversion

- a ftBlob BLOB content will be mapped into a TBlobData AnsiString variant

function ColumnVariant(const ColName: RawUTF8): Variant; overload;

Return a Column as a variant, from a supplied column name

function FetchAllAsJSON(Expanded: boolean; ReturnedRowCount: PPtrInt=nil): RawUTF8;

Return all rows content as a JSON string

- JSON data is retrieved with UTF-8 encoding

- if Expanded is true, JSON data is an array of objects, for direct use with any Ajax or .NET client:

```
[ { "col1":val11, "col2": "val12" }, { "col1":val21, ... } ]
```

- if Expanded is false, JSON data is serialized (used in TSQLTableJSON)

```
{ "FieldCount":1, "Values":["col1", "col2", val11, "val12", val21, .. ] }
```

- BLOB field value is saved as Base64, in the '"\uFFFF0base64encodedbinary"' format and contains true BLOB data

- if ReturnedRowCount points to an integer variable, it will be filled with the number of row data returned (excluding field names)

- similar to corresponding TSQLRequest.Execute method in SynSQLite3 unit

function FetchAllToBinary(Dest: TStream; MaxRowCount: cardinal=0; DataRowPosition: PCardinalDynArray=nil): cardinal;

Append all rows content as binary stream

- will save the column types and name, then every data row in optimized binary format (faster and smaller than JSON)

- you can specify a LIMIT for the data extent (default 0 meaning all data)

- generates the format expected by TSQldbProxyStatement

function FetchAllToJSON(JSON: TStream; Expanded: boolean): PtrInt;

Append all rows content as a JSON stream

- JSON data is added to the supplied TStream, with UTF-8 encoding
- if Expanded is true, JSON data is an array of objects, for direct use with any Ajax or .NET client:
[{ "col1":val11,"col2":"val12"}, {"col1":val21,... }]
- if Expanded is false, JSON data is serialized (used in TSQLTableJSON)
{ "FieldCount":1,"Values":["col1","col2",val11,"val12",val21,...] }
- BLOB field value is saved as Base64, in the ""\uFFFF0base64encodedbinary"" format and contains true BLOB data
- similar to corresponding TSQLRequest.Execute method in SynSQLite3 unit
- returns the number of row data returned (excluding field names)

function GetColumnVariant(const ColName: RawUTF8): Variant;

Return a Column as a variant, from a supplied column name

- since a property getter can't be an overloaded method, we define one for the Column[] property

function Instance: TSQLDBStatement;

Return the associated statement instance

function RowData: Variant;

Create a TSQLDBRowVariantType able to access any field content via late binding

- i.e. you can use Data.Name to access the 'Name' column of the current row
- this Variant will point to the corresponding TSQLDBStatement instance, so it's not necessary to retrieve its value for each row; but once the associated TSQLDBRows instance is released, you won't be able to access its data - use RowDocVariant instead

- typical use is:

```
var Row: Variant;  
(...)  
with MyConnProps.Execute('select * from table where name=?',[aName]) do begin  
  Row := RowData;  
  while Step do  
    writeln(Row.FirstName,Row.BirthDate);  
  ReleaseRows;  
end;
```

function Step(SeekFirst: boolean=false): boolean;

After a prepared statement has been prepared returning a ISQLDBRows interface, this method must be called one or more times to evaluate it

- you shall call this method before calling any Column*() methods
- return TRUE on success, with data ready to be retrieved by Column*()
- return FALSE if no more row is available (e.g. if the SQL statement is not a SELECT but an UPDATE or INSERT command)
- access the first or next row of data from the SQL Statement result: if SeekFirst is TRUE, will put the cursor on the first row of results, otherwise, it will fetch one row of data, to be called within a loop
- should raise an Exception on any error
- typical use may be:

```
var Customer: Variant;
begin
  with Props.Execute( 'select * from Sales.Customer where AccountNumber like ?',
    ['AW000001%'],@Customer) do begin
    while Step do // loop through all matching data rows
      assert(Copy(Customer.AccountNumber,1,8)='AW000001');
      ReleaseRows;
    end;
  end;
```

procedure ColumnBlobFromStream(Col: integer; Stream: TStream); overload;

Write a blob Column into the Stream parameter

- expected to be used with 'SELECT .. FOR UPDATE' locking statements

procedure ColumnBlobFromStream(const ColName: RawUTF8; Stream: TStream); overload;

Write a blob Column into the Stream parameter

procedure ColumnBlobToStream(Col: integer; Stream: TStream); overload;

Read a blob Column into the Stream parameter

procedure ColumnBlobToStream(const ColName: RawUTF8; Stream: TStream); overload;

Read a blob Column into the Stream parameter

procedure ColumnToSQLVar(Col: Integer; var Value: TSQLVar; var Temp: RawByteString);

Return a Column as a TSQLVar value, first Col is 0

- the specified Temp variable will be used for temporary storage of svtUTF8/svtBlob values

procedure ReleaseRows;

Release cursor memory and resources once Step loop is finished

- this method call is optional, but is better be used if the ISQLDBRows statement from taken from cache, and returned a lot of content which may still be in client (and server) memory
- will also free all temporary memory used for optional logging

procedure RowDocVariant(out aDocument: variant; aOptions: TDocVariantOptions=JSON_OPTIONS_FAST);

Create a TDocVariant custom variant containing all columns values

- will create a "fast" TDocVariant object instance with all fields

```
property Column[const ColName: RawUTF8]: Variant read GetColumnVariant;
```

Return a Column as a variant

- this default property can be used to write simple code like this:

```
procedure WriteFamily(const aName: RawUTF8);  
var I: ISQLDBRows;  
begin  
  I := MyConnProps.Execute('select * from table where name=?',[aName]);  
  while I.Step do  
    writeln(I['FirstName'], ' ', DateToStr(I['BirthDate']));  
  I.ReleaseRows;  
end;
```

- of course, using a variant and a column name will be a bit slower than direct access via the Column*() dedicated methods, but resulting code is fast in practice

```
ISQLDBStatement = interface(ISQLDBRows)
```

Generic interface to bind to prepared SQL query

- inherits from ISQLDBRows, so gives access to the result columns data
- not all TSQLDBStatement methods are available, but only those to bind parameters and retrieve data after execution
- reference counting mechanism of this interface will feature statement cache (if available) for NewThreadSafeStatementPrepared() or PrepareInlined()

```
function BoundCursor(Param: Integer): ISQLDBRows;
```

Return a special CURSOR parameter content as a SynDB result set

- this method is not about a column, but a parameter defined with BindCursor() before method execution
- Cursors are not handled internally by mORMot, but some databases (e.g. Oracle) usually use such structures to get data from stored procedures
- this method allow direct access to the data rows after execution

```
function ParamToVariant(Param: Integer; var Value: Variant; CheckIsOutParameter:  
boolean=true): TSQldbFieldType;
```

Retrieve the parameter content, after SQL execution

- the leftmost SQL parameter has an index of 1
- to be used e.g. with stored procedures:

```
query := 'BEGIN TEST_PKG.DUMMY(?, ?, ?, ?, ?); END;';  
stmt := Props.NewThreadSafeStatementPrepared(query, false);  
stmt.Bind(1, in1, paramIn);  
stmt.BindTextU(2, in2, paramIn);  
stmt.BindTextU(3, in3, paramIn);  
stmt.BindTextS(4, '', paramOut); // to be retrieved with out1: string  
stmt.Bind(5, 0, paramOut);      // to be retrieved with out2: integer  
stmt.ExecutePrepared;  
stmt.ParamToVariant(4, out1, true);  
stmt.ParamToVariant(5, out2, true);
```

- the parameter should have been bound with IO=paramOut or IO=paramInOut if CheckIsOutParameter is TRUE

```
function UpdateCount: Integer;
```

Gets a number of updates made by latest executed statement

```
procedure Bind(Param: Integer; Value: Int64; IO: TSQldbParamInOutType=paramIn);  
overload;
```

Bind an integer value to a parameter

- the leftmost SQL parameter has an index of 1

```
procedure Bind(Param: Integer; const Data: TSQLVar; IO:  
TSQldbParamInOutType=paramIn); overload;
```

Bind one TSQLVar value

- the leftmost SQL parameter has an index of 1

```
procedure Bind(const Params: array of const; IO: TSQldbParamInOutType=paramIn);  
overload;
```

Bind an array of const values

- parameters marked as ? should be specified as method parameter in Params[]
- BLOB parameters can be bound with this method, when set after encoding via BinToBase64WithMagic() call
- TDateTime parameters can be bound with this method, when encoded via a DateToSQL() or DateTimeToSQL() call

```
procedure Bind(Param: Integer; ParamType: TSQldbFieldType; const Value: RawUTF8;  
ValueAlreadyUnquoted: boolean; IO: TSQldbParamInOutType=paramIn); overload;
```

Bind one RawUTF8 encoded value

- the leftmost SQL parameter has an index of 1
- the value should match the BindArray() format, i.e. be stored as in SQL (i.e. number, 'quoted string', 'YYYY-MM-DD hh:mm:ss', null)

```
procedure Bind(Param: Integer; Value: double; IO: TSQldbParamInOutType=paramIn);  
overload;
```

Bind a double value to a parameter

- the leftmost SQL parameter has an index of 1

```
procedure BindArray(Param: Integer; const Values: array of double); overload;
```

Bind an array of double values to a parameter

- the leftmost SQL parameter has an index of 1
- this default implementation will raise an exception if the engine does not support array binding

```
procedure BindArray(Param: Integer; const Values: array of Int64); overload;
```

Bind an array of integer values to a parameter

- the leftmost SQL parameter has an index of 1
- this default implementation will raise an exception if the engine does not support array binding

```
procedure BindArray(Param: Integer; const Values: array of RawUTF8); overload;
```

Bind an array of RawUTF8 values to a parameter

- the leftmost SQL parameter has an index of 1
- values are stored as in SQL (i.e. 'quoted string')
- this default implementation will raise an exception if the engine does not support array binding

```
procedure BindArray(Param: Integer; ParamType: TSQldbFieldType; const Values:  
TRawUTF8DynArray; ValuesCount: integer); overload;
```

Bind an array of values to a parameter

- the leftmost SQL parameter has an index of 1
- values are stored as in SQL (i.e. number, 'quoted string', 'YYYY-MM-DD hh:mm:ss', null)
- this default implementation will raise an exception if the engine does not support array binding

procedure BindArrayCurrency(Param: Integer; **const** Values: array of currency);

Bind an array of currency values to a parameter

- the leftmost SQL parameter has an index of 1
- this default implementation will raise an exception if the engine does not support array binding

procedure BindArrayDateTime(Param: Integer; **const** Values: array of TDateTime);

Bind an array of TDateTime values to a parameter

- the leftmost SQL parameter has an index of 1
- values are stored as in SQL (i.e. 'YYYY-MM-DD hh:mm:ss')
- this default implementation will raise an exception if the engine does not support array binding

procedure BindBlob(Param: Integer; Data: pointer; Size: integer; IO:
TSQLDBParamInOutType=paramIn); overload;

Bind a Blob buffer to a parameter

- the leftmost SQL parameter has an index of 1

procedure BindBlob(Param: Integer; **const** Data: RawByteString; IO:
TSQLDBParamInOutType=paramIn); overload;

Bind a Blob buffer to a parameter

- the leftmost SQL parameter has an index of 1

procedure BindCurrency(Param: Integer; Value: currency; IO:
TSQLDBParamInOutType=paramIn); overload;

Bind a currency value to a parameter

- the leftmost SQL parameter has an index of 1

procedure BindCursor(Param: integer);

Bind a special CURSOR parameter to be returned as a SynDB result set

- Cursors are not handled internally by mORMot, but some databases (e.g. Oracle) usually use such structures to get data from stored procedures
- such parameters are mapped as ftUnknown
- use BoundCursor() method to retrieve the corresponding ISQLDBRows after execution of the statement

procedure BindDateTime(Param: Integer; Value: TDateTime; IO:
TSQLDBParamInOutType=paramIn); overload;

Bind a TDateTime value to a parameter

- the leftmost SQL parameter has an index of 1

procedure BindFromRows(**const** Fields: TSQLDBFieldTypeDynArray; Rows:
TSQLDBStatement);

Bind an array of fields from an existing SQL statement

- can be used e.g. after ColumnsToSQLInsert() method call for fast data conversion between tables

procedure BindNull(Param: Integer; IO: TSQLDBParamInOutType=paramIn; BoundType:
TSQLDBFieldType=ftNull);

Bind a NULL value to a parameter

- the leftmost SQL parameter has an index of 1
- some providers (e.g. Oledb during MULTI INSERT statements) expect the proper column type to be set in BoundType, even for NULL values

procedure BindTextP(Param: Integer; Value: PUTF8Char; IO: TSQldbParamInOutType=paramIn); overload;

Bind a UTF-8 encoded buffer text (#0 ended) to a parameter
- the leftmost SQL parameter has an index of 1

procedure BindTextS(Param: Integer; **const** Value: **string**; IO: TSQldbParamInOutType=paramIn); overload;

Bind a UTF-8 encoded string to a parameter
- the leftmost SQL parameter has an index of 1

procedure BindTextU(Param: Integer; **const** Value: RawUTF8; IO: TSQldbParamInOutType=paramIn); overload;

Bind a UTF-8 encoded string to a parameter
- the leftmost SQL parameter has an index of 1

procedure BindTextW(Param: Integer; **const** Value: WideString; IO: TSQldbParamInOutType=paramIn); overload;

Bind a UTF-8 encoded string to a parameter
- the leftmost SQL parameter has an index of 1

procedure BindVariant(Param: Integer; **const** Data: **Variant**; DataIsBlob: boolean; IO: TSQldbParamInOutType=paramIn);

Bind a Variant value to a parameter
- the leftmost SQL parameter has an index of 1
- will call all virtual Bind*() methods from the Data type
- if DataIsBlob is TRUE, will call BindBlob(RawByteString(Data)) instead of BindTextW(WideString(Variant)) - used e.g. by TQuery.AsBlob/AsBytes

procedure ExecutePrepared;

Execute a prepared SQL statement
- parameters marked as ? should have been already bound with Bind*() functions
- should raise an Exception on any error
- after execution, you can access any returned data via ISQldbRows methods

procedure ExecutePreparedAndFetchAllAsJSON(Expanded: boolean; **out** JSON: RawUTF8);

Execute a prepared SQL statement and return all rows content as a JSON string
- JSON data is retrieved with UTF-8 encoding
- if Expanded is true, JSON data is an array of objects, for direct use with any Ajax or .NET client:
[{ "col1":val11, "col2": "val12" }, { "col1":val21, ... }]
- if Expanded is false, JSON data is serialized (used in TSQLTableJSON)
{ "FieldCount":1, "Values": ["col1", "col2", val11, "val12", val21, ...] }
- BLOB field value is saved as Base64, in the ""\uFFFF0base64encodedbinary"" format and contains true BLOB data

property ForceBlobAsNull: boolean **read** GetForceBlobAsNull **write** SetForceBlobAsNull;

If set, any BLOB field won't be retrieved, and forced to be null
- this may be used to speed up fetching the results for SQL requests with * statements

property ForceDateWithMS: boolean **read** GetForceDateWithMS **write** SetForceDateWithMS;

If set, any ftDate field will contain the milliseconds information when serialized into ISO-8601 text
- this setting is private to each statement, since may vary depending on data definition (e.g. ORM TDateTime/TDateTimeMS)

TSQLDBDefinitionLimitClause = record

Defines the LIMIT clause to be inserted for a given SQL syntax
 - used by TSQLDBDefinitionLimitClause and SQLLimitClause() method

TSQLDBConnectionProperties = class(TObject)

Abstract class used to set Database-related properties
 - handle e.g. the Database server location and connection parameters (like UserID and password)
 - should also provide some Database-specific generic SQL statement creation (e.g. how to create a Table), to be used e.g. by the mORMot layer
 - this class level will handle a single "main connection" - you may inherit from TSQLDBConnectionThreadSafe to maintain one connection per thread

constructor Create(const aServerName, aDatabaseName, aUserID, aPassword: RawUTF8);
virtual;

Initialize the properties
 - children may optionally handle the fact that no UserID or Password is supplied here, by displaying a corresponding Dialog box

destructor Destroy; **override;**

Release related memory, and close MainConnection

class function ClassFrom(aDefinition: TSynConnectionDefinition):
 TSQLDBConnectionPropertiesClass;

Retrieve the registered class from the aDefinition.Kind string

function ColumnTypeNativeToDB(const aNativeType: RawUTF8; aScale: integer):
 TSQLDBFieldType; **virtual;**

Convert a textual column data type, as retrieved e.g. from SQLGetField, into our internal primitive types
 - default implementation will always return ftUTF8

class function CreateFrom(aDefinition: TSynConnectionDefinition):
 TSQLDBConnectionProperties; **virtual;**

Create a new TSQLDBConnectionProperties instance from the stored values

class function CreateFromFile(const aJSONFile: TFileName; aKey: cardinal=0):
 TSQLDBConnectionProperties;

Create a new TSQLDBConnectionProperties instance from a JSON file
 - as previously serialized with TSQLDBConnectionProperties.DefinitionToFile
 - you can specify a custom Key, if the default is not safe enough for you

class function CreateFromJSON(const aJSONDefinition: RawUTF8; aKey: cardinal=0):
 TSQLDBConnectionProperties; **virtual;**

Create a new TSQLDBConnectionProperties instance from a JSON content
 - as previously serialized with TSQLDBConnectionProperties.DefinitionToJSON
 - you can specify a custom Key, if the default is not safe enough for you

function DefinitionToJSON(Key: cardinal=0): RawUTF8; **virtual;**

Save the properties into a JSON file
 - you could use TSQLDBConnectionPropertiesDescription.CreateFromJSON() later on to instantiate the proper TSQLDBConnectionProperties class
 - you can specify a custom Key, if the default is not enough for you

class function EngineName: RawUTF8;

Return the database engine name, as computed from the class name

- 'TSQLDBConnectionProperties' will be trimmed left side of the class name

function Execute(const aSQL: RawUTF8; const Params: array of const ; RowsVariant: PVariant=nil; ForceBlobAsNull: boolean=false): ISQLDBRows;

Execute a SQL query, returning a statement interface instance to retrieve the result rows corresponding to the supplied SELECT statement

- will call NewThreadSafeStatement method to retrieve a thread-safe statement instance, then run the corresponding Execute() method

- raise an exception on error

- returns an ISQLDBRows to access any resulting rows (if ExpectResults is TRUE), and provide basic garbage collection, as such:

```
procedure WriteFamily(const aName: RawUTF8);
var I: ISQLDBRows;
begin
  I := MyConnProps.Execute('select * from table where name=?',[aName]);
  while I.Step do
    writeln(I['FirstName'],' ',DateToStr(I['BirthDate']));
  I.ReleaseRows;
end;
```

- if RowsVariant is set, you can use it to row column access via late binding, as such:

```
procedure WriteFamily(const aName: RawUTF8);
var R: Variant;
begin
  with MyConnProps.Execute('select * from table where name=?',[aName],@R) do begin
    while Step do
      writeln(R.FirstName,' ',DateToStr(R.BirthDate));
    ReleaseRows;
  end;
end;
```

- you can any BLOB field to be returned as null with the ForceBlobAsNull optional parameter

function ExecuteInlined(const SQLFormat: RawUTF8; const Args: array of const; ExpectResults: Boolean): ISQLDBRows; overload;

Create, prepare, bound inlined parameters and execute a thread-safe statement

- overloaded method using FormatUTF8() and inlined parameters

function ExecuteInlined(const aSQL: RawUTF8; ExpectResults: Boolean): ISQLDBRows; overload;

Create, prepare, bound inlined parameters and execute a thread-safe statement

- this implementation will call the NewThreadSafeStatement virtual method, then bound inlined parameters as :(1234): and call its Execute method

- raise an exception on error

function ExecuteNoResult(const aSQL: RawUTF8; const Params: array of const): integer;

Execute a SQL query, without returning any rows

- can be used to launch INSERT, DELETE or UPDATE statement, e.g.

- will call NewThreadSafeStatement method to retrieve a thread-safe statement instance, then run the corresponding Execute() method

- return the number of modified rows, i.e. the ISQLDBStatement.UpdateCount value (or 0 if the DB driver does not supply this value)

class function GetFieldDefinition(**const** Column: TSQLDBColumnDefine): RawUTF8;

Get one field/column definition as text

- return column type as 'Name [Type Length Precision Scale]'

class function GetFieldORMDefinition(**const** Column: TSQLDBColumnDefine): RawUTF8;

Get one field/column definition as text, targeting a TSQLRecord published property

- return e.g. property type information as:

'Name: RawUTF8 read fName write fName index 20;';

function GetForeignKey(**const** aTableName, aColumnName: RawUTF8): RawUTF8;

Retrieve a foreign key for a specified table and column

- first time it is called, it will retrieve all foreign keys from the remote database using virtual protected GetForeignKeys method into the protected fForeignKeys list: this may be slow, depending on the database access (more than 10 seconds waiting is possible)

- any further call will use this internal list, so response will be immediate

- the whole foreign key list is shared by all connections

function IsCachable(P: PUTF8Char): boolean; **virtual**;

Determine if the SQL statement can be cached

- used by TSQLDBConnection.NewStatementPrepared() for handling cache

function IsSQLKeyword(aWord: RawUTF8): boolean; **overload**;

Check if the supplied text word is not a keyword for the current database engine

- just a wrapper around the overloaded class function

class function IsSQLKeyword(aDB: TSQLDBDefinition; aWord: RawUTF8): boolean; **overload**; **virtual**;

Check if the supplied text word is not a keyword for a given database engine

function NewConnection: TSQLDBConnection; **virtual**;

Create a new connection

- call this method if the shared MainConnection is not enough (e.g. for multi-thread access)

- the caller is responsible of freeing this instance

function NewThreadSafeStatement: TSQLDBStatement;

Create a new thread-safe statement

- this method will call ThreadSafeConnection.NewStatement

function NewThreadSafeStatementPrepared(**const** SQLFormat: RawUTF8; **const** Args: **array of const**; ExpectResults: Boolean; RaiseExceptionOnError: Boolean=false): TSQLDBStatement; **overload**;

Create a new thread-safe statement from an internal cache (if any)

- this method will call the overloaded NewThreadSafeStatementPrepared method

- here Args[] array does not refer to bound parameters, but to values to be changed within SQLFormat in place of '%' characters (this method will call FormatUTF8() internally); parameters will be bound directly on the returned TSQLDBStatement instance

- this method should return a prepared statement instance on success

- on error, returns nil and you can check Connection.LastErrorMessage /

Connection.LastErrorException to retrieve corresponding error information (if

RaiseExceptionOnError is left to default FALSE value, otherwise, it will raise an exception)

```
function NewThreadSafeStatementPrepared(const aSQL: RawUTF8; ExpectResults: Boolean; RaiseExceptionOnError: Boolean=false): ISQLDBStatement; overload;
```

Create a new thread-safe statement from an internal cache (if any)

- will call ThreadSafeConnection.NewStatementPrepared
- this method should return a prepared statement instance on success
- on error, returns nil and you can check Connection.LastErrorMessage / Connection.LastErrorException to retrieve corresponding error information (if RaiseExceptionOnError is left to default FALSE value, otherwise, it will raise an exception)

```
function PrepareInlined(const SQLFormat: RawUTF8; const Args: array of const; ExpectResults: Boolean): ISQLDBStatement; overload;
```

Create, prepare and bound inlined parameters to a thread-safe statement

- overloaded method using FormatUTF8() and inlined parameters
- consider using ExecuteInlined() for direct execution

```
function PrepareInlined(const aSQL: RawUTF8; ExpectResults: Boolean): ISQLDBStatement; overload;
```

Create, prepare and bound inlined parameters to a thread-safe statement

- this implementation will call the NewThreadSafeStatement virtual method, then bound inlined parameters as :(1234): and return the resulting statement
- raise an exception on error
- consider using ExecuteInlined() for direct execution

```
function SharedTransaction(SessionID: cardinal; action: TSQLDBSharedTransactionAction): TSQLDBConnection; virtual;
```

Handle a transaction process common to all associated connections

- could be used to share a single transaction among several connections, or to run nested transactions even on DB engines which do not allow them
- will use a simple reference counting mechanism to allow nested transactions, identified by a session identifier
- will fail if the same connection is not used for the whole process, which would induce a potentially incorrect behavior
- returns the connection corresponding to the session, nil on error

```
function SQLAddColumn(const aTableName: RawUTF8; const aField: TSQLDBColumnCreate): RawUTF8; virtual;
```

Returns the SQL statement used to add a column to a Table

- should return the SQL "ALTER TABLE" statement needed to add a column to an existing table
- this default implementation will use internal fSQLCreateField and fSQLCreateFieldMax protected values, which contains by default the ANSI SQL Data Types and maximum 1000 inlined WideChars: inherited classes may change the default fSQLCreateField* content or override this method

```
function SQLAddIndex(const aTableName: RawUTF8; const aFieldNames: array of RawUTF8; aUnique: boolean; aDescending: boolean=false; const aIndexName: RawUTF8=''): RawUTF8; virtual;
```

Returns the SQL statement used to add an index to a Table

- should return the SQL "CREATE INDEX" statement needed to add an index to the specified column names of an existing table
- index will expect UNIQUE values in the specified columns, if Unique parameter is set to true
- this default implementation will return the standard SQL statement, i.e. 'CREATE [UNIQUE] INDEX index_name ON table_name (column_name[s])'

```
function SQLCreate(const aTableName: RawUTF8; const aFields:  
TSQLDBColumnCreateDynArray; aAddID: boolean): RawUTF8; virtual;
```

Returns the SQL statement used to create a Table

- should return the SQL "CREATE" statement needed to create a table with the specified field/column names and types
- if aAddID is TRUE, "ID Int64 PRIMARY KEY" column is added as first, and will expect the ORM to create an unique RowID value sent at INSERT (could use "select max(ID) from table" to retrieve the last value) - note that 'ID' is used instead of 'RowID' since it fails on Oracle e.g.
- this default implementation will use internal fSQLCreateField and fSQLCreateFieldMax protected values, which contains by default the ANSI SQL Data Types and maximum 1000 inlined WideChars: inherited classes may change the default fSQLCreateField* content or override this method

```
function SQLCreateDatabase(const aDatabaseName: RawUTF8; aDefaultPageSize:  
integer=0): RawUTF8; virtual;
```

SQL statement to create the corresponding database

- this default implementation will only handle dFirebird by now

```
function SQLDateToIso8601Quoted(DateTime: TDateTime): RawUTF8; virtual;
```

Convert a TDateTime into a ISO-8601 encoded time and date, as expected by the database provider

- e.g. SQLite3, DB2 and PostgreSQL will use non-standard ' ' instead of 'T'

```
function SQLFullTableName(const aTableName: RawUTF8): RawUTF8; virtual;
```

Return the fully qualified SQL table name

- will use ForcedSchemaName property (if applying), or return aTableName
- you can override this method to force the expected format

```
function SQLIso8601ToDate(const Iso8601: RawUTF8): RawUTF8; virtual;
```

Convert an ISO-8601 encoded time and date into a date appropriate to be pasted in the SQL request

- this default implementation will return the quoted ISO-8601 value, i.e. 'YYYY-MM-DDTHH:MM:SS' (as expected by Microsoft SQL server e.g.)
- returns to_date('...', 'YYYY-MM-DD HH24:MI:SS') for Oracle

```
function SQLLimitClause(ASmt: TSynTableStatement): TSQLDBDefinitionLimitClause;  
virtual;
```

Returns the information to adapt the LIMIT # clause in the SQL SELECT statement to a syntax matching the underlying DBMS

- e.g. TSQLRestStorageExternal.AdaptSQLForEngineList() calls this to let TSQLRestServer.URI by-pass virtual table mechanism

```
function SQLSelectAll(const aTableName: RawUTF8; const aFields:  
TSQLDBColumnDefineDynArray; aExcludeTypes: TSQLDBFieldTypes): RawUTF8; virtual;
```

Used to compute a SELECT statement for the given fields

- should return the SQL "SELECT ... FROM ..." statement to retrieve the specified column names of an existing table
- by default, all columns specified in aFields[] will be available: it will return "SELECT * FROM TableName"
- but if you specify a value in aExcludeTypes, it will compute the matching column names to ignore those kind of content (e.g. [stBlob] to save time and space)

function SQLTableName(const aTableName: RawUTF8): RawUTF8; **virtual**;

Return a SQL table name with quotes if necessary

- can be used e.g. with SELECT statements
- you can override this method to force the expected format

function ThreadSafeConnection: TSQLDBConnection; **virtual**;

Get a thread-safe connection

- this default implementation will return the MainConnection shared instance, so the provider should be thread-safe by itself
- TSQLDBConnectionPropertiesThreadSafe will implement a per-thread connection pool, via an internal TSQLDBConnection pool, per thread if necessary (e.g. for OleDb, which expect one TOleDbConnection instance per thread)

procedure ClearConnectionPool; **virtual**;

Release all existing connections

- can be called e.g. after a DB connection problem, to purge the connection pool, and allow automatic reconnection
- is called automatically if ConnectionTimeOutMinutes property is set
- warning: no connection shall still be used on the background (e.g. in multi-threaded applications), or some unexpected border effects may occur

procedure DefinitionTo(Definition: TSynConnectionDefinition); **virtual**;

Save the properties into a persistent storage object

- you can use TSQLDBConnectionPropertiesDescription.CreateFrom() later on to instantiate the proper TSQLDBConnectionProperties class
- current Definition.Key value will be used for the password encryption

procedure DefinitionToFile(const aJSONFile: TFileName; Key: cardinal=0);

Save the properties into a JSON file

- you could use TSQLDBConnectionPropertiesDescription.CreateFromFile() later on to instantiate the proper TSQLDBConnectionProperties class
- you can specify a custom Key, if the default is not enough for you

procedure GetFieldDefinitions(const aTableName: RawUTF8; out Fields: TRawUTF8DynArray; WithForeignKeys: boolean);

Get all field/column definition for a specified Table as text

- call the GetFields method and retrieve the column field name and type as 'Name [Type Length Precision Scale]'
- if WithForeignKeys is set, will add external foreign keys as '% tablename'

procedure GetFields(const aTableName: RawUTF8; out Fields: TSQLDBColumnDefineDynArray); **virtual**;

Retrieve the column/field layout of a specified table

- this default implementation will use protected SQLGetField virtual method to retrieve the field names and properties
- used e.g. by GetFieldDefinitions
- will call ColumnTypeNativeToDB protected virtual method to guess the each mORMot TSQLDBFieldType

```
procedure GetIndexes(const aTableName: RawUTF8; out Indexes:  
TSQLDBIndexDefineDynArray); virtual;
```

Retrieve the advanced indexed information of a specified Table

- this default implementation will use protected SQLGetIndex virtual method to retrieve the index names and properties
- currently only MS SQL and Oracle are supported

```
procedure GetProcedureNames(out Procedures: TRawUTF8DynArray); virtual;
```

Retrieve a list of stored procedure names from current connection

```
procedure GetProcedureParameters(const aProcName: RawUTF8; out Parameters:  
TSQLDBProcColumnDefineDynArray); virtual;
```

Retrieve procedure input/output parameter information

- aProcName: stored procedure name to retrieve parameter information.
- Parameters: parameter list info (name, datatype, direction, default)

```
procedure GetTableNames(out Tables: TRawUTF8DynArray); virtual;
```

Get all table names

- this default implementation will use protected SQLGetTableNames virtual method to retrieve the table names

```
procedure GetViewNames(out Views: TRawUTF8DynArray); virtual;
```

Get all view names

- this default implementation will use protected SQLGetViewNames virtual method to retrieve the view names

```
procedure SQLSplitProcedureName(const aProcName: RawUTF8; out Owner, Package,  
ProcName: RawUTF8); virtual;
```

Split a procedure name to its OWNER.PACKAGE.PROCEDURE full name (if applying)

- will use ForcedSchemaName property (if applying), or the OWNER. already available within the supplied table name

```
procedure SQLSplitTableName(const aTableName: RawUTF8; out Owner, Table: RawUTF8);  
virtual;
```

Split a table name to its OWNER.TABLE full name (if applying)

- will use ForcedSchemaName property (if applying), or the OWNER. already available within the supplied table name

```
property BatchMaxSentAtOnce: integer read fBatchMaxSentAtOnce write  
fBatchMaxSentAtOnce;
```

The maximum number of rows to be transmitted at once for batch sending

- e.g. Oracle handles array DML operation with iters <= 32767 at best
- if OnBatchInsert points to MultipleValuesInsert(), this value is ignored, and the maximum number of parameters is guessed per DBMS type

```
property BatchSendingAbilities: TSQLDBStatementCRUDs read fBatchSendingAbilities;
```

The abilities of the database for batch sending

- e.g. Oracle will handle array DML binds, or MS SQL bulk insert

property ConnectionTimeoutMinutes: cardinal **read** GetConnectionTimeoutMinutes **write** SetConnectionTimeoutMinutes;

Specify a maximum period of inactivity after which all connections will be flushed and recreated, to avoid potential broken connections issues

- in practice, recreating the connections after a while is safe and won't slow down the process - on the contrary, it may help reducing the consumed resources, and stabilize long running n-Tier servers

- ThreadSafeConnection method will check for the last activity on this TSQLDBConnectionProperties instance, then call ClearConnectionPool to release all active connections if the idle time elapsed was too long

- warning: no connection shall still be used on the background (e.g. in multi-threaded applications), or some unexpected issues may occur - for instance, ensure that your mORMot ORM server runs all its statements in blocking mode for both read and write:

```
aServer.AcquireExecutionMode[execORMGet] := am***;  
aServer.AcquireExecutionMode[execORMWrite] := am***;
```

here, safe blocking am*** modes are any mode but amUnlocked, i.e. either amLocked, amBackgroundThread or amMainThread

property DatabaseName: RawUTF8 **read** fDatabaseName;

The associated database name, as specified at creation

- not published, for security reasons (may be serialized otherwise)
- DatabaseNameSafe will be published, and delete any matching PasswordValue in DatabaseName

property DatabaseNameSafe: RawUTF8 **read** GetDatabaseNameSafe;

The associated database name, safely trimmed from the password

- would replace any matching Password value content from DatabaseName by '***' for security reasons, e.g. before serialization

property DateTimeFirstChar: AnsiChar **read** fDateTimeFirstChar **write** fDateTimeFirstChar;

Customize the ISO-8601 text format expected by the database provider

- is 'T' by default, as expected by the ISO-8601 standard
- will be changed e.g. for PostgreSQL, which expects ' ' instead
- as used by SQLDateToISO8601Quoted() and BindArray()

property DBMS: TSQLDBDefinition **read** GetDBMS;

The remote DBMS type, as stated by the inheriting class itself, or retrieved at connecton time (e.g. for ODBC)

property DBMSEngineName: RawUTF8 **read** GetDBMSName;

The remote DBMS type name, retrieved as text from the DBMS property

property Engine: RawUTF8 **read** fEngineName;

Return the database engine name, as computed from the class name

- 'TSQLDBConnectionProperties' will be trimmed left side of the class name

property ExecuteWhenConnected: TRawUTF8DynArray **read** fExecuteWhenConnected **write** fExecuteWhenConnected;

SQL statements what will be executed for each new connection usage scenarios examples:

- Oracle: force case-insensitive like
['ALTER SESSION SET NLS_COMP=LINGUISTIC', 'ALTER SESSION SET NLS_SORT=BINARY_CI']
- Postgres: disable notices and warnings
['SET client_min_messages to ERROR']
- SQLite3: turn foreign keys ON
['PRAGMA foreign_keys = ON']

property FilterTableViewSchemaName: boolean **read** fFilterTableViewSchemaName **write** fFilterTableViewSchemaName;

If GetTableNames/GetViewNames should only return the table names starting with 'ForcedSchemaName.' prefix

property ForcedSchemaName: RawUTF8 **read** fForcedSchemaName **write** fForcedSchemaName;

An optional Schema name to be used for SQLGetField() instead of UserID

- by default, UserID will be used as schema name, if none is specified (i.e. if table name is not set as SCHEMA.TABLE)
- depending on the DBMS identified, the class may also set automatically the default 'dbo' for MS SQL or 'public' for PostgreSQL
- you can set a custom schema to be used instead

property ForeignKeysData: RawByteString **read** GetForeignKeysData **write** SetForeignKeysData;

Can be used to store the fForeignKeys[] data in an external BLOB

- since GetForeignKeys can be (somewhat) slow, could save a lot of time

property LoggedSQLMaxSize: integer **read** fLoggedSQLMaxSize **write** fLoggedSQLMaxSize;

The maximum size, in bytes, of logged SQL statements

- setting 0 will log statement and parameters with no size limit
- setting -1 will log statement without any parameter value (just ?)
- setting any value >0 will log statement and parameters up to the number of bytes (default set to 2048 to log up to 2KB per statement)

property LogSQLStatementOnException: boolean **read** fLogSQLStatementOnException **write** fLogSQLStatementOnException;

Allow to log the SQL statement when any low-level ESQLErrorException is raised

property MainConnection: TSQLDBConnection **read** GetMainConnection;

Return a shared connection, corresponding to the given database

- call the ThreadSafeConnection method instead e.g. for multi-thread access, or NewThreadSafeStatement for direct retrieval of a new statement

property OnBatchInsert: TOnBatchInsert **read** fOnBatchInsert **write** fOnBatchInsert;

You can define a callback method able to handle multiple INSERT

- may execute e.g. INSERT with multiple VALUES (like MySQL, MSSQL, NexusDB, PostgreSQL or SQLite3), as defined by MultipleValuesInsert() callback

property OnProcess: TOnSQLDBProcess **read** fOnProcess **write** fOnProcess;

This event handler will be called during all process

- can be used e.g. to change the desktop cursor, or be notified on connection/disconnection/reconnection
- you can override this property directly in the TSQLDBConnection

property OnStatementInfo: TOnSQLDBInfo **read** fOnStatementInfo **write** fOnStatementInfo;

This event handler will be called when statements trigger some low-level information

property PassWord: RawUTF8 **read** fPassWord;

The associated User Password, as specified at creation

- not published, for security reasons (may be serialized otherwise)

property ReconnectAfterConnectionError: boolean **read** fReconnectAfterConnectionError **write** fReconnectAfterConnectionError;

Intercept connection errors at statement preparation and try to reconnect

- i.e. detect TSQLDBConnection.LastErrorWasAboutConnection in TSQLDBConnection.NewStatementPrepared
- warning: no connection shall still be used on the background (e.g. in multi-threaded applications), or some unexpected issues may occur - see AcquireExecutionMode[] recommendations in ConnectionTimeoutMinutes

property RollbackOnDisconnect: Boolean **read** fRollbackOnDisconnect **write** fRollbackOnDisconnect;

Defines if TSQLDBConnection.Disconnect shall Rollback any pending transaction

- some engines executes a COMMIT when the client is disconnected, others do raise an exception: this parameter ensures that any pending transaction is roll-backed before disconnection
- is set to TRUE by default

property ServerName: RawUTF8 **read** fServerName;

The associated server name, as specified at creation

property StatementCacheReplicates: integer **read** fStatementCacheReplicates **write** fStatementCacheReplicates;

If UseCache is true, how many statement replicates can be generated if the cached ISQLDBStatement is already used

- such replication is normally not needed in a per-thread connection, unless ISQLDBStatement are not released as soon as possible
- above this limit, no cache will be made, and a dedicated single-time statement will be prepared
- default is 0 to cache statements once - but you may try to increase this value if you run identical SQL with long-standing ISQLDBStatement; or you can set -1 if you don't want the warning log to appear

property StatementMaxMemory: Int64 **read** fStatementMaxMemory **write** fStatementMaxMemory;

Maximum bytes allowed for FetchAllToJSON/FetchAllToBinary methods

- if a result set exceeds this limit, an ESQLDBException is raised
- default is 512 shl 20, i.e. 512MB which is very high
- avoid unexpected OutOfMemory errors when incorrect statement is run

property StoreVoidStringAsNull: Boolean **read** fStoreVoidStringAsNull **write** fStoreVoidStringAsNull;

Defines if " string values are to be stored as SQL null

- by default, " will be stored as "
- but some DB engines (e.g. Jet or MS SQL) does not allow by default to store " values, but expect NULL to be stored instead

property UseCache: boolean **read** fUseCache **write** fUseCache;

TRUE if an internal cache of SQL statement should be used

- cache will be accessed for NewStatementPrepared() method only, by returning ISQLDBStatement interface instances
- default value is TRUE for faster process (e.g. TTestSQLite3ExternalDB regression tests will be two times faster with statement caching)
- will cache only statements containing ? parameters or a SELECT with no WHERE clause within

property UserID: RawUTF8 **read** fUserID;

The associated User Identifier, as specified at creation

property VariantStringAsWideString: boolean **read** fVariantWideString **write** fVariantWideString;

Set to true to force all variant conversion to WideString instead of the default faster AnsiString, for pre-Unicode version of Delphi

- by default, the conversion to Variant will create an AnsiString kind of variant: for pre-Unicode Delphi, avoiding WideString/OleStr content will speed up the process a lot, if you are sure that the current charset matches the expected one (which is very likely)
- set this property to TRUE so that the conversion to Variant will create a WideString kind of variant, to avoid any character data loss: the access to the property will be slower, but you won't have any potential data loss
- starting with Delphi 2009, the TEXT content will be stored as an UnicodeString in the variant, so this property is not necessary
- the Variant conversion is mostly used for the TQuery wrapper, or for the ISQLDBRows.Column[] property or ISQLDBRows.ColumnVariant() method; this won't affect other Column*() methods, or JSON production

TSQLDBProxyConnectionProtocol = class(TObject)

Server-side implementation of a proxy connection to any SynDB engine

- this default implementation will send the data without compression, digital signature, nor encryption
- inherit from this class to customize the transmission layer content

constructor Create(aAuthenticate: TSynAuthenticationAbstract); **reintroduce;**

Initialize a protocol, with a given authentication scheme

- if no authentication is given, none will be processed

destructor Destroy; **override;**

Release associated authentication class

property Authenticate: TSynAuthenticationAbstract **read** GetAuthenticate **write** fAuthenticate;

The associated authentication information

- you can manage users via AuthenticateUser/DisauthenticateUser methods

TSQLDBRemoteConnectionProtocol = class(TSQLDBProxyConnectionProtocol)

Server-side implementation of a remote connection to any SynDB engine

- implements digitally signed SynLZ-compressed binary message format, with simple symmetric encryption, as expected by SynDBRemote.pas

TSQLDBConnection = class(TObject)

Abstract connection created from TSQLDBConnectionProperties

- more than one TSQLDBConnection instance can be run for the same TSQLDBConnectionProperties

constructor Create(aProperties: TSQLDBConnectionProperties); **virtual;**

Connect to a specified database engine

destructor Destroy; **override;**

Release memory and connection

function IsConnected: boolean; **virtual; abstract;**

Return TRUE if Connect has been already successfully called

function NewStatement: TSQLDBStatement; **virtual; abstract;**

Initialize a new SQL query statement for the given connection

- the caller should free the instance after use

function NewStatementPrepared(const aSQL: RawUTF8; ExpectResults: Boolean; RaiseExceptionOnError: Boolean=false; AllowReconnect: Boolean=true): TSQLDBStatement; **virtual;**

Initialize a new SQL query statement for the given connection

- this default implementation will call the NewStatement method, and implement handle statement caching is UseCache=true - in this case, the TSQLDBStatement.Reset method shall have been overridden to allow binding and execution of the very same prepared statement
 - the same aSQL can cache up to 9 statements in this TSQLDBConnection
 - this method should return a prepared statement instance on success
 - on error, if RaiseExceptionOnError=false (by default), it returns nil and you can check LastErrorMessage and LastErrorException properties to retrieve corresponding error information
 - if TSQLDBConnectionProperties.ReconnectAfterConnectionError is set, any connection error will be trapped, unless AllowReconnect is false
 - on error, if RaiseExceptionOnError=true, an exception is raised

function NewTableFromRows(const TableName: RawUTF8; Rows: TSQLDBStatement; WithinTransaction: boolean; ColumnForcedTypes: TSQLDBFieldTypeDynArray=nil): integer;

Direct export of a DB statement rows into a new table of this database

- the corresponding table will be created within the current connection, if it does not exist
 - if the column types are not set, they will be identified from the first row of data
 - INSERTs will be nested within a transaction if WithinTransaction is TRUE
 - will raise an Exception in case of error

procedure Commit; virtual;

Commit changes of a Transaction for this connection

- StartTransaction method must have been called before
- this default implementation will check and set TransactionCount

procedure Connect; virtual;

Connect to the specified database

- should raise an Exception on error
- this default implementation will notify OnProgress callback for successful re-connection: it should be called in overridden methods AFTER actual connection process

procedure Disconnect; virtual;

Stop connection to the specified database

- should raise an Exception on error
- this default implementation will release all cached statements: so it should be called in overridden methods BEFORE actual disconnection

procedure RemoteProcessMessage(const Input: RawByteString; out Output: RawByteString; Protocol: TSQldbProxyConnectionProtocol); virtual;

Server-side implementation of a remote connection to any SynDB engine

- follow the compressed binary message format expected by the TSQldbRemoteConnectionPropertiesAbstract.ProcessMessage method
- any transmission protocol could call this method to execute the corresponding TSQldbProxyConnectionCommand on the current connection

procedure Rollback; virtual;

Discard changes of a Transaction for this connection

- StartTransaction method must have been called before
- this default implementation will check and set TransactionCount

procedure StartTransaction; virtual;

Begin a Transaction for this connection

- this default implementation will check and set TransactionCount

property Connected: boolean read IsConnected;

Returns TRUE if the connection was set

property InTransaction: boolean read GetInTransaction;

TRUE if StartTransaction has been called

- check if TransactionCount>0

property LastErrorException: ExceptClass read fErrorException;

Some error exception, e.g. during execution of NewStatementPrepared

property LastErrorMessage: RawUTF8 read fErrorMessage write fErrorMessage;

Some error message, e.g. during execution of NewStatementPrepared

property LastErrorWasAboutConnection: boolean read GetLastErrorWasAboutConnection;

TRUE if last error is a broken connection, e.g. during execution of NewStatementPrepared

- i.e. LastErrorException/LastErrorMessage concerns the database connection
- will use TSQldbConnectionProperties.ExceptionIsAboutConnection virtual method

property OnProcess: TOnSQLDBProcess **read** fOnProcess **write** fOnProcess;

This event handler will be called during all process

- can be used e.g. to change the desktop cursor
- by default, will follow TSQLDBConnectionProperties.OnProcess property

property Properties: TSQLDBConnectionProperties **read** fProperties;

The associated database properties

property RollbackOnDisconnect: Boolean **read** fRollbackOnDisconnect **write** fRollbackOnDisconnect;

Defines if Disconnect shall Rollback any pending transaction

- some engines executes a COMMIT when the client is disconnected, others do raise an exception: this parameter ensures that any pending transaction is roll-backed before disconnection
- is set to TRUE by default

property ServerDateTime: TDateTime **read** GetServerDateTime;

The current Date and Time, as retrieved from the server

- note that this value is the DB_SERVERTIME[] constant SQL value, so will most likely return a local time, not an UTC time
- this property will return the value as regular TDateTime

property ServerTimestamp: TTimeLog **read** GetServerTimestamp;

The current Date and Time, as retrieved from the server

- note that this value is the DB_SERVERTIME[] constant SQL value, so will most likely return a local time, not an UTC time
- this property will return the timestamp in TTimeLog / TTimeLogBits / Int64 value

property ServerTimestampAtConnection: TDateTime **read** fServerTimestampAtConnection;

The time returned by the server when the connection occurred

property TotalConnectionCount: integer **read** fTotalConnectionCount;

Number of successful connections for this instance

- can be greater than 1 in case of re-connection via Disconnect/Connect

property TransactionCount: integer **read** fTransactionCount;

Number of nested StartTransaction calls

- equals 0 if no transaction is active

TSQLDBStatement = class(TInterfacedObject)

Generic abstract class to implement a prepared SQL query

- inherited classes should implement the DB-specific connection in its overridden methods, especially Bind*(), Prepare(), ExecutePrepared, Step() and Column*() methods

constructor Create(aConnection: TSQLDBConnection); **virtual**;

Create a statement instance

function BoundCursor(Param: Integer): ISQLDBRows; **virtual**;

Return a special CURSOR parameter content as a SynDB result set

- this method is not about a column, but a parameter defined with BindCursor() before method execution
- Cursors are not handled internally by mORMot, but some databases (e.g. Oracle) usually use such structures to get data from stored procedures
- this method allow direct access to the data rows after execution
- this default method will raise an exception about unexpected behavior

function ColumnBlob(Col: integer): RawByteString; overload; **virtual**; **abstract**;

Return a Column as a blob value of the current Row, first Col is 0

function ColumnBlob(const ColName: RawUTF8): RawByteString; overload;

Return a Column as a blob value of the current Row, from a supplied column name

function ColumnBlobBytes(const ColName: RawUTF8): TBytes; overload;

Return a Column as a blob value of the current Row, from a supplied column name

function ColumnBlobBytes(Col: integer): TBytes; overload; **virtual**;

Return a Column as a blob value of the current Row, first Col is 0

- this function will return the BLOB content as a TBytes
- this default virtual method will call ColumnBlob()

function ColumnCount: integer;

The column/field count of the current Row

function ColumnCurrency(const ColName: RawUTF8): currency; overload;

Return a Column currency value of the current Row, from a supplied column name

function ColumnCurrency(Col: integer): currency; overload; **virtual**; **abstract**;

Return a Column currency value of the current Row, first Col is 0

function ColumnCursor(const ColName: RawUTF8): ISQLDBRows; overload;

Return a special CURSOR Column content as a SynDB result set

- Cursors are not handled internally by mORMot, but some databases (e.g. Oracle) usually use such structures to get data from stored procedures
- such columns are mapped as ftNull internally - so this method is the only one giving access to the data rows
- this default method will raise an exception about unexpected behavior

function ColumnCursor(Col: integer): ISQLDBRows; overload; **virtual**;

Return a special CURSOR Column content as a SynDB result set

- Cursors are not handled internally by mORMot, but some databases (e.g. Oracle) usually use such structures to get data from stored procedures
- such columns are mapped as ftNull internally - so this method is the only one giving access to the data rows
- this default method will raise an exception about unexpected behavior

function ColumnDateTime(const ColName: RawUTF8): TDateTime; overload;

Return a Column date and time value of the current Row, from a supplied column name

function ColumnDateTime(Col: integer): TDateTime; overload; **virtual**; **abstract**;

Return a Column date and time value of the current Row, first Col is 0

function ColumnDouble(**const** ColName: RawUTF8): double; overload;

Return a Column floating point value of the current Row, from a supplied column name

function ColumnDouble(Col: integer): double; overload; **virtual; abstract;**

Return a Column floating point value of the current Row, first Col is 0

function ColumnIndex(**const** aColumnName: RawUTF8): integer; **virtual; abstract;**

Returns the Column index of a given Column name

- Columns numeration (i.e. Col value) starts with 0

- returns -1 if the Column name is not found (via case insensitive search)

function ColumnInt(Col: integer): Int64; overload; **virtual; abstract;**

Return a Column integer value of the current Row, first Col is 0

function ColumnInt(**const** ColName: RawUTF8): Int64; overload;

Return a Column integer value of the current Row, from a supplied column name

function ColumnName(Col: integer): RawUTF8; **virtual; abstract;**

The Column name of the current Row

- Columns numeration (i.e. Col value) starts with 0

- it's up to the implementation to ensure than all column names are unique

function ColumnNull(Col: integer): boolean; **virtual; abstract;**

Returns TRUE if the column contains NULL

function ColumnsToSQLInsert(**const** TableName: RawUTF8; **var** Fields:
TSQLDBColumnCreateDynArray): RawUTF8; **virtual;**

Compute the SQL INSERT statement corresponding to this columns row

- and populate the Fields[] array with columns information (type and name)

- if the current column value is NULL, will return ftNull: it is up to the caller to set the proper field type

- the SQL statement is prepared with bound parameters, e.g.

insert into TableName (Col1,Col2) values (?,N)

- used e.g. to convert some data on the fly from one database to another, via the
TSQLDBConnection.NewTableFromRows method

function ColumnString(Col: integer): **string;** overload; **virtual;**

Return a Column text value as generic VCL string of the current Row, first Col is 0

- this default implementation will call ColumnUTF8

function ColumnString(**const** ColName: RawUTF8): **string;** overload;

Return a Column text value as generic VCL string of the current Row, from a supplied column name

function ColumnTimestamp(**const** ColName: RawUTF8): TTimeLog; overload;

Return a column date and time value of the current Row, from a supplied column name

- call ColumnDateTime or ColumnUTF8 to convert into TTimeLogBits/Int64 time stamp from a
TDateTime or text

function ColumnTimestamp(Col: integer): TTimeLog; overload;

Return a column date and time value of the current Row, first Col is 0

- call ColumnDateTime or ColumnUTF8 to convert into TTimeLogBits/Int64 time stamp from a
TDateTime or text

```
function ColumnToVariant(Col: integer; var Value: Variant): TSQLDBFieldType;  
virtual;
```

Return a Column as a variant, first Col is 0

- this default implementation will call Column*() method above
- a ftUTF8 TEXT content will be mapped into a generic WideString variant for pre-Unicode version of Delphi, and a generic UnicodeString (=string) since Delphi 2009: you may not loose any data during charset conversion
- a ftBlob BLOB content will be mapped into a TBlobData AnsiString variant

```
function ColumnType(Col: integer; FieldSize: PInteger=nil): TSQLDBFieldType;  
virtual; abstract;
```

The Column type of the current Row

- FieldSize can be set to store the size in chars of a ftUTF8 column (0 means BLOB kind of TEXT column)

```
function ColumnUTF8(Col: integer): RawUTF8; overload; virtual; abstract;
```

Return a Column UTF-8 encoded text value of the current Row, first Col is 0

```
function ColumnUTF8(const ColName: RawUTF8): RawUTF8; overload;
```

Return a Column UTF-8 encoded text value of the current Row, from a supplied column name

```
function ColumnVariant(Col: integer): Variant; overload;
```

Return a Column as a variant, first Col is 0

- this default implementation will call ColumnToVariant() method
- a ftUTF8 TEXT content will be mapped into a generic WideString variant for pre-Unicode version of Delphi, and a generic UnicodeString (=string) since Delphi 2009: you may not loose any data during charset conversion
- a ftBlob BLOB content will be mapped into a TBlobData AnsiString variant

```
function ColumnVariant(const ColName: RawUTF8): Variant; overload;
```

Return a Column as a variant, from a supplied column name

```
function FetchAllAsJSON(Expanded: boolean; ReturnedRowCount: PPtrInt=nil):  
RawUTF8;
```

Return all rows content as a JSON string

- JSON data is retrieved with UTF-8 encoding
- if Expanded is true, JSON data is an array of objects, for direct use with any Ajax or .NET client:
[{"col1":val11,"col2":"val12"}, {"col1":val21,...}]
- if Expanded is false, JSON data is serialized (used in TSQLTableJSON)
{ "FieldCount":1,"Values":["col1","col2",val11,"val12",val21,...] }
- BLOB field value is saved as Base64, in the ""\uFFFF0base64encodedbinary"" format and contains true BLOB data
- if ReturnedRowCount points to an integer variable, it will be filled with the number of row data returned (excluding field names)
- similar to corresponding TSQLRequest.Execute method in SynSQLite3 unit

function FetchAllToBinary(Dest: TStream; MaxRowCount: cardinal=0; DataRowPosition: PCardinalDynArray=nil): cardinal; **virtual**;

Append all rows content as binary stream

- will save the column types and name, then every data row in optimized binary format (faster and smaller than JSON)
- you can specify a LIMIT for the data extent (default 0 meaning all data)
- generates the format expected by TSQLDBProxyStatement

function FetchAllToCSVValues(Dest: TStream; Tab: boolean; CommaSep: AnsiChar=','; AddBOM: boolean=true): PtrInt;

Append all rows content as a CSV stream

- CSV data is added to the supplied TStream, with UTF-8 encoding
- if Tab=TRUE, will use TAB instead of ',' between columns
- you can customize the ',' separator - use e.g. the global ListSeparator variable (from SysUtils) to reflect the current system definition (some country use ',' as decimal separator, for instance our "douce France")
- AddBOM will add a UTF-8 Byte Order Mark at the beginning of the content
- BLOB fields will be appended as "blob" with no data
- returns the number of row data returned

function FetchAllToJSON(JSON: TStream; Expanded: boolean): PtrInt;

Append all rows content as a JSON stream

- JSON data is added to the supplied TStream, with UTF-8 encoding
- if Expanded is true, JSON data is an array of objects, for direct use with any Ajax or .NET client:
[{ "col1":val11, "col2": "val12" }, { "col1":val21, ... }]
- if Expanded is false, JSON data is serialized (used in TSQLTableJSON)
{ "FieldCount":1, "Values": ["col1", "col2", val11, "val12", val21, ...] }
- BLOB field value is saved as Base64, in the ""\uFFFF0base64encodedbinary"" format and contains true BLOB data
- similar to corresponding TSQLRequest.Execute method in SynSQLite3 unit
- returns the number of row data returned (excluding field names)
- warning: TSQLRestStorageExternal.EngineRetrieve in mORMotDB unit expects the Expanded=true format to return '[{...}]'#10

function ParamToVariant(Param: Integer; var Value: Variant; CheckIsOutParameter: boolean=true): TSQLDBFieldType; **virtual**;

Retrieve the parameter content, after SQL execution

- the leftmost SQL parameter has an index of 1
- to be used e.g. with stored procedures:

```

query := 'BEGIN TEST_PKG.DUMMY(?, ?, ?, ?, ?); END;';
stmt := Props.NewThreadSafeStatementPrepared(query, false);
stmt.Bind(1, in1, paramIn);
stmt.BindTextU(2, in2, paramIn);
stmt.BindTextU(3, in3, paramIn);
stmt.BindTextS(4, '', paramOut); // to be retrieved with out1: string
stmt.Bind(5, 0, paramOut);       // to be retrieved with out2: integer
stmt.ExecutePrepared;
stmt.ParamToVariant(4, out1, true);
stmt.ParamToVariant(5, out2, true);

```

- the parameter should have been bound with IO=paramOut or IO=paramInOut if CheckIsOutParameter is TRUE
- this implementation just check that Param is correct: overridden method should fill Value content

function RowData: Variant; virtual;

Create a TSQLDBRowVariantType able to access any field content via late binding

- i.e. you can use Data.Name to access the 'Name' column of the current row
- this Variant will point to the corresponding TSQLDBStatement instance, so it's not necessary to retrieve its value for each row
- typical use is:

```
var Row: Variant;
(...)
with MyConnProps.Execute('select * from table where name=?',[aName]) do begin
  Row := RowDaa;
  while Step do
    writeln(Row.FirstName,Row.BirthDate);
  ReleaseRows;
end;
```

function Step(SeekFirst: boolean=false): boolean; virtual; abstract;

After a statement has been prepared via Prepare() + ExecutePrepared() or Execute(), this method must be called one or more times to evaluate it

- you shall call this method before calling any Column*() methods
- return TRUE on success, with data ready to be retrieved by Column*()
- return FALSE if no more row is available (e.g. if the SQL statement is not a SELECT but an UPDATE or INSERT command)
- access the first or next row of data from the SQL Statement result: if SeekFirst is TRUE, will put the cursor on the first row of results, otherwise, it will fetch one row of data, to be called within a loop
- should raise an Exception on any error
- typical use may be (see also e.g. the mORMotDB unit):

```
var Query: TSQLDBStatement;
begin
  Query := Props.NewThreadSafeStatementPrepared('select AccountNumber from Sales.Customer
where AccountNumber like ?', ['AW000001%'],true);
  if Query<>nil then begin
    assert(SameTextU(Query.ColumnName(0),'AccountNumber'));
    while Query.Step do // Loop through all matching data rows
      assert(Copy(Query.ColumnUTF8(0),1,8)='AW000001');
    Query.ReleaseRows;
  end;
end;
```

function UpdateCount: integer; virtual;

Gets a number of updates made by latest executed statement

- default implementation returns 0

procedure Bind(Param: Integer; Value: double; IO: TSQLDBParamInOutType=paramIn); overload; virtual; abstract;

Bind a double value to a parameter

- the leftmost SQL parameter has an index of 1

```
procedure Bind(const Params: array of const; IO: TSQLDBParamInOutType=paramIn);  
overload; virtual;
```

Bind an array of const values

- parameters marked as ? should be specified as method parameter in Params[]
- BLOB parameters can be bound with this method, when set after encoding via BinToBase64WithMagic() call
- TDateTime parameters can be bound with this method, when encoded via a DateToSQL() or DateTimeToSQL() call
- any variant parameter will be bound with BindVariant(i,VVariant^,true,IO) i.e. with DataIsBlob=true
- this default implementation will call corresponding Bind*() method

```
procedure Bind(Param: Integer; ParamType: TSQLDBFieldType; const Value: RawUTF8;  
ValueAlreadyUnquoted: boolean; IO: TSQLDBParamInOutType=paramIn); overload;  
virtual;
```

Bind one RawUTF8 encoded value

- the leftmost SQL parameter has an index of 1
- the value should match the BindArray() format, i.e. be stored as in SQL (i.e. number, 'quoted string', 'YYYY-MM-DD hh:mm:ss', null) - e.g. as computed by TJSONObjectDecoder.Decode()

```
procedure Bind(Param: Integer; const Data: TSQLVar; IO:  
TSQLDBParamInOutType=paramIn); overload; virtual;
```

Bind one TSQLVar value

- the leftmost SQL parameter has an index of 1
- this default implementation will call corresponding Bind*() method

```
procedure Bind(Param: Integer; Value: Int64; IO: TSQLDBParamInOutType=paramIn);  
overload; virtual; abstract;
```

Bind an integer value to a parameter

- the leftmost SQL parameter has an index of 1

```
procedure BindArray(Param: Integer; const Values: array of double); overload;  
virtual;
```

Bind an array of double values to a parameter

- the leftmost SQL parameter has an index of 1
- this default implementation will raise an exception if the engine does not support array binding

```
procedure BindArray(Param: Integer; ParamType: TSQLDBFieldType; const Values:  
TRawUTF8DynArray; ValuesCount: integer); overload; virtual;
```

Bind an array of values to a parameter

- the leftmost SQL parameter has an index of 1
- values are stored as in SQL (i.e. number, 'quoted string', 'YYYY-MM-DD hh:mm:ss', null)
- this default implementation will raise an exception if the engine does not support array binding

```
procedure BindArray(Param: Integer; const Values: array of Int64); overload;  
virtual;
```

Bind an array of integer values to a parameter

- the leftmost SQL parameter has an index of 1
- this default implementation will raise an exception if the engine does not support array binding

```
procedure BindArray(Param: Integer; const Values: array of RawUTF8); overload;  
virtual;
```

Bind an array of RawUTF8 values to a parameter

- the leftmost SQL parameter has an index of 1
- values are stored as in SQL (i.e. 'quoted string')
- this default implementation will raise an exception if the engine does not support array binding

```
procedure BindArrayCurrency(Param: Integer; const Values: array of currency);  
virtual;
```

Bind an array of currency values to a parameter

- the leftmost SQL parameter has an index of 1
- this default implementation will raise an exception if the engine does not support array binding

```
procedure BindArrayDateTime(Param: Integer; const Values: array of TDateTime);  
virtual;
```

Bind an array of TDateTime values to a parameter

- the leftmost SQL parameter has an index of 1
- values are stored as in SQL (i.e. 'YYYY-MM-DD hh:mm:ss')
- this default implementation will raise an exception if the engine does not support array binding

```
procedure BindBlob(Param: Integer; Data: pointer; Size: integer; IO:  
TSQLDBParamInOutType=paramIn); overload; virtual; abstract;
```

Bind a Blob buffer to a parameter

- the leftmost SQL parameter has an index of 1

```
procedure BindBlob(Param: Integer; const Data: RawByteString; IO:  
TSQLDBParamInOutType=paramIn); overload; virtual; abstract;
```

Bind a Blob buffer to a parameter

- the leftmost SQL parameter has an index of 1

```
procedure BindCurrency(Param: Integer; Value: currency; IO:  
TSQLDBParamInOutType=paramIn); overload; virtual; abstract;
```

Bind a currency value to a parameter

- the leftmost SQL parameter has an index of 1

```
procedure BindCursor(Param: integer); virtual;
```

Bind a special CURSOR parameter to be returned as a SynDB result set

- Cursors are not handled internally by mORMot, but some databases (e.g. Oracle) usually use such structures to get data from stored procedures
- such parameters are mapped as ftUnknown
- use BoundCursor() method to retrieve the corresponding ISQLDBRows after execution of the statement
- this default method will raise an exception about unexpected behavior

```
procedure BindDateTime(Param: Integer; Value: TDateTime; IO:  
TSQLDBParamInOutType=paramIn); overload; virtual; abstract;
```

Bind a TDateTime value to a parameter

- the leftmost SQL parameter has an index of 1

```
procedure BindFromRows(const Fields: TSQLDBFieldTypeDynArray; Rows: TSQLDBStatement);
```

Bind an array of fields from an existing SQL statement

- can be used e.g. after ColumnsToSQLInsert() method call for fast data conversion between tables

```
procedure BindNull(Param: Integer; IO: TSQLDBParamInOutType=paramIn; BoundType: TSQLDBFieldType=ftNull); virtual; abstract;
```

Bind a NULL value to a parameter

- the leftmost SQL parameter has an index of 1

- some providers (e.g. OleDb during MULTI INSERT statements) expect the proper column type to be set in BoundType, even for NULL values

```
procedure BindTextP(Param: Integer; Value: PUTF8Char; IO: TSQLDBParamInOutType=paramIn); overload; virtual; abstract;
```

Bind a UTF-8 encoded buffer text (#0 ended) to a parameter

- the leftmost SQL parameter has an index of 1

```
procedure BindTextS(Param: Integer; const Value: string; IO: TSQLDBParamInOutType=paramIn); overload; virtual; abstract;
```

Bind a UTF-8 encoded string to a parameter

- the leftmost SQL parameter has an index of 1

```
procedure BindTextU(Param: Integer; const Value: RawUTF8; IO: TSQLDBParamInOutType=paramIn); overload; virtual; abstract;
```

Bind a UTF-8 encoded string to a parameter

- the leftmost SQL parameter has an index of 1

```
procedure BindTextW(Param: Integer; const Value: WideString; IO: TSQLDBParamInOutType=paramIn); overload; virtual; abstract;
```

Bind a UTF-8 encoded string to a parameter

- the leftmost SQL parameter has an index of 1

```
procedure BindVariant(Param: Integer; const Data: Variant; DataIsBlob: boolean; IO: TSQLDBParamInOutType=paramIn); virtual;
```

Bind a Variant value to a parameter

- the leftmost SQL parameter has an index of 1

- will call all virtual Bind*() methods from the Data type

- if DataIsBlob is TRUE, will call BindBlob(RawByteString(Data)) instead of BindTextW(WideString(Variant)) - used e.g. by TQuery.AsBlob/AsBytes

```
procedure ColumnBlobFromStream(const ColName: RawUTF8; Stream: TStream); overload;
```

Write a blob Column into the Stream parameter

- expected to be used with 'SELECT .. FOR UPDATE' locking statements

```
procedure ColumnBlobFromStream(Col: integer; Stream: TStream); overload; virtual;
```

Write a blob Column into the Stream parameter

- expected to be used with 'SELECT .. FOR UPDATE' locking statements

- default implementation will through an exception, since it is highly provider-specific; SynDBOracle e.g. implements it properly

```
procedure ColumnBlobToStream(const ColName: RawUTF8; Stream: TStream); overload;
```

Read a blob Column into the Stream parameter

procedure ColumnBlobToStream(Col: integer; Stream: TStream); overload; **virtual**;

Read a blob Column into the Stream parameter

- default implementation will just call ColumnBlob(), whereas some providers (like SynDBOracle) may implement direct support

procedure ColumnsToBinary(W: TFileBufferWriter; Null: pointer; **const** ColTypes: TSQLDBFieldTypeDynArray); **virtual**;

Append current row content as binary stream

- will save one data row in optimized binary format (if not in Null)
- virtual method called by FetchAllToBinary()
- follows the format expected by TSQLDBProxyStatement

procedure ColumnsToJSON(WR: TJSONWriter); **virtual**;

Append all columns values of the current Row to a JSON stream

- will use WR.Expand to guess the expected output format
- this default implementation will call Column*() methods above, but you should also implement a custom version with no temporary variable
- BLOB field value is saved as Base64, in the '"\uFFFF0base64encodedbinary"' format and contains true BLOB data (unless ForceBlobAsNull property was set)

procedure ColumnToSQLVar(Col: Integer; **var** Value: TSQLVar; **var** Temp: RawByteString); **virtual**;

Return a Column as a TSQLVar value, first Col is 0

- the specified Temp variable will be used for temporary storage of svtUTF8/svtBlob values

procedure Execute(**const** aSQL: RawUTF8; ExpectResults: Boolean; **const** Params: **array of const**); overload;

Prepare and Execute an UTF-8 encoded SQL statement

- parameters marked as ? should be specified as method parameter in Params[]
- BLOB parameters could not be bound with this method, but need an explicit call to BindBlob() method
- if ExpectResults is TRUE, then Step() and Column*() methods are available to retrieve the data rows
- should raise an Exception on any error
- this method will bind parameters, then call Execute() virtual method

procedure Execute(**const** SQLFormat: RawUTF8; ExpectResults: Boolean; **const** Args, Params: **array of const**); overload;

Prepare and Execute an UTF-8 encoded SQL statement

- parameters marked as % will be replaced by Args[] value in the SQL text
- parameters marked as ? should be specified as method parameter in Params[]
- so could be used as such, mixing both % and ? parameters:
`Statement.Execute('SELECT % FROM % WHERE RowID=?', true, [FieldName, TableName], [ID])`
- BLOB parameters could not be bound with this method, but need an explicit call to BindBlob() method
- if ExpectResults is TRUE, then Step() and Column*() methods are available to retrieve the data rows
- should raise an Exception on any error
- this method will bind parameters, then call Execute() virtual method

procedure Execute(**const** aSQL: RawUTF8; ExpectResults: Boolean); overload;

Prepare and Execute an UTF-8 encoded SQL statement

- parameters marked as ? should have been already bound with Bind*() functions above
- if ExpectResults is TRUE, then Step() and Column*() methods are available to retrieve the data rows
- should raise an Exception on any error
- this method will call Prepare then ExecutePrepared methods

procedure ExecutePrepared; **virtual**;

Execute a prepared SQL statement

- parameters marked as ? should have been already bound with Bind*() functions
- should raise an Exception on any error
- this void default implementation will call set fConnection.fLastAccess

procedure ExecutePreparedAndFetchAllAsJSON(Expanded: boolean; **out** JSON: RawUTF8); **virtual**;

Execute a prepared SQL statement and return all rows content as a JSON string

- JSON data is retrieved with UTF-8 encoding
- if Expanded is true, JSON data is an array of objects, for direct use with any Ajax or .NET client:
[{ "col1":val11, "col2": "val12" }, { "col1":val21, ... }]
- if Expanded is false, JSON data is serialized (used in TSQLTableJSON)
{ "FieldCount":1, "Values": ["col1", "col2", val11, "val12", val21, ...] }
- BLOB field value is saved as Base64, in the '"\uFFFF0base64encodedbinary"' format and contains true BLOB data
- this virtual implementation calls ExecutePrepared then FetchAllAsJSON()

procedure Prepare(**const** aSQL: RawUTF8; ExpectResults: Boolean); overload; **virtual**;

Prepare an UTF-8 encoded SQL statement

- parameters marked as ? will be bound later, before ExecutePrepared call
- if ExpectResults is TRUE, then Step() and Column*() methods are available to retrieve the data rows
- should raise an Exception on any error
- this default implementation will just store aSQL content and the ExpectResults parameter, and connect to the remote server if it was not already connected

procedure ReleaseRows; **virtual**;

Release cursor memory and resources once Step loop is finished

- this method call is optional, but is better be used if the ISQLDBRows statement was taken from cache, and returned a lot of content which may still be in client (and server) memory
- override to free cursor memory when ISQLDBStatement is back in cache

procedure Reset; **virtual**;

Reset the previous prepared statement

- some drivers expect an explicit reset before binding parameters and executing the statement another time
- this default implementation will just do nothing

procedure RowDocVariant(**out** aDocument: **variant**; aOptions: TDocVariantOptions=JSON_OPTIONS_FAST); **virtual**;

Create a TDocVariant custom variant containing all columns values

- will create a "fast" TDocVariant object instance with all fields

property CacheIndex: integer read fCacheIndex;

Low-level access to the statement cache index, after a call to Prepare()

- contains ≥ 0 if the database supports prepared statement cache (Oracle, Postgres) and query plan is cached; contains -1 in other cases

property Connection: TSQLDBConnection read fConnection;

The associated database connection

property CurrentRow: Integer read fCurrentRow;

The current row after Execute/Step call, corresponding to Column() methods*

- contains 0 before initial Step call, or a number ≥ 1 during data retrieval

property SQL: RawUTF8 read fSQL;

The prepared SQL statement, as supplied to Prepare() method

property SQLCurrent: RawUTF8 read GetSQLCurrent;

The prepared SQL statement, in its current state

- if statement is prepared, then equals SQLPrepared, otherwise, contains the raw SQL property content
- used internally by the implementation units, e.g. for errors logging

property SQLLogTimer: TPrecisionTimer read fSQLLogTimer;

Low-level access to the Timer used for last DB operation

property SQLPrepared: RawUTF8 read fSQLPrepared;

After a call to Prepare(), contains the query text to be passed to the DB

- depending on the DB, parameters placeholders are replaced by ?, :1, \$1 etc
- this SQL is ready to be used in any DB tool, e.g. to check the real execution plan/timing

property SQLWithInlinedParams: RawUTF8 read GetSQLWithInlinedParams;

The prepared SQL statement, with all '?' changed into the supplied parameter values

- such statement query plan usually differ from a real execution plan for prepared statements with parameters - see SQLPrepared property instead

property StripSemicolon: boolean read fStripSemicolon write fStripSemicolon;

Strip last semicolon in query

- expectation may vary, depending on the SQL statement and the engine
- default is true

property TotalRowsRetrieved: Integer read fTotalRowsRetrieved;

The total number of data rows retrieved by this instance

- is not reset when there is no more row of available data (Step returns false), or when Step() is called with SeekFirst=true

TSQLDBConnectionThreadSafe = class(TSQLDBConnection)

Abstract connection created from TSQLDBConnectionProperties

- this overridden class will defined an hidden thread ID, to ensure that one connection will be create per thread
- e.g. OleDB, ODBC and Oracle connections will inherit from this class

TSQLDBConnectionPropertiesThreadSafe = class(TSQLDBConnectionProperties)

Connection properties which will implement an internal Thread-Safe connection pool

constructor Create(const aServerName, aDatabaseName, aUserID, aPassword: RawUTF8);
override;

Initialize the properties

- this overridden method will initialize the internal per-thread connection pool

destructor Destroy; **override;**

Release related memory, and all per-thread connections

function ThreadSafeConnection: TSQLDBConnection; **override;**

Get a thread-safe connection

- this overridden implementation will define a per-thread TSQLDBConnection connection pool, via an internal pool

procedure ClearConnectionPool; **override;**

Release all existing connections

- this overridden implementation will release all per-thread TSQLDBConnection internal connection pool

- warning: no connection shall still be used on the background (e.g. in multi-threaded applications), or some unexpected border effects may occur

procedure EndCurrentThread; **virtual;**

You can call this method just before a thread is finished to ensure that the associated Connection will be released

- could be used e.g. in a try...finally block inside a TThread.Execute overridden method
 - could be used e.g. to call CoUnInitialize from thread in which CoInitialize was made, for instance via a method defined as such:

```
procedure TMyServer.OnHttpThreadTerminate(Sender: TObject);  
begin  
  fMyConnectionProps.EndCurrentThread;  
end;
```

- this method shall be called from the thread about to be terminated: e.g. if you call it from the main thread, it may fail to release resources

- within the mORMot server, mORMotDB unit will call this method for every terminating thread created for TSQLRestServerNamedPipeResponse or TSQLHttpServer multi-thread process

property ThreadingMode: TSQLDBConnectionPropertiesThreadSafeThreadingMode **read** fThreadingMode **write** fThreadingMode;

Set this property if you want to disable the per-thread connection pool

- to be used e.g. in database embedded mode (SQLite3/FireBird), when multiple connections may break stability and decrease performance

- see TSQLDBConnectionPropertiesThreadSafeThreadingMode for the possible values

TSQLDBParam = packed record

A structure used to store a standard binding parameter

- you can use your own internal representation of parameters (TOleDBStatement use its own TOleDBStatementParam type), but this type can be used to implement a generic parameter

- used e.g. by TSQLDBStatementWithParams as a dynamic array (and its inherited TSQLDBOracleStatement)

- don't change this structure, since it will be serialized as binary for TSQLDBProxyConnectionCommandExecute

VArray: TRawUTF8DynArray;

Storage used for bound array values

- number of items in array is stored in VInt64
- values are stored as in SQL (i.e. number, 'quoted string', 'YYYY-MM-DD hh:mm:ss', null)

VData: RawByteString;

Storage used for TEXT (ftUTF8) and BLOB (ftBlob) values

- ftBlob are stored as RawByteString
- ftUTF8 are stored as RawUTF8
- sometimes, may be ftInt64 or ftCurrency provided as SQLT_AVC text, or ftDate value converted to SQLT_TIMESTAMP

VDBType: word;

Used e.g. by TSQLDBOracleStatement

VInOut: TSQLDBParamInOutType;

Define if parameter can be retrieved after a stored procedure execution

VInt64: Int64;

Storage used for ftInt64, ftDouble, ftDate and ftCurrency value

VType: TSQLDBFieldType;

The column/parameter Value type

TSQLDBStatementWithParams = **class**(TSQLDBStatement)

Generic abstract class handling prepared statements with binding

- will provide protected fields and methods for handling standard TSQLDBParam parameters

constructor Create(aConnection: TSQLDBConnection); **override**;

Create a statement instance

- this overridden version will initialize the internal fParam* fields

function ParamToVariant(Param: Integer; var Value: Variant; CheckIsOutParameter: boolean=true): TSQLDBFieldType; **override**;

Retrieve the parameter content, after SQL execution

- the leftmost SQL parameter has an index of 1
- to be used e.g. with stored procedures
- this overridden function will retrieve the value stored in the protected fParams[] array: the ExecutePrepared method should have updated its content as expected

procedure Bind(Param: Integer; Value: double; IO: TSQLDBParamInOutType=paramIn); **overload**; **override**;

Bind a double value to a parameter

- the leftmost SQL parameter has an index of 1
- raise an Exception on any error

procedure Bind(Param: Integer; Value: Int64; IO: TSQLDBParamInOutType=paramIn); **overload**; **override**;

Bind an integer value to a parameter

- the leftmost SQL parameter has an index of 1
- raise an Exception on any error

```
procedure BindArray(Param: Integer; const Values: array of double); overload;  
override;
```

Bind an array of double values to a parameter

- the leftmost SQL parameter has an index of 1
- this default implementation will raise an exception if the engine does not support array binding
- this default implementation will call BindArray() after conversion into RawUTF8 items, stored in TSQLDBParam.VArray

```
procedure BindArray(Param: Integer; const Values: array of Int64); overload;  
override;
```

Bind an array of integer values to a parameter

- the leftmost SQL parameter has an index of 1
- this default implementation will call BindArray() after conversion into RawUTF8 items, stored in TSQLDBParam.VArray

```
procedure BindArray(Param: Integer; const Values: array of RawUTF8); overload;  
override;
```

Bind an array of RawUTF8 values to a parameter

- the leftmost SQL parameter has an index of 1
- values are stored as 'quoted string'
- this default implementation will raise an exception if the engine does not support array binding

```
procedure BindArray(Param: Integer; ParamType: TSQLDBFieldType; const Values:  
TRawUTF8DynArray; ValuesCount: integer); overload; override;
```

Bind an array of values to a parameter using OCI bind array feature

- the leftmost SQL parameter has an index of 1
- values are stored as in SQL (i.e. number, 'quoted string', 'YYYY-MM-DD hh:mm:ss', null)
- values are stored as in SQL (i.e. 'YYYY-MM-DD hh:mm:ss')

```
procedure BindArrayCurrency(Param: Integer; const Values: array of currency);  
override;
```

Bind an array of currency values to a parameter

- the leftmost SQL parameter has an index of 1
- this default implementation will raise an exception if the engine does not support array binding
- this default implementation will call BindArray() after conversion into RawUTF8 items, stored in TSQLDBParam.VArray

```
procedure BindArrayDateTime(Param: Integer; const Values: array of TDateTime);  
override;
```

Bind an array of TDateTime values to a parameter

- the leftmost SQL parameter has an index of 1
- values are stored as in SQL (i.e. 'YYYY-MM-DD hh:mm:ss')
- this default implementation will raise an exception if the engine does not support array binding
- this default implementation will call BindArray() after conversion into RawUTF8 items, stored in TSQLDBParam.VArray

```
procedure BindArrayRow(const aValues: array of const);
```

Bind a set of parameters for further array binding

- supplied parameters shall follow the BindArrayRowPrepare() supplied types (i.e. RawUTF8, Integer/Int64, double); you can also bind directly a TDateTime value if the corresponding binding has been defined as ftDate by BindArrayRowPrepare()

```
procedure BindArrayRowPrepare(const aParamTypes: array of TSQLDBFieldType;  
aExpectedMinimalRowCount: integer=0);
```

Start parameter array binding per-row process

- BindArray*() methods expect the data to be supplied "vertically": this method allow-per row binding
- call this method, then BindArrayRow() with the corresponding values for one statement row, then Execute to send the query

```
procedure BindBlob(Param: Integer; Data: pointer; Size: integer; IO:  
TSQLDBParamInOutType=paramIn); overload; override;
```

Bind a Blob buffer to a parameter

- the leftmost SQL parameter has an index of 1
- raise an Exception on any error

```
procedure BindBlob(Param: Integer; const Data: RawByteString; IO:  
TSQLDBParamInOutType=paramIn); overload; override;
```

Bind a Blob buffer to a parameter

- the leftmost SQL parameter has an index of 1
- raise an Exception on any error M

```
procedure BindCurrency(Param: Integer; Value: currency; IO:  
TSQLDBParamInOutType=paramIn); overload; override;
```

Bind a currency value to a parameter

- the leftmost SQL parameter has an index of 1
- raise an Exception on any error

```
procedure BindDateTime(Param: Integer; Value: TDateTime; IO:  
TSQLDBParamInOutType=paramIn); overload; override;
```

Bind a TDateTime value to a parameter

- the leftmost SQL parameter has an index of 1
- raise an Exception on any error

```
procedure BindFromRows(Rows: TSQLDBStatement); virtual;
```

Bind an array of fields from an existing SQL statement for array binding

- supplied Rows columns shall follow the BindArrayRowPrepare() supplied types (i.e. RawUTF8, Integer/Int64, double, date)
- can be used e.g. after ColumnsToSQLInsert() method call for fast data conversion between tables

```
procedure BindNull(Param: Integer; IO: TSQLDBParamInOutType=paramIn; BoundType:  
TSQLDBFieldType=ftNull); override;
```

Bind a NULL value to a parameter

- the leftmost SQL parameter has an index of 1
- raise an Exception on any error
- some providers (only OleDB during MULTI INSERT statements, so never used in this class) expect the proper column type to be set in BoundType

```
procedure BindTextP(Param: Integer; Value: PUTF8Char; IO:  
TSQLDBParamInOutType=paramIn); overload; override;
```

Bind a UTF-8 encoded buffer text (#0 ended) to a parameter

- the leftmost SQL parameter has an index of 1

```
procedure BindTextS(Param: Integer; const Value: string; IO:  
TSQLDBParamInOutType=paramIn); overload; override;
```

Bind a VCL string to a parameter

- the leftmost SQL parameter has an index of 1
- raise an Exception on any error

```
procedure BindTextU(Param: Integer; const Value: RawUTF8; IO:  
TSQLDBParamInOutType=paramIn); overload; override;
```

Bind a UTF-8 encoded string to a parameter

- the leftmost SQL parameter has an index of 1
- raise an Exception on any error

```
procedure BindTextW(Param: Integer; const Value: WideString; IO:  
TSQLDBParamInOutType=paramIn); overload; override;
```

Bind an OLE WideString to a parameter

- the leftmost SQL parameter has an index of 1
- raise an Exception on any error }

```
procedure ReleaseRows; override;
```

Release used memory

- this overridden implementation will free the fParams[] members (e.g. VData) but not the parameters themselves

```
procedure Reset; override;
```

Reset the previous prepared statement

- this overridden implementation will just do reset the internal fParams[]

```
TSQLDBStatementWithParamsAndColumns = class(TSQLDBStatementWithParams)
```

Generic abstract class handling prepared statements with binding and column description

- will provide protected fields and methods for handling both TSQLDBParam parameters and standard TSQLDBColumnProperty column description

```
constructor Create(aConnection: TSQLDBConnection); override;
```

Create a statement instance

- this overridden version will initialize the internal fColumn* fields

```
function ColumnIndex(const aColumnName: RawUTF8): integer; override;
```

Returns the Column index of a given Column name

- Columns numeration (i.e. Col value) starts with 0
- returns -1 if the Column name is not found (via case insensitive search)

```
function ColumnName(Col: integer): RawUTF8; override;
```

Retrieve a column name of the current Row

- Columns numeration (i.e. Col value) starts with 0
- it's up to the implementation to ensure than all column names are unique

function ColumnType(Col: integer; FieldSize: PInteger=nil): TSQldbFieldType;
override;

The Column type of the current Row

- ftCurrency type should be handled specifically, for faster process and avoid any rounding issue, since currency is a standard OleDB type
- FieldSize can be set to store the size in chars of a ftUTF8 column (0 means BLOB kind of TEXT column) - this implementation will store fColumns[Col].ColumnValueDBSize if ColumnValueInlined=true

property Columns: TSQldbColumnPropertyDynArray **read** fColumns;

Direct access to the columns description

- gives more details than the default ColumnType() function

ESQldbException = **class**(ESynException)

Generic Exception type, as used by the SynDB unit

constructor CreateUTF8(const Format: RawUTF8; const Args: array of const);

Constructor which will use FormatUTF8() instead of Format()

- if the first Args[0] is a TSQldbStatement class instance, the current SQL statement will be part of the exception message

property Statement: TSQldbStatement **read** fStatement;

Associated TSQldbStatement instance, if supplied as first parameter

ESQldbRemote = **class**(ESQldbException)

Exception raised during remote connection process

TSQldbProxyConnectionCommandExecute = **packed record**

Structure to embedd all needed parameters to execute a SQL statement

- used for cExecute, cExecuteToBinary, cExecuteToJSON and cExecuteToExpandedJSON commands of TSQldbProxyConnectionProperties.Process()
- set by TSQldbProxyStatement.ParamsToCommand() protected method

ArrayCount: integer;

If input parameters expected BindArray() process

Force: **set of** (fBlobAsNull, fDateWithMS, fNoUpdateCount);

How server side would handle statement execution

- fBlobAsNull and fDateWithMS do match ForceBlobAsNull and ForceDateWithMS ISQldbStatement properties
- fNoUpdateCount avoids to call ISQldbStatement.UpdateCount method, e.g. for performance reasons

Params: TSQldbParamDynArray;

Input parameters

- trunked to the exact number of parameters

SQL: RawUTF8;

The associated SQL statement

TSQLDBProxyConnectionPropertiesAbstract = class(TSQLDBConnectionProperties)

Implements a proxy-like virtual connection statement to a DB engine

- will generate TSQLDBProxyConnection kind of connection

destructor Destroy; override;

Will notify for proxy disconnection

function IsCachable(P: PUTF8Char): boolean; override;

Determine if the SQL statement can be cached

- always returns false, to force a new fake statement to be created

function NewConnection: TSQLDBConnection; override;

Create a new TSQLDBProxyConnection instance

- the caller is responsible of freeing this instance

procedure GetFields(const aTableName: RawUTF8; out Fields: TSQLDBColumnDefineDynArray); override;

Retrieve the column/field layout of a specified table

- calls Process(cGetFields,aTableName,Fields)

procedure GetIndexes(const aTableName: RawUTF8; out Indexes: TSQLDBIndexDefineDynArray); override;

Retrieve the advanced indexed information of a specified Table

- calls Process(cGetIndexes,aTableName,Indexes)

procedure GetTableNames(out Tables: TRawUTF8DynArray); override;

Get all table names

- this default implementation will use protected SQLGetTableNames virtual

- calls Process(cGetTableNames,self,Tables)

property HandleConnection: boolean read fHandleConnection write fHandleConnection;

Connect and Disconnect won't really connect nor disconnect the remote connection

- you can set this property to TRUE if you expect the remote connection by in synch with the remote proxy connection (should not be used in most cases, unless you are sure you have only one single client at a time)

property StartTransactionTimeOut: Int64 read fStartTransactionTimeOut write fStartTransactionTimeOut;

Milliseconds to way until StartTransaction is allowed by the server

- in the current implementation, there should be a single transaction at once on the server side: this is the time to try before reporting an ESQLDBRemote exception failure

TSQLDBProxyConnection = class(TSQLDBConnection)

Implements an abstract proxy-like virtual connection to a DB engine

- can be used e.g. for remote access or execution in a background thread

constructor Create(aProperties: TSQLDBConnectionProperties); override;

Connect to a specified database engine

function IsConnected: boolean; override;

Return TRUE if Connect has been already successfully called

```
function NewStatement: TSQLDBStatement; override;
```

Initialize a new SQL query statement for the given connection

```
procedure Commit; override;
```

Commit changes of a Transaction for this connection

```
procedure Connect; override;
```

Connect to the specified database

```
procedure Disconnect; override;
```

Stop connection to the specified database

```
procedure Rollback; override;
```

Discard changes of a Transaction for this connection

```
procedure StartTransaction; override;
```

Begin a Transaction for this connection

```
TSQLDBProxyStatementAbstract = class(TSQLDBStatementWithParamsAndColumns)
```

Implements a proxy-like virtual connection statement to a DB engine

- abstract class, with no corresponding kind of connection, but allowing access to the mapped data via Column*() methods
- will handle an internal binary buffer when the statement returned rows data, as generated by TSQLDBStatement.FetchAllToBinary()

```
function ColumnBlob(Col: integer): RawByteString; override;
```

Return a Column as a blob value of the current Row, first Col is 0

```
function ColumnCurrency(Col: integer): currency; override;
```

Return a Column currency value of the current Row, first Col is 0

- should retrieve directly the 64 bit Currency content, to avoid any rounding/conversion error from floating-point types

```
function ColumnData(Col: integer): pointer;
```

Direct access to the data buffer of the current row

- points to Double/Currency value, or variable-length Int64/UTF8/Blob
- points to nil if the column value is NULL

```
function ColumnDateTime(Col: integer): TDateTime; override;
```

Return a Column floating point value of the current Row, first Col is 0

```
function ColumnDouble(Col: integer): double; override;
```

Return a Column floating point value of the current Row, first Col is 0

```
function ColumnInt(Col: integer): Int64; override;
```

Return a Column integer value of the current Row, first Col is 0

```
function ColumnNull(Col: integer): boolean; override;
```

Returns TRUE if the column contains NULL

```
function ColumnString(Col: integer): string; override;
```

Return a Column text value as generic VCL string of the current Row, first Col is 0

function ColumnType(Col: integer; FieldSize: PInteger=nil): TSQLDBFieldType;
override;

The Column type of the current Row

function ColumnUTF8(Col: integer): RawUTF8; **override;**

Return a Column UTF-8 encoded text value of the current Row, first Col is 0

procedure ColumnsToBinary(W: TFileBufferWriter; Null: pointer; **const** ColTypes: TSQLDBFieldTypeDynArray); **override;**

Append current row content as binary stream

- will save one data row in optimized binary format (if not in Null)
- virtual method called by FetchAllToBinary()
- follows the format expected by TSQLDBProxyStatement

procedure ColumnsToJSON(WR: TJSONWriter); **override;**

Return all columns values into JSON content

property DataRowCount: integer **read** fDataRowCount;

Read-only access to the number of data rows stored

TSQLDBProxyStatement = class(TSQLDBProxyStatementAbstract)

Implements a proxy-like virtual connection statement to a DB engine

- is generated by TSQLDBProxyConnection kind of connection
- will use an internal binary buffer when the statement returned rows data, as generated by TSQLDBStatement.FetchAllToBinary() or JSON for ExecutePreparedAndFetchAllAsJSON() method (as expected by our ORM)

function FetchAllToBinary(Dest: TStream; MaxRowCount: cardinal=0; DataRowPosition: PCardinalDynArray=nil): cardinal; **override;**

Append all rows content as binary stream

- will save the column types and name, then every data row in optimized binary format (faster and smaller than JSON)
- you can specify a LIMIT for the data extent (default 0 meaning all data)
- generates the format expected by TSQLDBProxyStatement
- this overridden method will use the internal data copy of the binary buffer retrieved by ExecutePrepared, so would be almost immediate, and would allow e.g. direct consumption via our TSynSQLStatementDataSet
- note that DataRowPosition won't be set by this method: will be done e.g. in TSQLDBProxyStatementRandomAccess.Create

function Step(SeekFirst: boolean=false): boolean; **override;**

After a statement has been prepared via Prepare() + ExecutePrepared() or Execute(), this method must be called one or more times to evaluate it

function UpdateCount: integer; **override;**

Gets a number of updates made by latest executed statement

- this overridden method will return the integer value returned by cExecute command

procedure ExecutePrepared; **override**;

Execute a SQL statement

- for TSQLDBProxyStatement, preparation and execution are processed in one step, when this method is executed - as such, Prepare() won't call the remote process, but will just set fSQL
- this overridden implementation will use out optimized binary format as generated by TSQLDBStatement.FetchAllToBinary(), and not JSON

procedure ExecutePreparedAndFetchAllAsJSON(Expanded: boolean; **out** JSON: RawUTF8); **override**;

Execute a prepared SQL statement and return all rows content as a JSON string

- JSON data is retrieved with UTF-8 encoding
- if Expanded is true, JSON data is an array of objects, for direct use with any Ajax or .NET client:
 [{ "col1":val11, "col2": "val12" }, { "col1":val21, ... }]
- if Expanded is false, JSON data is serialized (used in TSQLTableJSON)
 { "FieldCount":1, "Values":["col1", "col2", val11, "val12", val21, ...] }
- BLOB field value is saved as Base64, in the '"\uFFFF0base64encodedbinary"' format and contains true BLOB data
- this overridden implementation will use JSON for transmission, and binary encoding only for parameters (to avoid unneeded conversions, e.g. when called from mORMotDB.pas)

property ForceNoUpdateCount: boolean **read** fForceNoUpdateCount **write** fForceNoUpdateCount;

Force no UpdateCount method call on server side

- may be needed to reduce server load, if this information is not needed

TSQLDBRemoteConnectionPropertiesAbstract =
class(TSQLDBProxyConnectionPropertiesAbstract)

Client-side implementation of a remote connection to any SynDB engine

- will compute binary compressed messages for the remote processing, ready to be served e.g. over HTTP via our SynDBRemote.pas unit
- abstract class which should override its protected ProcessMessage() method e.g. by TSQLDBRemoteConnectionPropertiesTest or

TSQLDBRemoteConnectionPropertiesTest =
class(TSQLDBRemoteConnectionPropertiesAbstract)

Fake proxy class for testing the remote connection to any SynDB engine

- resulting overhead due to our binary messaging: unnoticeable :)

constructor Create(aProps: TSQLDBConnectionProperties; **const** aUserID, aPassword: RawUTF8; aProtocol: TSQLDBProxyConnectionProtocolClass); **reintroduce**;

Create a test redirection to an existing local connection property

- you can specify a User/Password credential pair to also test the authentication via TSynAuthentication

TSQLDBProxyStatementRandomAccess = class(TSQLDBProxyStatementAbstract)

Implements a virtual statement with direct data access

- is generated with no connection, but allows direct random access to any data row retrieved from TSQLDBStatement.FetchAllToBinary() binary data
- GotoRow() method allows direct access to a row data via Column*()
- is used e.g. by TSynSQLStatementDataSet of SynDBVCL unit

constructor Create(Data: PByte; DataLen: integer; DataRowPosition: PCardinalDynArray=nil; IgnoreColumnDataSize: boolean=false); **reintroduce;**

Initialize the internal structure from a given memory buffer

- by default, ColumnDataSize would be computed from the supplied data, unless you set IgnoreColumnDataSize=true to set the value to 0 (and force e.g. SynDBVCL TSynBinaryDataSet.InternalInitFieldDefs define the field as ftDefaultMemo)

function GotoRow(Index: integer; RaiseExceptionOnWrongIndex: Boolean=false): boolean;

Change the current data Row

- if Index<DataRowCount, returns TRUE and you can access to the data via regular Column*() methods
- can optionally raise an ESQLDBException if Index is not correct

function Step(SeekFirst: boolean=false): boolean; **override;**

Change cursor position to the next available row

- this unexpected overridden method will raise a ESQLDBException

procedure ExecutePrepared; **override;**

Execute a prepared SQL statement

- this unexpected overridden method will raise a ESQLDBException

TSQLDBLib = class(TObject)

Access to a native library

- this generic class is to be used for any native connection using an external library
- is used e.g. in SynDBOracle by TSQLDBOracleLib to access the OCI library, or by SynDBODBC to access the ODBC library

destructor Destroy; **override;**

Release associated memory and linked library

property Handle: HMODULE **read** fHandle **write** fHandle;

The associated library handle

property LibraryPath: TFileName **read** fLibraryPath;

The loaded library path

ESQLQueryException = class(ESynException)

Generic Exception type raised by the TQuery class

TQueryValue = object(TObject)

Pseudo-class handling a TQuery bound parameter or column value

- will mimic both TField and TParam classes as defined in standard DB unit, by pointing both classes types to PQueryValue
- usage of an object instead of a class allow faster access via a dynamic array (and our TDynArrayHashed wrapper) for fast property name handling (via name hashing) and pre-allocation
- it is based on an internal Variant to store the parameter or column value

procedure Clear;

Set the column value to null

property AsBlob: TBlobData read GetBlob write SetBlob;

Access the BLOB Value as an AnsiString

- will work for all Delphi versions, including Unicode versions (i.e. since Delphi 2009)
- for a BLOB parameter or column, you should use AsBlob or AsBlob properties instead of AsString (this later won't work after Delphi 2007)

property AsBoolean: Boolean read GetBoolean write SetBoolean;

Access the Value as boolean

property AsBytes: TBytes read GetAsBytes write SetAsBytes;

Access the BLOB Value as array of byte (TBytes)

- will work for all Delphi versions, including Unicode versions (i.e. since Delphi 2009)
- for a BLOB parameter or column, you should use AsBlob or AsBlob properties instead of AsString (this later won't work after Delphi 2007)

property AsCurrency: Currency read GetCurrency write SetCurrency;

Access the Value as Currency

- avoid any rounding conversion, as with AsFloat

property AsDate: TDateTime read GetDateTime write SetDateTime;

Access the Value as TDate

property AsDateTime: TDateTime read GetDateTime write SetDateTime;

Access the Value as TDateTime

property AsFloat: double read GetDouble write SetDouble;

Access the Value as double

property AsInt64: Int64 read GetInt64 write SetInt64;

Access the Value as Int64

- note that under Delphi 5, Int64 is not handled: the Variant type only handle integer types, in this Delphi version :(

property AsInteger: integer read GetInteger write SetInteger;

Access the Value as Integer

property AsLargeInt: Int64 read GetInt64 write SetInt64;

Access the Value as Int64

- note that under Delphi 5, Int64 is not handled: the Variant type only handle integer types, in this Delphi version :(

property AsString: **string** **read** GetString **write** SetString;

Access the Value as String

- used in the VCL world for both TEXT and BLOB content (BLOB content will only work in pre-Unicode Delphi version, i.e. before Delphi 2009)

property AsTime: **TDateTime** **read** GetDateTime **write** SetDateTime;

Access the Value as TTime

property AsVariant: **Variant** **read** GetVariant **write** SetVariant;

Access the Value as Variant

property AsWideString: **SynUnicode** **read** GetAsWideString **write** SetAsWideString;

Access the Value as an unicode String

- will return a WideString before Delphi 2009, and an UnicodeString for Unicode versions of the compiler (i.e. our SynUnicode type)

property Bound: **Boolean** **write** SetBound;

Just do nothing - here for compatibility reasons with Clear + Bound := true

property FieldName: **string** **read** fName;

The associated (field) name

property IsNull: **Boolean** **read** GetIsNull;

Returns TRUE if the stored Value is null

property Name: **string** **read** fName;

The associated (parameter) name

property ParamType: **TParamType** **read** fParamType **write** fParamType;

Parameter type for queries or stored procedures

TQuery = class(TObject)

Class mapping VCL DB TQuery for direct database process

- this class can mimic basic TQuery VCL methods, but won't need any BDE installed, and will be faster for field and parameters access than the standard TDataSet based implementation; in fact, OleDB replaces the BDE or the DBExpress layer, or access directly to the client library (e.g. for TSQLDBOracleConnectionProperties which calls oci.dll)

- it is able to run basic queries as such:

```
Q := TQuery.Create(aSQLDBConnection);
try
  Q.SQL.Clear; // optional
  Q.SQL.Add('select * from DOMAIN.TABLE');
  Q.SQL.Add(' WHERE ID_DETAIL=:detail;');
  Q.ParamByName('DETAIL').AsString := '123420020100000430015';
  Q.Open;
  Q.First; // optional
  while not Q.Eof do begin
    assert(Q.FieldByName('id_detail').AsString='123420020100000430015');
    Q.Next;
  end;
  Q.Close; // optional
finally
  Q.Free;
end;
```

- since there is no underlying TDataSet, you can't have read and write access, or use the visual DB components of the VCL: it's limited to direct emulation of low-level SQL as in the above code, with one-direction retrieval (e.g. the Edit, Post, Append, Cancel, Prior, Locate, Lookup methods do not exist within this class)

- use ToDataSet() function from SynDBVCL.pas to create a TDataSet from such a TQuery instance, and link this request to visual DB components

- this class is Unicode-ready even before Delphi 2009 (via the TQueryValue AsWideString method), will natively handle Int64/TBytes field or parameter data, and will have less overhead than the standard DB components of the VCL

- you should better use TSQLDBStatement instead of this wrapper, but having such code-compatible TQuery replacement could make easier some existing code upgrade (e.g. to avoid deploying the deprecated BDE, generate smaller executable, access any database without paying a big fee, avoid rewriting a lot of existing code lines of a big application...)

constructor Create(aConnection: TSQLDBConnection);

Initialize a query for the associated database connection

destructor Destroy; **override;**

Release internal memory and statements

function ExecSQLAndReturnUpdateCount: integer;

Begin the SQL query, for a non SELECT statement

- will parse the entered SQL statement, and bind parameters

- the query will be released with a call to Close within this method

- this method will return the number of updated rows (i.e.

PreparedSQLDBStatement.UpdateCount)

function FieldByName(**const** aFieldName: **string**): TField;

Retrieve a column value from the current opened SQL query row

- will raise an ESQLQueryException error in case of error, e.g. if no column name matches the supplied name

function FindField(**const** aFieldName: **string**): TField;

Retrieve a column value from the current opened SQL query row

- will return nil in case of error, e.g. if no column name matches the supplied name

function ParamByName(**const** aParamName: **string**; CreateIfNotExisting: **boolean**=true): TParam;

Access a SQL statement parameter, entered as :aParamName in the SQL

- if the requested parameter do not exist yet in the internal fParams list, AND if CreateIfNotExisting=true, a new TQueryValue instance will be created and registered

procedure Close;

End the SQL query

- will release the SQL statement, results and bound parameters
- the query should be released with a call to Close before reopen

procedure ExecSQL;

Begin the SQL query, for a non SELECT statement

- will parse the entered SQL statement, and bind parameters
- the query will be released with a call to Close within this method
- will return the number of updated rows (i.e. PreparedSQLDBStatement.UpdateCount)

procedure First;

After a successfull Open, will get the first row of results

procedure Next;

After successfull Open and First, go the the next row of results

procedure Open;

Begin the SQL query, for a SELECT statement

- will parse the entered SQL statement, and bind parameters
- will then execute the SELECT statement, ready to use First/Eof/Next methods, the returned rows being available via FieldByName methods

procedure Prepare;

A do-nothing method, just available for compatibility purpose

property Active: **Boolean** **read** GetActive;

Equals true if the query is opened

property Bof: **Boolean** **read** GetBof;

Equals true if on first row

property Connection: **TSQLDBConnection** **read** fConnection;

The associated database connection

property Eof: **Boolean** **read** GetEof;

Equals true if there is some rows pending

property FieldCount: integer read GetFieldCount;

The number of columns in the current opened SQL query row

property Fields[aIndex: integer]: TField read GetField;

Retrieve a column value from the current opened SQL query row
 - will return nil in case of error, e.g. out of range index

property IsEmpty: Boolean read GetIsEmpty;

Equals true if there is no row returned

property ParamCount: integer read GetParamCount;

The number of bound parameters in the current SQL statement

property Params[aIndex: integer]: TParam read GetParam;

Retrieve a bound parameters in the current SQL statement
 - will return nil in case of error, e.g. out of range index

property PreparedSQLDBStatement: ISQLDBStatement read fPrepared;

Non VCL property to access the internal SynDB prepared statement
 - is nil if the TQuery is not prepared (e.g. after Close)

property RecordCount: integer read GetRecordCount;

Returns 0 if no record was retrieved, 1 if there was some records
 - not the exact count: just here for compatibility purpose with code like if
 aQuery.RecordCount>0 then ...

property SQL: TStringList read fSQL;

The SQL statement to be executed
 - statement will be prepared and executed via Open or ExecSQL methods
 - SQL.Clear will force a call to the Close method (i.e. reset the query, just as with the default VCL implementation)

property SQLAsText: string read GetSQLAsText;

The SQL statement with inlined bound parameters

property Tag: PtrInt read fTag write fTag;

User-customizable number attached to this instance
 - for compatibility with TComponent

Types implemented in the SynDB unit

PQueryValue = ^TQueryValue;

Pointer to TQuery bound parameter or column value

TBlobData = RawByteString;

Generic type used by TQuery / TQueryValue for BLOBs fields

TField = PQueryValue;

Pointer mapping the VCL DB TField class
 - to be used e.g. with code using local TField instances in a loop

TOnBatchInsert = **procedure**(Props: TSQLDBConnectionProperties; **const** TableName: RawUTF8; **const** FieldNames: TRawUTF8DynArray; **const** FieldTypes: TSQLDBFieldTypeArray; RowCount: integer; **const** FieldValues: TRawUTF8DynArrayDynArray) **of object**;

Defines a callback signature able to handle multiple INSERT

- may execute e.g. for 2 fields and 3 data rows on a database engine implementing INSERT with multiple VALUES (like MySQL, PostgreSQL, NexusDB, MSSQL or SQLite3), as implemented by `TSQLDBConnectionProperties.MultipleValuesInsert()` :

```
INSERT INTO TableName(FieldNames[0],FieldNames[1]) VALUES
  (FieldValues[0][0],FieldValues[1][0]),
  (FieldValues[0][1],FieldValues[1][1]),
  (FieldValues[0][2],FieldValues[1][2]);
```

- for other kind of DB which do not support multi values INSERT, may execute a dedicated driver command, like MSSQL "bulk insert" or Firebird "execute block"

TOnSQLDBInfo = procedure(Sender: TSQLDBStatement; const Msg: RawUTF8) of object;

Event handler called when the low-level driver send some warning information

- errors will trigger Exceptions, but sometimes the database driver returns some non critical information, which is logged and may be intercepted using the `TSQLDBConnectionProperties.OnStatementInfo` property
- may be used e.g. to track ORA-28001 or ORA-28002 about account expire
- is currently implemented by `SynDBOracle`, `SynDBODBC` and `SynOleDB` units

TOnSQLDBProcess = procedure(Sender: TSQLDBConnection; Event: TOnSQLDBProcessEvent) of object;

Event handler called during all external DB process

- event handler is specified by `TSQLDBConnectionProperties.OnProcess` or `TSQLDBConnection.OnProperties` properties

TOnSQLDBProcessEvent = (speConnected, speDisconnected, speNonActive, speActive, speConnectionLost, speReconnected, speStartTransaction, speCommit, speRollback);

Possible events notified to TOnSQLDBProcess callback method

- event handler is specified by `TSQLDBConnectionProperties.OnProcess` or `TSQLDBConnection.OnProcess` properties
- `speConnected` / `speDisconnected` will notify `TSQLDBConnection.Connect` and `TSQLDBConnection.Disconnect` calls
- `speNonActive` / `speActive` will be used to notify external DB blocking access, so can be used e.g. to change the mouse cursor shape (this trigger is re-entrant, i.e. it will be executed only once in case of nested calls)
- `speReconnected` will be called if `TSQLDBConnection` did successfully recover its database connection (on error, `TQuery` will call `speConnectionLost`): this event will be called by `TSQLDBConnection.Connect` after a regular `speConnected` notification
- `speConnectionLost` will be called by `TQuery` in case of broken connection, and if `Disconnect/Reconnect` did not restore it as expected (i.e. `speReconnected`)
- `speStartTransaction` / `speCommit` / `speRollback` will notify the corresponding `TSQLDBConnection.StartTransaction`, `TSQLDBConnection.Commit` and `TSQLDBConnection.Rollback` methods

TParam = PQueryValue;

Pointer mapping the VCL DB TParam class

- to be used e.g. with code using local `TParam` instances

TParamType = (ptUnknown, ptInput, ptOutput, ptInputOutput, ptResult);

Represent the use of parameters on queries or stored procedures

- same enumeration as with the standard DB unit from VCL

TQueryValueDynArray = array of TQueryValue;

A dynamic array of TQuery bound parameters or column values

- TQuery will use TDynArrayHashed for fast search

TSQLDBColumnCreateDynArray = array of TSQLDBColumnCreate;

Used to define how a table is to be created

TSQLDBColumnDefineDynArray = array of TSQLDBColumnDefine;

Used to define the column layout of a table schema

- e.g. for TSQLDBConnectionProperties.GetFields

TSQLDBColumnPropertyDynArray = array of TSQLDBColumnProperty;

Used to define a table/field column layout

TSQLDBConnectionPropertiesClass = class of TSQLDBConnectionProperties;

Specify the class of TSQLDBConnectionProperties

- sometimes used to create connection properties instances, from a set of available classes (see e.g. SynDBExplorer or sample 16)

TSQLDBConnectionPropertiesThreadSafeThreadingMode = (tmThreadPool, tmMainConnection, tmBackgroundThread);

Threading modes set to TSQLDBConnectionPropertiesThreadSafe.ThreadingMode

- default mode is to use a Thread Pool, i.e. one connection per thread
- or you can force to use the main connection
- or you can use a shared background thread process (not implemented yet)
- last two modes could be used for embedded databases (SQLite3/FireBird), when multiple connections may break stability, consume too much resources and/or decrease performance

TSQLDBDefinition = (dUnknown, dDefault, dOracle, dMSSQL, dJet, dMySQL, dSQLite, dFirebird, dNexusDB, dPostgreSQL, dDB2, dInformix);

The known database definitions

- will be used e.g. for TSQLDBConnectionProperties.SQLFieldCreate(), or for OleDB/ODBC/ZDBC tuning according to the connected database engine

TSQLDBDefinitionLimitPosition = (posNone, posWhere, posSelect, posAfter, posOuter);

Where the LIMIT clause should be inserted for a given SQL syntax

- used by TSQLDBDefinitionLimitClause and SQLLimitClause() method

TSQLDBDefinitions = set of TSQLDBDefinition;

Set of the available database definitions

TSQLDBFieldTypeDefinition = array[TSQLDBFieldType] of RawUTF8;

An array of RawUTF8, for each existing column type

- used e.g. by SQLCreate method
- ftUnknown maps int32 field (e.g. boolean), ftNull maps RawUTF8 index # field, ftUTF8 maps RawUTF8 blob field, other types map their default kind
- for UTF-8 text, ftUTF8 will define the BLOB field, whereas ftNull will expect to be formatted with an expected field length in ColumnAttr
- the RowID definition will expect the ORM to create a unique identifier, and will use the ftInt64 type definition for this and send it with the INSERT statement (some databases, like Oracle, do not support standard's IDENTITY attribute) - see <http://troels.arvin.dk/db/rdbms>

TSQLDBIndexDefineDynArray = array of TSQLDBIndexDefine;

Used to describe extended Index definition of a table schema

- e.g. for TSQLDBConnectionProperties.GetIndexes

TSQLDBParamDynArray = array of TSQLDBParam;

Dynamic array used to store standard binding parameters

- used e.g. by TSQLDBStatementWithParams (and its inherited TSQLDBOracleStatement)

```
TSQLDBParamInOutType = ( paramIn, paramOut, paramInOut );
```

The diverse type of bound parameters during a statement execution

- will be paramIn by default, which is the case 90% of time
- could be set to paramOut or paramInOut if must be refreshed after execution (for calling a stored procedure expecting such parameters)

```
TSQLDBProcColumnDefineDynArray = array of TSQLDBProcColumnDefine;
```

Used to define the parameter/column layout of a stored procedure schema

- e.g. for TSQLDBConnectionProperties.GetProcedureParameters

```
TSQLDBProxyConnectionCommand = ( cGetToken, cGetDBMS, cConnect, cDisconnect,
cTryStartTransaction, cCommit, cRollback, cServerTimestamp, cGetFields, cGetIndexes,
cGetTableNames, cGetForeignKeys, cExecute, cExecuteToBinary, cExecuteToJSON,
cExecuteToExpandedJSON, cQuit, cExceptionRaised );
```

Proxy commands implemented by TSQLDBProxyConnectionProperties.Process()

- method signature expect "const Input" and "var Output" arguments
- Input is not used for cConnect, cDisconnect, cGetForeignKeys, cTryStartTransaction, cCommit, cRollback and cServerTimestamp
- Input is the TSQLDBProxyConnectionProperties instance for cInitialize
- Input is the RawUTF8 table name for most cGet* metadata commands
- Input is the SQL statement and associated bound parameters for cExecute, cExecuteToBinary, cExecuteToJSON, and cExecuteToExpandedJSON, encoded as TSQLDBProxyConnectionCommandExecute record
- Output is not used for cConnect, cDisconnect, cCommit, cRollback and cExecute
- Output is TSQLDBDefinition (i.e. DBMS type) for cInitialize
- Output is TTimeLog for cServerTimestamp
- Output is boolean for cTryStartTransaction
- Output is TSQLDBColumnDefineDynArray for cGetFields
- Output is TSQLDBIndexDefineDynArray for cGetIndexes
- Output is TSynNameValue (fForeignKeys) for cGetForeignKeys
- Output is TRawUTF8DynArray for cGetTableNames
- Output is RawByteString result data for cExecuteToBinary
- Output is UpdateCount: integer text for cExecute
- Output is RawUTF8 result data for cExecuteToJSON and cExecuteToExpandedJSON

- calls could be declared as such:

```
Process(cGetToken,?,result: Int64);
Process(cGetDBMS,User#1Hash: RawUTF8,fDBMS: TSQLDBDefinition);
Process(cConnect,?,?);
Process(cDisconnect,?,?);
Process(cTryStartTransaction,?,started: boolean);
Process(cCommit,?,?);
Process(cRollback,?,?);
Process(cServerTimestamp,?,result: TTimeLog);
Process(cGetFields,aTableName: RawUTF8,Fields: TSQLDBColumnDefineDynArray);
Process(cGetIndexes,aTableName: RawUTF8,Indexes: TSQLDBIndexDefineDynArray);
Process(cGetTableNames,?,Tables: TRawUTF8DynArray);
Process(cGetForeignKeys,?,fForeignKeys: TSynNameValue);
Process(cExecute,Request: TSQLDBProxyConnectionCommandExecute,UpdateCount: integer);
Process(cExecuteToBinary,Request: TSQLDBProxyConnectionCommandExecute,Data: RawByteString);
Process(cExecuteToJSON,Request: TSQLDBProxyConnectionCommandExecute,JSON: RawUTF8);
Process(cExecuteToExpandedJSON,Request: TSQLDBProxyConnectionCommandExecute,JSON: RawUTF8);
```

- cExceptionRaised is a pseudo-command, used only for sending an exception to the client in case of

execution problem on the server side

```
TSQldbProxyConnectionProtocolClass = class of TSQldbProxyConnectionProtocol;
```

Specify the class of a proxy/remote connection to any SynDB engine

```
TSQldbSharedTransactionAction = ( transBegin, transCommitWithoutException,  
transCommitWithException, transRollback );
```

Actions implemented by TSQldbConnectionProperties.SharedTransaction()

```
TSQldbStatementCRUD = ( cCreate, cRead, cUpdate, cDelete, cPostgreBulkArray );
```

Identify a CRUD mode of a statement

- in addition to CRUD states, cPostgreBulkArray would identify if the ORM should generate unnested/any bound array statements - currently only supported by SynDBPostgres for bulk insert/update/delete

```
TSQldbStatementCRUDs = set of TSQldbStatementCRUD;
```

Identify the CRUD modes of a statement

- used e.g. for batch send abilities of a DB engine

```
TSQldbStatementGetCol = ( colNone, colNull, colWrongType, colDataFilled,  
colDataTruncated );
```

Possible column retrieval patterns

- used by TSQldbColumnProperty.ColumnValueState

Constants implemented in the SynDB unit

```
DB_FIELDS: array[TSQldbDefinition] of TSQldbFieldTypeDefinition = ( (' INT','  
NVARCHAR(%)',' BIGINT',' DOUBLE',' NUMERIC(19,4)',' TIMESTAMP',' CLOB',' BLOB'), ('  
INT',' NVARCHAR(%)',' BIGINT',' DOUBLE',' NUMERIC(19,4)',' TIMESTAMP',' CLOB','  
BLOB'), (' NUMBER(22,0)',' NVARCHAR2(%)',' NUMBER(22,0)',' BINARY_DOUBLE','  
NUMBER(19,4)',' DATE',' NCLOB',' BLOB'), (' int',' nvarchar(%)',' bigint',' float','  
money',' datetime',' nvarchar(max)',' varbinary(max)'), (' Long',' VarChar(%)','  
Decimal(19,0)',' Double',' Currency',' DateTime',' LongText',' LongBinary'), (' int','  
varchar(%) character set UTF8',' bigint',' double',' decimal(19,4)',' datetime','  
mediumtext character set UTF8',' mediumblob'), (' INTEGER',' TEXT',' INTEGER',' FLOAT','  
FLOAT',' TEXT',' TEXT',' BLOB'), (' INTEGER',' VARCHAR(%) CHARACTER SET UTF8','  
BIGINT',' FLOAT',' DECIMAL(18,4)',' TIMESTAMP',' BLOB SUB_TYPE 1 SEGMENT SIZE 2000  
CHARACTER SET UTF8',' BLOB SUB_TYPE 0 SEGMENT SIZE 2000'), (' INTEGER',' NVARCHAR(%)','  
LARGEINT',' REAL',' MONEY',' DATETIME',' NCLOB',' BLOB'), (' INTEGER',' TEXT','  
BIGINT',' DOUBLE PRECISION',' NUMERIC(19,4)',' TIMESTAMP',' TEXT',' BYTEA'), (' int','  
varchar(%)',' bigint',' real',' decimal(19,4)',' timestamp',' clob',' blob'), (' int','  
lvarchar(%)',' bigint',' smallfloat',' decimal(19,4)',' datetime year to  
fraction(3)',' clob',' blob') );
```

The known column data types corresponding to our TSQldbFieldType types

- will be used e.g. for TSQldbConnectionProperties.SQLFieldCreate()
- see TSQldbFieldTypeDefinition documentation to find out the mapping

```
DB_FIELDSMAX: array[TSQldbDefinition] of cardinal = ( 1000, 1000, 1333, 4000, 255, 4000,  
0, 32760, 32767, 0, 32700, 32700);
```

The known column data types corresponding to our TSQldbFieldType types

- will be used e.g. for TSQldbConnectionProperties.SQLFieldCreate()
- SQLite3 doesn't expect any field length, neither PostgreSQL, so set to 0

```
DB_HANDLECREATEINDEXIFNOTEXISTS = [dSQLite, dPostgreSQL];
```

The known database engines handling CREATE INDEX IF NOT EXISTS statement

```
DB_HANDLEINDEXONBLOBS = [dSQLite,dPostgreSQL];
```

The known database engines handling CREATE INDEX on BLOB columns

- SQLite3 does not have any issue about indexing any column
- PostgreSQL is able to index TEXT columns, which are some kind of CLOB

```
DB_SERVERTIME: array[TSQldbDefinition] of RawUTF8 = ( '', '', 'select sysdate from dual',  
'select GETDATE()', '', 'SELECT NOW()', '', 'select current_timestamp from  
rdb$database', 'SELECT CURRENT_TIMESTAMP', 'SELECT LOCALTIMESTAMP', 'select current  
timestamp from sysibm.sysdummy1', 'select CURRENT YEAR TO FRACTION(3) from SYSTABLES  
where tabid = 1' );
```

The known SQL statement to retrieve the server date and time

```
DB_SQLDESCENDINGINDEXPOS: array[TSQldbDefinition] of (posWithColumn, posGlobalBefore)  
= ( posWithColumn, posWithColumn, posWithColumn, posWithColumn, posWithColumn,  
posWithColumn, posWithColumn, posGlobalBefore, posWithColumn, posWithColumn,  
posWithColumn, posWithColumn);
```

Where the DESC clause shall be used for a CREATE INDEX statement

- only identified syntax exception is for FireBird

```
DB_SQLLIMITCLAUSE: array[TSQldbDefinition] of TSQldbDefinitionLimitClause = (  
(Position: posNone; InsertFmt:nil), (Position: posNone; InsertFmt:nil), (Position:  
posWhere; InsertFmt:'rownum<=%)'), (Position: posSelect; InsertFmt:'top(%) '),  
(Position: posSelect; InsertFmt:'top % '), (Position: posAfter; InsertFmt:' limit %'),  
(Position: posAfter; InsertFmt:' limit % '), (Position: posSelect; InsertFmt:'first %  
' ), (Position: posSelect; InsertFmt:'top % '), (Position: posAfter; InsertFmt:' limit  
' ), (Position: posAfter; InsertFmt:' fetch first % rows only'), (Position: posAfter;  
InsertFmt:' first % '));
```

*Return local server time by default Jet is local -> return local time SQLite is local -> return local time
the known SQL syntax to limit the number of returned rows in a SELECT*

- Position indicates if should be included within the WHERE clause, at the beginning of the SQL statement, or at the end of the SQL statement
- InsertFmt will replace '%' with the maximum number of lines to be retrieved
- used by TSQldbConnectionProperties.AdaptSQLLimitForEngineList()

```
DB_SQLOPERATOR: array[opEqualTo..opLike] of RawUTF8 = ( '=', '<>', '<', '<=', '>', '>=', '  
in ', ' is null', ' is not null', ' like ');
```

The SQL text corresponding to the identified WHERE operators for a SELECT

```
FIXEDLENGTH_SQLDBFIELDTYPE = [ftInt64, ftDouble, ftCurrency, ftDate];
```

TSQldbFieldType kind of columns which have a fixed width

```
MAP_FIELDTYPE2VARTYPE: array[TSQldbFieldType] of Word = ( varEmpty, varNull, varInt64,  
varDouble, varCurrency, varDate, varSynUnicode, varString);
```

Conversion matrix from TSQldbFieldType into variant type

Functions or procedures implemented in the SynDB unit

Functions or procedures	Description	Page
BoundArrayToJSONArray	Create a JSON array from an array of UTF-8 bound values	1269
LogTruncatedColumn	FtUnknown, ftNull, ftInt64, ftDouble, ftCurrency, ftDate, ftUTF8, ftBlob function helper logging some column truncation information text	1269

Functions or procedures	Description	Page
ReplaceParamsByNames	Replace all '?' in the SQL statement with named parameters like :AA :AB..	1269
ReplaceParamsByNumbers	Replace all '?' in the SQL statement with indexed parameters like \$1 \$2 ...	1269
ToText	Retrieve the text of a given Database SQL dialect enumeration	1270
ToText	Retrieve the ready-to-be displayed text of proxy commands implemented by TSQLDBProxyConnectionProperties.Process()	1270
ToText	Retrieve the text of a given Database field type enumeration	1270
TrimLeftSchema	Retrieve a table name without any left schema	1270
TSQLDBFieldTypeToString	Retrieve the ready-to-be displayed text of a given Database field type enumeration	1270

function BoundArrayToJSONArray(const Values: TRawUTF8DynArray): RawUTF8;

Create a JSON array from an array of UTF-8 bound values

- as generated during array binding, i.e. with quoted strings 'one','two' -> '{"one","two"}' and 1,2,3 -> '{1,2,3}'
- as used e.g. by PostgreSQL library

procedure LogTruncatedColumn(const Col: TSQLDBColumnProperty);

FtUnknown, ftNull, ftInt64, ftDouble, ftCurrency, ftDate, ftUTF8, ftBlob function helper logging some column truncation information text

function ReplaceParamsByNames(const aSQL: RawUTF8; var aNewSQL: RawUTF8; aStripSemicolon: boolean=true): integer;

Replace all '?' in the SQL statement with named parameters like :AA :AB..

- returns the number of ? parameters found within aSQL
- won't generate any SQL keyword parameters (e.g. :AS :OF :BY), to be compliant with Oracle OCI expectations
- any ending ';' character is deleted, unless aStripSemicolon is unset

function ReplaceParamsByNumbers(const aSQL: RawUTF8; var aNewSQL: RawUTF8; IndexChar: AnsiChar = '\$'; AllowSemicolon: boolean = false): integer;

Replace all '?' in the SQL statement with indexed parameters like \$1 \$2 ...

- returns the number of ? parameters found within aSQL
- as used e.g. by PostgreSQL & Oracle (:1 :2) library
- if AllowSemicolon is false (by default), reject any statement with ; (Postgres do not allow ; inside prepared statement); it should be true for Oracle

function ToText(Field: TSQLDBFieldType): PShortString; overload;

Retrieve the text of a given Database field type enumeration

- see also TSQLDBFieldTypeToString() function

function ToText(cmd: TSQLDBProxyConnectionCommand): PShortString; overload;

Retrieve the ready-to-be displayed text of proxy commands implemented by TSQLDBProxyConnectionProperties.Process()

function ToText(DBMS: TSQLDBDefinition): PShortString; overload;

Retrieve the text of a given Database SQL dialect enumeration
- see also TSQLDBConnectionProperties.GetDBMSName() method

function TrimLeftSchema(const TableName: RawUTF8): RawUTF8;

Retrieve a table name without any left schema
- e.g. TrimLeftSchema('SCHEMA.TABLENAME')='TABLENAME'

function TSQLDBFieldTypeToString(aType: TSQLDBFieldType): TShort16;

Retrieve the ready-to-be displayed text of a given Database field type enumeration

Variables implemented in the *SynDB* unit

SynDBLog: TSynLogClass=TSynLog;

The TSynLog class used for logging for all our SynDB related units
- you may override it with TSynLog, if available from mORMot.pas
- since not all exceptions are handled specifically by this unit, you may better use a common TSynLog class for the whole application or module

27.10. SynDBDataset.pas unit

Purpose: DB.pas TDataSet-based direct access classes (abstract TQuery-like)

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the SynDBDataset unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynDB</i>	Abstract database direct access classes - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1208
<i>SynLog</i>	Logging functions used by Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1368
<i>SynTable</i>	Filter/database/cache/buffer/security/search/multithread/OS features - as a complement to SynCommons, which tended to increase too much - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1728
<i>SynVirtualDataSet</i>	DB VCL read-only virtual dataset - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1848

SynDBDataset class hierarchy

Objects implemented in the SynDBDataset unit

Objects	Description	Page
ESQLError	Exception type associated to generic TDataSet / DB.pas unit Dataset connection	1272
TSQLDBDatasetConnectionProperties	implement properties shared by via the DB.pas TQuery-like connections	1272
TSQLDBDatasetStatement	implements a statement via the DB.pas TDataSet/TQuery-like connection	1274
TSQLDBDatasetStatementAbstract	implements an abstract statement via the DB.pas TDataSet/TQuery-like connection	1272

ESQLDBDataset = class(ESQLDBException)

Exception type associated to generic TDataSet / DB.pas unit Dataset connection

TSQLDBDatasetConnectionProperties =

class(TSQLDBConnectionPropertiesThreadSafe)

implement properties shared by via the DB.pas TQuery-like connections

constructor Create(**const** aServerName, aDatabaseName, aUserID, aPassword: RawUTF8);
override;

Initialize the properties to connect via TDataSet database access

- this overridden method will enable the BATCH process (emulated in
 TSQLDBDatasetStatement.ExecutePrepared, native e.g. for FireDAC)

property ForceInt64AsFloat: boolean **read** fForceInt64AsFloat **write**
 fForceInt64AsFloat;

Set to true to force all Int64 content to be processed as a truncated float

- by default, Int64 values will be bound either as an integer (if the value is within expected
 range), either as Int64 variant
 - on some versions of Delphi, and some version of TDataSet (e.g. BDE), you may have to use a
 conversion to double to avoid a runtime error

property ForceUseWideString: boolean **read** fForceUseWideString **write**
 fForceUseWideString;

*Set to true to force all text content to be processed as WideString instead of the default faster
 AnsiString, for pre-Unicode version of Delphi*

- by default, UTF-8 text parameter or column will use an AnsiString value: for pre-Unicode
 Delphi, avoiding WideString/OleStr content will speed up the process a lot, if you are sure that
 the current charset matches the expected one (which is very likely)
 - set this property to TRUE so that WideString will be used when working with the internal
 TDataSet, to avoid any character data loss: the access to the property will be slower, but you
 won't have any potential data loss
 - if the text value contains only ASCII 7 bit characters, it won't be converted to WideString (since
 it is not necessary)
 - starting with Delphi 2009, the TEXT content will be processed as an UnicodeString, so this
 property is not necessary for most cases, but it appeared that some providers expects it to be
 defined

TSQLDBDatasetStatementAbstract = class(TSQLDBStatementWithParamsAndColumns)

implements an abstract statement via the DB.pas TDataSet/TQuery-like connection

- dedicated abstract class, able to use any TDataSet with any kind of parameter linking (e.g.
 FireDAC/AnyDAC do have its own parameters type)

constructor Create(aConnection: TSQLDBConnection); **override;**

Create a statement instance

destructor Destroy; **override;**

Release the prepared statement

function ColumnBlob(Col: Integer): RawByteString; **override;**

Return a Column as a blob value of the current Row, first Col is 0

function ColumnCurrency(Col: Integer): currency; **override;**

Return a Column currency value of the current Row, first Col is 0

function ColumnDateTime(Col: Integer): TDateTime; **override;**

Return a Column date and time value of the current Row, first Col is 0

function ColumnDouble(Col: Integer): double; **override;**

Return a Column floating point value of the current Row, first Col is 0

function ColumnInt(Col: Integer): Int64; **override;**

Return a Column integer value of the current Row, first Col is 0

function ColumnNull(Col: Integer): boolean; **override;**

Returns TRUE if the column contains NULL

function ColumnUTF8(Col: Integer): RawUTF8; **override;**

Return a Column UTF-8 encoded text value of the current Row, first Col is 0

function Step(SeekFirst: boolean = false): boolean; **override;**

Access the next or first row of data from the SQL Statement result

- return true on success, with data ready to be retrieved by Column*() methods
- return false if no more row is available (e.g. if the SQL statement is not a SELECT but an UPDATE or INSERT command)
- if SeekFirst is TRUE, will put the cursor on the first row of results
- raise an ESQLDBDataset on any error

procedure ColumnsToJSON(WR: TJSONWriter); **override;**

Append all columns values of the current Row to a JSON stream

- will use WR.Expand to guess the expected output format
- BLOB field value is saved as Base64, in the '"\u0000base64encodedbinary"' format and contains true BLOB data

procedure ExecutePrepared; **override;**

Execute a prepared SQL statement

- parameters marked as ? should have been already bound with Bind*() functions
- this implementation will also loop through all internal bound array of values (if any), to implement BATCH mode even if the database library does not support array binding (only SynDBFireDAC does support it yet)
- this overridden method will log the SQL statement if sIISQL has been enabled in SynDBLog.Family.Level
- raise an ESQLDBDataset on any error

procedure Prepare(const aSQL: RawUTF8; ExpectResults: boolean = false); **overload;**
override;

Prepare an UTF-8 encoded SQL statement

- parameters marked as ? will be bound later, before ExecutePrepared call
- if ExpectResults is TRUE, then Step() and Column*() methods are available to retrieve the data rows
- raise an ESQLDBDataset on any error

procedure ReleaseRows; **override;**

Close the associated TQuery when ISQLDBStatement is back in cache

procedure Reset; override;

Reset the previous prepared statement

- this overridden implementation will reset all bindings and the cursor state
- raise an ESQLDBDataset on any error

TSQLDBDatasetStatement = class(TSQLDBDatasetStatementAbstract)

implements a statement via the DB.pas TDataSet/TQuery-like connection

- you should not use this abstract class directly, but one inherited implementation with overridden Dataset*() protected methods to handle the internal fQuery: TDataSet property

procedure Prepare(const aSQL: RawUTF8; ExpectResults: boolean = false); overload; override;

Prepare an UTF-8 encoded SQL statement

- parameters marked as ? will be bound later, before ExecutePrepared call
- if ExpectResults is TRUE, then Step() and Column*() methods are available to retrieve the data rows
- raise an ESQLDBDataset on any error

27.11. SynDBMidasVCL.pas unit

Purpose: Fill a VCL TClientDataSet from SynDB data access

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the SynDBMidasVCL unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynDB</i>	Abstract database direct access classes - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1208
<i>SynDBVCL</i>	DB VCL read/only dataset from SynDB data access - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1308

SynDBMidasVCL class hierarchy

Objects implemented in the SynDBMidasVCL unit

Objects	Description	Page
TSynDBDataSet	A TClientDataSet which allows to apply updates on a SynDB connection	1275

TSynDBDataSet = class(TCustomClientDataSet)

A TClientDataSet which allows to apply updates on a SynDB connection

- typical usage may be for instance over a SynDBRemote connection:

```

props := TSQLDBWinHTTPConnectionProperties.Create(...);
ds := TSynDBDataSet.Create(MainForm);
ds.CommandText := 'select * from people';
ds.Open;
// ... use ds as usual, including modifications
ds.ApplyUpdates(0);
  
```

constructor Create(AOwner: TComponent); **override;**

Initialize the instance

procedure From(Statement: TSQLDBStatement; MaxRowCount: cardinal=0);

Initialize the internal TDataSet from a SynDB TSQLDBStatement result set

- the supplied TSQLDBStatement can then be freed by the caller, since a private binary copy will be owned by this instance (in fDataSet.Data)

property Connection: TSQLDBConnectionProperties **read** GetConnection **write** SetConnection;

The associated SynDB connection

property DataSet: TSynDBSQLDataSet **read** fDataSet;

The associated SynDB TDataSet, used to retrieve and update data

property IgnoreColumnDataSize: boolean **read** fIgnoreColumnDataSize **write** fIgnoreColumnDataSize;

If field sizes should be left unset, allowing further filling with any data length

- by default, ColumnDataSize would be computed from the supplied data, unless you set IgnoreColumnDataSize=true to set the value to 0 (and force e.g. SynDBVCL TSynBinaryDataSet.InternalInitFieldDefs define the field as ftDefaultMemo)

Types implemented in the SynDBMidasVCL unit

TClientDataSetMode = (cdsNew, cdsAppend, cdsReplace);

How ToClientDataSet functions will fill the TClientDataSet instance

Functions or procedures implemented in the SynDBMidasVCL unit

Functions or procedures	Description	Page
ToClientDataSet	Fetch a SynDB TQuery result set into a new VCL TClientDataSet	1277
ToClientDataSet	Fetch a SynDB TSQLDBStatement result set into a new VCL TClientDataSet	1277
ToClientDataSet	Fetch a SynDB ISQLDBRows result set into a new VCL TClientDataSet	1277
ToClientDataSet	Fetch a SynDB TQuery result into an existing VCL TClientDataSet	1277
ToClientDataSet	Fetch a SynDB TSQLDBStatement result into an existing VCL TClientDataSet	1277

function ToClientDataSet(aDataSet: TClientDataSet; aStatement: SynDB.TQuery; aMaxRowCount: integer=0; aMode: TClientDataSetMode=cdsReplace; aLogChange: boolean=false): boolean; overload;

Fetch a SynDB TQuery result into an existing VCL TClientDataSet

- if aMaxRowCount>0, will return up to the specified number of rows

- current implementation will fill an existing TClientDataSet instance, from the supplied TQuery content

- for better speed with Delphi older than Delphi 2009 Update 3, it is recommended to use <http://andy.jgknet.de/blog/bugfix-units/midas-speed-fix-12>

```
function ToClientDataSet(aDataSet: TClientDataSet; aStatement: TSQLDBStatement;  
aMaxRowCount: integer=0; aMode: TClientDataSetMode=cdsReplace; aLogChange:  
boolean=false): boolean; overload;
```

Fetch a SynDB TSQLDBStatement result into an existing VCL TClientDataSet

- if aMaxRowCount>0, will return up to the specified number of rows
- current implementation will fill an existing TClientDataSet instance, from the supplied TSQLDBStatement content
- for better speed with Delphi older than Delphi 2009 Update 3, it is recommended to use <http://andy.jgknet.de/blog/bugfix-units/midas-speed-fix-12>

```
function ToClientDataSet(aOwner: TComponent; aStatement: ISQLDBRows; aMaxRowCount:  
integer=0): TSynDBDataSet; overload;
```

Fetch a SynDB ISQLDBRows result set into a new VCL TClientDataSet

- this overloaded function can use directly a result of the TSQLDBConnectionProperties.Execute() method, as such:
ds1.DataSet := ToClientDataSet(self, props.Execute('select * from table',[]));

```
function ToClientDataSet(aOwner: TComponent; aStatement: SynDB.TQuery; aMaxRowCount:  
integer=0): TSynDBDataSet; overload;
```

Fetch a SynDB TQuery result set into a new VCL TClientDataSet

- if aMaxRowCount>0, will return up to the specified number of rows
- current implementation will return a TClientDataSet instance, created from the supplied TQuery content
- for better speed with Delphi older than Delphi 2009 Update 3, it is recommended to use <http://andy.jgknet.de/blog/bugfix-units/midas-speed-fix-12>
- if you need a read/only TDataSet, you should better not use this function but ToDataSet() as defined in SynDBVCL which is much faster and uses much less resources

```
function ToClientDataSet(aOwner: TComponent; aStatement: TSQLDBStatement;  
aMaxRowCount: integer=0): TSynDBDataSet; overload;
```

Fetch a SynDB TSQLDBStatement result set into a new VCL TClientDataSet

- if aMaxRowCount>0, will return up to the specified number of rows
- current implementation will return a TClientDataSet instance, created from the supplied TSQLDBStatement content
- for better speed with Delphi older than Delphi 2009 Update 3, it is recommended to use <http://andy.jgknet.de/blog/bugfix-units/midas-speed-fix-12>
- if you need a read/only TDataSet, you should better not use this function but ToDataSet() function as defined in SynDBVCL which is much faster and uses much less resources

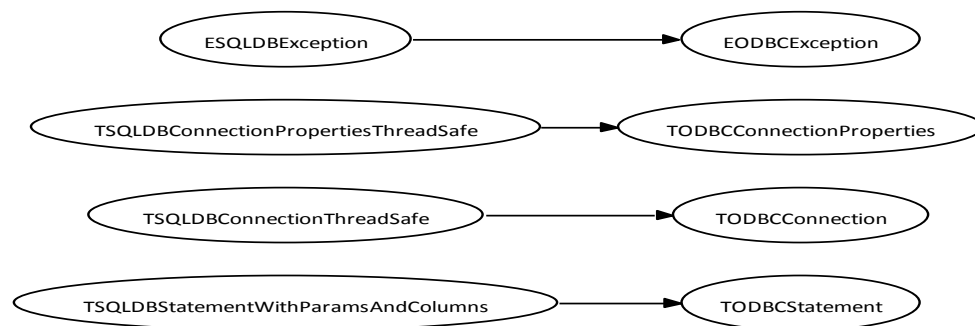

27.12. SynDBODBC.pas unit

Purpose: ODBC 3.x library direct access classes to be used with our SynDB architecture

- this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the *SynDBODBC* unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synapse projects - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynDB</i>	Abstract database direct access classes - this unit is a part of the freeware Synapse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1208
<i>SynLog</i>	Logging functions used by Synapse projects - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1368
<i>SynTable</i>	Filter/database/cache/buffer/security/search/multithread/OS features - as a complement to SynCommons, which tended to increase too much - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1728

SynDBODBC class hierarchy

Objects implemented in the *SynDBODBC* unit

Objects	Description	Page
EODBCException	Generic Exception type, generated for ODBC connection	1279
TODBCConnection	Implements a direct connection to the ODBC library	1280
TODBCConnectionProperties	Will implement properties shared by the ODBC library	1279
TODBCStatement	Implements a statement using a ODBC connection	1281

```
EODBCException = class(ESQLDBException)
```

Generic Exception type, generated for ODBC connection

```
TODBCConnectionProperties = class(TSQLDBConnectionPropertiesThreadSafe)
```

Will implement properties shared by the ODBC library

```
constructor Create(const aServerName, aDatabaseName, aUserID, aPassWord: RawUTF8);  
override;
```

Initialize the connection properties

- will raise an exception if the ODBC library is not available
- SQLConnect() API will be used if aServerName is set: it should contain the ODBC Data source name as defined in "ODBC Data Source Administrator" tool (C:\Windows\SysWOW64\odbcad32.exe for 32bit app on Win64) - in this case, aDatabaseName will be ignored
- SQLDriverConnect() API will be used if aServerName is "" and aDatabaseName is set - in this case, aDatabaseName should contain a full connection string like (e.g. for a local SQLEXPRESS instance):

```
'DRIVER=SQL Server Native Client 10.0;UID=.;server=.\SQLEXPRESS;'+  
'Trusted_Connection=Yes;MARS_Connection=yes'
```

see @<http://msdn.microsoft.com/en-us/library/ms715433> or when using Firebird ODBC:

```
'DRIVER=Firebird/InterBase(r) driver;CHARSET=UTF8;UID=SYSDBA;PWD=masterkey;'  
'DBNAME=MyServer/3051:C:\database\myData.fdb'  
'DRIVER=Firebird/InterBase(r) driver;CHARSET=UTF8;DBNAME=dbfile.fdb;'+  
'CLIENT=fbembed.dll'
```

for IBM DB2 and its official driver:

```
'Driver=IBM DB2 ODBC DRIVER;Database=SAMPLE;'+  
'Hostname=localhost;Port=50000;UID=db2admin;Pwd=db2Password'
```

for PostgreSQL - driver from <http://ftp.postgresql.org/pub/odbc/versions/msi>

```
'Driver=PostgreSQL Unicode;Database=postgres;'+  
'Server=localhost;Port=5432;UID=postgres;Pwd=postgresPassword'
```

for MySQL - driver from <https://dev.mysql.com/downloads/connector/odbc> (note: 5.2.6 and 5.3.1 driver seems to be slow in ODBC.FreeHandle)

```
'Driver=MySQL ODBC 5.2 UNICODE Driver;Database=test;'+  
'Server=localhost;Port=3306;UID=root;Pwd='
```

for IBM Informix and its official driver:

```
'Driver=IBM INFORMIX ODBC DRIVER;Database=SAMPLE;'+  
'Host=localhost;Server=<instance name on host>;Service=<service name  
in ../drivers/etc/services>;Protocol=olsoctcp;UID=<Windows/Linux user account>;  
Pwd=<Windows/Linux user account password>'
```

```
function NewConnection: TSQLDBConnection; override;
```

Create a new connection

- call this method if the shared MainConnection is not enough (e.g. for multi-thread access)
- the caller is responsible of freeing this instance
- this overridden method will create an TODBCConnection instance

```
procedure GetFields(const aTableName: RawUTF8; out Fields:  
TSQLDBColumnDefineDynArray); override;
```

Retrieve the column/field layout of a specified table

- will also check if the columns are indexed
- will retrieve the corresponding metadata from ODBC library if SQL direct access was not defined (e.g. for dDB2)

```
procedure GetForeignKeys; override;
```

Initialize fForeignKeys content with all foreign keys of this DB

- used by GetForeignKey method

```
procedure GetProcedureNames(out Procedures: TRawUTF8DynArray); override;
```

Retrieve a list of stored procedure names from current connection

```
procedure GetProcedureParameters(const aProcName: RawUTF8; out Parameters:  
TSQLDBProcColumnDefineDynArray); override;
```

Retrieve procedure input/output parameter information

- aProcName: stored procedure name to retrieve parameter information.
- Parameters: parameter list info (name, datatype, direction, default)

```
procedure GetTableNames(out Tables: TRawUTF8DynArray); override;
```

Get all table names

- will retrieve the corresponding metadata from ODBC library if SQL direct access was not defined

```
procedure GetViewNames(out Views: TRawUTF8DynArray); override;
```

Get all view names

- will retrieve the corresponding metadata from ODBC library if SQL direct access was not defined

```
property SQLDriverConnectPrompt: boolean read fSQLDriverConnectPrompt write  
fSQLDriverConnectPrompt;
```

If full connection string may prompt the user for additional information

- property used only with SQLDriverConnect() API (i.e. when aServerName is "" and aDatabaseName contains a full connection string)
- set to TRUE to allow UI prompt if needed

```
property SQLStatementTimeoutSec: integer read fSQLStatementTimeout write  
fSQLStatementTimeout;
```

The number of seconds to wait for a SQL statement to execute before canceling the query. When set to 0 (the default) there is no timeout. See ODBC SQL_QUERY_TIMEOUT documentation

```
TODBCConnection = class(TSQLDBConnectionThreadSafe)
```

Implements a direct connection to the ODBC library

```
constructor Create(aProperties: TSQLDBConnectionProperties); override;
```

Connect to a specified ODBC database

```
destructor Destroy; override;
```

Release memory and connection

```
function IsConnected: boolean; override;
```

Return TRUE if Connect has been already successfully called

function NewStatement: TSQLDBStatement; **override;**

Initialize a new SQL query statement for the given connection
- the caller should free the instance after use

procedure Commit; **override;**

Commit changes of a Transaction for this connection
- StartTransaction method must have been called before

procedure Connect; **override;**

Connect to the ODBC library, i.e. create the DB instance
- should raise an Exception on error

procedure Disconnect; **override;**

Stop connection to the ODBC library, i.e. release the DB instance
- should raise an Exception on error

procedure Rollback; **override;**

Discard changes of a Transaction for this connection
- StartTransaction method must have been called before

procedure StartTransaction; **override;**

Begin a Transaction for this connection
- current implementation do not support nested transaction with those methods: exception will be raised in such case

property DBMS: TSQLDBDefinition **read** fDBMS;

The remote DBMS type, as retrieved at ODBC connection opening

property DBMSName: RawUTF8 **read** fDBMSName;

The remote DBMS name, as retrieved at ODBC connection opening

property DBMSVersion: RawUTF8 **read** fDBMSVersion;

The remote DBMS version, as retrieved at ODBC connection opening

property DriverName: RawUTF8 **read** fDriverName;

The local driver name, as retrieved at ODBC connection opening

property SQLDriverFullString: RawUTF8 **read** fSQLDriverFullString;

The full connection string (expanded from ServerName)

TODBCStatement = class(TSQLDBStatementWithParamsAndColumns)

Implements a statement using a ODBC connection

constructor Create(aConnection: TSQLDBConnection); **override;**

Create a ODBC statement instance, from an existing ODBC connection
- the Execute method can be called once per TODBCStatement instance, but you can use the Prepare once followed by several ExecutePrepared methods
- if the supplied connection is not of TOleDBConnection type, will raise an exception

destructor Destroy; **override;**

Release all associated memory and ODBC handles

function ColumnBlob(Col: integer): RawByteString; **override;**

Return a Column as a blob value of the current Row, first Col is 0

- ColumnBlob() will return the binary content of the field if it was not a `ftBlob`, e.g. a 8 bytes `RawByteString` for a `vtInt64`/`vtDouble`/`vtDate`/`vtCurrency`, or a direct mapping of the `RawUnicode`

function ColumnCurrency(Col: integer): currency; **override;**

Return a Column currency value of the current Row, first Col is 0

- should retrieve directly the 64 bit Currency content, to avoid any rounding/conversion error from floating-point types

function ColumnDateTime(Col: integer): TDateTime; **override;**

Return a Column floating point value of the current Row, first Col is 0

function ColumnDouble(Col: integer): double; **override;**

Return a Column floating point value of the current Row, first Col is 0

function ColumnInt(Col: integer): Int64; **override;**

Return a Column integer value of the current Row, first Col is 0

function ColumnNull(Col: integer): boolean; **override;**

Returns TRUE if the column contains NULL

function ColumnUTF8(Col: integer): RawUTF8; **override;**

Return a Column UTF-8 encoded text value of the current Row, first Col is 0

function Step(SeekFirst: boolean=false): boolean; **override;**

After a statement has been prepared via `Prepare()` + `ExecutePrepared()` or `Execute()`, this method must be called one or more times to evaluate it

- you shall call this method before calling any `Column*()` methods

- return TRUE on success, with data ready to be retrieved by `Column*()`

- return FALSE if no more row is available (e.g. if the SQL statement is not a SELECT but an UPDATE or INSERT command)

- access the first or next row of data from the SQL Statement result: if `SeekFirst` is TRUE, will put the cursor on the first row of results, otherwise, it will fetch one row of data, to be called within a loop

- raise an `EODBException` or `ESQLDBException` exception on any error

function UpdateCount: integer; **override;**

Returns the number of rows updated by the execution of this statement

procedure ColumnsToJSON(WR: TJSONWriter); **override;**

Append all columns values of the current Row to a JSON stream

- will use `WR.Expand` to guess the expected output format

- fast overridden implementation with no temporary variable

- BLOB field value is saved as Base64, in the `""\uFFFF0base64encodedbinary"` format and contains true BLOB data

procedure ExecutePrepared; **override**;

Execute a prepared SQL statement

- parameters marked as ? should have been already bound with Bind*() functions
- this overridden method will log the SQL statement if sllSQL has been enabled in SynDBLog.Family.Level
- raise an EODBCEException or ESQLErrorException on any error

procedure Prepare(const aSQL: RawUTF8; ExpectResults: Boolean=false); **overload**;
override;

Prepare an UTF-8 encoded SQL statement

- parameters marked as ? will be bound later, before ExecutePrepared call
- if ExpectResults is TRUE, then Step() and Column*() methods are available to retrieve the data rows
- raise an EODBCEException or ESQLErrorException on any error

procedure ReleaseRows; **override**;

Close the ODBC statement cursor resources

procedure Reset; **override**;

Reset the previous prepared statement

- this overridden implementation will reset all bindings and the cursor state
- raise an EODBCEException on any error

Functions or procedures implemented in the SynDBODBC unit

Functions or procedures	Description	Page
ODBCInstalledDriversList	List all ODBC drivers installed, by reading the Windows Registry	1283

function ODBCInstalledDriversList(const aIncludeVersion: Boolean; var aDrivers: TStrings): boolean;

List all ODBC drivers installed, by reading the Windows Registry

- aDrivers is the output driver list container, which should be either nil (to create a new TStringList), or any existing TStrings instance (may be from VCL)
- aIncludeVersion: include the DLL driver version as <driver name>=<dll version> in aDrivers (somewhat slower)

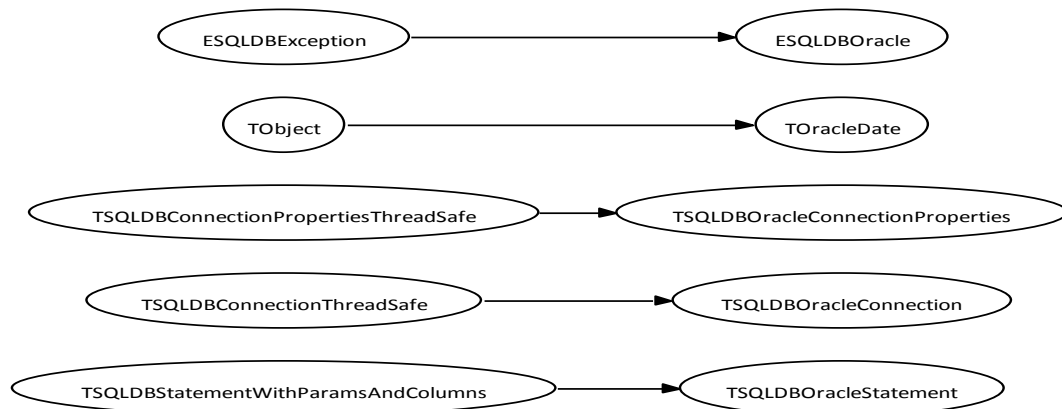

27.13. SynDBOracle.pas unit

Purpose: Oracle DB direct access classes (via OCI)

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the SynDBOracle unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynDB</i>	Abstract database direct access classes - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1208
<i>SynLog</i>	Logging functions used by Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1368
<i>SynTable</i>	Filter/database/cache/buffer/security/search/multithread/OS features - as a complement to SynCommons, which tended to increase too much - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1728

SynDBOracle class hierarchy

Objects implemented in the SynDBOracle unit

Objects	Description	Page
ESQLOracle	Exception type associated to the native Oracle Client Interface (OCI)	1285
TOracleDate	Memory structure used to store a date and time in native Oracle format	1285
TSQLOracleConnection	Implements a direct connection to the native Oracle Client Interface (OCI)	1287

Objects	Description	Page
TSQldbOracleConnectionProperties	Will implement properties shared by native Oracle Client Interface connections	1285
TSQldbOracleStatement	Implements a statement via the native Oracle Client Interface (OCI)	1288

ESQldbOracle = class(ESQldbException)

Exception type associated to the native Oracle Client Interface (OCI)

TOracleDate = object(TObject)

Memory structure used to store a date and time in native Oracle format

- follow the SQLT_DAT column type layout

function ToDateTime: TDateTime;

Convert an Oracle date and time into Delphi TDateTime

- this method will ignore any date before 30 Dec 1899 (i.e. any TDateTime result < 0), to avoid e.g. wrong DecodeTime() computation from retrieved value: if you need to retrieve dates before 1899, you should better retrieve the content using ISO-8601 text encoding

function ToIso8601(Dest: PUTF8Char): integer; overload;

Convert an Oracle date and time into its textual expanded ISO-8601

- will fill up to 21 characters, including double quotes

procedure From(const aIso8601: RawUTF8); overload;

Convert textual ISO-8601 into native Oracle date and time format

procedure From(const aValue: TDateTime); overload;

Convert Delphi TDateTime into native Oracle date and time format

procedure From(aIso8601: PUTF8Char; Length: integer); overload;

Convert textual ISO-8601 into native Oracle date and time format

procedure ToIso8601(var aIso8601: RawByteString); overload;

Convert an Oracle date and time into its textual expanded ISO-8601

- return the ISO-8601 text, without double quotes

TSQldbOracleConnectionProperties =

class(TSQldbConnectionPropertiesThreadSafe)

Will implement properties shared by native Oracle Client Interface connections

constructor Create(const aServerName, aDatabaseName, aUserID, aPassword: RawUTF8);
override;

Initialize the connection properties

- we don't need a database name parameter for Oracle connection: only aServerName is to be set
- you may specify the TNSName in aServerName, or a connection string like '//host[:port]/[service_name]', e.g. '//sales-server:1523/sales'
- connection is opened globally as UTF-8, to match the internal encoding of our units; but CHAR / NVARCHAR2 fields will use the Oracle charset as retrieved from the opened connection (to avoid any conversion error)

class function ExtractTnsName(const aServerName: RawUTF8): RawUTF8;

Extract the TNS listener name from a Oracle full connection string

- e.g. ExtractTnsName('1.2.3.4:1521/dbname') returns 'dbname'

function IsCachable(P: PUTF8Char): boolean; **override;**

Determine if the SQL statement can be cached

- always returns false, to force server-side caching only on this driver

function NewConnection: TSQLDBConnection; **override;**

Create a new connection

- call this method if the shared MainConnection is not enough (e.g. for multi-thread access)
- the caller is responsible of freeing this instance
- this overridden method will create an TSQLDBOracleConnection instance

property BlobPrefetchSize: integer **read** fBlobPrefetchSize **write** fBlobPrefetchSize;

The size (in bytes) of LOB prefetch

- is set to 4096 (4 KB) by default, but may be changed for tuned performance

property ClientVersion: RawUTF8 **read** GetClientVersion;

Returns the Client version e.g. 'oci.dll rev. 11.2.0.1'

property EnvironmentInitializationMode: integer **read**

fEnvironmentInitializationMode **write** fEnvironmentInitializationMode;

The OCI initialization mode used for the connection

- equals OCI_EVENTS or OCI_THREADED by default, since will likely be used in a multi-threaded context (even if this class is inheriting from TSQLDBConnectionPropertiesThreadSafe), and OCI_EVENTS is needed to support Oracle RAC Connection Load Balancing
- can be tuned depending on the configuration or the Oracle version

property IgnoreORA01453OnStartTransaction: boolean **read**

fIgnoreORA01453OnStartTransaction **write** fIgnoreORA01453OnStartTransaction;

When we execute a SELECT statement across a database link, a transaction lock is placed on the undo segments (transaction is implicitly started). Setting this options to true allow to ignore ORA-01453 during TSQLDBOracleConnection.StartTransaction call.

- see Oracle documentation

http://docs.oracle.com/cd/B28359_01/server.111/b28310/ds_appdev002.htm

property InternalBufferSize: integer **read** fInternalBufferSize **write** fInternalBufferSize;

The size (in bytes) of the internal buffer used to retrieve rows in statements

- default is 128 KB, which gives very good results

property OnPasswordChanged: TNotifyEvent **read** FOnPasswordChanged **write** FOnPasswordChanged;

Password changed event

property OnPasswordExpired: TOnPasswordExpired **read** FOnPasswordExpired **write** FOnPasswordExpired;

Password Expired event

property RowsPrefetchSize: integer **read** fRowsPrefetchSize **write** fRowsPrefetchSize;

The size (in bytes) of rows data prefetch at OCI driver level

- is set to 128 KB by default, but may be changed for tuned performance

property StatementCacheSize: integer **read** fStatementCacheSize **write** fStatementCacheSize;

The number of prepared statements cached by OCI on the Client side

- is set to 30 by default

- only used if UseCache=true

property UseWallet: boolean **read** fUseWallet **write** fUseWallet;

Use the Secure External Password Store for Password Credentials

- see Oracle documentation

http://docs.oracle.com/cd/B28359_01/network.111/b28531/authentication.htm#DBSEG97906

TSQldbOracleConnection = class(TSQldbConnectionThreadSafe)

Implements a direct connection to the native Oracle Client Interface (OCI)

constructor Create(aProperties: TSQldbConnectionProperties); **override**;

Prepare a connection to a specified Oracle database server

destructor Destroy; **override**;

Release memory and connection

function IsConnected: boolean; **override**;

Return TRUE if Connect has been already successfully called

function NewStatement: TSQldbStatement; **override**;

Initialize a new SQL query statement for the given connection

- if UseCache=true, this overridden implementation will use server-side Oracle statement cache -
in this case, StatementCacheSize will define how many statements are to be cached - not that
IsCachable() has been overridden to return false, so statement cache on client side is disabled
- the caller should free the instance after use

function PasswordChange: Boolean;

Allows to change the password of the current connected user

- will first launch the OnPasswordExpired event to retrieve the new password, then change it
and call OnPasswordChanged event on success

procedure Commit; **override**;

Commit changes of a Transaction for this connection

- StartTransaction method must have been called before

procedure Connect; override;

Connect to the specified Oracle database server

- should raise an Exception on error
- the connection will be globally opened with UTF-8 encoding; for CHAR / NVARCHAR2 fields, the DB charset encoding will be retrieved from the server, to avoid any truncation during data retrieval
- BlobPrefetchSize, RowsPrefetchSize and StatementCacheSize field values of the associated properties will be used to tune the opened connection

procedure Disconnect; override;

Stop connection to the specified Oracle database server

- should raise an Exception on error

procedure Rollback; override;

Discard changes of a Transaction for this connection

- StartTransaction method must have been called before

procedure StartTransaction; override;

Begin a Transaction for this connection

- current implementation do not support nested transaction with those methods: exception will be raised in such case
- by default, TSQLDBOracleStatement works in AutoCommit mode, unless StartTransaction is called

TSQLDBOracleStatement = class(TSQLDBStatementWithParamsAndColumns)

Implements a statement via the native Oracle Client Interface (OCI)

- those statements can be prepared on the Delphi side, but by default we enabled the OCI-side statement cache, not to reinvent the wheel this time
- note that bound OUT ftUTF8 parameters will need to be pre-allocated before calling - e.g. via BindTextU(StringOfChar(3000),paramOut)
- you can also bind an TInt64DynArray or TRawUTF8DynArray as parameter to be assigned later as an OCI_OBJECT so that you may write such statements:

```
var arr: TInt64DynArray = [1, 2, 3];
Query := TSQLDBOracleConnectionProperties.NewThreadSafeStatementPrepared(
  'select * from table where table.id in '+
  '(select column_value from table(cast(? as SYS.ODCINUMBERLIST)))');
Query.BindArray(1,arr);
Query.ExecutePrepared;
```

(use SYS.ODCIVARCHAR2LIST type cast for TRawUTF8DynArray values)

constructor Create(aConnection: TSQLDBConnection); override;

Create an OCI statement instance, from an existing OCI connection

- the Execute method can be called once per TSQLDBOracleStatement instance, but you can use the Prepare once followed by several ExecutePrepared methods
- if the supplied connection is not of TOleDBConnection type, will raise an exception

**constructor CreateFromExistingStatement(aConnection: TSQLDBConnection;
aStatement: pointer);**

Initialize the class from an existing OCI statement (and connection)

- to be called e.g. by ColumnCursor() for SQLT_RSET kind of column

destructor Destroy; **override**;

Release all associated memory and OCI handles

function BoundCursor(Param: Integer): ISQLDBRows; **override**;

Return a special CURSOR parameter content as a SynDB result set

- this method is not about a column, but a parameter defined with BindCursor() before method execution
- Cursors are not handled internally by mORMot, but some databases (e.g. Oracle) usually use such structures to get data from stored procedures
- this method allow direct access to the data rows after execution
- this overridden method will allow direct access to the data rows

function ColumnBlob(Col: integer): RawByteString; **override**;

Return a Column as a blob value of the current Row, first Col is 0

- ColumnBlob() will return the binary content of the field if it was not ftBlob, e.g. a 8 bytes RawByteString for a vtInt64/vtDouble/vtDate/vtCurrency, or a direct mapping of the RawUnicode

function ColumnBlobBytes(Col: integer): TBytes; **override**;

Return a Column as a blob value of the current Row, first Col is 0

- this function will return the BLOB content as a TBytes
- this default virtual method will call ColumnBlob()

function ColumnCurrency(Col: integer): currency; **override**;

Return a Column currency value of the current Row, first Col is 0

- should retrieve directly the 64 bit Currency content, to avoid any rounding/conversion error from floating-point types

function ColumnCursor(Col: integer): ISQLDBRows; **override**;

Return a special CURSOR Column content as a SynDB result set

- Cursors are not handled internally by mORMot, but Oracle usually use such structures to get data from stored procedures
- such columns are mapped as ftUTF8, with the rows converted to JSON
- this overridden method will allow direct access to the data rows

function ColumnDateTime(Col: integer): TDateTime; **override**;

Return a Column date and time value of the current Row, first Col is 0

function ColumnDouble(Col: integer): double; **override**;

Return a Column floating point value of the current Row, first Col is 0

function ColumnInt(Col: integer): Int64; **override**;

Return a Column integer value of the current Row, first Col is 0

function ColumnNull(Col: integer): boolean; **override**;

Returns TRUE if the column contains NULL

```
function ColumnToVariant(Col: integer; var Value: Variant): TSQLDBFieldType;  
override;
```

Return a Column as a variant

- this implementation will retrieve the data with no temporary variable (since TQuery calls this method a lot, we tried to optimize it)
- a ftUTF8 content will be mapped into a generic WideString variant for pre-Unicode version of Delphi, and a generic UnicodeString (=string) since Delphi 2009: you may not loose any data during charset conversion
- a ftBlob content will be mapped into a TBlobData AnsiString variant

```
function ColumnUTF8(Col: integer): RawUTF8; override;
```

Return a Column UTF-8 encoded text value of the current Row, first Col is 0

```
function Step(SeekFirst: boolean=false): boolean; override;
```

After a statement has been prepared via Prepare() + ExecutePrepared() or Execute(), this method must be called one or more times to evaluate it

- you shall call this method before calling any Column*() methods
- return TRUE on success, with data ready to be retrieved by Column*()
- return FALSE if no more row is available (e.g. if the SQL statement is not a SELECT but an UPDATE or INSERT command)
- access the first or next row of data from the SQL Statement result: if SeekFirst is TRUE, will put the cursor on the first row of results, otherwise, it will fetch one row of data, to be called within a loop
- raise an ESQLDBOracle on any error

```
function UpdateCount: integer; override;
```

Returns the number of rows updated by the execution of this statement

```
procedure BindCursor(Param: integer); override;
```

Bind a special CURSOR parameter to be returned as a SynDB result set

- Cursors are not handled internally by mORMot, but some databases (e.g. Oracle) usually use such structures to get data from stored procedures
- such parameters are mapped as ftUnknown, and is always of paramOut type
- use BoundCursor() method to retrieve the corresponding ISQLDBRows after execution of the statement
- this overridden method will prepare direct access to the data rows

```
procedure ColumnBlobFromStream(Col: integer; Stream: TStream); override;
```

Write a blob Column into the Stream parameter

- expected to be used with 'SELECT .. FOR UPDATE' locking statements

```
procedure ColumnBlobToStream(Col: integer; Stream: TStream); override;
```

Read a blob Column into the Stream parameter

```
procedure ColumnsToJSON(WR: TJSONWriter); override;
```

Append all columns values of the current Row to a JSON stream

- will use WR.Expand to guess the expected output format
- fast overridden implementation with no temporary variable (about 20% faster when run over high number of data rows)
- BLOB field value is saved as Base64, in the '"\uFFFF0base64encodedbinary"' format and contains true BLOB data

procedure ColumnToSQLVar(Col: Integer; var Value: TSQLVar; var Temp: RawByteString);
override;

Return a Column as a TSQLVar value, first Col is 0

- the specified Temp variable will be used for temporary storage of svtUTF8/svtBlob values
- this implementation will retrieve the data with no temporary variable, and handling ftCurrency/NUMBER(22,0) as fast as possible, directly from the memory buffers returned by OCI: it will ensure best performance possible when called from TSQLVirtualTableCursorExternal.Column method as defined in mORMotDB unit (i.e. mORMot external DB access)

procedure ExecutePrepared; **override;**

Execute a prepared SQL statement

- parameters marked as ? should have been already bound with Bind*() functions
- raise an ESQLDBOracle on any error

procedure Prepare(const aSQL: RawUTF8; ExpectResults: Boolean=false); **overload;**
override;

Prepare an UTF-8 encoded SQL statement

- parameters marked as ? will be bound later, before ExecutePrepared call
- if ExpectResults is TRUE, then Step() and Column*() methods are available to retrieve the data rows
- raise an ESQLDBOracle on any error
- if aSQL requires a trailing ';', you should end it with ';;' e.g. for

```
DB.ExecuteNoResult(
  'CREATE OR REPLACE FUNCTION ORA_POC(MAIN_TABLE IN VARCHAR2, REC_COUNT IN NUMBER, BATCH_SIZE
  IN NUMBER) RETURN VARCHAR2' +
  ' AS LANGUAGE JAVA' +
  ' NAME ''OraMain.selectTable(java.lang.String, int, int) return java.lang.String'';;', []);
```

procedure ReleaseRows; **override;**

Finalize the OCI cursor resources - not implemented yet

Types implemented in the SynDBOracle unit

TOnPasswordExpired = **function** (Sender: TSQLDBConnection; var APassword: RawUTF8):
 Boolean **of object**;

Event triggered when an expired password is detected

- will allow to provide a new password

TOracleDateArray = **array**[0..(maxInt div sizeof(TOracleDate))-1] **of** TOracleDate;

Wrapper to an array of TOracleDate items

Constants implemented in the SynDBOracle unit

OCI_UTF8 = \$367;

Defined here for overriding OCI_CHARSET_UTF8/OCI_CHARSET_WIN1252 if needed

Variables implemented in the SynDBOracle unit

`OCI_CHARSET_UTF8: cardinal = OCI_AL32UTF8;`

The OCI charset used for UTF-8 encoding

- OCI_UTF8 is a deprecated encoding, and OCI_AL32UTF8 should be preferred
- but you can fallback for OCI_UTF8 for compatibility purposes

`OCI_CHARSET_WIN1252: cardinal = OCI_WE8MSWIN1252;`

The OCI charset used for WinAnsi encoding

`SynDBOracleBlobChunksCount: integer = 250;`

How many blob chunks should be handled at once

`SynDBOracleOCIpath: TFileName;`

Optional folder where the Oracle Client Library is to be searched

- by default, the oci.dll library is searched in the system PATH, then in %ORACLE_HOME%\bin
- you can specify here a folder name in which the oci.dll is to be found

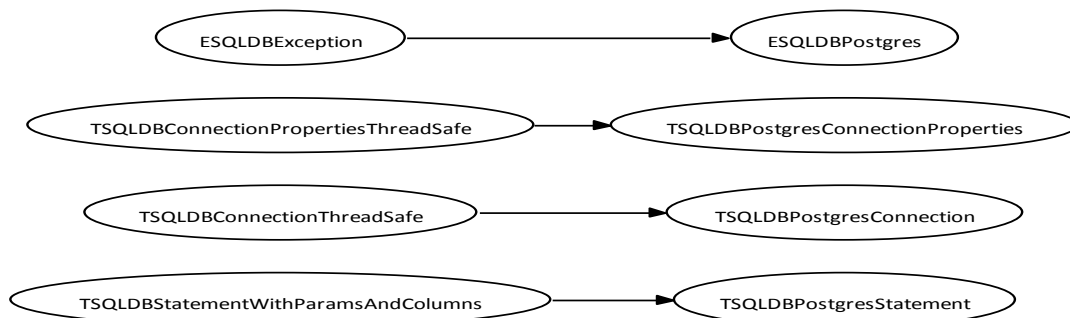

27.14. SynDBPostgres.pas unit

Purpose: PostgreSQL direct access classes for SynDB units (not DB.pas based)

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license - see LICENSE.md

Units used in the SynDBPostgres unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynCrypto</i>	Fast cryptographic routines (hashing and cypher) - implements AES,XOR,ADLER32,MD5,RC4,SHA1,SHA256,SHA384,SHA512,SHA3 and JWT - optimized for speed (tuned assembler and SSE3/SSE4/AES-NI/PADLOCK support) - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1143
<i>SynDB</i>	Abstract database direct access classes - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1208
<i>SynLog</i>	Logging functions used by Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1368
<i>SynTable</i>	Filter/database/cache/buffer/security/search/multithread/OS features - as a complement to SynCommons, which tended to increase too much - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1728

SynDBPostgres class hierarchy

Objects implemented in the SynDBPostgres unit

Objects	Description	Page
ESQDBPostgres	Exception type associated to the native libpg Interface	1294

Objects	Description	Page
TSQldbPostgresConnection	Implements a connection via the libpq access layer	1294
TSQldbPostgresConnectionProperties	Connection properties which will implement an internal Thread-Safe connection pool	1294
TSQldbPostgresStatement	Implements a statement via a Postgres database connection	1295

ESQldbPostgres = **class**(ESQldbException)

Exception type associated to the native libpq Interface

TSQldbPostgresConnectionProperties =
class(TSQldbConnectionPropertiesThreadSafe)

Connection properties which will implement an internal Thread-Safe connection pool

constructor Create(const aServerName, aDatabaseName, aUserID, aPassword: RawUTF8);
override;

Initialize the properties

- raise an exception in case libpq is not thread-safe
- aDatabaseName can be a Connection URI - see <https://www.postgresql.org/docs/current/libpq-connect.html#LIBPQ-CONNSTRING>
- if aDatabaseName contains connection URI with password we recommend to repeat password in aPassword parameter to prevent logging it (see TSQldbConnectionProperties.DatabaseNameSafe)
- better to use environment variables and postgres config file for connection parameters

function NewConnection: TSQldbConnection; **override;**

Create a new connection

- caller is responsible of freeing this instance
- this overridden method will create an TSQldbPostgresConnection instance

function Oid2FieldType(cOID: cardinal): TSQldbFieldType;

Add or replace mapping of OID into TSQldbFieldType

- in case mapping for OID is not defined, returns ftUTF8

procedure MapOid(cOid: cardinal; fieldType: TSQldbFieldType);

Add new (or override existed) OID to FieldType mapping

TSQldbPostgresConnection = **class**(TSQldbConnectionThreadSafe)

Implements a connection via the libpq access layer

function IsConnected: boolean; **override;**

Return TRUE if Connect has been already successfully called

function NewStatement: TSQldbStatement; **override;**

Create a new statement instance

procedure Commit; **override**;

Commit changes of a Transaction for this connection
- StartTransaction method must have been called before

procedure Connect; **override**;

Connect to the specified server
- should raise an ESQDBPostgres on error

procedure Disconnect; **override**;

Stop connection to the specified PostgreSQL database server
- should raise an ESQDBPostgres on error

procedure Rollback; **override**;

Discard changes of a Transaction for this connection
- StartTransaction method must have been called before

procedure StartTransaction; **override**;

Begin a Transaction for this connection

property Direct: pointer **read** fPGConn;

Direct access to the associated PPGconn connection

property PreparedCount: integer **read** fPreparedCount;

How many prepared statements are currently cached for this connection

TSQDBPostgresStatement = class(TSQDBStatementWithParamsAndColumns)

Implements a statement via a Postgres database connection

destructor Destroy; **override**;

Finalize the statement for a given connection

function ColumnBlob(Col: integer): RawByteString; **override**;

Return a Column as a blob value of the current Row, first Col is 0

function ColumnCurrency(Col: integer): currency; **override**;

Return a Column currency value of the current Row, first Col is 0

function ColumnDateTime(Col: integer): TDateTime; **override**;

Return a Column date and time value of the current Row, first Col is 0

function ColumnDouble(Col: integer): double; **override**;

Return a Column floating point value of the current Row, first Col is 0

function ColumnInt(Col: integer): int64; **override**;

Return a Column integer value of the current Row, first Col is 0

function ColumnNull(Col: integer): boolean; **override**;

Returns TRUE if the column contains NULL

function ColumnUTF8(Col: integer): RawUTF8; **override**;

Return a Column UTF-8 encoded text value of the current Row, first Col is 0

function Step(SeekFirst: boolean = False): boolean; **override;**

Access the next or first row of data from the SQL Statement result

- return true on success, with data ready to be retrieved by Column*() methods
- return false if no more row is available (e.g. if the SQL statement is not a SELECT but an UPDATE or INSERT command)
- if SeekFirst is TRUE, will put the cursor on the first row of results
- raise an ESQLDBPostgres on any error

function UpdateCount: integer; **override;**

Gets a number of updates made by latest executed statement

procedure ColumnsToJSON(WR: TJSONWriter); **override;**

Append all columns values of the current Row to a JSON stream

- overridden method to avoid temporary memory allocation or conversion

procedure ExecutePrepared; **override;**

Execute a prepared SQL statement

- parameters marked as ? should have been already bound with Bind*() functions
- this implementation will also handle bound array of values (if any)
- this overridden method will log the SQL statement if sllSQL has been enabled in SynDBLog.Family.Level
- raise an ESQLDBPostgres on any error

procedure Prepare(const aSQL: RawUTF8; ExpectResults: boolean = False); **overload;**
override;

Prepare an UTF-8 encoded SQL statement

- parameters marked as ? will be bound later, before ExecutePrepared call
- if ExpectResults is TRUE, then Step() and Column*() methods are available to retrieve the data rows
- raise an ESQLDBPostgres on any error

procedure ReleaseRows; **override;**

Clear(fRes) when ISQLDBStatement is back in cache

procedure Reset; **override;**

Reset the previous prepared statement

- this overridden implementation will reset all bindings and the cursor state
- raise an ESQLDBPostgres on any error

property PreparedParamsCount: integer **read** fPreparedParamsCount;

How many parameters founded during prepare stage

Variables implemented in the SynDBPostgres unit

SynDBPostgresLibrary: TFileName;

Allow to specify a libpq library file name to use

27.15. SynDBRemote.pas unit

Purpose: Remote access to any RDBMS via HTTP using our SynDB architecture

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the SynDBRemote unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynCrtSock</i>	Classes implementing TCP/UDP/HTTP client and server protocol - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1086
<i>SynDB</i>	Abstract database direct access classes - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1208
<i>SynTable</i>	Filter/database/cache/buffer/security/search/multithread/OS features - as a complement to SynCommons, which tended to increase too much - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1728

SynDBRemote class hierarchy

Objects implemented in the SynDBRemote unit

Objects	Description	Page
TSQDBHTTPConnectionPropertiesAbstract	Implements a generic HTTP client, able to access remotely any SynDB	1299
TSQDBHttpRequestConnectionProperties	Implements an abstract HTTP client via THttpRequest abstract class, able to access remotely any SynDB	1300
TSQDLSrvrAbstract	Implements a generic HTTP server, able to publish any SynDB connection	1298
TSQDLSrvrHttpApi	Implements a SynDB HTTP server using fast http.sys kernel-mode server	1299
TSQDLSrvrSockets	Implements a SynDB HTTP server via the user-land Sockets API	1299
TSQDBSocketConnectionProperties	Implements a HTTP client via sockets, able to access remotely any SynDB	1300

Objects	Description	Page
TSQLDBWinHTTPConnectionProperties	Implements a HTTP client via WinHTTP API, able to access remotely any SynDB	1300
TSQLDBWinINETConnectionProperties	Implements a HTTP client via WinINET API, able to access remotely any SynDB	1300

TSQLDBServerAbstract = class(TObject)

Implements a generic HTTP server, able to publish any SynDB connection

- do not instantiate this class, but rather use TSQLDBServerHttpApi or TSQLDBServerSockets - this abstract class won't set any HTTP server

constructor Create(aProperties: TSQLDBConnectionProperties; **const** aDatabaseName: RawUTF8; **const** aPort: RawUTF8=SYNDB_DEFAULT_HTTP_PORT; **const** aUserName: RawUTF8=''; **const** aPassword: RawUTF8=''; aHttps: boolean=false; aThreadPoolCount: integer=1; aProtocol: TSQLDBProxyConnectionProtocolClass=nil; aThreadMode: TSQLDBConnectionPropertiesThreadSafeThreadingMode=tmMainConnection; aAuthenticate: TSynAuthenticationAbstract=nil); **virtual**;

Publish the SynDB connection on a given HTTP port and URI

- this generic constructor won't initialize the HTTP server itself: use overridden constructors instead

- URI would follow the supplied aDatabaseName parameter on the given port e.g.

http://serverip:8092/remotedb for

```
Create(aProps, 'remotedb');
```

- you can optionally register one user credential, or change the transmission Protocol which is TSQLDBRemoteConnectionProtocol by default

- aProperties.ThreadingMode will be set to the optional aThreadMode parameter tmMainConnection by default, which would also set ProcessLocked to TRUE - in fact, you should better use a single thread for the process, but you may define a small thread pool for the process IF the provider supports it

destructor Destroy; **override**;

Released used memory

property DatabaseName: RawUTF8 **read** fDatabaseName;

The associated database name

property Port: RawUTF8 **read** fPort;

The associated port number

property ProcessLocked: boolean **read** fProcessLocked **write** fProcessLocked;

If the internal Process() method would be protected by a critical section

- set to TRUE if constructor's aThreadMode is left to its default tmMainConnection value

property Properties: TSQLDBConnectionProperties **read** fProperties **write** fProperties;

The associated database connection properties

property Protocol: TSQLDBProxyConnectionProtocol **read** fProtocol **write** fProtocol;

The associated communication protocol

- to manage user authentication, use AuthenticateUser/DisauthenticateUser methods of Protocol.Authenticate

TSQLDBServerSockets = class(TSQLDBServerAbstract)

Implements a SynDB HTTP server via the user-land Sockets API

constructor Create(aProperties: TSQLDBConnectionProperties; **const** aDatabaseName: RawUTF8; **const** aPort: RawUTF8=SYNDB_DEFAULT_HTTP_PORT; **const** aUserName: RawUTF8=''; **const** aPassword: RawUTF8=''; aHttps: boolean=false; aThreadPoolCount: integer=1; aProtocol: TSQLDBProxyConnectionProtocolClass=nil; aThreadMode: TSQLDBConnectionPropertiesThreadSafeThreadingMode=tmMainConnection; aAuthenticate: TSynAuthenticationAbstract=nil); **override**;

Publish the SynDB connection on a given HTTP port and URI using sockets

- URI would follow the supplied aDatabaseName parameter on the given port e.g.

http://serverip:8092/remotedb for

Create(aProps, 'remotedb');

- you can optionally register one user credential

- parameter aHttps is ignored by this class

TSQLDBServerHttpApi = class(TSQLDBServerAbstract)

Implements a SynDB HTTP server using fast http.sys kernel-mode server

- under Windows, this class is faster and more stable than TSQLDBServerSockets

constructor Create(aProperties: TSQLDBConnectionProperties; **const** aDatabaseName: RawUTF8; **const** aPort: RawUTF8=SYNDB_DEFAULT_HTTP_PORT; **const** aUserName: RawUTF8=''; **const** aPassword: RawUTF8=''; aHttps: boolean=false; aThreadPoolCount: integer=1; aProtocol: TSQLDBProxyConnectionProtocolClass=nil; aThreadMode: TSQLDBConnectionPropertiesThreadSafeThreadingMode=tmMainConnection; aAuthenticate: TSynAuthenticationAbstract=nil); **override**;

Publish the SynDB connection on a given HTTP port and URI using http.sys

- URI would follow the supplied aDatabaseName parameter on the given port e.g.

http://serverip:8092/remotedb for

Create(aProps, 'remotedb');

- you can optionally register one user credential

**TSQLDBHTTPConnectionPropertiesAbstract =
class(TSQLDBRemoteConnectionPropertiesAbstract)**

Implements a generic HTTP client, able to access remotely any SynDB

- do not instantiate this class, but rather use TSQLDBSocketConnectionProperties

TSQLDBWinHTTPConnectionProperties TSQLDBWinInetConnectionProperties

property KeepAliveMS: cardinal **read** fKeepAliveMS **write** fKeepAliveMS;

Time (in milliseconds) to keep the connection alive with the server

- default is 60000, i.e. one minute

property Port: RawByteString **read** GetPort;

The associated port number

property Server: RawByteString **read** GetServer;

The associated server IP address or name

```
TSQLDBSocketConnectionProperties =  
class(TSQLDBHTTPConnectionPropertiesAbstract)
```

Implements a HTTP client via sockets, able to access remotely any SynDB

```
constructor Create(const aServerName,aDatabaseName, aUserID,aPassWord: RawUTF8);  
override;
```

Initialize the properties for remote access via HTTP using sockets

- aServerName should be the HTTP server address as 'server:port'
- aDatabaseName would be used to compute the URI as in TSQLDBServerAbstract
- the user/password credential should match server-side authentication

```
destructor Destroy; override;
```

Released used memory

```
property Socket: THttpClientSocket read fSocket;
```

Low-level direct access to the Socket implementation instance

```
TSQLDBHttpRequestConnectionProperties =  
class(TSQLDBHTTPConnectionPropertiesAbstract)
```

Implements an abstract HTTP client via THttpRequest abstract class, able to access remotely any SynDB

- never instantiate this class, but rather TSQLDBWinHTTPConnectionProperties or TSQLDBWinINetConnectionProperties

```
destructor Destroy; override;
```

Released used memory

```
property Client: THttpRequest read fClient;
```

Low-level direct access to the WinHTTP implementation instance

```
TSQLDBWinHTTPConnectionProperties =  
class(TSQLDBHttpRequestConnectionProperties)
```

Implements a HTTP client via WinHTTP API, able to access remotely any SynDB

```
constructor Create(const aServerName,aDatabaseName, aUserID,aPassWord: RawUTF8);  
override;
```

Initialize the properties for remote access via HTTP using WinHTTP

- aServerName should be the HTTP server address as 'server:port'
- aDatabaseName would be used to compute the URI as in TSQLDBServerAbstract
- the user/password credential should match server-side authentication

```
TSQLDBWinINetConnectionProperties =  
class(TSQLDBHttpRequestConnectionProperties)
```

Implements a HTTP client via WinINet API, able to access remotely any SynDB

```
constructor Create(const aServerName,aDatabaseName, aUserID,aPassWord: RawUTF8);  
override;
```

Initialize the properties for remote access via HTTP using WinINet

- aServerName should be the HTTP server address as 'server:port'
- aDatabaseName would be used to compute the URI as in TSQLDBServerAbstract
- the user/password credential should match server-side authentication

Types implemented in the *SynDBRemote* unit

```
TSQLDBServerClass = class of TSQLDBServerAbstract;
```

Used to define the HTTP server class for publishing a SynDB connection

```
TSQLDBServerRemote = TSQLDBServerHttpApi;
```

The default SynDB HTTP server class on each platform

Constants implemented in the *SynDBRemote* unit

```
SYNDB_DEFAULT_HTTP_PORT = '8092';
```

Default HTTP port to be used for SynDB remote access if none is specified

27.16. SynDBSQLite3.pas unit

Purpose: SQLite3 direct access classes to be used with our SynDB architecture

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

The *SynDBSQLite3* unit is quoted in the following items

SWRS #	Description	Page
DI-2.2.1	The <i>SQLite3</i> engine shall be embedded to the framework	2558

Units used in the *SynDBSQLite3* unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynDB</i>	Abstract database direct access classes - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1208
<i>SynLog</i>	Logging functions used by Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1368
<i>SynSQLite3</i>	SQLite3 Database engine direct access - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1653
<i>SynTable</i>	Filter/database/cache/buffer/security/search/multithread/OS features - as a complement to SynCommons, which tended to increase too much - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1728

SynDBSQLite3 class hierarchy

Objects implemented in the *SynDBSQLite3* unit

Objects	Description	Page
TSQLDBSQLite3Connection	Implements a direct connection to the SQLite3 engine	1303
TSQLDBSQLite3ConnectionProperties	Will implement properties shared by the SQLite3 engine	1303

Objects	Description	Page
TSQldbSQLite3Statement	Implements a statement using the SQLite3 engine	1304

TSQldbSQLite3ConnectionProperties = class(TSQldbConnectionProperties)

Will implement properties shared by the SQLite3 engine

Used for DI-2.2.1 (page 2558).

constructor Create(aDB: TSQldbDatabase); **reintroduce**; **override**;

Initialize access to an existing SQLite3 engine

- this overloaded constructor allows to access via SynDB methods to an existing SQLite3 database, e.g. TSQldbRestServerDB.DB (from mORMotSQLite3.pas)

constructor Create(const aServerName, aDatabaseName, aUserID, aPassword: RawUTF8); **override**;

Initialize access to a SQLite3 engine with some properties

- only used parameter is aServerName, which should point to the SQLite3 database file to be opened (one will be created if none exists)
- if specified, the password will be used to cypher this file on disk (the main SQLite3 database file is encrypted, not the wal file during run); the password may be a JSON-serialized TSynSignerParams object, or will use AES-OFB-128 after SHAKE_128 with rounds=1000 and a fixed salt on plain password text
- other parameters (DataBaseName, UserID) are ignored

function NewConnection: TSQldbConnection; **override**;

Create a new connection

- call this method if the shared MainConnection is not enough (e.g. for multi-thread access)
- the caller is responsible of freeing this instance

property MainSQLite3DB: TSQldbDatabase **read** GetMainDB;

Direct access to the main SQLite3 DB instance

- can be used to tune directly the database properties

property UseMormotCollations: boolean **read** fUseMormotCollations **write** SetUseMormotCollations;

TRUE if you want the SQL creation fields to use mORMot collation

- default value is TRUE for use within the mORMot framework, to use dedicated UTF-8 collation and full Unicode support, and Iso8601 handling
- when set to FALSE, SQLCreate() method will return standard ASCII SQLite collations for TEXT: it will make interaction with other programs more compatible, at database file level

TSQldbSQLite3Connection = class(TSQldbConnection)

Implements a direct connection to the SQLite3 engine

Used for DI-2.2.1 (page 2558).

function IsConnected: boolean; **override**;

Return TRUE if Connect has been already successfully called

function NewStatement: TSQLDBStatement; **override;**

Initialize a new SQL query statement for the given connection
- the caller should free the instance after use

procedure Commit; **override;**

Commit changes of a Transaction for this connection
- StartTransaction method must have been called before

procedure Connect; **override;**

Connect to the SQLite3 engine, i.e. create the DB instance
- should raise an Exception on error

procedure Disconnect; **override;**

Stop connection to the SQLite3 engine, i.e. release the DB instance
- should raise an Exception on error

procedure Rollback; **override;**

Discard changes of a Transaction for this connection
- StartTransaction method must have been called before

procedure StartTransaction; **override;**

Begin a Transaction for this connection
- current implementation do not support nested transaction with those methods: exception will be raised in such case

property DB: TSQLDataBase **read** fDB;

The associated SQLite3 DB instance
- assigned to not nil after successful connection

property LockingMode: TSQLLockingMode **read** GetLockingMode **write** SetLockingMode;

Query or change the SQLite3 file-based locking mode, i.e. the way it locks the file
- default ImNormal is ACID and safe
- ImExclusive gives better performance in case of a number of write transactions, so can be used to release a mORMot server power: but you won't be able to access the database file from outside the process (like a "normal" database engine)

property Synchronous: TSQLSynchronousMode **read** GetSynchronous **write** SetSynchronous;

Query or change the SQLite3 file-based synchronization mode, i.e. the way it waits for the data to be flushed on hard drive
- default smFull is very slow, but achieve 100% ACID behavior
- smNormal is faster, and safe until a catastrophic hardware failure occurs
- smOff is the fastest, data should be safe if the application crashes, but database file may be corrupted in case of failure at the wrong time

TSQDBSQLite3Statement = class(TSQLDBStatement)

Implements a statement using the SQLite3 engine
Used for DI-2.2.1 (page 2558).

constructor Create(aConnection: TSQLDBConnection); **override;**

Create a SQLite3 statement instance, from an existing SQLite3 connection

- the Execute method can be called once per TSQLDBSQLite3Statement instance, but you can use the Prepare once followed by several ExecutePrepared methods
- if the supplied connection is not of TOleDBConnection type, will raise an exception

destructor Destroy; **override;**

Release all associated memory and SQLite3 handles

function ColumnBlob(Col: integer): RawByteString; **override;**

Return a Column as a blob value of the current Row, first Col is 0

- ColumnBlob() will return the binary content of the field if it was not ftBlob, e.g. a 8 bytes RawByteString for a vtInt64/vtDouble/vtDate/vtCurrency, or a direct mapping of the RawUnicode

function ColumnCurrency(Col: integer): currency; **override;**

Return a Column currency value of the current Row, first Col is 0

- should retrieve directly the 64 bit Currency content, to avoid any rounding/conversion error from floating-point types

function ColumnDateTime(Col: integer): TDateTime; **override;**

Return a Column floating point value of the current Row, first Col is 0

function ColumnDouble(Col: integer): double; **override;**

Return a Column floating point value of the current Row, first Col is 0

function ColumnIndex(const aColumnName: RawUTF8): integer; **override;**

Returns the Column index of a given Column name

- Columns numeration (i.e. Col value) starts with 0
- returns -1 if the Column name is not found (via case insensitive search)

function ColumnInt(Col: integer): Int64; **override;**

Return a Column integer value of the current Row, first Col is 0

function ColumnName(Col: integer): RawUTF8; **override;**

Retrieve a column name of the current Row

- Columns numeration (i.e. Col value) starts with 0
- it's up to the implementation to ensure that all column names are unique

function ColumnNull(Col: integer): boolean; **override;**

Returns TRUE if the column contains NULL

function ColumnType(Col: integer; FieldSize: PInteger=nil): TSQLDBFieldType;
override;

The Column type of the current Row

- ftCurrency type should be handled specifically, for faster process and avoid any rounding issue, since currency is a standard OleDB type

function ColumnUTF8(Col: integer): RawUTF8; **override;**

Return a Column UTF-8 encoded text value of the current Row, first Col is 0

function Step(SeekFirst: boolean=false): boolean; **override**;

After a statement has been prepared via Prepare() + ExecutePrepared() or Execute(), this method must be called one or more times to evaluate it

- you shall call this method before calling any Column*() methods
- return TRUE on success, with data ready to be retrieved by Column*()
- return FALSE if no more row is available (e.g. if the SQL statement is not a SELECT but an UPDATE or INSERT command)
- access the first or next row of data from the SQL Statement result: if SeekFirst is TRUE, will put the cursor on the first row of results, otherwise, it will fetch one row of data, to be called within a loop
- raise an ESQLite3Exception exception on any error

function UpdateCount: integer; **override**;

Gets a number of updates made by latest executed statement

procedure Bind(Param: Integer; Value: Int64; IO: TSQldbParamInOutType=paramIn);
overload; **override**;

Bind an integer value to a parameter

- the leftmost SQL parameter has an index of 1

procedure Bind(Param: Integer; Value: double; IO: TSQldbParamInOutType=paramIn);
overload; **override**;

Bind a double value to a parameter

- the leftmost SQL parameter has an index of 1

procedure BindBlob(Param: Integer; Data: pointer; Size: integer; IO:
TSQldbParamInOutType=paramIn); overload; **override**;

Bind a Blob buffer to a parameter

- the leftmost SQL parameter has an index of 1

procedure BindBlob(Param: Integer; **const** Data: RawByteString; IO:
TSQldbParamInOutType=paramIn); overload; **override**;

Bind a Blob buffer to a parameter

- the leftmost SQL parameter has an index of 1

procedure BindCurrency(Param: Integer; Value: currency; IO:
TSQldbParamInOutType=paramIn); overload; **override**;

Bind a currency value to a parameter

- the leftmost SQL parameter has an index of 1

procedure BindDateTime(Param: Integer; Value: TDateTime; IO:
TSQldbParamInOutType=paramIn); overload; **override**;

Bind a TDateTime value to a parameter

- the leftmost SQL parameter has an index of 1

procedure BindNull(Param: Integer; IO: TSQldbParamInOutType=paramIn; BoundType:
TSQldbFieldType=ftNull); **override**;

Bind a NULL value to a parameter

- the leftmost SQL parameter has an index of 1

procedure BindTextP(Param: Integer; Value: UTF8Char; IO:
TSQldbParamInOutType=paramIn); overload; **override**;

Bind a UTF-8 encoded buffer text (#0 ended) to a parameter

- the leftmost SQL parameter has an index of 1

```
procedure BindTextS(Param: Integer; const Value: string; IO:
TSQLDBParamInOutType=paramIn); overload; override;
```

Bind a UTF-8 encoded string to a parameter
- the leftmost SQL parameter has an index of 1

```
procedure BindTextU(Param: Integer; const Value: RawUTF8; IO:
TSQLDBParamInOutType=paramIn); overload; override;
```

Bind a UTF-8 encoded string to a parameter
- the leftmost SQL parameter has an index of 1

```
procedure BindTextW(Param: Integer; const Value: WideString; IO:
TSQLDBParamInOutType=paramIn); overload; override;
```

Bind a UTF-8 encoded string to a parameter
- the leftmost SQL parameter has an index of 1

```
procedure ColumnsToJSON(WR: TJSONWriter); override;
```

Append all columns values of the current Row to a JSON stream
- will use WR.Expand to guess the expected output format
- fast overridden implementation with no temporary variable
- BLOB field value is saved as Base64, in the "\uFFFF0base64encodedbinary" format and contains true BLOB data

```
procedure ExecutePrepared; override;
```

Execute a prepared SQL statement
- parameters marked as ? should have been already bound with Bind*() functions
- raise an ESQLDBException on any error

```
procedure Prepare(const aSQL: RawUTF8; ExpectResults: Boolean=false); overload; override;
```

Prepare an UTF-8 encoded SQL statement
- parameters marked as ? will be bound later, before ExecutePrepared call
- if ExpectResults is TRUE, then Step() and Column*() methods are available to retrieve the data rows
- raise an ESQLDBException on any error

```
procedure ReleaseRows; override;
```

Finalize the cursor

```
procedure Reset; override;
```

Reset the previous prepared statement

Functions or procedures implemented in the SynDBSQLite3 unit

Functions or procedures	Description	Page
RowsToSQLite3	Direct export of a DB statement rows into a SQLite3 database	1307

```
function RowsToSQLite3(const Dest: TFileName; const TableName: RawUTF8; Rows:
TSQLDBStatement; UseMormotCollations: boolean): integer;
```

Direct export of a DB statement rows into a SQLite3 database
- the corresponding table will be created within the specified DB file

27.17. SynDBVCL.pas unit

Purpose: DB VCL read/only dataset from SynDB data access

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the SynDBVCL unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynDB</i>	Abstract database direct access classes - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1208
<i>SynTable</i>	Filter/database/cache/buffer/security/search/multithread/OS features - as a complement to SynCommons, which tended to increase too much - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1728
<i>SynVirtualDataSet</i>	DB VCL read-only virtual dataset - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1848

SynDBVCL class hierarchy

Objects implemented in the SynDBVCL unit

Objects	Description	Page
TSynBinaryDataSet	Read-only virtual TDataSet able to access a binary buffer as returned by TSQLStatement.FetchAllToBinary method or directly a TSQLStatement	1308
TSynDBSQLDataSet	TDataSet able to execute any SQL as SynDB's TSQLStatement result set	1309

```
TSynBinaryDataSet = class(TSynVirtualDataSet)
```

Read-only virtual TDataSet able to access a binary buffer as returned by TSQLStatement.FetchAllToBinary method or directly a TSQLStatement

```
destructor Destroy; override;
```

Finalize the class instance

```
procedure From(Statement: TSQLDBStatement; MaxRowCount: cardinal=0;
IgnoreColumnDataSize: boolean=false); overload; virtual;
```

Initialize the virtual TDataSet from a SynDB TSQLDBStatement result set

- the supplied TSQLDBRows instance can safely be freed by the caller, since a private binary copy will be owned by this instance (in Data)
- by default, ColumnDataSize would be computed from the supplied data, unless you set IgnoreColumnDataSize=true to set the value to 0 (and force e.g. SynDBVCL TSynBinaryDataSet.InternalInitFieldDefs define the field as ftDefaultMemo) or you define some FieldDefs.Items[].Size values for ftUTF8 column sizes before calling this From() method

```
procedure From(const BinaryData: RawByteString; DataRowPosition:
PCardinalDynArray=nil; IgnoreColumnDataSize: boolean=false); overload; virtual;
```

Initialize the virtual TDataSet from a FetchAllToBinary() buffer

- by default, ColumnDataSize would be computed from the supplied data, unless you set IgnoreColumnDataSize=true to set the value to 0 (and force e.g. SynDBVCL TSynBinaryDataSet.InternalInitFieldDefs define the field as ftDefaultMemo) or you define some FieldDefs.Items[].Size values for ftUTF8 column sizes before calling this From() method

```
property Data: RawByteString read fData;
```

Read-only access to the internal binary buffer

```
property DataAccess: TSQLDBProxyStatementRandomAccess read fDataAccess;
```

Read-only access to the internal SynDB data

```
TSynDBSQLDataSet = class(TSynBinaryDataSet)
```

TDataSet able to execute any SQL as SynDB's TSQLStatement result set

- this class is not meant to be used by itself, but via TSynDBDataSet, defined in SynDBMidasVCL.pas, as a data provider able to apply updates to the remote SynDB connection
- typical usage may be for instance over a SynDBRemote connection:

```
props := TSQLDBWinHTTPConnectionProperties.Create(...);
ds := TSynDBSQLDataSet.Create(MainForm);
ds.CommandText := 'select * from people';
ds.Open;
// ... use ds
ds.Close;
ds.CommandText := 'select * from customer where id=(10)';
ds.Open;
// ... use ds
```

```
procedure From(Statement: TSQLDBStatement; MaxRowCount: cardinal=0;
IgnoreColumnDataSize: boolean=false); override;
```

Initialize the internal TDataSet from a SynDB TSQLDBStatement result set

- the supplied TSQLDBStatement can then be freed by the caller, since a private binary copy will be owned by this instance (in fDataSet.Data)
- by default, ColumnDataSize would be computed from the supplied data, unless you set IgnoreColumnDataSize=true to set the value to 0 (and force e.g. SynDBVCL TSynBinaryDataSet.InternalInitFieldDefs define the field as ftDefaultMemo) or you define some FieldDefs.Items[].Size values for ftUTF8 column sizes before calling this From() method

property CommandText: **string** **read** fCommandText **write** fCommandText;

The SQL statement to be executed

- since this statement will be executed via Connection.ExecuteInlined, you can specify optionally inlined parameters to this SQL text

property Connection: TSQLDBConnectionProperties **read** fConnection **write** fConnection;

The associated connection properties

Functions or procedures implemented in the SynDBVCL unit

Functions or procedures	Description	Page
BinaryToDataSet	Fetch a SynDB's TSQLDBStatement.FetchAllToBinary buffer into a VCL DataSet	1310
ToDataSet	Fetch a SynDB's TSQLDBStatement result into a VCL DataSet	1311
ToDataSet	Fetch a SynDB's TQuery result into a VCL DataSet	1311
ToDataSet	Fetch a SynDB ISQLDBRows result set into a VCL DataSet	1311

function BinaryToDataSet(aOwner: TComponent; **const** aBinaryData: RawByteString): TSynBinaryDataSet;

Fetch a SynDB's TSQLDBStatement.FetchAllToBinary buffer into a VCL DataSet

- just a wrapper around TSynBinaryDataSet.Create + Open

- if you need a writable TDataSet, you can use the slower ToClientDataSet() function as defined in SynDBMidasVCL.pas

function ToDataSet(aOwner: TComponent; aStatement: ISQLDBRows; aMaxRowCount: integer=0): TSynBinaryDataSet; overload;

Fetch a SynDB ISQLDBRows result set into a VCL DataSet

- this overloaded function can use directly a result of the TSQLDBConnectionProperties.Execute() method, as such:

```
ds1.DataSet := ToDataSet(self, props.Execute('select * from table', []));
```

function ToDataSet(aOwner: TComponent; aStatement: SynDB.TQuery; aMaxRowCount: integer=0): TSynBinaryDataSet; overload;

Fetch a SynDB's TQuery result into a VCL DataSet

- if aMaxRowCount>0, will return up to the specified number of rows

- current implementation will return a TSynSQLStatementDataSet instance, using an optimized internal binary buffer: the supplied TQuery can be released

- if you need a writable TDataSet, you can use the slower ToClientDataSet() function as defined in SynDBMidasVCL.pas

```
function ToDataSet(aOwner: TComponent; aStatement: TSQLDBStatement; aMaxRowCount:  
integer=0): TSynBinaryDataSet; overload;
```

Fetch a SynDB's TSQLDBStatement result into a VCL DataSet

- just a wrapper around TSynSQLStatementDataSet.Create + Open
- if aMaxRowCount>0, will return up to the specified number of rows
- current implementation will return a TSynSQLStatementDataSet instance, using an optimized internal binary buffer: the supplied statement can be released
- if you need a writable TDataSet, you can use the slower ToClientDataSet() function as defined in SynDBMidasVCL.pas

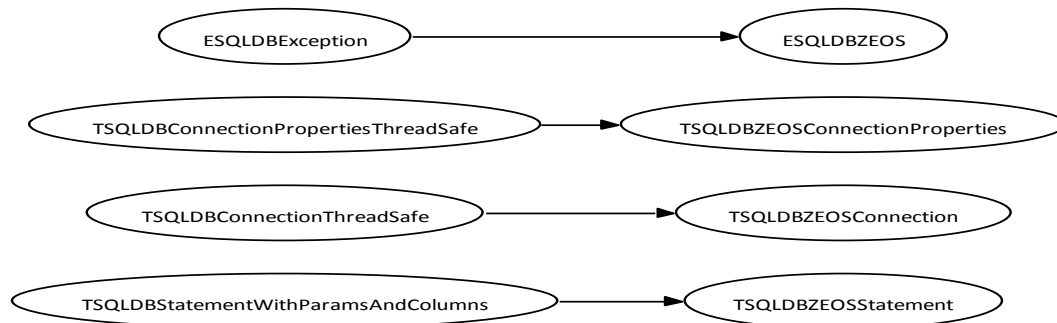

27.18. SynDBZeos.pas unit

Purpose: ZEOS 7.x direct access classes for SynDB units (not DB.pas based)

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the *SynDBZeos* unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynDB</i>	Abstract database direct access classes - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1208
<i>SynLog</i>	Logging functions used by Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1368
<i>SynTable</i>	Filter/database/cache/buffer/security/search/multithread/OS features - as a complement to SynCommons, which tended to increase too much - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1728

SynDBZeos class hierarchy

Objects implemented in the *SynDBZeos* unit

Objects	Description	Page
ESQldbZEOS	Exception type associated to the ZEOS database components	1313
TSQLDBZEOSConnection	Implements a connection via the ZEOS access layer	1315
TSQLDBZEOSConnectionProperties	Implement properties shared by ZEOS connections	1313
TSQLDBZEOSStatement	Implements a statement via a ZEOS database connection	1315

ESQLDBZEOS = class(ESQLDBException)

Exception type associated to the ZEOS database components

**TSQLDBZEOSConnectionProperties =
 class(TSQLDBConnectionPropertiesThreadSafe)**

Implement properties shared by ZEOS connections

constructor Create(**const** aServerName, aDatabaseName, aUserID, aPassWord: RawUTF8);
override;

Initialize the properties to connect to the ZEOS engine

- aServerName shall contain the ZEOS URI, e.g:

zdbc:firebird-2.0://127.0.0.1:3050/model?username=sysdba;password=masterkey
 zdbc:mysql://192.168.2.60:3306/world?username=root;password=dev
 sqlite

i.e. '[zdbc:]PROTOCOL://HOST:PORT[/DATABASE][?paramname=value]'

- you can define the TZConnection.LibraryLocation property by setting a '?LibLocation=...'
 parameter within the aServerName URL value

- or simply use TSQLDBZEOSConnectionProperties.URI() class method

- aDatabaseName, aUserID, aPassWord are used if not already set as URI in aServerName value

- you can use Protocols property to retrieve all available protocol names

- note that when run from mORMot's ORM, this class will by default create one connection per
 thread, which makes some clients (e.g. PostgreSQL) unstable and consuming a lot of resources -
 you should better maintain one single connection, by setting after Create:

aExternalDBProperties.ThreadingMode := tmMainConnection;

or by adding 'syndb_singleconnection=true' as URI property

constructor CreateWithZURL(**const** aURL: TZURL; aDBMS: TSQLDBDefinition; aOwnsURL:
 Boolean); **virtual;**

Initialize raw properties to connect to the ZEOS engine

- using Zeos' TZURL detailed class - see: src\core\ZURL.pas

- this gives all possibilities to add Properties before a connection is opened

- you can define the protocol by hand eg. "odbc_w"/"OleDB" and define TSQLDBDefinition to
 describe the server syntax SynDB and the ORM use behind the abstract driver

destructor Destroy; **override;**

Finalize properties internal structures

function GetDatabaseMetadata(**out** meta: IZDatabaseMetadata): boolean;

Access to the database metadata, as retrieved by ZEOS

- returns TRUE if metadata interface has been retrieved

function NewConnection: TSQLDBConnection; **override;**

Create a new connection

- caller is responsible of freeing this instance

- this overridden method will create an TSQLDBZEOSConnection instance

```
class function URI(aServer: TSQLDBDefinition; const aServerName: RawUTF8; const
aLibraryLocation: TFileName=''; aLibraryLocationAppendExePath: boolean=true):
RawUTF8; overload;
```

Compute the ZEOS URI for a given database engine

- the optional server name can contain a port number, specified after ':'
- you can set an optional full path to the client library name, to be completed on the left side with the executable path
- possible use may be:

```
PropsOracle := TSQLDBZEOSConnectionProperties.Create(
  TSQLDBZEOSConnectionProperties.URI(dOracle, '', 'oci64\oci.dll'),
  'tnsname', 'user', pass');
PropsFirebird := TSQLDBZEOSConnectionProperties.Create(
  TSQLDBZEOSConnectionProperties.URI(dFirebird, '', 'Firebird\fbembed.dll'),
  'databasefilename', '', '');
PropsFirebird := TSQLDBZEOSConnectionProperties.Create(
  TSQLDBZEOSConnectionProperties.URI(dFirebird, '192.168.1.10:3055',
  'c:\Firebird_2_5\bin\fbclient.dll', false),
  '3camadas', 'sysdba', 'masterkey');
```

```
class function URI(const aProtocol, aServerName: RawUTF8; const aLibraryLocation:
TFileName=''; aLibraryLocationAppendExePath: boolean=true): RawUTF8; overload;
```

Compute the ZEOS URI for a given protocol

- if a TSQLDBDefinition may have several protocols (e.g. MSSQL), you can use this overloaded method to select the exact protocol to use if the default one fixed by TSQLDBDefinition does not match your needs
- the protocol name should contain the trailing : character, e.g. 'firebird-2.0:' if the default 'firebird-2.5:' is not correct

```
procedure GetFields(const aTableName: RawUTF8; out Fields:
TSQLDBCColumnDefineDynArray); override;
```

Retrieve the column/field layout of a specified table

- this overridden method will use ZDBC metadata to retrieve the information

```
procedure GetTableNames(out Tables: TRawUTF8DynArray); override;
```

Get all table names

- this overridden method will use ZDBC metadata to retrieve the information
- PostgreSQL note: it was reported that some table names expects to be quoted for this DB engine - and ZDBC won't do it for yourself - please ensure you specify the correct quoted table name e.g. when you register the external PostgreSQL table via function VirtualTableExternalRegister()

```
property DBMSName: RawUTF8 read fDBMSName;
```

The remote DBMS name, as retrieved from ServerName, i.e. ZEOS URL

```
property SupportsArrayBindings: boolean read fSupportsArrayBindings;
```

If the associated ZDBC provider supports parameters array binding

- you should use the BindArray() methods only if this property is TRUE

```
property ZeosStatementParams: TStrings read fStatementParams;
```

Direct access to the internal statement parameters

- i.e. will be used by IZConnection.PrepareStatementWithParams()
- default values (set in Create method) try to achieve best performance

property ZeosURL: TZURL read fURL;

Direct access to the internal TZURL connection parameters

TSQLDBZEOSConnection = class(TSQLDBConnectionThreadSafe)

Implements a connection via the ZEOS access layer

constructor Create(aProperties: TSQLDBConnectionProperties); **override**;

Prepare a connection to a specified ZEOS database server

function IsConnected: boolean; **override**;

Return TRUE if Connect has been already successfully called

function NewStatement: TSQLDBStatement; **override**;

Create a new statement instance

procedure Commit; **override**;

Commit changes of a Transaction for this connection

- StartTransaction method must have been called before

procedure Connect; **override**;

Connect to the specified ZEOS server

- should raise an ESQLDBZEOS on error

procedure Disconnect; **override**;

Stop connection to the specified ZEOS database server

- should raise an ESQLDBZEOS on error

procedure Rollback; **override**;

Discard changes of a Transaction for this connection

- StartTransaction method must have been called before

procedure StartTransaction; **override**;

Begin a Transaction for this connection

property Database: IZConnection read fDatabase;

Access to the associated ZEOS connection instance

TSQLDBZEOSStatement = class(TSQLDBStatementWithParamsAndColumns)

Implements a statement via a ZEOS database connection

function ColumnBlob(Col: Integer): RawByteString; **override**;

Return a Column as a blob value of the current Row, first Col is 0

function ColumnCurrency(Col: Integer): currency; **override**;

Return a Column currency value of the current Row, first Col is 0

function ColumnDateTime(Col: Integer): TDateTime; **override**;

Return a Column date and time value of the current Row, first Col is 0

function ColumnDouble(Col: Integer): double; **override**;

Return a Column floating point value of the current Row, first Col is 0

function ColumnInt(Col: Integer): Int64; **override;**

Return a Column integer value of the current Row, first Col is 0

function ColumnNull(Col: Integer): boolean; **override;**

Returns TRUE if the column contains NULL

function ColumnUTF8(Col: Integer): RawUTF8; **override;**

Return a Column UTF-8 encoded text value of the current Row, first Col is 0

function Step(SeekFirst: boolean = false): boolean; **override;**

Access the next or first row of data from the SQL Statement result

- return true on success, with data ready to be retrieved by Column*() methods
- return false if no more row is available (e.g. if the SQL statement is not a SELECT but an UPDATE or INSERT command)
- if SeekFirst is TRUE, will put the cursor on the first row of results
- raise an ESQLDBZeos on any error

function UpdateCount: integer; **override;**

Gets a number of updates made by latest executed statement

procedure ColumnsToJSON(WR: TJSONWriter); **override;**

Append all columns values of the current Row to a JSON stream

- will use WR.Expand to guess the expected output format
- this overridden implementation will call fResultSet methods to avoid creating most temporary variable

procedure ExecutePrepared; **override;**

Execute a prepared SQL statement

- parameters marked as ? should have been already bound with Bind*() functions
- this implementation will also handle bound array of values (if any), if IZDatabaseInfo.SupportsArrayBindings is true for this provider
- this overridden method will log the SQL statement if sISQL has been enabled in SynDBLog.Family.Level
- raise an ESQLDBZeos on any error

procedure Prepare(const aSQL: RawUTF8; ExpectResults: boolean = false); **overload;**
override;

Prepare an UTF-8 encoded SQL statement

- parameters marked as ? will be bound later, before ExecutePrepared call
- if ExpectResults is TRUE, then Step() and Column*() methods are available to retrieve the data rows
- raise an ESQLDBZeos on any error

procedure ReleaseRows; **override;**

Free IZResultSet/IZResultSetMetaData when ISQLDBStatement is back in cache

procedure Reset; **override;**

Reset the previous prepared statement

- this overridden implementation will reset all bindings and the cursor state
- raise an ESQLDBZeos on any error

property JSONComposeOptions: TZJSONComposeOptions **read** fJSONComposeOptions **write** fJSONComposeOptions **default** [jcoEndJSONObject];

The ColumnsToJSON options provided by ZDBC

- jcoEndJSONObject: cancels last comma, adds the close object bracket '}' and add's the next comma. If not set you can continue writting some custom data into your object json but you also have to finalize each row-object then.
- jcoMongoISODate: formats the date,time,datetime values as mongo ISODate("YYYY-MM-DDTHH:NN:ssZ"). Milliseconds are included. So the values are recognized as date type by mongodb. Otherwise mongo threads them as strings. This option might be usefull if you export sql rows using a json streamed file which will be used as an import-file with your mongodb. If set the options jcoDATETIME_MAGIC and jcoMilliseconds are ignored
- jcoDATETIME_MAGIC add the JSON_SQLDATE_MAGIC on top of data before adding the ISO date,time,datetime value quoted strings
- jcoMilliseconds compose the time/datetime values with milliseconds
- jcsSkipNulls ignore null columns. So neither fieldname nor the null value will be composed into your JSON. For real big JSON contents it saves loads of space. e.g. if you import a JSON into a mongo cluster you'll have a significant space difference if null's are simply ignored.

Functions or procedures implemented in the SynDBZeos unit

Functions or procedures	Description	Page
SetZEOSProtocols	To be called in order to populate the global ZEOSProtocols list	1317

procedure SetZEOSProtocols;

To be called in order to populate the global ZEOSProtocols list

Variables implemented in the SynDBZeos unit

ZEOSProtocols: TRawUTF8DynArray;

List of all available ZEOS protocols

- you have to call SetZEOSProtocols before using it, to update this global list with all initialized ZPlain*Driver units
- to be used e.g. within ZEOS URI, as TSQLDBZEOSConnectionProperties.ServerName

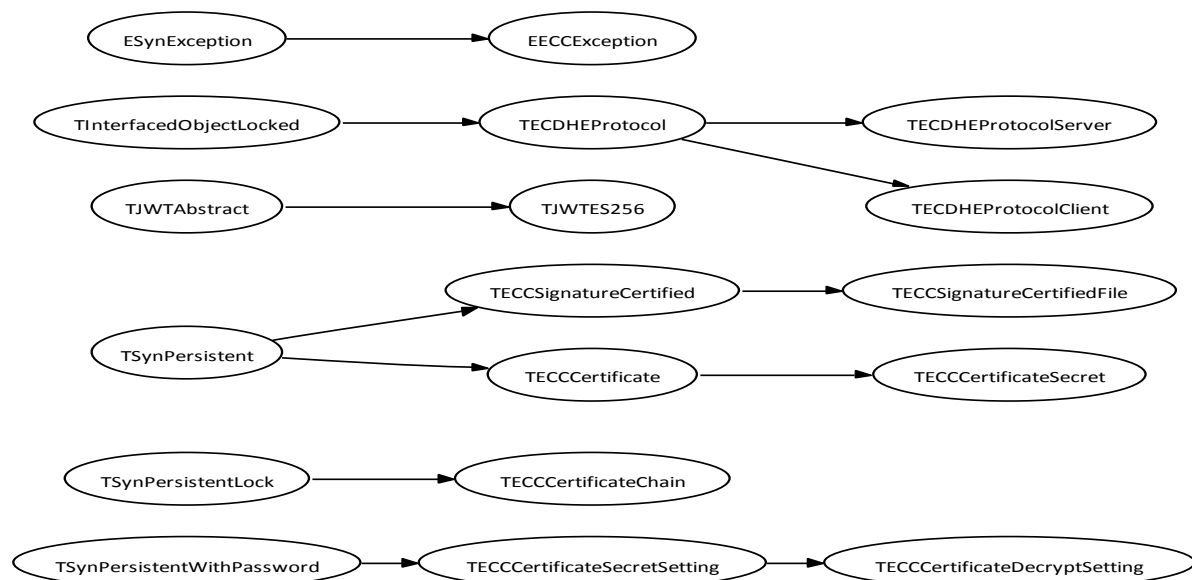

27.19. SynEcc.pas unit

Purpose: Certificate-based public-key cryptography using ECC-secp256r1

- this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the SynEcc unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synapse projects - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynCrypto</i>	Fast cryptographic routines (hashing and cypher) - implements AES,XOR,ADLER32,MD5,RC4,SHA1,SHA256,SHA384,SHA512,SHA3 and JWT - optimized for speed (tuned assembler and SSE3/SSE4/AES-NI/PADLOCK support) - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1143
<i>SynTable</i>	Filter/database/cache/buffer/security/search/multithread/OS features - as a complement to SynCommons, which tended to increase too much - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1728

SynEcc class hierarchy

Objects implemented in the SynEcc unit

Objects	Description	Page
EECCException	Exception class associated with this SynEcc unit	1323

Objects	Description	Page
TECCCertificate	A public certificate using ECC secp256r1 cryptography	1323
TECCCertificateChain	Manage PKI certificates using ECC secp256r1 cryptography	1334
TECCCertificateContent	Store a TECCCertificate binary buffer for ECC secp256r1 cryptography	1320
TECCCertificateDecryptSetting	Store settings pointing to a local .private file containing a secret key for .synecc file decryption	1331
TECCCertificateSecret	A public/private certificate using ECC secp256r1 cryptography	1326
TECCCertificateSecretSetting	Store settings pointing to a local .private file containing a secret key	1330
TECCCertificateSigned	The certification information of a TECCCertificate	1319
TECCSignatureCertified	A ECDSA secp256r1 digital signature of some content, signed by an authority	1331
TECCSignatureCertifiedContent	Store a TECCSignatureCertified binary buffer for ECDSA secp256r1 signature	1320
TECCSignatureCertifiedFile	Handle a .sign file content as generated by TECCCertificateSecret.SignFile	1333
TECDHEAlgo	Defines one protocol Algorithm recognized by TECDHEProtocol	1322
TECDHEFrameClient	The binary handshake message, sent by client to server	1322
TECDHEFrameServer	The binary handshake message, sent back from server to client	1323
TECDHEProtocol	Abstract ECDHE secure protocol with unilateral or mutual authentication	1340
TECDHEProtocolClient	Implements ECDHE secure protocol on client side	1342
TECDHEProtocolServer	Implements ECDHE secure protocol on server side	1342
TECIESHeader	Binary header of a .synecc file, encrypted via ECC secp256r1	1321
TJWTES256	Implements JSON Web Tokens using 'ES256' algorithm	1343

TECCCertificateSigned = packed record

The certification information of a TECCCertificate

- as stored in TECCCertificateContent.Signed
- defined in a separate record, to be digitally signed in the Signature field
- map TECCCertificate.Version 1 of the binary format
- "self-signed" certificates may be used as "root" certificates in the TECCCertificateChain list

AuthorityIssuer: TECCCertificateIssuer;

Identify the authority issuer used for signing

- is either genuine random bytes, or some Baudot-encoded text
- may equal Issuer, if was self-signed

AuthoritySerial: TECCCertificateID;

Genuine identifier of the authority certificate used for signing

- should be used to retrieve the associated PublicKey used to compute the Signature field
- may equal Serial, if was self-signed

IssueDate: TECCDate;

When this certificate was generated

Issuer: TECCCertificateIssuer;

Identify the certificate issuer

- is either genuine random bytes, or some Baudot-encoded text

PublicKey: TECCPublicKey;

The ECDSA secp256r1 public key of this certificate

- may be used later on for signing or key derivation

Serial: TECCCertificateID;

A genuine identifier for this certificate

- is used later on to validate other certificates in chain

ValidityEnd: TECCDate;

Certificate valid not after

ValidityStart: TECCDate;

Certificate valid not before

TECCCertificateContent = packed record

Store a TECCCertificate binary buffer for ECC secp256r1 cryptography

- i.e. a certificate public key, with its ECDSA signature
- would be stored in 173 bytes

CRC: cardinal;

FNV-1a checksum of all previous fields

- we use fnv32 and not crc32c here to avoid collision with crc64c hashing
- avoiding to compute slow ECDSA verification in case of corruption, due e.g. to unexpected transmission/bug/fuzzing
- should be the very last field in the record

Signature: TECCSignature;

SHA-256 + ECDSA secp256r1 signature of the Certificate record

Signed: TECCCertificateSigned;

The certification information, digitally signed in the Signature field

Version: word;

The TECCCertificate format version

TECCSignatureCertifiedContent = packed record

Store a TECCSignatureCertified binary buffer for ECDSA secp256r1 signature

- i.e. the digital signature of some content

AuthorityIssuer: TECCCertificateIssuer;

Identify the authority issuer used for signing

- is either genuine random bytes, or some Baudot-encoded text

AuthoritySerial: TECCCertificateID;

Genuine identifier of the authority certificate used for signing

- should be used to retrieve the associated PublicKey used to compute the Signature field

Date: TECCDate;

When this signature was generated

Signature: TECCSignature;

SHA-256 + ECDSA secp256r1 digital signature of the content

Version: word;

The TECCSignatureCertificated format version

TECIESHeader = packed record

Binary header of a .synecc file, encrypted via ECC secp256r1

- as generated by TECCCertificate.Encrypt/EncryptFile, and decoded by
TECCCertificateSecret.Decrypt

- a sign-then-encrypt pattern may have been implemented for additional safety

algo: TECIESAlgo;

Actual encryption algorithm used

crc: cardinal;

A crc32c hash of the header (excluding this field)

date: TECCDate;

When this encryption was performed

hmac: THash256;

The Message Authentication Code of the encrypted content

magic: THash128;

Contains 'SynEccEncrypted'#26

- so every .synecc file starts with those characters as signature

rec: TECCCertificateIssuer;

TECCCertificate.Issuer of the recipient public key used for encryption

- is either genuine random bytes, or some Baudot-encoded text

recid: TECCCertificateID;

TECCCertificate.Serial of the recipient public key used for encryption

rndpub: TECCPublicKey;

The genuine random public key used for encryption

sign: TECCSignatureCertifiedContent;

Optional ECDSA secp256r1 digital signature of the plain content

size: cardinal;

The size of the plain content (may be compressed before encryption)

unixts: cardinal;

Optional timestamp, in Unix seconds since 1970, of the source file

TECDHEAlgo = packed record

Defines one protocol Algorithm recognized by TECDHEProtocol

- only safe and strong parameters are allowed, and the default values (i.e. all fields set to 0) will ensure a very good combination
- in current implementation, there is no negotiation between nodes: client and server should have the very same algorithm

auth: TECDHEAuth;

The current Authentication scheme

ef: TECDHEEF;

The current Encryption Function

kdf: TECDHEKDF;

The current Key Derivation Function

mac: TECDHEMAC;

The current Message Authentication Code

TECDHEFrameClient = packed record

The binary handshake message, sent by client to server

- the frame will always have the same fixed size of 290 bytes (i.e. 388 base64-encoded chars, which could be transmitted in a HTTP header), for both mutual or unilateral authentication
- ephemeral keys may be included for perfect forward security

algo: TECDHEAlgo;

Expected algorithm used

QCA: TECCCertificateContent;

Client public key, with its certificate

- may be zero, in case of unilateral authentication (algo=authServer)

QE: TECCPublicKey;

Client-generated ephemeral public key

- may be zero, in case of unilateral authentication (algo=authClient)

RndA: THash128;

A client-generated random seed

Sign: TECCSignature;

SHA-256 + ECDSA secp256r1 signature of the previous fields, computed with the client private key

- i.e. ECDSASign(dA,sha256(algo|RndA|QCA|QE))
- may be zero, in case of unilateral authentication (algo=authServer)

TECDHEFrameServer = packed record

The binary handshake message, sent back from server to client

- the frame will always have the same fixed size of 306 bytes (i.e. 408 base64-encoded chars, which could be transmitted in a HTTP header), for both mutual or unilateral authentication
- ephemeral keys may be included for perfect forward security

algo: TECDHEAlgo;

Algorithm used by the server

QCB: TECCCertificateContent;

Server public key, with its certificate

- may be zero, in case of unilateral authentication (algo=authClient)

QF: TECCPublicKey;

Server-generated ephemeral public key

- may be zero, in case of unilateral authentication (algo=authServer)

RndA: THash128;

Client-generated random seed

RndB: THash128;

A server-generated random seed

Sign: TECCSignature;

SHA-256 + ECDSA secp256r1 signature of the previous fields, computed with the server private key

- i.e. ECDSASign(dB,sha256(algo|RndA|RndB|QCB|QF))
- may be zero, in case of unilateral authentication (algo=authClient)

EECCException = class(ESynException)

Exception class associated with this SynEcc unit

TECCCertificate = class(TSynPersistent)

A public certificate using ECC secp256r1 cryptography

- implements a custom binary format, with validation period, and chaining
- could be used for safe data signing, and authentication
- in fact, Base64 published property is enough to persist this instance: but consider also ToBase64/FromBase64/LoadFromStream/SaveToStream methods

constructor Create; **override;**

Initialize this certificate

constructor CreateFrom(const binary: TECCCertificateContent); **virtual;**

Initialize this certificate from a supplied certificate binary

- will raise an EECCException if the supplied binary is incorrect

```
constructor CreateFromAuth(const AuthPubKey: TFileName; const AuthBase64, AuthSerial: RawUTF8); virtual;
```

Initialize this certificate from a set of potential inputs

- will first search from a .public file name, base-64 encoded binary, or a serial number which be used to search for a local .public file (as located by ECCKeyFileFind)
- will raise an EECCEXception if no supplied media is correct

```
constructor CreateFromBase64(const base64: RawUTF8); virtual;
```

Initialize this certificate from a supplied base-64 encoded binary

- will raise an EECCEXception if the supplied base64 is incorrect

```
function CheckCRC: boolean;
```

Fast check of the binary buffer storage of this certificate

- ensure Content.CRC has the expected value, using FNV-1a checksum
- does not validate the certificate against the certificates chain, nor perform any ECC signature: use TECCCertificateChain.IsValid instead

```
function Encrypt(const Plain: RawByteString; Signature: TECCSignatureCertified=nil; FileDateTime: TDateTime=0; const KDFSalt: RawUTF8='salt'; KDFRounds: integer=DEFAULT_ECCROUNDS; const MACSalt: RawUTF8='hmac'; MACRounds: integer=100; Algo: TECIESAlgo=ecaUnknown): RawByteString;
```

Encrypt using the ECIES scheme, using this public certificate as key, via AES-256-CFB/PKCS7 over PBKDF2_HMAC_SHA256, and HMAC_SHA256

- returns the encrypted content, in the .synecc optimized format
- optional salt information used for PBKDF2 or HMAC can be customized
- ecaUnknown algorithm will use either ecaPBKDF2_HMAC_SHA256_AES256_CFB or ecaPBKDF2_HMAC_SHA256_AES256_CFB_SYNLZ depending if the supplied contain is compressible or not - but you may force another algorithm
- you can optionally associate an ECDSA secp256r1 digital signature, and a timestamp which may be used when re-creating a decyphered file
- use TECCCertificateSecret.Decrypt to uncypher the resulting content

```
function EncryptFile(const FileToCrypt: TFileName; const DestFile: TFileName=''; const Salt: RawUTF8='salt'; SaltRounds: integer=DEFAULT_ECCROUNDS; Algo: TECIESAlgo=ecaUnknown; IncludeSignFile: boolean=true): boolean;
```

Encrypt a file using the ECIES scheme, using this public certificate as key, via AES-256-CFB/PKCS7 over PBKDF2_HMAC_SHA256, and HMAC_SHA256

- by default, will create a FileToCrypt.synecc encrypted file
- ecaUnknown algorithm will use either ecaPBKDF2_HMAC_SHA256_AES256_CFB or ecaPBKDF2_HMAC_SHA256_AES256_CFB_SYNLZ depending if the supplied contain is compressible or not - but you may force another algorithm
- any available .sign ECDSA secp256r1 digital signature file will be recognized and embedded to the resulting .synecc content
- optional salt information used for PBKDF2 can be customized, to lock the encrypted file with the supplied password

function FromAuth(**const** AuthPubKey: TFileName; **const** AuthBase64, AuthSerial: RawUTF8): boolean;

Retrieve the certificate from a set of potential inputs

- will first search from a .public file name, base-64 encoded binary, or a serial number which be used to search for a local .public file in the current folder or ECCKeyFileFolder (as located by ECCKeyFileFind)
- returns true on success, false otherwise

function FromBase64(**const** base64: RawUTF8): boolean;

Retrieve the certificate from some base-64 encoded binary

- will use LoadFromStream serialization
- returns true on success, false otherwise

function FromFile(**const** filename: TFileName): boolean;

Retrieve the certificate from the "Base64": JSON entry of a .public file

- will use FromBase64/LoadFromStream serialization
- returns true on success, false otherwise

function LoadFromStream(Stream: TStream): boolean;

Retrieve the certificate from some base-64 encoded binary

- returns true on success, false otherwise

function PublicToBase64: RawUTF8;

Persist only the public certificate as some base-64 encoded binary

- will follow TECCCertificate.SaveToStream/ToBase64 serialization, even when called from a TECCCertificateSecret instance
- could be used to safely publish the public information of a newly created certificate

function SaveToStream(Stream: TStream): boolean;

Persist the certificate as some binary

- returns true on success (i.e. this class stores a certificate), false otherwise

function ToBase64: RawUTF8;

Persist the certificate as some base-64 encoded binary

- will use SaveToStream serialization

function ToFile(**const** filename: TFileName): boolean;

Save the public key as a .public json file

- i.e. a json containing all published properties of this instance
- persist ToVariant() as an human-readable JSON file

function ToVariant(withBase64: boolean=true): **variant**;

Returns a TDocVariant object of all published properties of this instance

- excludes the Base64 property content if withBase64 is set to false

property AuthorityIssuer: RawUTF8 **read** GetAuthorityIssuer;

Identify the authority issuer used for signing, as text

property AuthoritySerial: RawUTF8 **read** GetAuthoritySerial;

Hexadecimal text of the authority certificate identifier used for signing

property Base64: RawUTF8 **read** PublicToBase64 **write** SetBase64;

Base-64 encoded text of the whole certificate binary information

- only the public part of the certificate will be shown: any private key of a TECCCertificateSecret instance would be trimmed

property Content: TECCCertificateContent **read** fContent **write** fContent;

Low-level access to the binary buffer used ECC secp256r1 cryptography

- you should not use this property, but other methods

property IsSelfSigned: boolean **read** GetIsSelfSigned;

If this certificate has been signed by itself

- a self-signed certificate will have its AuthoritySerial/AuthorityIssuer fields matching Serial/Issuer, and should be used as "root" certificates

property IssueDate: RawUTF8 **read** GetIssueDate;

When this certificate was generated, as ISO-8601 text

property Issuer: RawUTF8 **read** GetIssuer;

Identify the certificate issuer, as text

property Serial: RawUTF8 **read** GetSerial;

The genuine identifier of this certificate, as hexadecimal text

property Signature: TECCSignature **read** fContent.Signature;

SHA-256 + ECDSA secp256r1 signature of the Certificate record

property Signed: TECCCertificateSigned **read** fContent.Signed;

The certification information, digitally signed in the Signature field

property ValidityEnd: RawUTF8 **read** GetValidityEnd;

Valid not after this date, as ISO-8601 text

property ValidityStart: RawUTF8 **read** GetValidityStart;

Valid not before this date, as ISO-8601 text

property Version: word **read** fContent.Version;

The TECCCertificate format version

- currently equals 1

TECCCertificateSecret = class(TECCCertificate)

A public/private certificate using ECC secp256r1 cryptography

- will store TECCCertificate public and associated private secret key

- implements a custom binary format, with validation period, and chaining

- could be used for safe data signing via SignToBase64/SignFile, and authentication / key derivation

- allows optional anti-forensic diffusion during storage via AFSplitStripes

constructor CreateFromSecureBinary(Data: pointer; Len: integer; **const** Password: RawUTF8; PBKDF2Rounds: integer=DEFAULT_ECCRounds; AES: TAESAbstractClass=nil); overload;

Create a certificate with its private secret key from a password-protected secure binary buffer

- may be used on a constant array in executable, created via SaveToSource()
- perform all reverse steps from SaveToSecureBinary() method
- will raise an EECCEXception if the supplied Binary is incorrect

constructor CreateFromSecureBinary(**const** Binary: RawByteString; **const** Password: RawUTF8; PBKDF2Rounds: integer=DEFAULT_ECCRounds; AES: TAESAbstractClass=nil); overload;

Create a certificate with its private secret key from a password-protected secure binary buffer

- perform all reverse steps from SaveToSecureBinary() method
- will raise an EECCEXception if the supplied Binary is incorrect

constructor CreateFromSecureFile(**const** FolderName: TFileName; **const** Serial, Password: RawUTF8; PBKDF2Rounds: integer=DEFAULT_ECCRounds; AES: TAESAbstractClass=nil); overload;

Create a certificate with its private secret key from an encrypted secure .private binary file stored in a given folder

- overloaded constructor retrieving the file directly from its folder
- perform all reverse steps from SaveToSecureFile() method
- will raise an EECCEXception if the supplied file is incorrect

constructor CreateFromSecureFile(**const** FileName: TFileName; **const** Password: RawUTF8; PBKDF2Rounds: integer=DEFAULT_ECCRounds; AES: TAESAbstractClass=nil); overload;

Create a certificate with its private secret key from an encrypted secure .private binary file and its associated password

- perform all reverse steps from SaveToSecureFile() method
- will raise an EECCEXception if the supplied file is incorrect

constructor CreateNew(Authority: TECCCertificateSecret; **const** IssuerText: RawUTF8=''; ExpirationDays: integer=0; StartDate: TDateTime=0; ParanoidVerify: boolean=true);

Generate a new certificate, signed using the supplied Authority

- if Authority is nil, will generate a self-signed certificate
- the supplied Issuer name would be stored using AsciiToBaudot(), truncated to the Issuer buffer size, i.e. 16 bytes - if Issuer is "", TAESPRNG.Fill() will be used
- you may specify some validity time range, if needed
- default ParanoidVerify=true will validate the certificate digital signature via a call ecdsa_verify() to ensure its usefulness
- would take around 4 ms under a 32-bit compiler, and 1 ms under 64-bit

destructor Destroy; **override**;

Finalize the instance, and safe erase fPrivateKey stored buffer

```
function Decrypt(const Encrypted: RawByteString; out Decrypted: RawByteString;  
Signature: PECCSignatureCertifiedContent=nil; MetaData: PRawJSON=nil;  
FileDateTime: PDateTime=nil; const KDFSalt: RawUTF8='salt'; KDFRounds:  
integer=DEFAULT_ECCROUNDS; const MACSalt: RawUTF8='hmac'; MACRounds: integer=100):  
TECCDecrypt;
```

Decrypt using the ECIES scheme, using this private certificate as key, via AES-256-CFB/PKCS7 over PBKDF2_HMAC_SHA256, and HMAC_SHA256

- expects TECCCertificate.Crypt() cyphered content with its public key
- returns the decrypted content, or "" in case of failure
- optional shared information used for PBKDF2 or HMAC can be customized
- optionally, you can retrieve the sign-then-encrypt ECDSA secp256r1 signature and metadata stored in the header (to be checked via TECCCertificateChain.IsSigned method), and/or the associated file timestamp

```
function DecryptFile(const FileToDecrypt: TFileName; const DestFile: TFileName='';  
const Salt: RawUTF8='salt'; SaltRounds: integer=DEFAULT_ECCROUNDS; Signature:  
PECCSignatureCertifiedContent=nil; MetaData: PRawJSON=nil): TECCDecrypt;
```

Decrypt using the ECIES scheme, using this private certificate as key, decrypt a file using the ECIES scheme, using this private certificate as key, via AES-256-CFB/PKCS7 over PBKDF2_HMAC_SHA256, and HMAC_SHA256

- makes the reverse operation of TECCCertificate.EncryptFile method
- by default, will erase the (.synecc) extension to FileToDecrypt name
- optional salt information used for PBKDF2 can be customized, to unlock the encrypted file with the supplied password
- optionally, you can retrieve the sign-then-encrypt ECDSA secp256r1 signature stored in the header for TECCCertificateChain.IsSigned() in supplied Signature^ and MetaData^ values

```
function HasSecret: boolean;
```

Returns TRUE if the private secret key is not filled with zeros

```
function LoadFromSecureBinary(Data: pointer; Len: integer; const PassWord: RawUTF8;  
PBKDF2Rounds: integer=DEFAULT_ECCROUNDS; AES: TAESAbstractClass=nil): boolean;  
overload;
```

Read a private secret key from an encrypted secure binary buffer

- perform all reverse steps from SaveToSecureBinary() method
- returns TRUE on success, FALSE otherwise

```
function LoadFromSecureBinary(const Binary: RawByteString; const PassWord: RawUTF8;  
PBKDF2Rounds: integer=DEFAULT_ECCROUNDS; AES: TAESAbstractClass=nil): boolean;  
overload;
```

Read a private secret key from an encrypted secure binary buffer

- perform all reverse steps from SaveToSecureBinary() method
- returns TRUE on success, FALSE otherwise

```
function LoadFromSecureFile(const FileName: TFileName; const PassWord: RawUTF8;  
PBKDF2Rounds: integer=DEFAULT_ECCROUNDS; AES: TAESAbstractClass=nil): boolean;
```

Read a private secret key from an encrypted .private binary file

- perform all reverse steps from SaveToSecureFile() method
- returns TRUE on success, FALSE otherwise

```
function SaveToSecureBinary(const Password: RawUTF8; AFStripes: integer=64;  
PBKDF2Rounds: integer=DEFAULT_ECCROUNDS; AES: TAESAbstractClass=nil; NoHeader:  
boolean=false): RawByteString;
```

Backup the private secret key into an encrypted secure binary buffer

- you should keep all your private keys in a safe place
- will use anti-forensic diffusion of the private key (64 stripes = 2KB)
- then AES-256-CFB encryption (or the one specified in AES parameter) will be performed from PBKDF2_HMAC_SHA256 derivation of an user-supplied password

```
function SaveToSecureFile(const Password: RawUTF8; const DestFolder: TFileName;  
AFStripes: integer=64; PBKDF2Rounds: integer=DEFAULT_ECCROUNDS; AES:  
TAESAbstractClass=nil; NoHeader: boolean=false): boolean;
```

Backup the private secret key into an encrypted .private binary file

- you should keep all your private keys in a safe dedicated folder
- filename will be the certificate hexadecimal as 'Serial.private'
- will use anti-forensic diffusion of the private key (64 stripes = 2KB)
- then AES-256-CFB encryption (or the one specified in AES parameter) will be performed from PBKDF2_HMAC_SHA256 derivation of an user-supplied password

```
function SaveToSecureFileName(FileNumber: integer=0): TFileName;
```

Computes the 'Serial.private' file name of this certificate

- as used by SaveToSecureFile()

```
function SaveToSecureFiles(const Password: RawUTF8; const DestFolder: TFileName;  
DestFileCount: integer; AFStripes: integer=64; PBKDF2Rounds:  
integer=DEFAULT_ECCROUNDS; AES: TAESAbstractClass=nil; NoHeader: boolean=false):  
boolean;
```

Backup the private secret key into several encrypted -###.private binary files

- secret sharing can be used to store keys at many different places, e.g. on several local or remote drives, and therefore enhance privacy and safety
- it will use anti-forensic diffusion of the private key to distribute it into pieces, in a manner that a subset of files can not regenerate the key: as a result, a compromission of one sub-file won't affect the secret key
- filename will be the certificate hexadecimal as 'Serial-###.private'
- AES-256-CFB encryption (or the one specified in AES parameter) will be performed from PBKDF2_HMAC_SHA256 derivation of an user-supplied password

```
function SaveToSource(const ConstName, Comment, Password: RawUTF8; IncludePassword:  
boolean=true; AFStripes: integer=0; PBKDF2Rounds: integer=100; AES:  
TAESAbstractClass=nil; IncludeRaw: boolean=true): RawUTF8;
```

Backup the private secret key into an encrypted source code constant

- may be used to integrate some private keys within an executable
- if ConstName="", _HEXASERIAL will be used, from 24 first chars of Serial
- the password may also be included as ConstName_PASS associated constant, and as ConstName_CYPH in TSynPersistentWithPassword/TECCCertificateSecretSetting encrypted format

function SignFile(const FileToSign: TFileName; const MetaNameValuePairs: array of const): TFileName;

Compute a .sign digital signature of any file

- SHA-256/ECDSA digital signature is included in a JSON document
- you can set some additional metadata information for the "meta": field
- will raise an EECCEXception if FileToSign does not exist
- returns the .sign file name, which is in fact FileToSign+'.sign'
- use TECCSignatureCertifiedFile class to load and validate such files

function SignToBase64(Data: pointer; Len: integer): RawUTF8; overload;

Compute a base-64 encoded signature of some digital content

- memory buffer will be hashed using SHA-256, then will be signed using ECDSA over the private secret key of this certificate instance
- you could later on verify this text signature according to the public key of this certificate, calling TECCCertificateChain.IsSigned()
- create internally a temporary TECCSignatureCertified instance

function SignToBase64(const Hash: THash256): RawUTF8; overload;

Compute a base-64 encoded signature of some digital content hash

- signature will be certified by private secret key of this instance
- you could later on verify this text signature according to the public key of this certificate, calling TECCCertificateChain.IsSigned()
- supplied hash is likely to be from SHA-256, but could be e.g. crc256c
- create internally a temporary TECCSignatureCertified instance

property AFSplitStripes: integer **read** fAFSplitStripes;

How many anti-forensic diffusion stripes are used for private key storage

- default is 0, meaning no diffusion, i.e. 32 bytes of storage space
- you may set e.g. to 32 to activate safe diffusion to 1KB of storage for ToBase64/SaveToStream methods
- is modified temporarily by SaveToSecure() method

property StoreOnlyPublicKey: boolean **read** fStoreOnlyPublicKey **write** fStoreOnlyPublicKey;

Disable private secret key storage in SaveToStream()

- default is false, i.e. the private secret key will be serialized
- you may set TRUE here so that SaveToStream() would store only the public certificate, as expected by a TECCCertificate class
- is used e.g. by PublicToBase64 method to trim the private information

TECCCertificateSecretSetting = **class**(TSynPersistentWithPassword)

Store settings pointing to a local .private file containing a secret key

- following TECCCertificateSecret secure binary file format
- you may use "ECC infocrypt" command to retrieve SaveToSource constants

constructor Create; **override**;

Initialize the settings with default values

function CertificateSecret(const FolderName: TFileName): TECCCertificateSecret;

Generate a TECCCertificateSecret instance corresponding to the settings

- is a wrapper around TECCCertificateSecret.CreateFromSecureFile
- will read the FileName file (if supplied), or search for the <Serial>.private file in the supplied folder otherwise, then use associated Password/PasswordRounds values to uncypher it
- returns nil if Serial and FileName are "", or raise an exception on unexpected error
- caller is responsible of freeing the returned class instance

property FileName: TFileName read fFileName write fFileName;

The first characters of the .private file holding the secret key

- equals "" by default, meaning no private secret is defined
- you may use the Serial property instead to search in an application specific folder

property Password: RawUTF8 read fPassword write fPassword;

The password used to protect the .private file

- matches the -authpass parameter used with "ECC decrypt" command, but with TSynPersistentWithPassword encryption
- i.e. matches ConstName_CYPH as generated by TECCCertificateSecret.SaveToSource

property PasswordRounds: integer read fPasswordRounds write fPasswordRounds;

Number of PBKDF2 rounds to be applied to the associated password

- matches ConstName_ROUNDS as generated by TECCCertificateSecret.SaveToSource
- matches the -authrounds parameter used with "ECC decrypt" command
- default is DEFAULT_ECCROUNDS, i.e. 60000

property Serial: RawUTF8 read fSerial write fSerial;

The first characters of the .private file holding the secret key

- equals "" by default, meaning no private secret is defined
- you may use the FileName property instead to specify a full path name

TECCCertificateDecryptSetting = class(TECCCertificateSecretSetting)

Store settings pointing to a local .private file containing a secret key for .synecc file decryption

- following TECCCertificateSecret secure binary file format
- publishes Salt and SaltRounds values, as expected by TECCCertificateSecret.Decrypt method

constructor Create; **override**;

Initialize the settings with default values

property Salt: RawUTF8 read fSalt write fSalt;

The Salt passphrase used to protect the .synecc encrypted file

- matches the -saltpass parameter used with "ECC crypt" command
- default is 'salt'

property SaltRounds: integer read fSaltRounds write fSaltRounds;

Number of PBKDF2 rounds to be applied to the associated Salt

- matches the -saltrounds parameter used with "ECC crypt" command
- default is DEFAULT_ECCROUNDS, i.e. 60000

TECCSignatureCertified = class(TSynPersistent)

A ECDSA secp256r1 digital signature of some content, signed by an authority

constructor Create; override;

Initialize this signature

constructor CreateFrom(const binary: TECCSignatureCertifiedContent; NoException: boolean=false);

Initialize this signature from a supplied binary

- will raise an EECCEXception if the supplied binary content is incorrect

constructor CreateFromBase64(const base64: RawUTF8; NoException: boolean=false);

Initialize this signature from a supplied base-64 encoded binary

- will raise an EECCEXception if the supplied base64 is incorrect

constructor CreateFromFile(const signfilename: TFileName; NoException: boolean=false);

Initialize this signature from the "sign": field of a JSON .sign file

- will raise an EECCEXception if the supplied file is incorrect

constructor CreateNew(Authority: TECCCertificateSecret; Data: pointer; Len: integer); overload;

Compute a new signature of some digital content

- memory buffer will be hashed using SHA-256, then will be signed using ECDSA over the private secret key of the supplied Authority certificate

constructor CreateNew(Authority: TECCCertificateSecret; const Hash: THash256); overload;

Compute a new signature of some digital content hash

- supplied hash is likely to be from SHA-256, but could be e.g. crc256c

- the hash will be signed using ECDSA over the private secret key of the supplied Authority certificate

function Check: boolean;

Fast check of the binary buffer storage of this signature

- performs basic checks, avoiding any void date, authority or signature

- use Verify() or TECCCertificateChain.IsSigned() methods for full digital signature validation

function FromBase64(const base64: RawUTF8): boolean;

Retrieve the signature from some base-64 encoded binary

- returns true on success, false otherwise

function FromFile(const signfilename: TFileName): boolean; virtual;

Retrieve the signature from the "sign": field of a JSON .sign file

- returns true on success, false otherwise

function SaveToDERBinary: RawByteString;

Save the ECDSA signature into a ASN.1's binary DER buffer

- note that DER content only stores the ECDSA digital signature, so all certification information is lost

function SaveToDERFile(const FileName: TFileName): boolean;

Save the ECDSA signature into a ASN.1's binary DER file

- note that DER content only stores the ECDSA digital signature, so all certification information is lost - consider using TECCSignatureCertifiedFile instead

- returns TRUE on success, FALSE otherwise

function ToBase64: RawUTF8;

Persist the signature as some base-64 encoded binary

function ToVariant: variant; virtual;

Returns a TDocVariant object of all published properties of this instance

function Verify(Authority: TECCCertificate; const hash: THash256): TECCValidity; overload;

Check if this digital signature matches a given data hash

- will check internal properties of the certificate (e.g. validity dates), and validate the stored ECDSA signature according to the public key of the supplied signing authority
- supplied hash is likely to be from SHA-256, but could be e.g. crc256c
- this method is thread-safe, and not blocking

function Verify(Authority: TECCCertificate; Data: pointer; Len: integer): TECCValidity; overload;

Check if this digital signature matches a given memory buffer

- will check internal properties of the certificate (e.g. validity dates), and validate the stored ECDSA signature according to the public key of the supplied signing authority
- will compute and verify the SHA-256 hash of the supplied data
- this method is thread-safe, and not blocking

property AuthorityIssuer: RawUTF8 read GetAuthorityIssuer;

Identify the authority issuer used for signing, as text

property AuthoritySerial: RawUTF8 read GetAuthoritySerial;

Hexadecimal text of the authority certificate identifier used for signing

property Content: TECCSignatureCertifiedContent read fContent write fContent;

Low-level access to the binary buffer used ECDSA secp256r1 cryptography

- you should not use this property, but other methods

property Date: RawUTF8 read GetDate;

When this signature was generated, as ISO-8601 text

property Version: word read fContent.Version;

The TECCSignatureCertified format version

- currently equals 1

TECCSignatureCertifiedFile = class(TECCSignatureCertified)

Handle a .sign file content as generated by TECCCertificateSecret.SignFile

- JSON document of a SHA-256/ECDSA secp256r1 digital signature

constructor CreateFromDecryptedFile(const aDecryptedContent: RawByteString; const Signature: TECCSignatureCertifiedContent; const MetaData: RawJSON);

Create and set .sign fields after TECCCertificateSecret.Decrypt() process

- will compute Size, and MD5/SHA-256 hashes from aDecryptedContent
- will raise an EECCEXception if the supplied parameters are incorrect

function FromDecryptedFile(const aDecryptedContent: RawByteString; const Signature: TECCSignatureCertifiedContent; const MetaData: RawJSON): boolean;

Compute .sign fields after TECCCertificateSecret.Decrypt() process

- will compute Size, and MD5/SHA-256 hashes from aDecryptedContent

function FromFile(**const** aFileName: TFileName): boolean; **override**;

Read a .sign digital signature file

- as previously generated by TECCCertificateSecret.SignFile
- will append '.sign' to aFileName, if it does not match this extension
- returns true on success, false otherwise

function FromFileJson(**const** aFileContent: RawUTF8): boolean;

Read a .sign digital signature JSON content

- as previously generated by TECCCertificateSecret.SignFile
- returns true on success, false otherwise

property LowLevelInfo: TDocVariantData **read** fLowLevelInfo;

Low-level access to the whole JSON document members

property MD5: RawUTF8 **read** fMD5;

The MD5 hexadecimal signature as stored in the .sign file

property MD5Digest: TMD5Digest **read** fMD5Digest;

The MD5 binary hash as stored in the .sign file

property MetaData: **variant** **read** fMetaData;

The meta data document as stored in the .sign file

property SHA256: RawUTF8 **read** fSHA256;

The SHA-256 hexadecimal signature as stored in the .sign file

property SHA256Digest: TSHA256Digest **read** fSHA256Digest;

The SHA-256 binary hash as stored in the .sign file

property Size: integer **read** fSize;

The signed file size in bytes, as stored in the .sign file

TECCCertificateChain = class(TSynPersistentLock)

Manage PKI certificates using ECC secp256r1 cryptography

- will implement a simple and efficient public-key infrastructure (PKI), based on JSON objects or even plain base-64 encoded JSON strings
- consider using TECCCertificateChainFile from mORMot.pas if you want to use convenient human-readable JSON serialization in files

constructor CreateFromArray(**const** values: TRawUTF8DynArray);

Initialize the certificate store from an array of base-64 encoded strings

- a TRawUTF8DynArray value is very convenient when storing the certificates chain as part of JSON settings, e.g. TDDAppSettings
- will call LoadFromArray(), and raise EECCException on any error

constructor CreateFromFile(const jsonfile: TFileName);

Initialize the certificate store from some JSON-serialized .ca file

- the file would store plain verbose information of all certificates, i.e. base-64 full information (containing only public keys) and also high-level published properties of all stored certificates (e.g. Serial)
- as such, this file format is more verbose than CreateFromJson/SaveToJson and may be convenient for managing certificates with a text/json editor
- you may use SaveToFile() method to create such JSON file
- will call LoadFromFile(), and raise EECCException on any error

constructor CreateFromFiles(const files: array of TFileName);

Initialize the certificate store from an array of .public file names

- raise EECCException on any error when reading a .public file

constructor CreateFromJson(const json: RawUTF8);

Initialize the certificate store from some JSON array of strings

- the serialization format is just a JSON array of base-64 encoded certificates (with only public keys) - so diverse from CreateFromFile()
- will call LoadFromJson(), and raise EECCException on any error

destructor Destroy; **override;**

Finalize the certificate store

function Add(cert: TECCCertificate): integer;

Register a certificate in the internal certificate chain

- returns the index of the newly inserted certificate
- returns -1 on error, e.g. if the certificate was not valid, or its serial was already part of the internal list
- any self-signed certificate will be rejected: use AddSelfSigned() instead
- this method is thread-safe

function AddSelfSigned(cert: TECCCertificate): integer;

Register a self-signed certificate in the internal certificate chain

- a self-signed certificate will have its AuthoritySerial/AuthorityIssuer fields matching Serial/Issuer, and should be used as "root" certificates
- returns -1 on error, e.g. if the certificate was not valid, not self-signed or its serial was already part of the internal list
- this method is thread-safe

function GetBySerial(const Serial: TECCCertificateID): TECCCertificate; **overload;**

Search for a certificate from its binary identifier

- this method is not thread-safe, unless you use Safe.Lock/Unlock

function GetBySerial(const Serial: RawUTF8): TECCCertificate; **overload;**

Search for a certificate from its hexadecimal text identifier

- this method is not thread-safe, unless you use Safe.Lock/Unlock

function GetBySerial(const Serial: TECCCertificateID; **out** PublicKey: TECCPublicKey): boolean; **overload;**

Search for a certificate public key from its binary identifier

- returns TRUE if the Serial identifier was found, FALSE otherwise
- this method is thread-safe, since it will make a private copy of the key

```
function GetBySerial(const Serial: TECCCertificateID; out Content: TECCCertificateContent): boolean; overload;
```

Search for a certificate binary content from its binary identifier

- returns TRUE if the Serial identifier was found, FALSE otherwise
- this method is thread-safe, since it will make a private copy of the content

```
function IsAuthorized(const base64sign: RawUTF8): boolean; overload;
```

Check if the digital signature is recognized by the stored certificates

- will check that the supplied base64 encoded text is a ECC signature, and that its AuthoritySerial is part of the Items[] list
- this method won't perform the ECDSA verification: use IsSigned() instead
- this method is thread-safe, and not blocking

```
function IsAuthorized(const sign: TECCSignatureCertifiedContent): boolean; overload;
```

Check if the digital signature is recognized by the stored certificates

- will check that sign.AuthoritySerial is part of the Items[] list
- this method won't perform the ECDSA verification: use IsSigned() instead
- this method is thread-safe, and not blocking

```
function IsAuthorized(sign: TECCSignatureCertified): boolean; overload;
```

Check if the digital signature is recognized by the stored certificates

- will check that sign.AuthoritySerial is part of the Items[] list
- this method won't perform the ECDSA verification: use IsSigned() instead
- this method is thread-safe, and not blocking

```
function IsSigned(const sign: TECCSignatureCertifiedContent; Data: pointer; Len: integer): TECCValidity; overload;
```

Check if the digital signature of a given memory buffer is valid

- will check internal properties of the certificate (e.g. validity dates), and validate the stored ECDSA signature according to the public key of the associated signing authority (which should be stored in Items[])
- will compute and verify the SHA-256 hash of the supplied data
- this method is thread-safe, and not blocking

```
function IsSigned(const base64sign: RawUTF8; const hash: THash256): TECCValidity; overload;
```

Verify the base-64 encoded digital signature of a given hash

- will check internal properties of the certificate (e.g. validity dates), and validate the stored ECDSA signature according to the public key of the associated signing authority (which should be stored in Items[])
- supplied hash is likely to be from SHA-256, but could be e.g. crc256c
- this method is thread-safe, and not blocking

```
function IsSigned(const base64sign: RawUTF8; Data: pointer; Len: integer): TECCValidity; overload;
```

Verify the base-64 encoded digital signature of a given memory buffer

- will check internal properties of the certificate (e.g. validity dates), and validate the stored ECDSA signature according to the public key of the associated signing authority (which should be stored in Items[])
- will compute and verify the SHA-256 hash of the supplied data
- this method is thread-safe, and not blocking

function IsSigned(const sign: TECCSignatureCertifiedContent; const hash: THash256): TECCValidity; overload;

Check if the digital signature of a given data hash is valid

- will check internal properties of the certificate (e.g. validity dates), and validate the stored ECDSA signature according to the public key of the associated signing authority (which should be stored in Items[])
- supplied hash is likely to be from SHA-256, but could be e.g. crc256c
- this method is thread-safe, and not blocking

function IsSigned(sign: TECCSignatureCertified; const hash: THash256): TECCValidity; overload;

Check if the digital signature of a given data hash is valid

- will check internal properties of the certificate (e.g. validity dates), and validate the stored ECDSA signature according to the public key of the associated signing authority (which should be stored in Items[])
- supplied hash is likely to be from SHA-256, but could be e.g. crc256c
- this method is thread-safe, and not blocking

function IsSigned(sign: TECCSignatureCertified; Data: pointer; Len: integer): TECCValidity; overload;

Check if the digital signature of a given memory buffer is valid

- if sign is a TECCSignatureCertifiedFile, the Size, MD5 and SHA256 fields stored in the .sign file content will be checked against the supplied data before ECDSA signature, and would return ecvCorrupted on error
- it will then check internal properties of the certificate (e.g. validity dates), and validate the stored SHA-256/ECDSA signature according to the public key of the associated signing authority (stored in Items[])
- this method is thread-safe, and not blocking

function IsSigned(sign: TECCSignatureCertifiedFile): TECCValidity; overload;

Check if the digital signature file (.sign content) is valid

- will check internal properties of the certificate (e.g. validity dates), and validate the stored ECDSA signature according to the public key of the associated signing authority (which should be stored in Items[])
- will use TECCSignatureCertifiedFile Size, MD5 and SHA256 fields, so could be used without any actual memory buffer
- this method is thread-safe, and not blocking

function IsValid(const content: TECCCertificateContent; ignoreDate: boolean=false): TECCValidity; overload;

Check if the certificate is valid, against known certificates chain

- will check internal properties of the certificate (e.g. validity dates, unless ignoreDate=TRUE), and validate the stored ECDSA signature according to the public key of the associated signing authority (which should be valid, and stored in Items[])
- consider setting IsValidCached property to TRUE to reduce resource use
- this method is thread-safe, and not blocking

function IsValid(cert: TECCertificate): TECCValidity; overload;

Check if the certificate is valid, against known certificates chain

- will check internal properties of the certificate (e.g. validity dates), and validate the stored ECDSA signature according to the public key of the associated signing authority (which should be stored in Items[])
- consider setting IsValidCached property to TRUE to reduce resource use
- this method is thread-safe, and not blocking

function LoadFromArray(const values: TRawUTF8DynArray): boolean;

Load a certificates chain from an array of base-64 encoded content

- follows SaveToArray format
- would create only TECCertificate instances with their public keys, since no private key, therefore no TECCertificateSecret is expected

function LoadFromFile(const jsonfile: TFileName): boolean;

Load a certificates chain from some JSON-serialized .ca file

- you may use SaveToFile() method to create such JSON file
- would create only TECCertificate instances with their public keys, since no private key, therefore no TECCertificateSecret is expected
- if jsonfile is not in the current folder, will try ECCKeyFileFolder

function LoadFromFileContent(const cjsoncontent: RawUTF8): boolean;

Load a certificates chain from some JSON-serialized .ca file content

- you may use SaveToFileContent method to create such JSON content
- would create only TECCertificate instances with their public keys, since no private key, therefore no TECCertificateSecret is expected

function LoadFromJson(const json: RawUTF8): boolean;

Load a certificates chain from a JSON array of strings

- follows SaveToJson format, i.e. base-64 encoded strings
- would create only TECCertificate instances with their public keys, since no private key, therefore no TECCertificateSecret is expected

function SaveToArray: TRawUTF8DynArray;

Save the whole certificates chain as an array of base-64 encoded content

- each certificate would be stored via PublicToBase64() into a RawUTF8
- any private key would be trimmed from the output: private secret keys should NOT be kept in the main chain, in which only public keys will appear

function SaveToFile(const jsonfile: TFileName): boolean;

Save the whole certificates chain as a .ca JSON file

- is in fact the human-friendly JSON serialization of this instance
- the .ca file would store plain verbose information of all certificates, i.e. base-64 full information (containing only public keys) and also high-level published properties of all stored certificates (e.g. Serial)
- as such, this file format is more verbose than CreateFromJson/SaveToJson and may be convenient for managing certificates with a text/json editor

function SaveToFileContent: RawUTF8;

Save the whole certificates chain as a JSON content, matching .ca format

- is in fact the human-friendly JSON serialization of this instance
- would store plain verbose information of all certificates, i.e. base-64 full information (containing only public keys) and also high-level published properties of all stored certificates (e.g. Serial)
- as such, .ca file format is more verbose than CreateFromJson/SaveToJson and may be convenient for managing certificates with a text/json editor

function SaveToFileVariant: variant;

Save the whole certificates chain as a JSON object, matching .ca format

- is in fact the human-friendly JSON serialization of this instance
- would store plain verbose information of all certificates, i.e. base-64 full information (containing only public keys) and also high-level published properties of all stored certificates (e.g. Serial)
- as such, .ca file format is more verbose than CreateFromJson/SaveToJson and may be convenient for managing certificates with a text/json editor

function SaveToJson: RawUTF8;

Save the whole certificates chain as a JSON array

- each certificate would be stored via PublicToBase64() into a JSON string
- any private key would be trimmed from the output JSON: private secret keys should NOT be kept in the main chain, in which only public keys should appear

function ValidateItems: TECCCertificateObjArray;

Check all stored certificates and their authorization chain

- returns nil if all items were valid
- returns the list of any invalid instances
- do not free the returned items, since they are reference to Items[]

procedure Clear;

Delete all stored certificates

- this method is thread-safe, calling Safe.Lock/Unlock

property Count: integer **read** GetCount;

How many certificates are currently stored in the certificates chain

property IsValidCached: boolean **read** fIsValidCached **write** SetIsValidCached;

If the IsValid() calls should maintain a cache of all valid certificates

- will use a naive but very efficient crc64c hashing of previous contents
- since ecdsa_verify() is very demanding, such a cache may have a huge speed benefit if the certificates are about to be supplied several times
- is disabled by default, for paranoid safety

property Items: TECCCertificateObjArray **read** fItems;

Low-level access to the internal certificates chain

- thread-safe process may be done using
Safe.Lock; try ... finally Safe.Unlock; end;

TECDHEProtocol = class(TInterfacedObjectLocked)

Abstract ECDHE secure protocol with unilateral or mutual authentication

- inherited TECDHEProtocolClient and TECDHEProtocolServer classes will implement a secure client/server transmission, with a one-way handshake and asymmetric encryption
- will validate ECDSA signatures using certificates of the associated PKI
- will create an ephemeral ECC key pair for perfect forward security
- will use ECDH to compute a shared ephemeral session on both sides, for AES-128 or AES-256 encryption, and HMAC with anti-replay - default algorithm will use fast and safe AES-CFB 128-bit encryption, with efficient AES-CRC 256-bit MAC, and full hardware acceleration on Intel CPUs

constructor Create(aAuth: TECDHEAuth; aPKI: TECCCertificateChain; aPrivate: TECCCertificateSecret); **reintroduce**; overload; **virtual**;

Initialize the ECDHE protocol with a PKI and a private secret key

- if aPKI is not set, the certificates won't be validated and the protocol will allow self-signed credentials
- aPrivate should always be set for mutual or unilateral authentication
- will implement unilateral authentication if aPrivate=nil for this end

constructor CreateFrom(aAnother: TECDHEProtocol); **virtual**;

Will create another instance of this communication protocol

destructor Destroy; **override**;

Finalize the instance

- also erase all temporary secret keys, for safety

function CheckError(const aEncrypted: RawByteString): TProtocolResult; **virtual**;

Check for any transmission error of the supplied encrypted text

- returns sprSuccess if the stored CRC of the encrypted flow matches
- returns sprInvalidMAC in case of wrong aEncrypted input
- is only implemented for MAC=macDuringEF, otherwise returns sprUnsupported
- to be called before Decrypt(), since this later method will change the internal KM[false] sequence number

function Clone: IProtocol;

Will create another instance of this communication protocol

function Decrypt(const aEncrypted: RawByteString; out aPlain: RawByteString): TProtocolResult; **virtual**;

Decrypt a message on one side, as transmitted from the other side

- will use the Encryption Function EF, according to the shared secret key
- returns sprInvalidMAC in case of wrong aEncrypted input (e.g. packet corruption, MiM or Replay attacks attempts)
- this method is thread-safe

class function FromKey(const aKey: RawUTF8; aServer: boolean): TECDHEProtocol;

Creates a new TECDHEProtocolClient or TECDHEProtocolServer from a text key

- expected layout is values separated by ; with at least a=... pair
- if needed, you can specify p=... as the password file name (searching for first matching unique file name with .private extension in the current directory of in ECCKeyFileFolder), and pw=...;pr=... for the associated password protection (password content and rounds)
- optional ca=...;a=...;k=...;e=...;m=... switches will match PKI, Auth, KDF, EF and MAC properties of this class instance (triming left lowercase chars)
- global value set by FromKeySetCA() is used as PKI, unless ca=.. is set (as a .ca file name, or as ca=base64,base64 or ca="base64","base64")
- a full text key with default values may be:
a=musal;k=hmacsha256;e=aescrc128;m=duringef;p=34a2;pw=passwordFor34a2;
pr=60000;ca=websockets
- returns nil if aKey does not match this format, i.e. has no p=...pw=..

class function FromKeyCompute(const privkey, privpassword: RawUTF8; privrounds: integer=DEFAULT_ECCROUNDS; const pki: RawUTF8=''; auth: TECDHEAuth=authMutual; kdf: TECDHEKDF=kdfHmacSha256; ef: TECDHEEF=efAesCrc128; mac: TECDHEMAC=macDuringEF; customkey: cardinal=0): RawUTF8;

Computes a TSynPersistentWithPassword key expected by FromKey

- the .private key file name, and its associated password/rounds should be specified, but for unilateral authentication on the other side
- pki should be a .ca file name, 'base64,base64' or '"base64","base64"'
- result of this method can be stored directly in a .settings file, to enable the TECDHEProtocol safe protocol for transmission

function ProcessHandshake(const MsgIn: RawUTF8; out MsgOut: RawUTF8): TProtocolResult; **virtual; abstract;**

Initialize the communication by exchanging some client/server information

- this method should be overridden with the proper implementation

procedure Encrypt(const aPlain: RawByteString; out aEncrypted: RawByteString); **virtual;**

Encrypt a message on one side, ready to be transmitted to the other side

- will use the Encryption Function EF, according to the shared secret key
- this method is thread-safe

class procedure FromKeySetCA(aPKI: TECCCertificateChain);

Defines the default PKI instance to be used by FromKey

- used if the ca=... property is not set in the aKey value

property Auth: TECDHEAuth **read** fAlgo.auth;

The current Authentication scheme

- this value on client side should match server's Authorized
- this value on server side may change if the client forced another mode

property CertificateValidity: TECCValidity **read** fCertificateValidity;

After handshake, contains the information about the other side public key certificate validity, against the shared PKI

property EF: TECDHEEF **read** fAlgo.ef **write** fAlgo.ef;

The current Encryption Function

- this value should match on both client and server sides

property EFSalt: RawByteString **read** fEFSalt **write** fEFSalt;

The current salt, used by the Key Derivation Function KDF to compute the key supplied to the Encryption Function EF

- equals 'ecdhesalt' by default
- this value should match on both client and server sides

property KDF: TECDHEKDF **read** fAlgo.kdf **write** fAlgo.kdf;

The current Key Derivation Function

- this value should match on both client and server sides

property MAC: TECDHEMAC **read** fAlgo.mac **write** fAlgo.mac;

The current Message Authentication Code

- this value should match on both client and server sides

property MACSalt: RawByteString **read** fMACSalt **write** fMACSalt;

The current salt, used by the Key Derivation Function KDF to compute the key supplied to the Message Authentication Code MAC

- equals 'ecdhemac' by default
- this value should match on both client and server sides

property PKI: TECCCertificateChain **read** fPKI;

Shared public-key infrastructure, used to validate exchanged certificates

- will be used for authenticity validation of ECDSA signatures

TECDHEProtocolClient = **class**(TECDHEProtocol)

Implements ECDHE secure protocol on client side

constructor Create(aAuth: TECDHEAuth; aPKI: TECCCertificateChain; aPrivate: TECCCertificateSecret); **override**;

Initialize the ECDHE protocol on the client side

- will check that aAuth is compatible with the supplied aPKI/aPrivate

function ProcessHandshake(const MsgIn: RawUTF8; out MsgOut: RawUTF8): TProtocolResult; **override**;

Initialize the client communication

- if MsgIn is '', will call ComputeHandshake
- if MsgIn is set, will call ValidateHandshake

function ValidateHandshake(const aServer: TECDHEFrameServer): TProtocolResult;

Validate the authentication frame sent back by the server

procedure ComputeHandshake(out aClient: TECDHEFrameClient);

Generate the authentication frame sent from the client

TECDHEProtocolServer = **class**(TECDHEProtocol)

Implements ECDHE secure protocol on server side

constructor Create(aAuth: TECDHEAuth; aPKI: TECCCertificateChain; aPrivate: TECCCertificateSecret); **override**;

Initialize the ECDHE protocol on the client side

- will check that aAuth is compatible with the supplied aPKI/aPrivate

constructor CreateFrom(aAnother: TECDHEProtocol); **override;**

Will create another instance of this communication protocol

function ComputeHandshake(const aClient: TECDHEFrameClient; out aServer: TECDHEFrameServer): TProtocolResult;

Generate the authentication frame corresponding to the client request

- may change Auth property if the Client requested another authentication scheme, allowed in Authorized setting and compatible with fPrivate

function ProcessHandshake(const MsgIn: RawUTF8; out MsgOut: RawUTF8): TProtocolResult; **override;**

Initialize the server communication

- will call ComputeHandshake

property Authorized: TECDHEAuths **read** fAuthorized **write** fAuthorized;

The Authentication Schemes allowed by this server

- by default, only the aAuth value specified to Create is allowed
- you can set e.g. [authMutual,authServer] for a weaker pattern

TJWTES256 = class(TJWTAbstract)

Implements JSON Web Tokens using 'ES256' algorithm

- i.e. ECDSA using the P-256 curve and the SHA-256 hash algorithm
- as defined in <http://tools.ietf.org/html/rfc7518> paragraph 3.4
- since ECDSA signature and verification is CPU consuming (under x86, it takes 2.5 ms, but only 0.3 ms on x64) you may enable CacheTimeoutSeconds

constructor Create(aCertificate: TECCCertificate; aClaims: TJWTClaims; const aAudience: array of RawUTF8; aExpirationMinutes: integer=0; aIDIdentifier: TSynUniqueIdentifierProcess=0; aIDObfuscationKey: RawUTF8=''); **reintroduce;**

Initialize the JWT processing instance using ECDSA P-256 algorithm

- the supplied set of claims are expected to be defined in the JWT payload
- the supplied ECC certificate should be a TECCCertificate storing the public key needed for Verify(), or a TECCCertificateSecret storing also the private key required by Compute()
- aCertificate is owned by this instance if property OwnCertificate is true
- aAudience are the allowed values for the jrcAudience claim
- aExpirationMinutes is the deprecation time for the jrcExpirationTime claim
- aIDIdentifier and aIDObfuscationKey are passed to a TSynUniqueIdentifierGenerator instance used for jrcJwtID claim

destructor Destroy; **override;**

Finalize the instance

property Certificate: TECCCertificate **read** fCertificate;

Access to the associated TECCCertificate instance

- which may be a TECCCertificateSecret for Compute() private key

property OwnCertificate: boolean **read** fOwnCertificate **write** fOwnCertificate;

If the associated TECCCertificate is to be owned by this instance

Types implemented in the SynEcc unit

PECCCertificateContent = ^TECCCertificateContent;

Points to a TECCCertificate binary buffer for ECC secp256r1 cryptography

PECCCertificateSigned = ^TECCCertificateSigned;

Points to certification information of a TECCCertificate

PECCSignatureCertifiedContent = ^TECCSignatureCertifiedContent;

Points to a TECCSignatureCertified buffer for ECDSA secp256r1 signature

PECDHEAlgo = ^TECDHEAlgo;

Points to one protocol Algorithm recognized by TECDHEProtocol

PECIESHeader = ^TECIESHeader;

Points to the binary header of a .synecc encrypted file

TECCCertificateID = **type** THash128;

Used to identify a TECCCertificate

- could be generated by TAEsprng.Fill() method

TECCCertificateIssuer = **type** THash128;

Used to identify a TECCCertificate issuer

- could be generated by AsciiToBaudot(), with truncation to 16 bytes (up to 25 Ascii-7 characters)

TECCCertificateObjArray = **array of** TECCCertificate;

Used to store a list of TECCCertificate instances

- e.g. in TECCCertificateChain.Items

- TJSONSerializer.RegisterObjArrayForJSON done in dddInfraApps and not in this unit to avoid dependency to mORMot.pas

TECCDate = **word**;

Used to store a date in a TECCCertificate

- i.e. 16-bit number of days since 1 August 2016

- use NowECCDate, ECCDate(), ECCToDateTime() or ECCText() functions

TECCDecrypt = (ecdDecrypted, ecdDecryptedWithSignature, ecdNoContent, ecdCorrupted, ecdInvalidSerial, ecdNoPrivateKey, ecdInvalidMAC, ecdDecryptError, ecdWriteFileError);

The error codes returned by TECCCertificateSecret.Decrypt()

- see also ECC_VALIDDECRYPT constant

TECCHash = THash256;

Store a 256-bit hash, as expected by ECC secp256r1 cryptography

- see e.g. ecdsa_sign() and ecdsa_verify() functions

TECCPrivateKey = **array[0..ECC_BYTES-1] of** byte;

Store a private key for ECC secp256r1 cryptography

- use ecc_make_key() to generate such a key

- stored in compressed form, i.e. each private key consumes 32 bytes of memory

TECCPublicKey = **array[0..ECC_BYTES] of** byte;

Store a public key for ECC secp256r1 cryptography

- use ecc_make_key() to generate such a key

- stored in compressed form with its standard byte header, i.e. each public key consumes 33 bytes of memory

TECCPublicKeyUncompressed = **array[0..(ECC_BYTES*2)-1] of** byte;

Store a public key for ECC secp256r1 cryptography

- use `ecc_uncompress_key_pas()` to compute such a key from a `TECCPublicKey`
- stored in uncompressed form, consuming 64 bytes of memory

TECCSecretKey = THash256;

Store an encryption key, as generated by ECC secp256r1 cryptography

- use `ecdh_shared_secret()` to compute such a key from public/private keys
- 256-bit / 32 bytes derivation from secp256r1 ECDH is expected to have at least 247 bits of entropy so could better be derivated via a KDF before used as encryption secret - see [@http://crypto.stackexchange.com/a/9428/40200](http://crypto.stackexchange.com/a/9428/40200)

TECCSignature = array[0..(ECC_BYTES*2)-1] of byte;

Store a signature, as generated by ECC secp256r1 cryptography

- see e.g. `ecdsa_sign()` and `ecdsa_verify()` functions
- contains ECDSA's R and S integers
- each ECC signature consumes 64 bytes of memory

TEccSignatureDer = array[0..(ECC_BYTES * 2) + 7] of byte;

Store a signature, in the DER format

- static allocated buffer as returned by `EccSignToDer()`

TECCValidity = (ecvUnknown, ecvValidSigned, ecvValidSelfSigned, ecvNotSupported, ecvBadParameter, ecvCorrupted, ecvInvalidDate, ecvUnknownAuthority, ecvDeprecatedAuthority, ecvInvalidSignature);

Indicate the validity state of a ECDSA signature against a certificate

- as returned by low-level `ECCVerify()` function, and `TECCSignatureCertified.Verify`, `TECCCertificateChain.IsValid` or `TECCCertificateChain.IsSigned` methods
- see also `ECC_VALIDSIGN` constant

TECDHEAuth = (authMutual, authServer, authClient);

The Authentication schemes recognized by TECDHEProtocol

- specifying the authentication allows a safe one-way handshake

TECDHEAuths = set of TECDHEAuth;

Set of Authentication schemes recognized by TECDHEProtocolServer

TECDHEEF = (efAesCrc128, efAesCfb128, efAesOfb128, efAesCtr128, efAesCbc128, efAesCrc256, efAesCfb256, efAesOfb256, efAesCtr256, efAesCbc256);

The Encryption Functions recognized by TECDHEProtocol

- all supported AES chaining blocks have their 128-bit and 256-bit flavours
- default `efAesCrc128` will use the dedicated `TAESCFBCRC` class, i.e. AES-CFB encryption with on-the-fly 256-bit CRC computation of the plain and encrypted blocks, and AES-encryption of the CRC to ensure cryptographic level message authentication and integrity - associated `TECDHEMAC` property should be `macDuringEF`
- other values will define `TAESCFB/TAESOFB/TAESCTR/TAESCBC` in 128-bit or 256-bit mode, in conjunction with a `TECDHEMAC` setting
- AES-NI hardware acceleration will be used, if available - under x86-64, `efAesOfb128` will potentially give the best performance
- of course, weak ECB mode is not available

TECDHEKDF = (kdfHmacSha256);

The Key Derivation Functions recognized by TECDHEProtocol

- used to compute the EF secret and MAC secret from shared ephemeral secret

- only HMAC SHA-256 safe algorithm is proposed currently

```
TECDHEMAC = ( macDuringEF, macHmacSha256, macHmacCrc256c, macHmacCrc32c, macXxHash32, macNone );
```

The Message Authentication Codes recognized by TECDHEProtocol

- default macDuringEF (680MB/s for efAesCrc128 with SSE4.2 and AES-NI) means that no separated MAC is performed, but done during encryption step: only supported by efAesCrc128 or efAesCrc256 (may be a future AES-GCM)
- macHmacSha256 is the safest, but slow, especially when used as MAC for AES-NI accelerated encryption (110MB/s with efAesCfb128, to be compared with macDuringEF, which produces a similar level of MAC)
- macHmacCrc256c and macHmacCrc32c are faster (550-650MB/s with efAesCfb128), and prevent transmission errors but not message integrity or authentication since composition of two crcs is a multiplication by a polynomial - see <http://mslc.ctf.su/wp/boston-key-party-ctf-2016-hmac-crc-crypto-5pts>
- macXxHash32 will use the xxhash32() algorithm, fastest without SSE4.2
- macNone (800MB/s, which is the speed of AES-NI encryption itself for a random set of small messages) won't check errors, but only replay attacks

```
TECDHEProtocolClass = class of TECDHEProtocol;
```

Meta-class of the TECDHEProtocol type

```
TECIESAlgo = ( ecaUnknown, ecaPBKDF2_HMAC_SHA256_AES256_CFB, ecaPBKDF2_HMAC_SHA256_AES256_CBC, ecaPBKDF2_HMAC_SHA256_AES256_OFB, ecaPBKDF2_HMAC_SHA256_AES256_CTR, ecaPBKDF2_HMAC_SHA256_AES256_CFB_SYNLZ, ecaPBKDF2_HMAC_SHA256_AES256_CBC_SYNLZ, ecaPBKDF2_HMAC_SHA256_AES256_OFB_SYNLZ, ecaPBKDF2_HMAC_SHA256_AES256_CTR_SYNLZ, ecaPBKDF2_HMAC_SHA256_AES128_CFB_SYNLZ, ecaPBKDF2_HMAC_SHA256_AES128_CBC_SYNLZ, ecaPBKDF2_HMAC_SHA256_AES128_OFB_SYNLZ, ecaPBKDF2_HMAC_SHA256_AES128_CTR_SYNLZ, ecaPBKDF2_HMAC_SHA256_AES128_CFB, ecaPBKDF2_HMAC_SHA256_AES128_CBC, ecaPBKDF2_HMAC_SHA256_AES128_OFB, ecaPBKDF2_HMAC_SHA256_AES128_CTR );
```

The known algorithms implemented in ECIES encryption

- supports AES 256-bit encryption with safe block modes (weak ECB mode is not available) - or AES 128-bit if needed (e.g. for regulatory issues)
- safe HMAC SHA-256 is used as Message Authentication Code algorithm
- optional SynLZ compression can be enabled

Constants implemented in the SynEcc unit

```
ECCERTIFICATEPUBLIC_FILEEXT = '.public';
```

File extension of the JSON file storing a TECCertificate public key

```
ECCERTIFICATESECRET_FILEEXT = '.private';
```

File extension of the binary encrypted file storing a private key

- as generated by TECCertificateSecret.SaveToSecureFile method

```
ECCERTIFICATESIGN_FILEEXT = '.sign';
```

File extension of the JSON file storing a digital signature of a file

- by convention, this .sign extension is appended to the original file name
- as generated by TECCertificateSecret.SignFile, and loaded by the TECCSignatureCertifiedFile class

```
ECCERTIFICATES_FILEEXT = '.ca';
```

File extension of the JSON file storing a certificate authorities chain

- as generated by mORMot.pas TECCertificateChainFile.SaveToFile() and loaded by

TECCCertificateChain.LoadFromFile

ECC_BYTES = sizeof(THash256);

The size of the 256-bit memory structure used for secp256r1

- map 32 bytes of memory

ECC_VALIDDECRYPT = [ecdDecrypted, ecdDecryptedWithSignature];

TECCDecrypt results indicating a valid decryption process

ECC_VALIDSIGN = [ecvValidSigned, ecvValidSelfSigned];

TECCValidity results indicating a valid digital signature

ENCRYPTED_FILEEXT = '.synecc';

File extension of the ECIES encrypted file

- with optional digital signature of the plain content

- as generated by TECCCertificate.Encrypt/EncryptFile, and decoded via TECCCertificateSecret.Decrypt

Functions or procedures implemented in the SynEcc unit

Functions or procedures	Description	Page
ECCCheck	Fast check of the binary buffer storage of a signature	1349
ECCCheck	Fast check of the binary buffer storage of a certificate	1349
ECCCheckDate	Fast check of the dates stored in a certificate binary buffer	1349
ECCDate	Convert a supplied TDateTime value into a TECCDate integer value	1349
ECCID	Convert a supplied hexadecimal buffer into a TECCCertificateID binary buffer	1349
ECCIssuer	Convert some Ascii-7 text into a TECCCertificateIssuer binary buffer	1349
ECCKeyFileFind	Search the single .public or .private file starting with the supplied file name	1349
ECCKeyFileFolder	Retrieve the private local folder used to store .public or .private files	1349
ECCSelfSigned	Fast check if the binary buffer storage of a certificate was self-signed	1349
ECCSign	Convert a supplied base-64 text into a TECCSignatureCertifiedContent binary buffer	1350
EccSignToDer	Convert a raw signature into a DER compatible content	1350
ECCText	Convert a supplied TECCCertificateID binary buffer into proper text	1350
ECCText	Convert a supplied a TECCDate integer value into a ISO-8601 text value	1350
ECCText	Convert a supplied TECCCertificateIssuer binary buffer into proper text	1350
ECCText	Convert a supplied TECCSignatureCertifiedContent binary buffer into proper text	1350
ECCText	Convert a supplied TECCSignature binary buffer into proper text	1350

Functions or procedures	Description	Page
ECCToDateTime	Convert a supplied a TECCDate integer value into a TDateTime value	1350
ECCVerify	Low-level verification of a TECCSignatureCertifiedContent binary buffer	1350
ecc_make_key	Create a public/private key pair	1350
ecc_make_key_pas	Pascal function to create a secp256r1 public/private key pair	1350
ecc_uncompress_key_pas	Uncompress a public key for ECC secp256r1 cryptography	1351
ecdh_shared_secret	Compute a shared secret given your secret key and someone else's public key	1351
ecdh_shared_secret_pas	Pascal function to compute a secp256r1 shared secret given your secret key and someone else's public key (in compressed format)	1351
ecdh_shared_secret_pas	Pascal function to compute a secp256r1 shared secret given your secret key and someone else's public key (in uncompressed/flat format)	1351
ecdsa_sign	Generate an ECDSA signature for a given hash value	1351
ecdsa_sign_pas	Pascal function to generate an ECDSA secp256r1 signature for a given hash value	1351
ecdsa_verify	Verify an ECDSA signature	1351
ecdsa_verify_pas	Pascal function to verify an ECDSA secp256r1 signature from someone else's public key (in compressed format)	1352
ecdsa_verify_pas	Pascal function to verify an ECDSA secp256r1 signature from someone else's public key (in uncompressed/flat format)	1352
ECIESHeader	Validate the binary header of a .synecc file buffer, encrypted via ECC secp256r1	1352
ECIESHeader	Extract the binary header of a .synecc file buffer, encrypted via ECC secp256r1	1352
ECIESHeaderFile	Extract the binary header of a .synecc file, encrypted via ECC secp256r1	1352
ECIESHeaderText	Convert the binary header of a .synecc file buffer into a JSON object	1352
ECIESHeaderText	Convert the header of a .synecc file into a JSON object	1352
ECIESKeyFileFind	Search the single .public or .private file used to crypt a given content	1352
FillZero	Fill all bytes of this ECC private key buffer with zero	1353
IsEqual	Compare two TECCCertificateIssuer binary buffer values	1353
IsEqual	Compare two TECCCertificateID binary buffer values	1353
IsZero	Ensure a TECCCertificateID binary buffer is not void, i.e. filled with 0	1353
IsZero	Ensure a TECCCertificateIssuer binary buffer is not void, i.e. filled with 0	1353

Functions or procedures	Description	Page
NowECCDate	Returns the current UTC date, as a TECCDate integer value	1353

function ECCCheck(const content: TECCCertificateContent): boolean; overload;

Fast check of the binary buffer storage of a certificate

- ensure content.CRC has the expected value, using FNV-1a checksum
- does not validate the certificate against the certificates chain, nor perform any ECC signature: use TECCCertificateChain.IsValid instead

function ECCCheck(const content: TECCSignatureCertifiedContent): boolean; overload;

Fast check of the binary buffer storage of a signature

- just check that the date and authority are set

function ECCCheckDate(const content: TECCCertificateContent): boolean;

Fast check of the dates stored in a certificate binary buffer

- could be validated against ECCCheck()

function ECCDate(const DateTime: TDateTime): TECCDate;

Convert a supplied TDateTime value into a TECCDate integer value

- i.e. 16-bit number of days since 1 August 2016
- returns 0 if the supplied value is invalid, i.e. out of range

function ECCID(const Text: RawUTF8; out ID: TECCCertificateID): boolean;

Convert a supplied hexadecimal buffer into a TECCCertificateID binary buffer

- returns TRUE if the supplied Text was a valid hexadecimal buffer

function ECCIssuer(const Text: RawUTF8; out Issuer: TECCCertificateIssuer): boolean;

Convert some Ascii-7 text into a TECCCertificateIssuer binary buffer

- using Emile Baudot encoding
- returns TRUE on Text truncation to fit into the 16 bytes

function ECCKeyFileFind(var TruncatedFileName: TFileName; privkey: boolean): boolean;

Search the single .public or .private file starting with the supplied file name

- as used in the ECC.dpr command-line sample project
- returns true and set the full file name of the matching file
- returns false if there is no match, or more than one matching file
- will also search in ECCKeyFileFolder, if the supplied folder is not enough

function ECCKeyFileFolder: TFileName;

Retrieve the private local folder used to store .public or .private files

- it is better to store all your key files in a single place, for easier and safer management
- under Windows, returns 'C:\Users\username\AppData\Local\Synopse\Keys\'
- under Linux, returns '\$HOME/.synopse/keys/'

function ECCSelfSigned(const content: TECCCertificateContent): boolean;

Fast check if the binary buffer storage of a certificate was self-signed

- a self-signed certificate will have its AuthoritySerial/AuthorityIssuer fields matching Serial/Issuer

function ECCSign(**const** base64: RawUTF8; **out** content: TECCSignatureCertifiedContent): boolean;

Convert a supplied base-64 text into a TECCSignatureCertifiedContent binary buffer

function EccSignToDer(**const** sign: TEccSignature; **out** der: TEccSignatureDer): integer;

Convert a raw signature into a DER compatible content

- returns the number of bytes encoded into der[] buffer

function ECCText(**const** sign: TECCSignatureCertifiedContent): RawUTF8; overload;

Convert a supplied TECCSignatureCertifiedContent binary buffer into proper text

- returns base-64 encoded text, or "" if the signature was filled with zeros

function ECCText(**const** sign: TECCSignature): RawUTF8; overload;

Convert a supplied TECCSignature binary buffer into proper text

- returns base-64 encoded text, or "" if the signature was filled with zeros

function ECCText(**const** Issuer: TECCCertificateIssuer): RawUTF8; overload;

Convert a supplied TECCCertificateIssuer binary buffer into proper text

- returns Ascii-7 text if was stored using Baudot encoding

- or returns hexadecimal values, if it was 16 bytes of random binary

function ECCText(**const** ID: TECCCertificateID): RawUTF8; overload;

Convert a supplied TECCCertificateID binary buffer into proper text

- returns hexadecimal values, or "" if the ID is filled with zeros

function ECCText(ECCDate: TECCDate; Expanded: boolean=true): RawUTF8; overload;

Convert a supplied a TECCDate integer value into a ISO-8601 text value

- i.e. 16-bit number of days since 1 August 2016

function ECCToDateTime(ECCDate: TECCDate): TDateTime;

Convert a supplied a TECCDate integer value into a TDateTime value

- i.e. 16-bit number of days since 1 August 2016

function ECCVerify(**const** sign: TECCSignatureCertifiedContent; **const** hash: THash256; **const** auth: TECCCertificateContent): TECCValidity;

Low-level verification of a TECCSignatureCertifiedContent binary buffer

- will verify all internal signature fields according to a supplied authority, then will perform the

ECDSA verification of the supplied 256-bit hash with the authority public key

- as used by TECCSignatureCertified.Verify and TECCCertificateChain.IsValid

function ecc_make_key(**out** pub: TECCPublicKey; **out** priv: TECCPrivateKey): boolean; cdecl;

Create a public/private key pair

- using secp256r1 curve, i.e. NIST P-256, or OpenSSL prime256v1

- directly low-level access to the statically linked micro-ecc library function

- returns true if the key pair was generated successfully in pub/priv

- returns false if an error occurred

- this function is thread-safe and does not perform any memory allocation

function ecc_make_key_pas(**out** PublicKey: TECCPublicKey; **out** PrivateKey: TECCPrivateKey): boolean;

Pascal function to create a secp256r1 public/private key pair

- used only on targets (e.g. ARM/PPC) when the static .o version is not available

```
procedure ecc_uncompress_key_pas(const Compressed: TECCPublicKey; out Uncompressed: TECCPublicKeyUncompressed);
```

Uncompress a public key for ECC secp256r1 cryptography

- convert from its compressed form with its standard byte header (33 bytes of memory) into uncompressed/flat form (64 bytes of memory)

```
function ecdh_shared_secret(const pub: TECCPublicKey; const priv: TECCPrivateKey; out secret: TECCSecretKey): boolean; cdecl;
```

Compute a shared secret given your secret key and someone else's public key

- using secp256r1 curve, i.e. NIST P-256, or OpenSSL prime256v1
- directly low-level access to the statically linked micro-ecc library function
- note: it is recommended that you hash the result of ecdh_shared_secret before using it for symmetric encryption or HMAC (via an intermediate KDF)
- returns true if the shared secret was generated successfully in secret
- returns false if an error occurred
- this function is thread-safe and does not perform any memory allocation

```
function ecdh_shared_secret_pas(const PublicPoint: TECCPublicKeyUncompressed; const PrivateKey: TECCPrivateKey; out Secret: TECCSecretKey): boolean; overload;
```

Pascal function to compute a secp256r1 shared secret given your secret key and someone else's public key (in uncompressed/flat format)

- this overloaded function is slightly faster than the one using TECCPublicKey, since public key doesn't need to be uncompressed

```
function ecdh_shared_secret_pas(const PublicKey: TECCPublicKey; const PrivateKey: TECCPrivateKey; out Secret: TECCSecretKey): boolean; overload;
```

Pascal function to compute a secp256r1 shared secret given your secret key and someone else's public key (in compressed format)

- used only on targets (e.g. ARM/PPC) when the static .o version is not available

```
function ecdsa_sign(const priv: TECCPrivateKey; const hash: TECCHash; out sign: TECCSignature): boolean; cdecl;
```

Generate an ECDSA signature for a given hash value

- using secp256r1 curve, i.e. NIST P-256, or OpenSSL prime256v1
- directly low-level access to the statically linked micro-ecc library function
- returns true if the signature generated successfully in sign
- returns false if an error occurred
- this function is thread-safe and does not perform any memory allocation

```
function ecdsa_sign_pas(const PrivateKey: TECCPrivateKey; const Hash: TECCHash; out Signature: TECCSignature): boolean;
```

Pascal function to generate an ECDSA secp256r1 signature for a given hash value

- used only on targets (e.g. ARM/PPC) when the static .o version is not available

```
function ecdsa_verify(const pub: TECCPublicKey; const hash: TECCHash; const sign: TECCSignature): boolean; cdecl;
```

Verify an ECDSA signature

- using secp256r1 curve, i.e. NIST P-256, or OpenSSL prime256v1
- directly low-level access to the statically linked micro-ecc library function
- returns true if the signature is valid
- returns false if an error occurred
- this function is thread-safe and does not perform any memory allocation

```
function ecdsa_verify_pas(const PublicKey: TECCPublicKeyUncompressed; const Hash: TECCHash; const Signature: TECCSignature): boolean; overload;
```

Pascal function to verify an ECDSA secp256r1 signature from someone else's public key (in uncompressed/flat format)

- this overloaded function is slightly faster than the one using TECCPublicKey, since public key doesn't need to be uncompressed

```
function ecdsa_verify_pas(const PublicKey: TECCPublicKey; const Hash: TECCHash; const Signature: TECCSignature): boolean; overload;
```

Pascal function to verify an ECDSA secp256r1 signature from someone else's public key (in compressed format)

- used only on targets (e.g. ARM/PPC) when the static .o version is not available

```
function ECIESHeader(const encrypted: RawByteString; out head: TECIESHeader): boolean; overload;
```

Extract the binary header of a .synecc file buffer, encrypted via ECC secp256r1

- match the format generated by TECCCertificate.Encrypt/EncryptFile
- returns true on success, false otherwise

```
function ECIESHeader(const head: TECIESHeader): boolean; overload;
```

Validate the binary header of a .synecc file buffer, encrypted via ECC secp256r1

- will check against the expected layout, and values stored (e.g. crc)
- returns true if head is a valid .synecc header, false otherwise

```
function ECIESHeaderFile(const encryptedfile: TFileName; out head: TECIESHeader; const rawencryptedfile: TFileName=''): boolean;
```

Extract the binary header of a .synecc file, encrypted via ECC secp256r1

- match the format generated by TECCCertificate.Encrypt/EncryptFile
- returns true on success, false otherwise
- if rawencryptedfile is specified, will also create such a file with the raw encrypted content (i.e. excluding the encryptedfile header)

```
function ECIESHeaderText(const encryptedfile: TFileName; const rawencryptedfile: TFileName=''): RawUTF8; overload;
```

Convert the header of a .synecc file into a JSON object

- returns "" if the header is not a valid .synecc file
- if rawencryptedfile is specified, will also create such a file with the raw encrypted content (i.e. excluding the encryptedfile header)

```
function ECIESHeaderText(const head: TECIESHeader): RawUTF8; overload;
```

Convert the binary header of a .synecc file buffer into a JSON object

- returns "" if the header is not a valid .synecc file

```
function ECIESKeyFileFind(const encrypted: RawByteString; out keyfile: TFileName; privkey: boolean=true): boolean;
```

Search the single .public or .private file used to crypt a given content

- match the format generated by TECCCertificate.Encrypt/EncryptFile
- returns true on success, false otherwise
- will also search in ECCKeyFileFolder, if the current folder is not enough

procedure FillZero(out Priv: TECCPrivateKey); overload;

Fill all bytes of this ECC private key buffer with zero
- may be used to cleanup stack-allocated content
... finally FillZero(PrivateKey); end;

function IsEqual(const id1,id2: TECCCertificateID): boolean; overload;

Compare two TECCCertificateID binary buffer values

function IsEqual(const issuer1,issuer2: TECCCertificateIssuer): boolean; overload;

Compare two TECCCertificateIssuer binary buffer values

function IsZero(const issuer: TECCCertificateIssuer): boolean; overload;

Ensure a TECCCertificateIssuer binary buffer is not void, i.e. filled with 0

function IsZero(const id: TECCCertificateID): boolean; overload;

Ensure a TECCCertificateID binary buffer is not void, i.e. filled with 0

function NowECCDate: TECCDate;

Returns the current UTC date, as a TECCDate integer value
- i.e. 16-bit number of days since 1 August 2016

27.20. SynFastWideString.pas unit

Purpose: This unit will patch the System.pas RTL to use a custom NON OLE COMPATIBLE WideString type, NOT using the slow Windows API, but FastMM4 (without COW)
- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Functions or procedures implemented in the *SynFastWideString* unit

Functions or procedures	Description	Page
WideStringFree	This low-level helper can be used to free a WideString returned by COM/OLE	1354

```
procedure WideStringFree(var TrueBSTRWideStringVariable: WideString);
```

This low-level helper can be used to free a WideString returned by COM/OLE

- WideString instances created with this unit can be safely sent to any COM/OLE object, as soon as they are constant parameters, but not a "var" parameter or a callback function result
- any WideString instance returned by a COM object should NOT be released by Delphi automatically, since the following would create a memory error:

```
TrueBSTRWideStringVariable := '';
```

- if you are using SynFastWideString, you should use this procedure to release true BSTR WideString instance, as such:

```
type
  _Catalog = interface(IDispatch)
    // this method will be safe to use with our unit
    function Create(const ConnectString: WideString): OleVariant; safecall;
    // this method won't be safe, since it returns a true BSTR as WideString
    function GetObjectOwner(const ObjectName: WideString; ObjectType: OleVariant;
      ObjectTypeId: OleVariant): WideString; safecall;
  end;
...
function CheckCatalogOwner(const catalog: _Catalog): string;
var bstr: WideString;
begin
  try // force manual handling of this true BSTR instance lifetime
    bstr := catalog.GetObjectOwner('name',null,null);
    result := bstr; // conversion to string will work
  finally
    WideStringFree(bstr); // manual release, and set bstr := nil
  end;
end;
```

- do a regular TrueBSTRWideStringVariable := '' since Delphi 2009, or call the low-level oleaut32.dll API for older versions, as expected by COM

27.21. SynGdiPlus.pas unit

Purpose: GDI+ library API access

- adds GIF, TIF, PNG and JPG pictures read/write support as standard TGraphic
- make available most useful GDI+ drawing methods
- allows Antialiased rendering of any EMF file using GDI+
- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

The *SynGdiPlus* unit is quoted in the following items

SWRS #	Description	Page
DI-2.3.2	A reporting feature, with full preview and export as PDF or TXT files, shall be integrated	2560

SynGdiPlus class hierarchy

Objects implemented in the *SynGdiPlus* unit

Objects	Description	Page
TGdipBitmapData	Data as retrieved by GdipFull.BitmapLockBits	1356
TGDIPPlus	Handle picture related GDI+ library calls	1356
TGDIPPlusFull	Handle most GDI+ library calls	1358
TGdipPointF	GDI+ floating point coordinates for a point	1356
TGdipRect	GDI+ integer coordinates rectangles	1356
TGdipRectF	GDI+ floating point coordinates rectangles	1356
TGifImage	Sub class to handle .GIF file extension	1358
TImageAttributes	An object wrapper to handle gdi+ image attributes	1356

Objects	Description	Page
TJpegImage	Sub class to handle .JPG file extension	1358
TPngImage	Sub class to handle .PNG file extension	1358
TSynLibrary	An object wrapper to load dynamically a library	1356
TSynPicture	GIF, PNG, TIFF and JPG pictures support using GDI+ library	1357
TTiffImage	Sub class to handle .TIF file extension	1358

TGdipRect = record

GDI+ integer coordinates rectangles

- use width and height instead of right and bottom

TGdipRectF = record

GDI+ floating point coordinates rectangles

- use width and height instead of right and bottom

TGdipPointF = record

GDI+ floating point coordinates for a point

TGdipBitmapData = record

Data as retrieved by GdiFull.BitmapLockBits

TImageAttributes = class(TObject)

An object wrapper to handle gdi+ image attributes

TSynLibrary = class(TObject)

An object wrapper to load dynamically a library

function Exists: boolean;

Return TRUE if the library and all procedures were found

TGDIPlus = class(TSynLibrary)

Handle picture related GDI+ library calls

Used for DI-2.3.2 (page 2560).

constructor Create(const aDllFileName: TFileName); reintroduce;

Load the GDI+ library and all needed procedures

- returns TRUE on success

- library is loaded dynamically, therefore the executable is able to launch before Windows XP, but GDI + functions (e.g. GIF, PNG, TIFF and JPG pictures support) won't be available in such case

destructor Destroy; override;

Unload the GDI+ library

```
function DrawAntiAliased(Source: TMetafile; ScaleX: integer=100; ScaleY: integer=100; aSmoothing: TSmoothingMode=smAntiAlias; aTextRendering: TTextRenderingHint=trhClearTypeGridFit): TBitmap; overload;
```

Draw the corresponding EMF metafile into a bitmap created by the method

- this default TGDIPPlus implementation uses GDI drawing only
- use a TGDIPPlusFull instance for true GDI+ AntiAliased drawing
- you can specify a zoom factor by the ScaleX and ScaleY parameters in percent: e.g. 100 means 100%, i.e. no scaling
- returned image is a DIB (device-independent bitmap)

Used for DI-2.3.2 (page 2560).

```
procedure DrawAntiAliased(Source: TMetafile; Dest: HDC; R: TRect; aSmoothing: TSmoothingMode=smAntiAlias; aTextRendering: TTextRenderingHint=trhClearTypeGridFit); overload; virtual;
```

Draw the corresponding EMF metafile into a given device context

- this default implementation uses GDI drawing only
- use TGDIPPlusFull overridden method for true GDI+ AntiAliased drawing

Used for DI-2.3.2 (page 2560).

```
procedure RegisterPictures;
```

Registers the .jpg .jpeg .gif .png .tif .tiff file extensions to the program

- TPicture can now load such files
- you can just launch Gdip.RegisterPictures to initialize the GDI+ library

```
TSynPicture = class(TGraphic)
```

GIF, PNG, TIFF and JPG pictures support using GDI+ library

- cf @<http://msdn.microsoft.com/en-us/library/ms536393> for available image formats

```
function GetImageFormat: TGDIPPictureType;
```

Guess the picture type from its internal format

- return gptBMP if no format is found

```
class function IsPicture(const FileName: TFileName): TGraphicClass;
```

Return TRUE if the supplied filename is a picture handled by TSynPicture

```
function RectNotBiggerThan(MaxPixelsForBiggestSide: Integer): TRect;
```

Calculate a TRect which fit the specified maximum pixel number

- if any side of the picture is bigger than the specified pixel number, the TRect is sized down in order than the biggest size if this value

```
function SaveAs(Stream: TStream; Format: TGDIPPictureType; CompressionQuality: integer=80; IfBitmapSetResolution: single=0): TGdipStatus;
```

Save the picture into any GIF/PNG/JPG/TIFF format

- CompressionQuality is used for gptJPG format saving and is expected to be from 0 to 100; for gptTIF format, use ord(TGDIPPEncoderValue) to define the parameter; by default, will use ord(evCompressionLZW) to save the TIFF picture with LZW - for gptTIF, only valid values are ord(evCompressionLZW), ord(evCompressionCCITT3), ord(evCompressionCCITT4), ord(evCompressionRle) and ord(evCompressionNone)

function ToBitmap: TBitmap;

Create a bitmap from the corresponding picture

- kind of returned image is DIB (device-independent bitmap)

property NativeImage: THandle **read** fImage;

Return the GDI+ native image handle

TPngImage = **class**(TSynPicture)

Sub class to handle .PNG file extension

TJpegImage = **class**(TSynPicture)

Sub class to handle .JPG file extension

procedure SaveToStream(Stream: TStream); **override**;

Implements the saving feature

property CompressionQuality: integer **read** fCompressionQuality **write** fCompressionQuality;

The associated encoding quality (from 0 to 100)

- set to 80 by default

TGifImage = **class**(TSynPicture)

Sub class to handle .GIF file extension

TTiffImage = **class**(TSynPicture)

Sub class to handle .TIF file extension

- GDI+ seems not able to load all Tiff file formats, depending on the Windows version and third-party libraries installed

- this overridden class implements multiple pages

function GetPageCount: integer;

Retrieve the number of pages in the TIFF file

procedure ExtractPage(index: integer; wBMP: TBitmap);

Extract a page from the TIFF and assign it to a bitmap

property ActivePageIndex: integer **read** fActivePage **write** SelectPage;

Multi-page

- default Frame/Page Index is 0

TGDIPlusFull = **class**(TGDIPlus)

Handle most GDI+ library calls

- an instance of this object is initialized by this unit: you don't have to create a new instance

constructor Create(aDllFileName: TFileName='');

Load the GDI+ library and all needed procedures

- returns TRUE on success
- library is loaded dynamically, therefore the executable is able to launch before Windows XP, but GDI+ functions (e.g. GIF, PNG, TIFF and JPG pictures support or AntiAliased drawing) won't be available
- if no GdiPlus.dll file name is available, it will search the system for the most recent version of GDI+ (either GDIPLUS.DLL in the current directory, either the Office 2003 version, either the OS version - 1.1 is available only since Vista and Seven; XP only shipped with version 1.1)

function ConvertToEmfPlus(Source: TMetafile; Dest: HDC; aSmoothing: TSmoothingMode=smAntiAlias; aTextRendering: TTextRenderingHint=trhClearTypeGridFit): THandle;

Convert a supplied EMF metafile into a EMF+ (i.e. GDI+ metafile)

- i.e. allows antialiased drawing of the EMF metafile
- if GDI+ is not available or conversion failed, return 0
- return a metafile handle, to be released after use (e.g. with DrawImageRect) by DisposeImage()

function MetaFileToStream(Source: TMetafile): IStream;

Internal method used for GDI32 metafile loading

procedure DrawAntiAliased(Source: TMetafile; Dest: HDC; R: TRect; aSmoothing: TSmoothingMode=smAntiAlias; aTextRendering: TTextRenderingHint=trhClearTypeGridFit); overload; **override**;

Draw the corresponding EMF metafile into a given device context

- this overridden implementation handles GDI+ AntiAliased drawing
- if GDI+ is not available, it will use default GDI32 function

property ForceInternalConvertToEmfPlus: boolean **read** fForceInternalConvertToEmfPlus **write** fForceInternalConvertToEmfPlus;

Can be set to true if to force DrawAntiAliased() method NOT to use native GDI+ 1.1 conversion, even if available

- we found out that GDI+ 1.1 was not as good as our internal conversion function written in Delphi, e.g. for underlined fonts or font fallback
- programs can set this property to true to avoid using GDI+ 1.1

property ForceUseDrawString: boolean **read** fUseDrawString **write** fUseDrawString;

If TRUE, text will be rendered using DrawString and not DrawDriverString if the content has some chars non within 0000-05ff Unicode BMP range

- less accurate for individual character positioning (e.g. justification), but will handle UniScribe positioning and associated font fallback
- is disable by default, and enabled only for chars >= \$600
- note that the GdiConvertToEmfPlus() GDI+ 1.1 method does not handle font fallback, so our internal conversion is more accurate thanks to this parameter

property NativeConvertToEmfPlus: boolean **read** getNativeConvertToEmfPlus;

Return true if DrawAntiAliased() method will use native GDI+ conversion, i.e. if GDI+ installed version is 1.1

Types implemented in the SynGdiPlus unit

TEmfType = (etEmf0, etEmf1, etEmf2, etEmfOnly, etEmfPlusOnly, etEmfPlusDual);

GDI+ types of conversion from EMF to EMF+

```
TFillMode = ( fmAlternate, fmWinding );
```

GDI+ available filling modes

```
TGDIPCombineMode = ( cmReplace, cmIntersect, cmUnion, cmXor, cmExclude, cmComplement );
```

Region combine mode (used by SetClipRegion, etc.)

```
TGDIPEncoderValue = ( evColorTypeCMYK, evColorTypeYCK, evCompressionLZW,
evCompressionCCITT3, evCompressionCCITT4, evCompressionRle, evCompressionNone,
evScanMethodInterlaced, evScanMethodNonInterlaced, evVersionGif87, evVersionGif89,
evRenderProgressive, evRenderNonProgressive, evTransformRotate90,
evTransformRotate180, evTransformRotate270, evTransformFlipHorizontal,
evTransformFlipVertical, evMultiFrame, evLastFrame, evFlush, evFrameDimensionTime,
evFrameDimensionResolution, evFrameDimensionPage );
```

The optional TIFF compression levels

- use e.g. ord(evCompressionCCITT4) to save a TIFF picture as CCITT4

```
TGDIPPictureType = ( gptGIF, gptPNG, gptJPG, gptBMP, gptTIF );
```

Allowed types for image saving

```
TGdipPointFArray = array[0..1000] of TGdipPointF;
```

GDI+ floating point coordinates for an array of points

```
TGdipStatus = ( stOk, stGenericError, stInvalidParameter, stOutOfMemory, stObjectBusy,
stInsufficientBuffer, stNotImplemented, stWin32Error, stWrongState, stAborted,
stFileNotFound, stValueOverflow, stAccessDenied, stUnknownImageFormat,
stFontFamilyNotFound, stFontStyleNotFound, stNotTrueTypeFont,
stUnsupportedGdiplusVersion, stGdiplusNotInitialized, stPropertyNotFound,
stPropertyNotSupported );
```

GDI+ error codes

```
TLockModeOption = ( lmRead, lmWrite, lmUserInputBuf );
```

GDI+ lock mode for Gdiplus.BitmapLockBits

```
TLockModeOptions = set of TLockModeOption;
```

GDI+ lock mode settings for Gdiplus.BitmapLockBits

```
TSmoothingMode = ( smDefault, smHighSpeed, smHighQuality, smNone, smAntiAlias );
```

GDI+ line drawing smoothing types

```
TTextRenderingHint = ( trhDefault, trhSingleBitPerPixelGridFit, trhSingleBitPerPixel,
trhAntiAliasGridFit, trhAntiAlias, trhClearTypeGridFit );
```

GDI+ text rendering smoothing types

```
TUnit = ( uWorld, uDisplay, uPixel, uPoint, uInch, uDocument, uMillimeter, uGdi );
```

GDI+ available coordinates units

Constants implemented in the *SynGdiPlus* unit

```
GDIPPictureExt: array [TGDIPEncoderValue] of TFileName =
( '.gif', '.png', '.jpg', '.bmp', '.tif' );
```

The corresponding file extension for every saving format type

Functions or procedures implemented in the *SynGdiPlus* unit

Functions or procedures	Description	Page
BitmapToRawByteString	Helper to save a specified TBitmap into GIF/PNG/JPG/TIFF format	1361
DrawEmfGdip	Draw the specified GDI TMetaFile (emf) using the GDI-plus antialiased engine	1361
ExpectGDIPlusFull	Will set global Gdip instance from a TGDIPPlusFull, if available	1362
GdipLock	Enter global critical section for safe use of SynGdiPlus from multiple threads	1362
GdipTest	Test function	1362
GdipUnlock	Leave global critical section for safe use of SynGdiPlus from multiple threads	1362
JpegRecompress	Recompress a JPEG binary in-place	1362
LoadFrom	Helper function to create a bitmap from any GIF/PNG/JPG/TIFF/EMF/WMF file	1362
LoadFrom	Helper function to create a bitmap from any EMF content	1362
LoadFromRawByteString	Helper to load a specified graphic from GIF/PNG/JPG/TIFF format content	1362
PictureName	Retrieve a ready to be displayed name of the supplied Graphic Class	1362
SaveAs	Helper to save a specified graphic into GIF/PNG/JPG/TIFF format	1363
SaveAs	Helper to save a specified graphic into GIF/PNG/JPG/TIFF format	1363
SaveAsRawByteString	Helper to save a specified graphic into GIF/PNG/JPG/TIFF format	1363

function BitmapToRawByteString(Bitmap: TBitmap; **out** DataRawByteString; Format: TGDIPPictureType; CompressionQuality: integer=80; MaxPixelsForBiggestSide: cardinal=0; BitmapSetResolution: single=0): TGdipStatus;

Helper to save a specified TBitmap into GIF/PNG/JPG/TIFF format

- CompressionQuality is only used for gptJPG format saving and is expected to be from 0 to 100
- if MaxPixelsForBiggestSide is set to something else than 0, the resulting picture biggest side won't exceed this pixel number
- this method is thread-safe (using GdipLock/GdipUnlock globals)

procedure DrawEmfGdip(aHDC: HDC; Source: TMetaFile; **var** R: TRect; ForceInternalAntiAliased: boolean; ForceInternalAntiAliasedFontFallBack: boolean=false);

Draw the specified GDI TMetaFile (emf) using the GDI-plus antialiased engine

- by default, no font fall-back is implemented (for characters not included within the font glyphs), but you may force it via the corresponding parameter (used to set the TGDIPPlusFull.ForceUseDrawString property)
- this method is thread-safe (using GdipLock/GdipUnlock globals)

procedure ExpectGDIPlusFull(ForceInternalAntiAliased: boolean=true;
ForceInternalAntiAliasedFontFallback: boolean=true);

Will set global Gdip instance from a TGDIPPlusFull, if available

- this GDI+ 1.1 version (i.e. gdiplus11.dll) allows proper TMetaFile antialiasing, as requested by LoadFrom and DrawEmfGdip functions

procedure GdipLock;

Enter global critical section for safe use of SynGdiPlus from multiple threads

procedure GdipTest(const JpegFile: TFileName);

Test function

procedure GdipUnlock;

Leave global critical section for safe use of SynGdiPlus from multiple threads

function JpegRecompress(const jpeg: AnsiString; quality: integer=80): AnsiString;

Recompress a JPEG binary in-place

- no sizing is done, but a bitmap is created from the supplied JPEG, and re-compressed as JPEG using the specified quality

- may be used to ensure a JPEG binary is a JPEG is a JPEG

- this method is thread-safe (using GdipLock/GdipUnlock globals)

function LoadFrom(const MetaFile: TMetaFile): TBitmap; overload;

Helper function to create a bitmap from any EMF content

- the file is drawn with a special antialiased GDI+ drawing method (if the global Gdip var is a TGDIPPlusFull instance)

- this method is thread-safe (using GdipLock/GdipUnlock globals)

function LoadFrom(const FileName: TFileName): TBitmap; overload;

Helper function to create a bitmap from any GIF/PNG/JPG/TIFF/EMF/WMF file

- if file extension is .EMF, the file is drawn with a special antialiased GDI+ drawing method (if the global Gdip var is a TGDIPPlusFull instance)

- this method is thread-safe (using GdipLock/GdipUnlock globals)

function LoadFromRawByteString(const Picture: AnsiString): TBitmap;

Helper to load a specified graphic from GIF/PNG/JPG/TIFF format content

- this method is thread-safe (using GdipLock/GdipUnlock globals)

function PictureName(Pic: TGraphicClass): string;

Retrieve a ready to be displayed name of the supplied Graphic Class

procedure SaveAs(Graphic: TPersistent; Stream: TStream; Format: TGDIPPictureType;
CompressionQuality: integer=80; MaxPixelsForBiggestSide: cardinal=0;
BitmapSetResolution: single=0); overload;

Helper to save a specified graphic into GIF/PNG/JPG/TIFF format

- CompressionQuality is only used for gptJPG format saving and is expected to be from 0 to 100

- if MaxPixelsForBiggestSide is set to something else than 0, the resulting picture biggest side won't exceed this pixel number

- this method is thread-safe (using GdipLock/GdipUnlock globals)

```
procedure SaveAs(Graphic: TPersistent; const FileName: TFileName; Format:
TGDIPPictureType; CompressionQuality: integer=80; MaxPixelsForBiggestSide:
cardinal=0; BitmapSetResolution: single=0); overload;
```

Helper to save a specified graphic into GIF/PNG/JPG/TIFF format

- CompressionQuality is only used for gptJPG format saving and is expected to be from 0 to 100
- if MaxPixelsForBiggestSide is set to something else than 0, the resulting picture biggest side won't exceed this pixel number
- this method is thread-safe (using GdipLock/GdipUnlock globals)

```
procedure SaveAsRawByteString(Graphic: TPersistent; out DataRawByteString; Format:
TGDIPPictureType; CompressionQuality: integer=80; MaxPixelsForBiggestSide:
cardinal=0; BitmapSetResolution: single=0);
```

Helper to save a specified graphic into GIF/PNG/JPG/TIFF format

- CompressionQuality is only used for gptJPG format saving and is expected to be from 0 to 100
- if MaxPixelsForBiggestSide is set to something else than 0, the resulting picture biggest side won't exceed this pixel number
- this method is thread-safe (using GdipLock/GdipUnlock globals)

Variables implemented in the *SynGdiPlus* unit

```
Gdip: TGDIPPlus = nil;
```

GDI+ library instance

- only initialized at program startup if the NOTSYNPICTUREREGISTER is NOT defined (which is not the default)
- Gdip.Exists return FALSE if the GDI+ library is not available in this operating system (e.g. on Windows 2000) nor the current executable folder
- you can run ExpectGDIPlusFull to ensure you use GDI+ 1.1

```
GdipCS: TRTLCriticalSection;
```

Mutex used by GdipLock/GdipUnlock

27.22. SynLizard.pas unit

Purpose: Lizard (LZ5) compression routines (statically linked for FPC)
- licensed under a MPL/GPL/LGPL tri-license; original Lizard is BSD 2-Clause

Units used in the *SynLizard* unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718

SynLizard class hierarchy

Objects implemented in the *SynLizard* unit

Objects	Description	Page
TSynLizard	Lizard (formerly LZ5) lossless compression algorithm	1364
TSynLizardDynamic	Try to load Lizard as an external library	1366

TSynLizard = class(TObject)

Lizard (formerly LZ5) lossless compression algorithm

- provides efficient compression with very fast decompression
- this class implements direct low-level access to the Lizard API - consider using AlgoLizard/AlgoLizardFast global instances for easier use

```
compress: function(src, dst: pointer; srcSize, maxDstSize, compressionLevel: integer): integer; cdecl;
```

Compresses srcSize bytes from src into already allocated dst buffer of size maxDstSize - which should be >= Lizard_compressBound(srcSize)

- returns number of bytes written into dst (necessarily <= maxDstSize), or 0 if compression fails due to too small maxDstSize, <0 on other failure
- compressionLevel is from LIZARD_MIN_CLEVEL (10) to LIZARD_MAX_CLEVEL(49), any value <10 (e.g. 0) will use 17, and value >49 will use 49

Lev	Comp	Decomp	CompSize	Ratio
7332	MB/s	8719 MB/s	211947520	100.00 (move)
10	346 MB/s	2610 MB/s	103402971	48.79
12	103 MB/s	2458 MB/s	86232422	40.69
15	50 MB/s	2552 MB/s	81187330	38.31
19	3.04 MB/s	2497 MB/s	77416400	36.53
21	157 MB/s	1795 MB/s	89239174	42.10
23	30 MB/s	1778 MB/s	81097176	38.26
26	6.63 MB/s	1734 MB/s	74503695	35.15
29	1.37 MB/s	1634 MB/s	68694227	32.41
30	246 MB/s	909 MB/s	85727429	40.45
32	94 MB/s	1244 MB/s	76929454	36.30
35	47 MB/s	1435 MB/s	73850400	34.84
39	2.94 MB/s	1502 MB/s	69807522	32.94
41	126 MB/s	961 MB/s	76100661	35.91
43	28 MB/s	1101 MB/s	70955653	33.48
46	6.25 MB/s	1073 MB/s	65413061	30.86
49	1.27 MB/s	1064 MB/s	60679215	28.63

```
compressBound: function(inputSize: integer): integer; cdecl;
```

Maximum size that Lizard compression may output in a "worst case" scenario

```
compress_extState: function(state: pointer; src, dst: pointer; srcSize, maxDstSize, compressionLevel: integer): integer; cdecl;
```

Compresses using an external pre-allocated state buffer

```
decompress_safe: function(src, dst: pointer; srcSize, maxDstSize: integer): integer; cdecl;
```

Decompresses srcSize bytes from src into already allocated dst buffer

- returns number of bytes written to dst (<= maxDstSize), or <=0 on failure
- this function is protected against buffer overflow exploits

```
decompress_safe_partial: function(src, dst: pointer; srcSize, targetDstSize, maxDstSize: integer): integer; cdecl;
```

Partial decompression srcSize bytes from src into already allocated dst buffer

- returns number of bytes written to dst (<= maxDstSize), or <=0 on failure
- number can be <targetDstSize should the compressed block to decode be smaller
- this function is protected against buffer overflow exploits

```
sizeofState: function(compressionLevel: integer): integer; cdecl;
```

How much memory must be allocated for compress_extState()

```
versionNumber: function: integer; cdecl;
```

Version number of the linked Lizard library

```
constructor Create; virtual;
```

/ will initialize the library

TSynLizardDynamic = class(TSynLizard)

Try to load Lizard as an external library

- static linking is currently available only on FPC Win32/64 and Linux32/64
- this class is expected to access Lizard1-32.dll/Lizard1-64.dll files for Delphi, e.g. as such:
TSynLizardDynamic.AlgoRegister;

constructor Create(**const** aLibraryFile: TFileName = ''; aRaiseNoException: boolean = false); **reintroduce**;

Will first search in the executable folder, then within the system path

- raise an Exception if the library file is not found, or not valid - unless aRaiseNoException is set to true

destructor Destroy; **override**;

Unload the external library

class function AlgoRegister: boolean;

Ensure Lizard compression is available

- returns TRUE if Lizard compression is available
- if there is a local Lizard1-32.dll/Lizard1-64.dll file, try to load it

property LibraryName: TFileName **read** fLibraryName;

The loaded library file name

property Loaded: boolean **read** fLoaded;

Set to TRUE if Create succeeded

- may be used if aRaiseNoException parameter has been defined

Constants implemented in the *SynLizard* unit

LIZARD_DEFAULT_CLEVEL = 0;

Default compression level for TSynLizard.compress

- 0 value will let the library use level 17 - slow but efficient - method
- as used by AlgoLizard global TSynCompress instance

LIZARD_HUFFMAN_CLEVEL = 41;

Fast huffman compression level for TSynLizard.compress

- better compression ratio than LIZARD_DEFAULT_CLEVEL, better compression speed, but slower decompression

LIZARD_LIB_NAME = 'Lizard1-32.dll';

Default TSynLizardDynamic file name

- mainly for Delphi, since FPC will use static linked .o files under Windows and Linux Intel 32/64 bits
- to be downloaded from <https://synopse.info/files/SynLizardLibs.7z>

LIZARD_MAX_CLEVEL = 49;

Maximum compression level for TSynLizard.compress

LIZARD_MIN_CLEVEL = 10;

Minimum compression level for TSynLizard.compress

- as used by AlgoLizardFast global TSynCompress instance

Variables implemented in the *SynLizard* unit

AlgoLizard: TAlgoCompress;

Implement Lizard compression in level 17 (LIZARD_DEFAULT_CLEVEL) as AlgoID=4
- is set by TSynLizard.Create, so available e.g. if library is statically linked, or once TSynLizardDynamic.Create has been successfully called

AlgoLizardFast: TAlgoCompress;

Implement Lizard compression in level 10 (LIZARD_MIN_CLEVEL) as AlgoID=5
- is set by TSynLizard.Create, so available e.g. if library is statically linked, or once TSynLizardDynamic.Create has been successfully called

AlgoLizardHuffman: TAlgoCompress;

Implement Lizard compression in level 41 (LIZARD_HUFFMAN_CLEVEL) as AlgoID=6
- is set by TSynLizard.Create, so available e.g. if library is statically linked, or once TSynLizardDynamic.Create has been successfully called

Lizard: TSynLizard;

Direct access to the low-level Lizard (LZ5) library
- is defined by default if Lizard was statically linked (under FPC)
- otherwise, you should execute explicitly:
`if Lizard = nil then
 Lizard := TSynLizardDynamic.Create;`

27.23. SynLog.pas unit

Purpose: Logging functions used by Synapse projects

- this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the SynLog unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synapse projects - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynLZ</i>	SynLZ Compression routines - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1399
<i>SynTable</i>	Filter/database/cache/buffer/security/search/multithread/OS features - as a complement to SynCommons, which tended to increase too much - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1728

SynLog class hierarchy

Objects implemented in the SynLog unit

Objects	Description	Page
ESynLogSilent	An exception which wouldn't be logged and intercepted by this unit	1372
ISynLog	A generic interface used for logging a method	1372
ISynLogCallback	A mORMot-compatible callback definition	1373
TAutoLockerDebug	Reference-counted block code critical section with context logging	1387
TFileStreamWithoutWriteError	File stream which ignores I/O write errors	1381
TSynLog	A per-family and/or per-thread log file content	1381
TSynLogCallback	Store a subscribe to ISynLogCallback	1373
TSynLogCallbacks	Can manage a list of ISynLogCallback registrations	1373
TSynLogExceptionInfo	Storage of the information associated with an intercepted exception	1392
TSynLogFamily	Regroup several logs under an unique family name	1375
TSynLogFile	Used to parse a .log file, as created by TSynLog, into high-level data	1388
TSynLogFileProc	Used by TSynLogFile to refer to a method profiling in a .log file	1388
TSynLogFileView	Used to parse a .log file and process into VCL/LCL/FMX	1391
TSynLogSettings	Store simple log-related settings	1374
TSynLogThreadContext	Thread-specific internal context used during logging	1381
TSynLogThreadRecursion	TSynLogThreadContext will define a dynamic array of such information	1380
TSynMapFile	Retrieve a .map file content, to be used e.g. with TSynLog to provide additional debugging information	1370
TSynMapSymbol	A debugger symbol, as decoded by TSynMapFile from a .map file	1369
TSynMapUnit	A debugger unit, as decoded by TSynMapFile from a .map file	1370

TSynMapSymbol = packed record

A debugger symbol, as decoded by TSynMapFile from a .map file

Name: RawUTF8;

Symbol internal name

Start: integer;

Starting offset of this symbol in the executable

- addresses are integer, since map be <0 in Kylix .map files

Stop: integer;

End offset of this symbol in the executable

- addresses are integer, since map be <0 in Kylix .map files

TSynMapUnit = packed record

A debugger unit, as decoded by TSynMapFile from a .map file

Addr: TIntegerDynArray;

Start code address of each source code line

FileName: RawUTF8;

Associated source file name

Line: TIntegerDynArray;

List of all mapped source code lines of this unit

Symbol: TSynMapSymbol;

Name, Start and Stop of this Unit

TSynMapFile = class(TObject)

Retrieve a .map file content, to be used e.g. with TSynLog to provide additional debugging information

- original .map content can be saved as .mab file in a more optimized format

constructor Create(**const** aExeName: TFileName=''; MabCreate: boolean=true);

Get the available debugging information

- if aExeName is specified, will use it in its search for .map/.mab
- if aExeName is not specified, will use the currently running .exe/.dll
- it will first search for a .map matching the file name: if found, will be read to retrieve all necessary debugging information - a .mab file will be also created in the same directory (if MabCreate is TRUE)
- if .map is not available, will search for the .mab file
- if no .mab is available, will search for a .mab appended to the .exe/.dll
- if nothing is available, will log as hexadecimal pointers, without debugging information

function AbsoluteToOffset(aAddressAbsolute: PtrUInt): integer;

Compute the relative memory address from its absolute (pointer) value

class function FindFileName(**const** unitname: RawUTF8): TFileName;

Returns the file name of

- if unitname = "", returns the main file name of the current executable

function FindLocation(aAddressAbsolute: PtrUInt): RawUTF8; overload;

Return the symbol location according to the supplied absolute address

- i.e. unit name, symbol name and line number (if any), as plain text
- returns "" if no match found

class function FindLocation(exc: ESynException): RawUTF8; overload;

Return the symbol location according to the supplied ESynException

- i.e. unit name, symbol name and line number (if any), as plain text
- under FPC, currently calls BacktraceStrFunc() which may be very slow

class function FindStackTrace(**const** Ctxt: TSynLogExceptionContext): TRawUTF8DynArray;

Return the low-level stack trace exception information into human-friendly text

function FindSymbol(aAddressOffset: integer): integer;

Retrieve a symbol according to a relative code address
- use fast $O(\log n)$ binary search

function FindUnit(aAddressOffset: integer; **out** LineNumber: integer): integer;
overload;

Retrieve an unit and source line, according to a relative code address
- use fast $O(\log n)$ binary search

function FindUnit(**const** aUnitName: RawUTF8): integer; overload;

Retrieve an unit information, according to the unit name
- will search within Units array

class function FromCurrentExecutable: TSynMapFile;

Returns the global TSynMapFile instance associated with the current executable

function SaveToFile(**const** aFileName: TFileName=''): TFileName;

Save all debugging information in the .mab custom binary format
- if no file name is specified, it will be saved as ExeName.mab or DllName.mab
- this file content can be appended to the executable via SaveToExe method
- this function returns the created file name

class procedure Log(W: TTextWriter; aAddressAbsolute: PtrUInt; AllowNotCodeAddr: boolean);

Add some debugging information about the supplied absolute memory address
- will create a global TSynMapFile instance for the current process, if necessary
- if no debugging information is available (.map or .mab), will write the raw address pointer as hexadecimal
- under FPC, currently calls BacktraceStrFunc() which may be very slow

procedure SaveToExe(**const** aExeName: TFileName);

Append all debugging information to an executable (or library)
- the executable name must be specified, because it's impossible to write to the executable of a running process
- this method will work for .exe and for .dll (or .ocx)

procedure SaveToJson(**const** aJsonFile: TFileName; aHumanReadable: Boolean=false);
overload;

Save all debugging information as a JSON file
- may be useful from debugging purposes

procedure SaveToJson(W: TTextWriter); overload;

Save all debugging information as JSON content
- may be useful from debugging purposes

procedure SaveToStream(aStream: TStream);

Save all debugging information in our custom binary format

property FileName: TFileName **read** fMapFile;

The associated file name

property HasDebugInfo: boolean **read** fHasDebugInfo;

Equals true if a .map or .mab debugging information has been loaded

property Symbols: TSynMapSymbolDynArray **read** fSymbol;

All symbols associated to the executable

property Units: TSynMapUnitDynArray **read** fUnit;

All units, including line numbers, associated to the executable

ESynLogSilent = **class**(ESynException)

An exception which wouldn't be logged and intercepted by this unit

- only this exact class will be recognized by TSynLog: inheriting it will trigger the interception, as any other regular exception

ISynLog = **interface**(IUnknown)

A generic interface used for logging a method

- you should create one TSynLog instance at the beginning of a block code using TSynLog.Enter: the ISynLog will be released automatically by the compiler at the end of the method block, marking it's execution end

- all logging expect UTF-8 encoded text, i.e. usually English text

function Instance: TSynLog;

Retrieve the associated logging instance

procedure Log(Level: TSynLogInfo; **const** aName: RawUTF8; aTypeInfo: pointer; **const** aValue; Instance: TObject); overload;

Call this method to add the content of most low-level types to the log at a specified level

- TSynLog will handle enumerations and dynamic array; TSQLog will be able to write TObject/TSQRecord and sets content as JSON

procedure Log(Level: TSynLogInfo=sllTrace); overload;

Call this method to add the caller address to the log at the specified level

- if the debugging info is available from TSynMapFile, will log the unit name, associated symbol and source code line

procedure Log(Level: TSynLogInfo; **const** TextFmt: RawUTF8; **const** TextArgs: array of **const**; Instance: TObject=nil); overload;

Call this method to add some information to the log at a specified level

- will use TTextWriter.Add(...,twOnSameLine) to append its content

- % = #37 indicates a string, integer, floating-point, class parameter to be appended as text (e.g. class name), any variant as JSON...

- note that cardinal values should be type-casted to Int64() (otherwise the integer mapped value will be transmitted, therefore wrongly)

- if Instance is set, it will log the corresponding class name and address (to be used if you didn't call TSynLog.Enter() method first)

procedure Log(Level: TSynLogInfo; **const** Text: RawUTF8; Instance: TObject=nil; TextTruncateAtLength: integer=maxInt); overload;

Call this method to add some information to the log at a specified level

- if Instance is set and Text is not "", it will log the corresponding class name and address (to be used e.g. if you didn't call TSynLog.Enter() method first)

- if Instance is set and Text is "", will behave the same as Log(Level,Instance), i.e. write the Instance as JSON content

procedure Log(Level: TSynLogInfo; Instance: TObject); overload;

Call this method to add the content of an object to the log at a specified level

- TSynLog will write the class and hexa address - TSQLLog will write the object JSON content

procedure LogLines(Level: TSynLogInfo; LinesToLog: PUTF8Char; aInstance: TObject=nil; **const** IgnoreWhenStartWith: PAnsiChar=nil);

Call this method to add some multi-line information to the log at a specified level

- LinesToLog content will be added, one line per one line, delimited by #13#10 (CRLF)

- if a line starts with IgnoreWhenStartWith (already uppercase), it won't be added to the log content (to be used e.g. with '--' for SQL statements)

ISynLogCallback = **interface**(IInvokable)

A mORMot-compatible callback definition

- used to notify a remote mORMot server via interface-based services for any incoming event, using e.g. TSynLogCallbacks.Subscribe

procedure Log(Level: TSynLogInfo; **const** Text: RawUTF8);

Each line of the TTextWriter internal instance will trigger this method

- the format is similar to TOnTextWriterEcho, as defined in SynCommons

- an initial call with Level=sllNone and the whole previous Text may be transmitted, if ReceiveExistingKB is set for TSynLogCallbacks.Subscribe()

TSynLogCallback = **record**

Store a subscribe to ISynLogCallback

TSynLogCallbacks = **class**(TSynPersistentLock)

Can manage a list of ISynLogCallback registrations

Registration: TSynLogCallbackDynArray;

Direct access to the registration storage

Registrations: TDynArray;

High-level access to the registration storage

TrackedLog: TSynLogFamily;

The TSynLog family actually associated with those callbacks

constructor Create(aTrackedLog: TSynLogFamily); **reintroduce**;

Initialize the registration storage for a given TSynLogFamily instance

destructor Destroy; **override**;

Finalize the registration storage for a given TSynLogFamily instance

function OnEcho(Sender: TTextWriter; Level: TSynLogInfo; **const** Text: RawUTF8): boolean;

Notify a given log event

- matches the TOnTextWriterEcho signature

function Subscribe(**const** Levels: TSynLogInfos; **const** Callback: ISynLogCallback; ReceiveExistingKB: cardinal=0): integer; **virtual**;

Register a callback for a given set of log levels

- you can specify a number of KB of existing log content to send to the monitoring tool, before the actual real-time process

procedure Unsubscribe(**const** Callback: ISynLogCallback); **virtual**;

Unregister a callback previously registered by Subscribe()

property Count: integer **read** fCount;

How many registrations are currently defined

TSynLogSettings = **class**(TSynPersistent)

Store simple log-related settings

- see also TDDLogSettings in dddInfraSettings.pas and TSynDaemonSettings in mORMotService.pas, which may be more integrated

constructor Create; **override**;

Set some default values

procedure SetLog(aLogClass: TSynLogClass = nil);

Define the log information into the supplied TSynLog class

- if you don't call this method, the logging won't be initiated

property DestinationPath: TFileName **read** fDestinationPath **write** fDestinationPath;

Allow to customize where the logs should be written

- default is the system log folder (e.g. /var/log on Linux)

property Levels: TSynLogInfos **read** fLevels **write** fLevels;

The log levels to be used for the log file

- i.e. a combination of none or several logging event

- if "*" is serialized, unneeded slNone won't be part of the set

- default is LOG_STACKTRACE

property LogClass: TSynLogClass **read** fLogClass;

Read-only access to the TSynLog class, if SetLog() has been called

property RotateFileCount: integer **read** fRotateFileCount **write** fRotateFileCount;

How many files will be rotated (default is 2)

TSynLogFamily = class(TObject)

Regroup several logs under an unique family name

- you should usually use one family per application or per architectural module: e.g. a server application may want to log in separate files the low-level Communication, the DB access, and the high-level process

- initialize the family settings before using them, like in this code:

```
with TSynLogDB.Family do begin
  Level := LOG_VERBOSE;
  PerThreadLog := ptOneFilePerThread;
  DestinationPath := 'C:\Logs';
end;
```

- then use the logging system inside a method:

```
procedure TMyDB.MyMethod;
var log: ISynLog;
begin
  log := TSynLogDB.Enter(self, 'MyMethod');
  // do some stuff
  log.Log(sllInfo, 'method run with no problem and value=', [value]);
end; // here log will be released and method leaving will be logged
```

constructor Create(aSynLog: TSynLogClass);

Intialize for a TSynLog class family

- add it in the global SynLogFileFamily[] list

destructor Destroy; **override;**

Release associated memory

- will archive older DestinationPath*.log files, according to ArchiveAfterDays value and ArchivePath

function GetExistingLog(MaximumKB: cardinal): RawUTF8;

Can be used to retrieve up to a specified amount of KB of existing log

- expects a single file to be opened for this family

- will retrieve the log content for the current file, truncating the text up to the specified number of KB (an up to 128 MB at most)

function SynLog: TSynLog;

Retrieve the corresponding log file of this thread and family

- creates the TSynLog if not already existing for this current thread

procedure EchoRemoteStart(aClient: TObject; **const** aClientEvent: TOnTextWriterEcho; aClientOwnedByFamily: boolean);

Register one object and one echo callback for remote logging

- aClient is typically a mORMot's TSQLHttpClient or a TSynLogCallbacks instance as defined in this unit

- if aClientOwnedByFamily is TRUE, its life time will be manage by this TSynLogFamily: it will stay alive until this TSynLogFamily is destroyed, or the EchoRemoteStop() method called

- aClientEvent should be able to send the log row to the remote server

procedure EchoRemoteStop;

Stop echo remote logging

- will free the aClient instance supplied to EchoRemoteStart

procedure OnThreadEnded(Sender: TThread);

Callback to notify the current logger that its thread is finished

- method follows TNotifyThreadEvent signature, which can be assigned to TSynBackgroundThreadAbstract.OnAfterExecute
- is called e.g. by TSQLRest.EndCurrentThread

property ArchiveAfterDays: Integer **read** fArchiveAfterDays **write** fArchiveAfterDays;

Number of days before OnArchive event will be called to compress or delete deprecated files

- will be set by default to 7 days
- will be used by Destroy to call OnArchive event handler on time

property ArchivePath: TFileName **read** fArchivePath **write** fArchivePath;

The folder where old log files must be compressed

- by default, is in the executable folder, i.e. the same as DestinationPath
- the 'log\' sub folder name will always be appended to this value
- will then be used by OnArchive event handler to produce, with the current file date year and month, the final path (e.g. 'ArchivePath\Log\YYYYMM*.log.synlz' or 'ArchivePath\Log\YYYYMM.zip')

property AutoFlushTimeOut: cardinal **read** fAutoFlush **write** fAutoFlush;

The time (in seconds) after which the log content must be written on disk, whatever the current content size is

- by default, the log file will be written for every 4 KB of log (see BufferSize property) - this will ensure that the main application won't be slow down by logging
- in order not to loose any log, a background thread can be created and will be responsible of flushing all pending log content every period of time (e.g. every 10 seconds)

property BufferSize: integer **read** fBufferSize **write** fBufferSize;

The internal in-memory buffer size, in bytes

- this is the number of bytes kept in memory before flushing to the hard drive; you can call TSynLog.Flush method or set AutoFlushTimeOut to true in order to force the writing to disk
- is set to 4096 by default (4 KB is the standard hard drive cluster size)

property CustomFileName: TFileName **read** fCustomFileName **write** fCustomFileName;

Can be used to customized the default file name

- by default, the log file name is computed from the executable name (and the computer name if IncludeComputerNameInFileName is true)
- you can specify your own file name here, to be used instead
- this file name should not contain any folder, nor file extension (which are set by DestinationPath and DefaultExtension properties)

property DefaultExtension: TFileName **read** fDefaultExtension **write** fDefaultExtension;

The file extension to be used

- is '.log' by default

property DestinationPath: TFileName **read** fDestinationPath **write** SetDestinationPath;

The folder where the log must be stored

- by default, is in the executable folder

property EchoCustom: TOnTextWriterEcho **read** fEchoCustom **write** SetEchoCustom;

Can be set to a callback which will be called for each log line

- could be used with a third-party logging system
- EchoToConsole or EchoCustom can be activated separately
- you may even disable the integrated file output, via NoFile := true

property EchoToConsole: TSynLogInfos **read** fEchoToConsole **write** SetEchoToConsole;

If the some kind of events shall be echoed to the console

- note that it will slow down the logging process a lot (console output is slow by nature under Windows, but may be convenient for interactive debugging of services, for instance
- this property shall be set before any actual logging, otherwise it will have no effect
- can be set e.g. to LOG_VERBOSE in order to echo every kind of events
- EchoCustom or EchoToConsole can be activated separately

property EchoToConsoleUseJournal: boolean **read** fEchoToConsoleUseJournal **write** SetEchoToConsoleUseJournal;

For Linux with journald

- if true: redirect all EchoToConsole logging into journald service
- such logs can be exported into a format which can be viewed by our LogView tool using a command (replacing UNIT with your unit name and PROCESS with the executable name):
"journalctl -u UNIT --no-hostname -o short-iso-precise --since today | grep "PROCESS\[.*\]: .
" > todaysLog.log"

property EndOfLineCRLF: boolean **read** fEndOfLineCRLF **write** fEndOfLineCRLF;

Define how the logger will emit its line feed

- by default (FALSE), a single LF (#10) char will be written, to save storage space
- you can set this property to TRUE, so that CR+LF (#13#10) chars will be appended instead
- TSynLogFile class and our LogView tool will handle both patterns

property ExceptionIgnore: TList **read** fExceptionIgnore;

You can add some exceptions to be ignored to this list

- for instance, EConvertError may be added to the list, as such:
TSQLLog.Family.ExceptionIgnore.Add(EConvertError);
- you may also trigger ESynLogSilent exceptions for silent process
- see also ExceptionIgnoreCurrentThread property, if you want a per-thread filtering of all exceptions

property ExceptionIgnoreCurrentThread: boolean **read** GetExceptionIgnoreCurrentThread **write** SetExceptionIgnoreCurrentThread;

Allow to (temporarily) ignore exceptions in the current thread

- this property will affect all TSynLogFamily instances, for the current thread
- may be used in a try...finally block e.g. when notifying the exception to a third-party service, or during a particular process
- see also ExceptionIgnore property - which is also checked in addition to this flag

property FileExistsAction: TSynLogExistsAction **read** fFileExistsAction **write** fFileExistsAction;

How existing log file shall be handled

property HighResolutionTimestamp: boolean **read** fHRTimestamp **write** fHRTimestamp;

If TRUE, will log high-resolution time stamp instead of ISO 8601 date and time

- this is less human readable, but allows performance profiling of your application on the customer side (using TSynLog.Enter methods)
- set to FALSE by default, or if RotateFileCount and RotateFileSizeKB / RotateFileDailyAtHour are set (the high resolution frequency is set in the log file header, so expects a single file)

property Ident: integer **read** fIdent;

Index in global SynLogFileFamily[] and SynLogFileIndexThreadVar[] lists

property IncludeComputerNameInFileName: boolean **read**

fIncludeComputerNameInFileName **write** fIncludeComputerNameInFileName;

If TRUE, the log file name will contain the Computer name - as 'MyComputer'

property Level: TSynLogInfos **read** fLevel **write** SetLevel;

The current level of logging information for this family

- can be set e.g. to LOG_VERBOSE in order to log every kind of events

property LevelStackTrace: TSynLogInfos **read** fLevelStackTrace **write** fLevelStackTrace;

The levels which will include a stack trace of the caller

- by default, contains sllStackTrace, sllException, sllExceptionOS plus sllError, sllFail, sllLastError, sllDDDError for Delphi only - since FPC BacktraceStrFunc() function is very slow
- exceptions will always trace the stack

property LocalTimestamp: boolean **read** fLocalTimestamp **write** fLocalTimestamp;

By default, time logging will use error-safe UTC values as reference

- you may set this property to TRUE to store local time instead

property NoEnvironmentVariable: boolean **read** fNoEnvironmentVariable **write** fNoEnvironmentVariable;

Force no environment variables to be written to the log file

- may be usefull if they contain some sensitive information

property NoFile: boolean **read** fNoFile **write** fNoFile;

Force no log to be written to any file

- may be usefull in conjunction e.g. with EchoToConsole or any other third-party logging component

property OnArchive: TSynLogArchiveEvent **read** fOnArchive **write** fOnArchive;

Event called to archive the .log content after a defined delay

- Destroy will parse DestinationPath folder for *.log files matching ArchiveAfterDays property value
- you can set this property to EventArchiveDelete in order to delete deprecated files, or EventArchiveSynLZ to compress the .log file into our proprietary SynLZ format: resulting file name will be ArchivePath\log\YYYYMM*.log.synlz (use FileUnSynLZ function to uncompress it)
- if you use SynZip.EventArchiveZip, the log files will be archived in ArchivePath\log\YYYYMM.zip
- the aDestinationPath parameter will contain 'ArchivePath\log\YYYYMM\'
- this event handler will be called one time per .log file to archive, then one last time with aOldLogFileName="" in order to close any pending archive (used e.g. by EventArchiveZip to open the .zip only once)

property OnBeforeException: TSynLogOnBeforeException **read** fOnBeforeException **write** fOnBeforeException;

You can let exceptions be ignored from a callback

- if set and returns true, the given exception won't be logged
- execution of this event handler is protected via the logs global lock
- may be handy e.g. when working with code triggering a lot of exceptions (e.g. Indy), where ExceptionIgnore could be refined

property OnRotate: TSynLogRotateEvent **read** fOnRotate **write** fOnRotate;

Event called to perform a custom file rotation

- will be checked by TSynLog.PerformRotation to customize the rotation process and do not perform the default step, if the callback returns TRUE

property PerThreadLog: TSynLogPerThreadMode **read** fPerThreadLog **write** fPerThreadLog;

Define how thread will be identified during logging process

- by default, ptMergedInOneFile will indicate that all threads are logged in the same file, in occurrence order (so multi-thread process on server side may be difficult to interpret)
- if RotateFileCount and RotateFileSizeKB/RotateFileDailyAtHour are set, will be ignored (internal thread list shall be defined for one process)

property RotateFileCount: cardinal **read** fRotateFileCount **write** fRotateFileCount;

Auto-rotation of logging files

- set to 0 by default, meaning no rotation
- can be set to a number of rotating files: rotation and compression will happen, and main file size will be up to RotateFileSizeKB number of bytes, or when RotateFileDailyAtHour time is reached
- if set to 1, no .synlz backup will be created, so the main log file will be restarted from scratch when it reaches RotateFileSizeKB size or when RotateFileDailyAtHour time is reached
- if set to a number > 1, some rotated files will be compressed using the SynLZ algorithm, and will be named e.g. as MainLogFileName.0.synlz .. MainLogFileName.7.synlz for RotateFileCount=9 (total count = 9, including 1 main log file and 8 .synlz files)

property RotateFileDailyAtHour: integer **read** fRotateFileAtHour **write** fRotateFileAtHour;

Fixed hour of the day where logging files rotation should be performed

- by default, equals -1, meaning no rotation
- you can set a time value between 0 and 23 to force the rotation at this specified hour
- is not used if RotateFileCount is left to its default 0

property RotateFileNoCompression: boolean **read** fRotateFileNoCompression **write** fRotateFileNoCompression;

If set to TRUE, no #.synlz will be created at rotation but plain #.log file

property RotateFileSizeKB: cardinal **read** fRotateFileSize **write** fRotateFileSize;

Maximum size of auto-rotated logging files, in kilo-bytes (per 1024 bytes)

- specify the maximum file size upon which .synlz rotation takes place
- is not used if RotateFileCount is left to its default 0

property StackTraceLevel: byte **read** fStackTraceLevel **write** fStackTraceLevel;

The recursive depth of stack trace symbol to write

- used only if exceptions are handled, or by sllStackTrace level
- default value is 30, maximum is 255
- if stOnlyAPI is defined as StackTraceUse under Windows XP, maximum value may be around 60, due to RtlCaptureStackBackTrace() API limitations

property StackTraceUse: TSynLogStackTraceUse **read** fStackTraceUse **write** fStackTraceUse;

How the stack trace shall use only the Windows API

- the class will use low-level RtlCaptureStackBackTrace() API to retrieve the call stack: in some cases, it is not able to retrieve it, therefore a manual walk of the stack can be processed - since this manual call can trigger some unexpected access violations or return wrong positions, you can disable this optional manual walk by setting it to stOnlyAPI
- default is stManualAndAPI, i.e. use RtlCaptureStackBackTrace() API and perform a manual stack walk if the API returned no address (or <3); but within the IDE, it will use stOnlyAPI, to ensure no annoying AV occurs

property SynLogClass: TSynLogClass **read** fSynLogClass;

The associated TSynLog class

property SynLogClassName: string **read** GetSynLogClassName;

The associated TSynLog class

property WithInstancePointer: boolean **read** fWithInstancePointer **write** fWithInstancePointer;

If TRUE, will log the pointer with an object instance class if available

- set to TRUE by default, for better debugging experience

property WithUnitName: boolean **read** fWithUnitName **write** fWithUnitName;

If TRUE, will log the unit name with an object instance if available

- unit name is available from RTTI if the class has published properties
- set to TRUE by default, for better debugging experience

TSynLogThreadRecursion = record

TSynLogThreadContext will define a dynamic array of such information

- used by TSynLog.Enter methods to handle recursivity calls tracing

Caller: PtrUInt;

The caller address, ready to display stack trace dump if needed

EnterTimestamp: Int64;

The time stamp at enter time

Instance: TObject;

Associated class instance to be displayed

MethodName: PUTF8Char;

Method name (or message) to be displayed

- may be a RawUTF8 if MethodNameLocal=mnEnterOwnMethodName

MethodNameLocal: (mnAlways, mnEnter, mnLeave, mnEnterOwnMethodName);

If the method name is local, i.e. shall not be displayed at Leave()

RefCount: integer;

Internal reference count used at this recursion level by TSynLog._AddRef

TSynLogThreadContext = record

Thread-specific internal context used during logging

- this structure is a hashed-per-thread variable

ID: TThreadID;

The corresponding Thread ID

Recursion: array of TSynLogThreadRecursion;

Used by TSynLog.Enter methods to handle recursivity calls tracing

RecursionCapacity: integer;

Number of items available in Recursion[]

- faster than length(Recursion)

RecursionCount: integer;

Number of items stored in Recursion[]

ThreadName: RawUTF8;

The associated thread name

TFileStreamWithoutWriteError = class(TFileStream)

File stream which ignores I/O write errors

- in case disk space is exhausted, TFileStreamWithoutWriteError.WriteBuffer won't throw any exception, so application will continue to work

- used by TSynLog to let the application continue with no exception, even in case of a disk/partition full of logs

function Write(const Buffer; Count: Longint): Longint; override;

This overridden function returns Count, as if it was always successful

TSynLog = class(TObject)

A per-family and/or per-thread log file content

- you should create a sub class per kind of log file

TSynLogDB = class(TSynLog);

- the TSynLog instance won't be allocated in heap, but will share a per-thread (if Family.PerThreadLog=ptOneFilePerThread) or global private log file instance

- was very optimized for speed, if no logging is written, and even during log write (using an internal TTextWriter)

- can use available debugging information via the TSynMapFile class, for stack trace logging for exceptions, sllStackTrace, and Enter/Leave labelling

constructor `Create(aFamily: TSynLogFamily=nil); virtual;`

Intialize for a TSynLog class instance

- WARNING: not to be called directly! Use Enter or Add class function instead

destructor `Destroy; override;`

Release all memory and internal handles

class function `Add: TSynLog;`

Retrieve the current instance of this TSynLog class

- to be used for direct logging, without any Enter/Leave:

`TSynLogDB.Add.Log(11Error, 'The % statement didn''t work', [SQL]);`

- to be used for direct logging, without any Enter/Leave (one parameter version - just the same as previous):

`TSynLogDB.Add.Log(11Error, 'The % statement didn''t work', SQL);`

- is just a wrapper around `Family.SynLog` - the same code will work:

`TSynLogDB.Family.SynLog.Log(11Error, 'The % statement didn''t work', [SQL]);`

```
class function Enter(aInstance: TObject=nil; aMethodName: PUTF8Char=nil;
aMethodNameLocal: boolean=false): ISynLog; overload;
```

Handle generic method enter / auto-leave tracing

- this is the main method to be called within a procedure/function to trace:

```
procedure TMyDB.SQLExecute(const SQL: RawUTF8);
var log: ISynLog;
begin
  log := TSynLogDB.Enter(self, 'SQLExecute');
  // do some stuff
  log.Log(sllInfo, 'SQL=',[SQL]);
end; // here log will be released, and method leaving will be logged
```

- returning a ISynLog interface will allow you to have an automated sllLeave log created when the method is left (thanks to the hidden try..finally block generated by the compiler to protect the ISynLog var)

- WARNING: due to a limitation (feature?) of the FPC compiler and Delphi 10.4 and later, you NEED to hold the returned value into a local ISynLog variable; as a benefit, it is always convenient to define a local variable to store the returned ISynLog and use it for any specific logging within the method execution

- on Delphi earlier to 10.4 (and not FPC), you could just call Enter() inside the method block, without any ISynLog interface variable - but it is not very future-proof to write the following code:

```
procedure TMyDB.SQLFlush;
begin
  TSynLogDB.Enter(self, 'SQLFlush');
  // do some stuff
end;
```

- if no Method name is supplied, it will use the caller address, and will write it as hexa and with full unit and symbol name, if the debugging information is available (i.e. if TSynMapFile retrieved the .map content; note that this is not available yet on FPC):

```
procedure TMyDB.SQLFlush;
var log: ISynLog;
begin
  log := TSynLogDB.Enter(self);
  // do some stuff
end;
```

- note that supplying a method name is faster than using the .map content: if you want accurate profiling, it's better to use a method name or not to use a .map file - note that this method name shall be a constant, and not a locally computed variable, since it may trigger some random GPF at runtime - if it is a local variable, you can set aMethodNameLocal=true

- if TSynLogFamily.HighResolutionTimestamp is TRUE, high-resolution time stamp will be written instead of ISO 8601 date and time: this will allow performance profiling of the application on the customer side

- Enter() will write the class name (and the unit name for classes with published properties, if TSynLogFamily.WithUnitName is true) for both enter (+) and leave (-) events:

```
20110325 19325801 +   MyDBUnit.TMyDB(004E11F4).SQLExecute
20110325 19325801 info   SQL=SELECT * FROM Table;
20110325 19325801 -   01.512.320
```

```
class function Enter(const TextFmt: RawUTF8; const TextArgs: array of const;  
aInstance: TObject=nil): ISynLog; overload;
```

Handle method enter / auto-leave tracing, with some custom text

- this overloaded method would not write the method name, but the supplied text content, after expanding the parameters like FormatUTF8()
- it will append the corresponding sllLeave log entry when the method ends

```
class function Family: TSynLogFamily; overload;
```

Retrieve the family of this TSynLog class type

```
function LogClass: TSynLogClass;
```

The associated TSynLog class

```
class function Void: TSynLogClass;
```

Returns a logging class which will never log anything

- i.e. a TSynLog sub-class with Family.Level := []

```
procedure CloseLogFile;
```

Flush all log content to file and close the file

```
class procedure DebuggerNotify(Level: TSynLogInfo; const Format: RawUTF8; const  
Args: array of const);
```

Low-level method helper which can be called to make debugging easier

- log some warning message to the TSynLog family
- will force a manual breakpoint if tests are run from the IDE

```
procedure DisableRemoteLog(value: boolean);
```

Allow to temporary disable remote logging

- to be used within a try ... finally section:

```
log.DisableRemoteLog(true);  
try  
  log.Log(...); // won't be propagated to the remote log  
finally  
  log.DisableRemoteLog(false);  
end;
```

```
procedure Flush(ForceDiskWrite: boolean);
```

Flush all log content to file

- if ForceDiskWrite is TRUE, will wait until written on disk (slow)

```
procedure ForceRotation;
```

Force log rotation; Can be used for example inside SUGHUP signal handler

procedure Log(Level: TSynLogInfo; aInstance: TObject); overload;

Call this method to add the content of an object to the log at a specified level

- this default implementation will just write the class name and its hexa pointer value, and handle TList, TCollections and TStringList - for instance:

```
TSynLog.Add.Log(sllDebug, GarbageCollector);
```

will append this line to the log:

```
20110330 10010005 debug {"TObjectList(00B1AD60)":["TObjectList(00B1AE20)", "TObjectList(00B1AE80)"]}
```

- if aInstance is an Exception, it will handle its class name and Message:

```
20110330 10010005 debug "EClassName(00C2129A)": "Exception message"
```

- use TSQLLog from mORMot.pas unit to add the record content, written as human readable JSON

procedure Log(Level: TSynLogInfo; const aName: RawUTF8; aTypeInfo: pointer; const aValue; Instance: TObject); overload;

Call this method to add the content of most low-level types to the log at a specified level

- this overridden implementation will write the value content, written as human readable JSON: handle dynamic arrays and enumerations

- TSQLLog from mORMot.pas unit will be able to write TObject/TSQLRecord and sets content as JSON

procedure Log(Level: TSynLogInfo); overload;

Call this method to add the caller address to the log at the specified level

- if the debugging info is available from TSynMapFile, will log the unit name, associated symbol and source code line

procedure Log(Level: TSynLogInfo; const TextFmt: RawUTF8; const TextArg: RawUTF8; aInstance: TObject=nil); overload;

Same as Log(Level, TextFmt, []) but with one RawUTF8 parameter

procedure Log(Level: TSynLogInfo; const TextFmt: RawUTF8; const TextArgs: array of const; aInstance: TObject=nil); overload;

Call this method to add some information to the log at the specified level

- will use TTextWriter.Add(..., twOnSameLine) to append its content

- % = #37 indicates a string, integer, floating-point, class parameter to be appended as text (e.g. class name), any variant as JSON...

- note that cardinal values should be type-casted to Int64() (otherwise the integer mapped value will be transmitted, therefore wrongly)

procedure Log(Level: TSynLogInfo; const Text: RawUTF8; aInstance: TObject=nil; TextTruncateAtLength: integer=maxInt); overload;

Call this method to add some information to the log at the specified level

- if Instance is set and Text is not "", it will log the corresponding class name and address (to be used e.g. if you didn't call TSynLog.Enter() method first) - for instance

```
TSQLLog.Add.Log(sllDebug, 'GarbageCollector', GarbageCollector);
```

will append this line to the log:

```
000000000002DB9 debug TObjectList(00425E68) GarbageCollector
```

- if Instance is set and Text is "", will behave the same as Log(Level, Instance), i.e. write the Instance as JSON content

```
procedure Log(Level: TSynLogInfo; const TextFmt: RawUTF8; const TextArg: Int64;
aInstance: TObject=nil); overload;
```

Same as Log(Level,TextFmt,[]) but with one Int64 parameter

```
procedure LogLines(Level: TSynLogInfo; LinesToLog: PUTF8Char; aInstance:
TObject=nil; const IgnoreWhenStartWith: PAnsiChar=nil);
```

Call this method to add some multi-line information to the log at a specified level

- LinesToLog content will be added, one line per one line, delimited by

`13#10` (CRLF)

- if a line starts with IgnoreWhenStartWith (already uppercase), it won't be added to the log content (to be used e.g. with '--' for SQL statements)

```
procedure LogThreadName(const Name: RawUTF8; IgnoreIfAlreadySet: boolean=false);
```

Allows to identify the current thread with a textual representation

- would append an sllInfo entry with "SetThreadName ThreadID=Name" text

- entry would also be replicated at the beginning of any rotated log file

```
procedure ManualEnter(aMethodName: PUTF8Char; aInstance: TObject = nil);
```

Manual low-level TSynLog.Enter execution without the ISynLog

- may be used to log Enter/Leave stack from non-pascal code

- each call to ManualEnter should be followed by a matching ManualLeave

- aMethodName should be a not nil constant text

```
procedure ManualLeave;
```

Manual low-level ISynLog release after TSynLog.Enter execution

- each call to ManualEnter should be followed by a matching ManualLeave

```
procedure NotifyThreadEnded;
```

You may call this method when a thread is ended

- should be called in the thread context which is about to terminate, in a situation where no other logging may occur from this thread any more

- it will release all thread-specific resource used by this TSynLog

- is called e.g. by TSQLRest.EndCurrentThread, via TSynLogFamily.OnThreadEnded

```
procedure Release;
```

Flush all log content to file, close the file, and release the instance

- you should never call the Free method directly, since the instance is registered in a global TObjectList and an access violation may occur at application closing: you can use this Release method if you are sure that you won't need this TSynLog instance any more

- ensure there is no pending Leave element in a stack-allocated ISynLog (see below)

- can be used e.g. to release the instance when finishing a thread when

Family.PerThreadLog=ptOneFilePerThread:

```
var
```

```
  TThreadLogger : TSynLogClass = TSynLog;
```

```
procedure TMyThread.Execute;
```

```
var log : ISynLog;
```

```
begin
```

```
  log := TThreadLogger.Enter(self);
```

```
  ...
```

```
  log := nil; // to force logging end of method
```

```
  TThreadLogger.SynLog.Release;
```

```
end;
```

property FileName: TFileName read fFileName;

The associated file name containing the log

- this is accurate only with the default implementation of the class: any child may override it with a custom logging mechanism

property FileSize: Int64 read GetFileSize;

The current size, in bytes, of the associated file containing the log

property GenericFamily: TSynLogFamily read fFamily;

The associated logging family

property ThreadContextCount: integer read fThreadContextCount;

The current number of thread contexts associated with this instance

- doesn't match necessarily the number of threads of the process, but the threads which are still marked as active for this TSynLog
- a huge number may therefore not indicate a potential "out of memory" error, but a broken logic with missing NotifyThreadEnded calls

property Writer: TTextWriterWithEcho read fWriter;

Direct access to the low-level writing content

- should usually not be used directly, unless you ensure it is safe

TAutoLockerDebug = **class**(TAutoLocker)

Reference-counted block code critical section with context logging

- race conditions are difficult to track: you could use this TAutoLockerDebug instead of plain TAutoLocker class, to log some information at each Enter/Leave process, and track unexpected blocking issues
- see also the global USELOCKERDEBUG conditional, defined in Synopse.inc, which may be used to enable verbose logging at compile time:

```
fSafe: IAutoLocker;  
...  
{ $ifdef USELOCKERDEBUG }  
fSafe := TAutoLockerDebug.Create(fLogClass, aModel.Root); // more verbose  
{ $else }  
fSafe := TAutoLocker.Create;  
{ $endif }
```

constructor Create(aLog: TSynLogClass; **const** aIdentifier: RawUTF8); **reintroduce**;

Initialize the mutex, which would log its Enter/Leave process

- the supplied identifier should be a short text, able to specify the lock execution context, e.g. the resource which is actually protected
- an associated TSynLog instance should be specified as logging target

procedure Enter; **override**;

Enter the mutex

procedure Leave; **override**;

Leave the mutex

TSynLogFileProc = record

Used by TSynLogFile to refer to a method profiling in a .log file

- i.e. map a sllEnter/sllLeave event in the .log file

Index: cardinal;

The index of the sllEnter event in the TSynLogFile.fLevels[] array

ProperTime: cardinal;

The time elapsed in this method and not in nested methods

- computed from Time property, minus the nested calls

Time: cardinal;

The associated time elapsed in this method (in micro seconds)

- computed from the sllLeave time difference (high resolution timer)

TSynLogFile = class(TMemoryMapText)

Used to parse a .log file, as created by TSynLog, into high-level data

- this particular TMemoryMapText class will retrieve only valid event lines (i.e. will fill EventLevel[] for each line <> sllNone)

- Count is not the global text line numbers, but the number of valid events within the file (LinePointers/Line/Strings will contain only event lines) - it will not be a concern, since the .log header is parsed explicitly

constructor Create; **override**;

Initialize internal structure

function EventCount(**const** aSet: TSynLogInfos): integer;

Return the number of matching events in the log

function EventDateTime(aIndex: integer): TDateTime;

Retrieve the date and time of an event

- returns 0 in case of an invalid supplied index

function EventString(index: integer; **const** replaceTabs: RawUTF8=''; maxutf8len: Integer=0; includeFirstColumns: boolean=false): **string**;

Retrieve the description text of an event, as native VCL string

- returns '' if supplied index is out of range

- if the text is not truly UTF-8 encoded, would use the current system codepage to create a valid string

- you may specify a text to replace all #9 characters occurrences

- is used e.g. in TMainLogView.ListDrawCell

function LineContains(**const** aUpperSearch: RawUTF8; aIndex: Integer): Boolean; **override**;

Returns TRUE if the supplied text is contained in the corresponding line

function ThreadName(ThreadID, CurrentLogIndex: integer): RawUTF8;

Returns the name of a given thread, according to the position in the log

function ThreadNames(CurrentLogIndex: integer): TRawUTF8DynArray;

Returns the name of all threads, according to the position in the log
- result[0] stores the name of ThreadID = 1

function ThreadRows(ThreadID: integer): cardinal;

Returns the number of occurrences of a given thread

procedure AddInMemoryLine(const aNewLine: RawUTF8); **override**;

Add a new line to the already parsed content
- overridden method which would identify the freq=%%,%% pseudo-header

procedure GetDays(out Days: TDateTimeDynArray);

Returns all days of this log file
- only available for low-resolution timestamp, i.e. Freq=0

procedure LogProcSort(Order: TLogProcSortOrder);

Sort the LogProc[] array according to the supplied order

property ComputerHost: RawUTF8 **read** fHost;

The computer host name in which the process was running on

property CPU: RawUTF8 **read** fCPU;

The computer CPU in which the process was running on
- returns e.g. '1*0-15-1027'

property DayChangeIndex: TIntegerDynArray **read** fDayChangeIndex;

The row indexes where the day changed
- only available for low-resolution timestamp, i.e. Freq=0
- if set, contains at least [0] if the whole log is over a single day

property DayCount: TIntegerDynArray **read** fDayCount;

The number of rows for each DayChangeIndex[] value

property DetailedOS: RawUTF8 **read** fOSDetailed;

The computer Operating System in which the process was running on
- returns e.g. '2.3=5.1.2600' for Windows XP
- under Linux, it will return the full system version, e.g.
'Ubuntu=Linux-3.13.0-43-generic#72-Ubuntu-SMP-Mon-Dec-8-19:35:44-UTC-2014'

property EventLevel: TSynLogInfoDynArray **read** fLevels;

Retrieve the level of an event
- is calculated by Create() constructor
- EventLevel[] array index is from 0 to Count-1

property EventLevelUsed: TSynLogInfos **read** fLevelUsed;

Retrieve all used event levels
- is calculated by Create() constructor

property EventText[index: integer]: RawUTF8 **read** GetEventText;

Retrieve the description text of an event
- returns '' if supplied index is out of range
- see also EventString() function, for direct VCL use

property EventThread: TWordDynArray read fThreads;

Retrieve all event thread IDs

- contains something if TSynLogFamily.PerThreadLog was ptIdentifiedInOnFile
- for ptMergedInOneFile (default) or ptOneFilePerThread logging process, the array will be void (EventThread=nil)

property ExecutableDate: TDateTime read fExeDate;

The associated executable build date and time

property ExecutableName: RawUTF8 read fExeName;

The associated executable name (with path)

- returns e.g. 'C:\Dev\lib\SQLite3\exe\TestSQL3.exe'

property ExecutableVersion: RawUTF8 read fExeVersion;

The associated executable version

- returns e.g. '0.0.0.0'

property Framework: RawUTF8 read fFramework;

The associated framework information

- returns e.g. 'TSQLLog 1.18.2765 ERTL FTS3'

property Freq: Int64 read fFreq;

High-resolution time stamp frequency, as retrieved from log file header

- equals 0 if date time resolution, >0 if high-resolution time stamp

property Headers: RawUTF8 read fHeaders;

Custom headers, to be searched as .ini content

property InstanceName: RawUTF8 read fInstanceName;

For a library, the associated instance name (with path)

- returns e.g. 'C:\Dev\lib\SQLite3\exe\TestLibrary.dll'
- for an executable, will be left void

property IntelCPU: TIntelCpuFeatures read fIntelCPU;

The available CPU features, as recognized at program startup

- is extracted from the last part of the CPU property text
- you could use the overloaded ToText() function to show it in an human-friendly way

property LevelUsed: TSynLogInfos read fLevelUsed;

All used event levels, as retrieved at log file content parsing

property LogProc: PSynLogFileProcArray read fLogProcCurrent;

Profiled methods information

- is calculated by Create() constructor
- will contain the slEnter index, with the associated elapsed time
- number of items in the array is retrieved by the LogProcCount property

property LogProcCount: integer read fLogProcCurrentCount;

Number of profiled methods in this .log file

- i.e. number of items in the LogProc[] array

property LogProcMerged: boolean read fLogProcIsMerged write SetLogProcMerged;

If the method information must be merged for the same method name

property LogProcOrder: TLogProcSortOrder **read** fLogProcSortInternalOrder;

The current sort order

property OS: TWindowsVersion **read** fOS;

The computer Operating System in which the process was running on
- equals wUnknown on Linux or BSD - use DetailedOS instead

property RunningUser: RawUTF8 **read** fUser;

The computer user name who launched the process

property ServicePack: integer **read** fOSServicePack;

The Operating System Service Pack number
- not defined on Linux or BSD - use DetailedOS instead

property StartDateTime: TDateTime **read** fStartDateTime;

The date and time at which the log file was started

property ThreadsCount: cardinal **read** fThreadMax;

The number of threads

property Wow64: boolean **read** fWow64;

If the 32 bit process was running under WOW 64 virtual emulation

TSynLogFileView = class(TSynLogFile)

Used to parse a .log file and process into VCL/LCL/FMX
- would handle e.g. selection and search feature

function GetCell(aCol, aRow: integer; **out** aLevel: TSynLogInfo): **string**;

Returns the ready-to-be text of a cell of the main TDrawGrid

function GetLineForClipboard(aRow: integer): **string**;

Returns the ready-to-be copied text of a selected row

function GetLineForMemo(aRow, aTop, aBottom: integer): **string**;

Returns the ready-to-be displayed text of one or several selected rows

function SearchEnterLeave(aRow: integer): integer;

Search for the matching Enter/Leave item, from the current row index
- returns -1 if no match was found

function SearchNextEvent(aEvent: TSynLogInfo; aRow: integer): integer;

Search for the next matching TSynLogInfo, from the current row index
- returns -1 if no match was found

function SearchNextSameThread(aRow: integer): integer;

Search for the next matching thread, from the current row index
- returns -1 if no match was found

function SearchNextSelected(aIndex: integer): integer;

Search for the next row index, appearing after the supplied item index
- returns -1 if no match was found

function SearchNextText(const aPattern: RawUTF8; aRow, aDelta: integer): integer;

Search for the next matching text, from the current row index
 - returns -1 if no match was found

function SearchNextThread(aRow: integer): integer;

Search for the next diverse thread, from the current row index
 - returns -1 if no match was found

function SearchPreviousSameThread(aRow: integer): integer;

Search for the previous matching thread, from the current row index
 - returns -1 if no match was found

function SearchPreviousText(const aPattern: RawUTF8; aRow: integer): integer;

Search for the previous matching text, from the current row index
 - returns -1 if no match was found

function SearchThread(aThreadID: word; aRow: integer): integer;

Search for the next specified thread, from the current row index
 - returns -1 if no match was found

function Select(aRow: integer): integer; **virtual**;

Fill all rows matching Events and Threads[] properties in Selected[]
 - you may specify the current selected row index, which would return the closest one after the selection has been applied

procedure AddInMemoryLine(const aNewLine: RawUTF8); **override**;

Add a new line to the already parsed content
 - overridden method would add the inserted index to Selected[]

procedure SetAllThreads(enabled: boolean);

Set all Threads[] to a specified value

property Events: TSynLogInfos **read** fEvents **write** fEvents;

Define the current selection range, according to event kinds
 - once you have set Events and Threads[], call Select() to fill Selected[]

property Selected: TIntegerDynArray **read** fSelected;

The row indexes of the selected entries

property SelectedCount: integer **read** fSelectedCount;

How many entries are currently stored in Selected[]

property Threads[thread: integer]: boolean **read** GetThreads **write** SetThreads;

Define the current selection range, according to a thread ID
 - here the supplied thread ID starts at 1
 - once you have set Events and Threads[], call Select() to fill Selected[]

TSynLogExceptionInfo = record

Storage of the information associated with an intercepted exception
 - as returned by GetLastException() function

Addr: RawUTF8;

Ready-to-be-displayed text of the exception address

Context: `TSynLogExceptionContext;`

Low-level calling context

- as used by `TSynLogExceptionToStr` callbacks

Message: `string;`

Associated `Exception.Message` content (if any)

Types implemented in the *SynLog* unit

`PSynLogThreadContext = ^TSynLogThreadContext;`

Pointer to thread-specific context information

`TLogProcSortOrder = (soNone, soByName, soByOccurrence, soByTime, soByProperTime);`

Used by `TSynLogFile.LogProcSort` method

`TSynLogArchiveEvent = function(const aOldLogFileName, aDestinationPath: TFileName): boolean;`

This event can be set for a `TSynLogFamily` to archive any deprecated log into a custom compressed format

- will be called by `TSynLogFamily` when `TSynLogFamily.Destroy` identify some outdated files
- the `aOldLogFileName` will contain the .log file with full path
- the `aDestinationPath` parameter will contain 'ArchivePath\log\YYYYMM\'
- should return true on success, false on error
- example of matching event handler are `EventArchiveDelete/EventArchiveSynLZ` or `EventArchiveZip` in `SynZip.pas`
- this event handler will be called one time per .log file to archive, then one last time with `aOldLogFileName=""` in order to close any pending archive (used e.g. by `EventArchiveZip` to open the .zip only once)

`TSynLogCallbackDynArray = array of TSynLogCallback;`

Store the all subscribed `ISynLogCallback`

`TSynLogClass = class of TSynLog;`

Class-reference type (metaclass) of a `TSynLog` family

- since `TSynLog` classes store their information per type, you usually will store a reference to a logging family (i.e. logging settings) using a `TSynLogClass` variable, whereas `TSynLog` would point to the active logging instance

`TSynLogExceptionInfoDynArray = array of TSynLogExceptionInfo;`

Storage of the information associated with one or several exceptions

- as returned by `GetLastExceptions()` function

`TSynLogExistsAction = (acOverwrite, acAppend);`

How file existing shall be handled during logging

`TSynLogFileProcDynArray = array of TSynLogFileProc;`

Used by `TSynLogFile` to refer to global method profiling in a .log file

- i.e. map all `sllEnter/sllLeave` event in the .log file

`TSynLogFilter = (lfNone, lfAll, lfErrors, lfExceptions, lfProfile, lfDatabase, lfClientServer, lfDebug, lfCustom, lfDDD);`

A list of log events families, used to gather events by type

`TSynLogOnBeforeException = function(const aExceptionContext: TSynLogExceptionContext;`

const aThreadName: RawUTF8): boolean of object;

Callback signature used by TSynLogFamily.OnBeforeException

- should return false to log the exception, or true to ignore it

TSynLogPerThreadMode = (ptMergedInOneFile, ptOneFilePerThread, ptIdentifiedInOnFile, ptNoThreadProcess);

How threading is handled by the TSynLogFamily

- proper threading expects the TSynLog.NotifyThreadEnded method to be called when a thread is about to terminate, e.g. from TSQLRest.EndCurrentThread
- by default, ptMergedInOneFile will indicate that all threads are logged in the same file, in occurrence order
- if set to ptOneFilePerThread, it will create one .log file per thread
- if set to ptIdentifiedInOnFile, a new column will be added for each log row, with the corresponding ThreadID - LogView tool will be able to display per-thread logging, if needed - note that your application shall use a thread pool (just like all mORMot servers classes do), otherwise some random hash collision may occur if Thread IDs are not recycled enough
- if set to ptNoThreadProcess, no thread information is gathered, and all Enter/Leave would be merged into a single call - but it may be mandatory to use this option if TSynLog.NotifyThreadEnded is not called (e.g. from legacy code), and that your process experiment instability issues

TSynLogRotateEvent = function(aLog: TSynLog; const aOldLogFileName: TFileName): boolean;

This event can be set for a TSynLogFamily to customize the file rotation

- will be called by TSynLog.PerformRotation
- should return TRUE if the function did process the file name
- should return FALSE if the function did not do anything, so that the caller should perform the rotation as usual

TSynLogStackTraceUse = (stManualAndAPI, stOnlyAPI, stOnlyManual);

How stack trace shall be computed during logging

TSynMapSymbolDynArray = array of TSynMapSymbol;

A dynamic array of symbols, as decoded by TSynMapFile from a .map file

TSynMapUnitDynArray = array of TSynMapUnit;

A dynamic array of units, as decoded by TSynMapFile from a .map file

TSyslogFacility = (sfKern, sfUser, sfMail, sfDaemon, sfAuth, sfSyslog, sfLpr, sfNews, sfUucp, sfClock, sfAuthpriv, sfFtp, sfNtp, sfAudit, sfAlert, sfCron, sfLocal0, sfLocal1, sfLocal2, sfLocal3, sfLocal4, sfLocal5, sfLocal6, sfLocal7);

Syslog message facilities as defined by RFC 3164

TSyslogSeverity = (ssEmerg, ssAlert, ssCrit, ssErr, ssWarn, ssNotice, ssInfo, ssDebug);

Syslog message severities as defined by RFC 5424

Constants implemented in the SynLog unit

LOG_CONSOLE_COLORS: array[TSynLogInfo] of TConsoleColor = (ccLightGray, ccWhite, ccLightGray, ccLightBlue, ccBrown, ccLightRed, ccGreen, ccGreen, ccLightRed, ccLightRed, ccLightRed, ccLightGray, ccCyan, ccLightRed, ccBrown, ccBlue, ccLightCyan, ccMagenta, ccCyan, ccLightCyan, ccLightCyan, ccLightMagenta, ccLightMagenta, ccMagenta, ccLightGray, ccLightGray, ccLightGray, ccLightGray, ccLightMagenta, ccLightRed, ccWhite, ccLightBlue);

Console colors corresponding to each logging level

- SynCommons' TextColor()

```
LOG_DEBUGERROR: array[boolean] of TSynLogInfo = (sllDebug, sllError);
```

May be used to log as Debug or Error event, depending on an Error: boolean

```
LOG_FILTER: array[TSynLogFilter] of TSynLogInfos = ( [],  
[succ(sllNone)..high(TSynLogInfo)],  
[sllError,sllLastError,sllException,sllExceptionOS], [sllException,sllExceptionOS],  
[sllEnter,sllLeave], [sllSQL,sllCache,sllDB], [sllClient,sllServer,sllServiceCall,  
sllServiceReturn], [sllDebug,sllTrace,sllEnter],  
[sllCustom1..sllCustom4],[sllDDDError,sllDDDDInfo]);
```

sllNone, sllInfo, sllDebug, sllTrace, sllWarning, sllError, sllEnter, sllLeave sllLastError, sllException, sllExceptionOS, sllMemory, sllStackTrace, sllFail, sllSQL, sllCache, sllResult, sllDB, sllHTTP, sllClient, sllServer, sllServiceCall, sllServiceReturn, sllUserAuth, sllCustom1, sllCustom2, sllCustom3, sllCustom4, sllNewRun, sllDDDError, sllDDDDInfo, sllMonitoring how TLogFilter map TSynLogInfo events

```
LOG_INFOWARNING: array[boolean] of TSynLogInfo = (sllInfo, sllWarning);
```

May be used to log as Info or Warning event, depending on an Error: boolean

```
LOG_LEVEL_COLORS: array[Boolean,TSynLogInfo] of integer = (  
($FFFFFF,$DCC0C0,$DCDCDC,$C0C0C0,$8080C0,$8080FF,$C0DCC0,$DCDCC0,$C0C0F0,$C080FF,  
$C080F0,$C080C0,$C080C0,$4040FF,$B08080,$B0B080,$8080DC,$80DC80,$DC8080,  
$DCFF00,$DCD000,$DCDC80,$DC80DC,$DCDCDC,$D0D0D0,$D0D0DC,$D0D0C0,$D0D0E0,  
$20E0D0,$8080FF,$DCCDCD,$C0C0C0),  
($000000,$000000,$000000,$000000,$000000,$FFFFFF,$000000,$000000,  
$FFFFFF,$FFFFFF,$FFFFFF,$000000,$000000,  
$FFFFFF,$FFFFFF,$000000,$FFFFFF,$000000,$000000,$000000,$000000,  
$000000,$000000,$000000,  
$000000,$000000,$000000,$000000,$000000,$FFFFFF,$000000,$000000));
```

RGB colors corresponding to each logging level

- matches the TColor values, as used by the VCL

```
LOG_LEVEL_TEXT: array[TSynLogInfo] of string[7] = ( ' ', ' info ', ' debug ', ' trace  
, ' warn ', ' ERROR ', ' + ', ' - ', ' OSERR ', ' EXC ', ' EXCOS ', ' mem ', ' stack  
, ' fail ', ' SQL ', ' cache ', ' res ', ' DB ', ' http ', ' clnt ', ' srvr ', ' call  
, ' ret ', ' auth ', ' cust1 ', ' cust2 ', ' cust3 ', ' cust4 ', ' rotat ', ' dddER  
, ' dddIN ', ' mon ');
```

The text equivalency of each logging level, as written in the log file

- PCardinal(@LOG_LEVEL_TEXT[L][3])^ will be used for fast level matching so text must be unique for characters [3..6] -> e.g. 'UST4'

```
LOG_MAGIC = $ABA51051;
```

The "magic" number used to identify .log.synlz compressed files, as created by TSynLogFamily.EventArchiveSynLZ

```
LOG_STACKTRACE: TSynLogInfos = [sllException,sllExceptionOS,  
sllLastError,sllError,sllDDDError];
```

Contains the logging levels for which stack trace should be dumped

- which are mainly exceptions or application errors

```
LOG_TO_SYSLOG: array[TSynLogInfo] of TSyslogSeverity = ( ssDebug, ssInfo, ssDebug,  
ssDebug, ssNotice, ssWarn, ssDebug, ssDebug, ssWarn, ssErr, ssErr, ssDebug, ssDebug,  
ssNotice, ssDebug, ssDebug, ssDebug, ssDebug, ssDebug, ssDebug, ssDebug, ssDebug,  
ssDebug, ssDebug, ssDebug, ssDebug, ssDebug, ssDebug, ssNotice, ssWarn, ssInfo,  
ssDebug);
```

Used to convert a TSynLog event level into a syslog message severity

LOG_TRACEWARNING: `array[boolean] of TSynLogInfo = (sllTrace, sllWarning);`

May be used to log as Trace or Warning event, depending on an Error: boolean

LOG_VERBOSE: `TSynLogInfos = [succ(sllNone)..high(TSynLogInfo)];`

Can be set to TSynLogFamily.Level in order to log all available events

MAX_SYNLOGFAMILY = 15;

Up to 16 TSynLogFamily, i.e. TSynLog children classes can be defined

Functions or procedures implemented in the SynLog unit

Functions or procedures	Description	Page
EventArchiveDelete	A TSynLogArchiveEvent handler which will delete older .log files	1396
EventArchiveSynLZ	A TSynLogArchiveEvent handler which will compress older .log files using our proprietary SynLZ format	1397
GetLastException	Makes a thread-safe copy of the latest intercepted exception	1397
GetLastExceptions	Returns a TDocVariant array of the latest intercepted exception texts	1397
GetLastExceptions	Makes a thread-safe copy of the latest intercepted exceptions	1397
GetLastExceptionText	Returns some text about the latest intercepted exception	1397
IsActiveLogFile	Check if the supplied file name is a currently working log file	1397
SyslogMessage	Append some information to a syslog message memory buffer	1397
ToCaption	Returns the ready-to-be displayed text of a TSynLogFilter value	1397
ToCaption	Returns the ready-to-be displayed text of a TSynLogInfo value	1397
ToText	Convert low-level exception information into some human-friendly text	1398
ToText	Returns the trimmed text value of a logging levels set	1398
ToText	SllNone, sllInfo, sllDebug, sllTrace, sllWarning, sllError, sllEnter, sllLeave, sllLastError, sllException, sllExceptionOS, sllMemory, sllStackTrace, sllFail, sllSQL, sllCache, sllResult, sllDB, sllHTTP, sllClient, sllServer, sllServiceCall, sllServiceReturn, sllUserAuth, sllCustom1, sllCustom2, sllCustom3, sllCustom4, sllNewRun, sllDDDError, sllDDDDInfo, sllMonitoring); returns the trimmed text value of a logging level	1398
ToText	Returns a method event as text, using the .map/.mab information if available	1398

function EventArchiveDelete(**const** aOldLogFileName, aDestinationPath: TFileName): boolean;

A TSynLogArchiveEvent handler which will delete older .log files

function EventArchiveSynLZ(**const** aOldLogFileName, aDestinationPath: TFileName): boolean;

A TSynLogArchiveEvent handler which will compress older .log files using our proprietary SynLZ format

- resulting file will have the .synlz extension and will be located in the aDestinationPath directory, i.e. TSynLogFamily.ArchivePath+'log\YYYYMM\'
- use UnSynLZ.dpr tool to uncompress it into .log textual file
- SynLZ is much faster than zip for compression content, but proprietary

function GetLastException(**out** info: TSynLogExceptionInfo): boolean;

Makes a thread-safe copy of the latest intercepted exception

procedure GetLastExceptions(**out** result: TSynLogExceptionInfoDynArray; Depth: integer=0); overload;

Makes a thread-safe copy of the latest intercepted exceptions

function GetLastExceptions(Depth: integer=0): **variant**; overload;

Returns a TDocVariant array of the latest intercepted exception texts

- runs ToText() over all information returned by overloaded GetLastExceptions

function GetLastExceptionText: RawUTF8;

Returns some text about the latest intercepted exception

function IsActiveLogFile(**const** aFileName: TFileName): boolean;

Check if the supplied file name is a currently working log file

- may be used to avoid e.g. infinite recursion when monitoring the log file

function SyslogMessage(facility: TSyslogFacility; severity: TSyslogSeverity; **const** msg, procid, msgid: RawUTF8; destbuffer: PUTF8Char; destsize: PtrInt; trimmsgfromlog: boolean): PtrInt;

Append some information to a syslog message memory buffer

- following <https://tools.ietf.org/html/rfc5424> specifications
- ready to be sent via UDP to a syslog remote server
- returns the number of bytes written to destbuffer (which should have destsize > 127)

function ToCaption(event: TSynLogInfo): **string**; overload;

Returns the ready-to-be displayed text of a TSynLogInfo value

function ToCaption(filter: TSynLogFilter): **string**; overload;

Returns the ready-to-be displayed text of a TSynLogFilter value

function ToText(event: TSynLogInfo): RawUTF8; overload;

sllNone, sllInfo, sllDebug, sllTrace, sllWarning, sllError, sllEnter, sllLeave, sllLastError, sllException, sllExceptionOS, sllMemory, sllStackTrace, sllFail, sllSQL, sllCache, sllResult, sllDB, sllHTTP, sllClient, sllServer, sllServiceCall, sllServiceReturn, sllUserAuth, sllCustom1, sllCustom2, sllCustom3, sllCustom4, sllNewRun, sllDDDError, sllDDDInfo, sllMonitoring); returns the trimmed text value of a logging level

- i.e. 'Warning' for sllWarning

function ToText(**const** Event: TMethod): RawUTF8; overload;

Returns a method event as text, using the .map/.mab information if available

function ToText(**var** info: TSynLogExceptionInfo): RawUTF8; overload;

Convert low-level exception information into some human-friendly text

function ToText(events: TSynLogInfos): ShortString; overload;

Returns the trimmed text value of a logging levels set

Variables implemented in the *SynLog* unit

GlobalCurrentHandleExceptionSynLog: TSynLog;

Low-level variable used internally by this unit

- do not access this variable in your code: defined here to allow inlining

GlobalThreadLock: TRTLCriticalSection;

Low-level variable used internally by this unit

- do not access this variable in your code: defined here to allow inlining

TSynLogTestLog: TSynLogClass = TSynLog;

The kind of .log file generated by TSynTestsLogged

27.24. SynLZ.pas unit

Purpose: SynLZ Compression routines

- licensed under a MPL/GPL/LGPL tri-license; version 1.18

Functions or procedures implemented in the SynLZ unit

Functions or procedures	Description	Page
SynLZcompress1	Optimized x86/x64 asm version of the 1st compression algorithm	1399
SynLZcompress1pas	1st compression algorithm uses hashing with a 32bits control word	1399
SynLZcompress2	2nd compression algorithm optimizing pattern copy	1399
SynLZcompressdestlen		1399
SynLZdecompress1	Optimized x86/x64 asm version of the 1st compression algorithm	1399
SynLZdecompress1partial	1st compression algorithm uses hashing with a 32bits control word	1399
SynLZdecompress1pas	1st compression algorithm uses hashing with a 32bits control word	1400
SynLZdecompress2	2nd compression algorithm optimizing pattern copy	1400
SynLZdecompressdestlen	Get uncompressed size from lz-compressed buffer (to reserve memory, e.g.)	1400

function SynLZcompress1(src: PAnsiChar; size: integer; dst: PAnsiChar): integer;
Optimized x86/x64 asm version of the 1st compression algorithm

function SynLZcompress1pas(src: PAnsiChar; size: integer; dst: PAnsiChar): integer;
1st compression algorithm uses hashing with a 32bits control word

function SynLZcompress2(src: PAnsiChar; size: integer; dst: PAnsiChar): integer;
2nd compression algorithm optimizing pattern copy
- this algorithm is a bit smaller, but slower, so the 1st method is preferred

function SynLZcompressdestlen(in_len: integer): integer;
Get maximum possible (worse) compressed size for out_p

function SynLZdecompress1(src: PAnsiChar; size: integer; dst: PAnsiChar): integer;
Optimized x86/x64 asm version of the 1st compression algorithm

function SynLZdecompress1partial(src: PAnsiChar; size: integer; dst: PAnsiChar; maxDst: integer): integer;

1st compression algorithm uses hashing with a 32bits control word

- this overload function is slower, but will allow to uncompress only the start of the content (e.g. to read some metadata header)

- it will also check for dst buffer overflow, so will be more secure than other functions, which expect the content to be verified (e.g. via CRC)

function SynLZdecompress1pas(src: PAnsiChar; size: integer; dst: PAnsiChar): integer;

1st compression algorithm uses hashing with a 32bits control word

- this is the fastest pure pascal implementation

function SynLZdecompress2(src: PAnsiChar; size: integer; dst: PAnsiChar): integer;

2nd compression algorithm optimizing pattern copy

- this algorithm is a bit smaller, but slower, so the 1st method is preferred

function SynLZdecompressdestlen(in_p: PAnsiChar): integer;

Get uncompressed size from lz-compressed buffer (to reserve memory, e.g.)

27.25. SynLZO.pas unit

Purpose: Fast LZO Compression routines

- licensed under a MPL/GPL/LGPL tri-license; version 1.13

Functions or procedures implemented in the SynLZO unit

Functions or procedures	Description	Page
CompressSynLZO	(de)compress a data content using the SynLZO algorithm	1401
lzopas_compress	Compress in_p(in_len) into out_p	1401
lzopas_compressdestlen	Get maximum possible (worse) compressed size for out_p	1401
lzopas_decompress	Uncompress in_p(in_len) into out_p (must be allocated before call), returns out_len	1401
lzopas_decompressdestlen	Get uncompressed size from lzo-compressed buffer (to reserve memory, e.g.)	1401

```
function CompressSynLZO(var Data: AnsiString; Compress: boolean): AnsiString;
  (de)compress a data content using the SynLZO algorithm
  - as expected by THttpSocket.RegisterCompress
  - will return 'synlzo' as ACCEPT-ENCODING: header parameter
  - will store a hash of both compressed and uncompressed stream: if the data is corrupted during
    transmission, will instantly return "
```

```
function lzopas_compress(in_p: PAnsiChar; in_len: integer; out_p: PAnsiChar):
integer;
  Compress in_p(in_len) into out_p
  - out_p must be at least lzopas_compressdestlen(in_len) bytes long
  - returns compressed size in out_p
```

```
function lzopas_compressdestlen(in_len: integer): integer;
  Get maximum possible (worse) compressed size for out_p
```

```
function lzopas_decompress(in_p: PAnsiChar; in_len: integer; out_p: PAnsiChar):
Integer;
  Uncompress in_p(in_len) into out_p (must be allocated before call), returns out_len
  - may write up to out_len+3 bytes in out_p
  - the decompression mode is "fast-unsafe" -> CRC/Adler32 in_p data before call
```

```
function lzopas_decompressdestlen(in_p: PAnsiChar): integer;
  Get uncompressed size from lzo-compressed buffer (to reserve memory, e.g.)
```

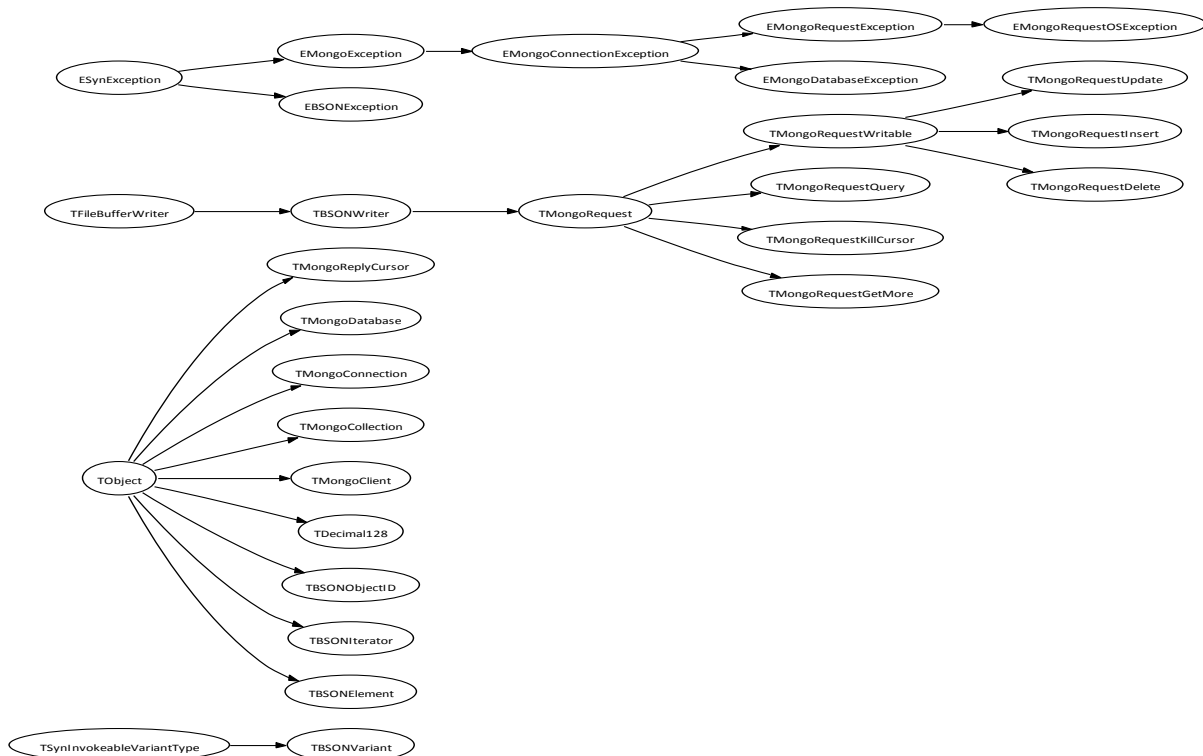

27.26. SynMongoDB.pas unit

Purpose: MongoDB document-oriented database direct access classes

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the *SynMongoDB* unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynCrtSock</i>	Classes implementing TCP/UDP/HTTP client and server protocol - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1086
<i>SynCrypto</i>	Fast cryptographic routines (hashing and cypher) - implements AES,XOR,ADLER32,MD5,RC4,SHA1,SHA256,SHA384,SHA512,SHA3 and JWT - optimized for speed (tuned assembler and SSE3/SSE4/AES-NI/PADLOCK support) - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1143
<i>SynLog</i>	Logging functions used by Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1368
<i>SynTable</i>	Filter/database/cache/buffer/security/search/multithread/OS features - as a complement to SynCommons, which tended to increase too much - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1728

SynMongoDB class hierarchy

Objects implemented in the *SynMongoDB* unit

Objects	Description	Page
EBSONException	Exception type used for BSON process	1407
EMongoConnectionException	Exception type used for MongoDB process, once connected	1441
EMongoException	Exception type used for MongoDB process	1417
EMongoRequestException	Exception type used for MongoDB query process	1441
EMongoRequestOSException	Exception type used for MongoDB query process after an Operating System error (e.g. in case of socket error)	1442
TBSON24	24-bit storage, mapped as a 3 bytes buffer	1407
TBSONElement	Data structure used during BSON binary decoding of one BSON element	1410
TBSONIterator	Data structure used for iterating over a BSON binary buffer	1413
TBSONObjectID	BSON ObjectID 12-byte internal binary representation	1407
TBSONVariant	Custom variant type used to store some special BSON elements	1409
TBSONVariantData	Memory structure used for some special BSON storage as variant	1408
TBSONWriter	Used to write the BSON context	1413

Objects	Description	Page
TDecimal128	Handles a 128-bit decimal value	1405
TDecimal128Bits	Binary representation of a 128-bit decimal, stored as 16 bytes	1404
TMongoClient	Remote access to a MongoDB server	1428
TMongoCollection	Remote access to a MongoDB collection	1432
TMongoConnection	One TCP/IP connection to a MongoDB server	1425
TMongoDatabase	Remote access to a MongoDB database	1431
TMongoReplyCursor	Map a MongoDB server reply message as sent by the database	1422
TMongoReplyHeader	Internal low-level binary structure mapping the TMongoReply header	1421
TMongoRequest	Abstract class used to create MongoDB Wire Protocol client messages	1417
TMongoRequestDelete	A MongoDB client message to delete one or more documents in a collection	1419
TMongoRequestGetMore	A MongoDB client message to continue the query of one or more documents in a collection, after a TMongoRequestQuery message	1420
TMongoRequestInsert	A MongoDB client message to insert one or more documents in a collection	1418
TMongoRequestKillCursor	A MongoDB client message to close one or more active cursors	1421
TMongoRequestQuery	A MongoDB client message to query one or more documents in a collection	1419
TMongoRequestUpdate	A MongoDB client message to update a document in a collection	1418
TMongoRequestWritable	A MongoDB client abstract ancestor which is able to create a BULK command message for MongoDB >= 2.6 instead of older dedicated Wire messages	1418
TMongoWireHeader	Internal low-level binary structure mapping all message headers	1421

TDecimal128Bits = record

Binary representation of a 128-bit decimal, stored as 16 bytes

- i.e. IEEE 754-2008 128-bit decimal floating point as used in the BSON Decimal128 format, and processed by the TDecimal128 object

TDecimal128 = object(TObject)

Handles a 128-bit decimal value

- i.e. IEEE 754-2008 128-bit decimal floating point as used in the BSON Decimal128 format, i.e. betDecimal128 TBSONElementType
- the betFloat BSON format stores a 64-bit floating point value, which doesn't have exact decimals, so may suffer from rounding or approximation
- for instance, if you work with Delphi currency values, you may store betDecimal128 values in MongoDB - the easiest way is to include it as a TBSONVariant instance, via the NumberDecimal() function
- there is no mathematical operator/methods for Decimal128 Value Objects, as required by MongoDB specifications: any computation must be done explicitly on native language value representation (e.g. currency, TBCD or any BigNumber library) - use ToCurr/FromCurr or ToText/FromText to make the appropriate safe conversions

Bits: TDecimal128Bits;

The raw binary storage

function Equals(**const** other: TDecimal128): boolean;

Fast bit-per-bit value comparison

function FromFloat(**const** value: TSynExtended; precision: integer=0): boolean;

Fills with a native floating-point value

- note that it doesn't make much sense to use this method: you should rather use the native betFloat BSON format, with native double precision
- this method is just a wrapper around ExtendedToShort and ToText, so you should provide the expected precision, from the actual storage variable (you may specify e.g. SINGLE_PRECISION or EXTENDED_PRECISION if you don't use a double kind of value)

function FromText(**const** text: RawUTF8): TDecimal128SpecialValue; overload;

Fills from the text representation of a decimal value

- returns dsvValue or one of the dsvNaN, dsvZero, dsvPosInf, dsvNegInf special value indicator otherwise on succes
- returns dsvError on parsing failure

function FromText(text: PUTF8Char; textlen: integer): TDecimal128SpecialValue; overload;

Fills from the text representation of a decimal value

- returns dsvValue or one of the dsvNaN, dsvZero, dsvPosInf, dsvNegInf special value indicator otherwise on succes
- returns dsvError on parsing failure

function FromVariant(**const** value: **variant**): boolean;

Convert a variant into one Decimal128 value

- will first check for a TBSONVariant containing a betDecimal128 (e.g. as retrieved via the ToVariant method)
- will recognize currency and VariantToInt64() stored values
- then will try to convert the variant from its string value, expecting a floating-point text content
- returns TRUE if conversion was made, FALSE on any error

function IsSpecial: TDecimal128SpecialValue;

Checks if the value matches one of the known special values
- will search for dsvNan, dsvZero, dsvPosInf, dsvNegInf, dsvMin, dsvMax

function ToCurr: currency; overload;

Converts this Decimal128 value to a fixed decimal value
- by design, some information may be lost during conversion, unless the value has been stored previously via the FromCurr() method - in this case, conversion is immediate and accurate

function ToFloat: TSynExtended;

Converts this Decimal128 value to a floating-point value
- by design, some information may be lost during conversion
- note that it doesn't make much sense to use this method: you should rather use the native betFloat BSON format, with native double precision

function ToText(out Buffer: TDecimal128Str): integer; overload;

Converts the value to its string representation
- returns the number of AnsiChar written to Buffer

function ToText: RawUTF8; overload;

Converts this Decimal128 value to its string representation

function ToVariant: variant; overload;

Convert this Decimal128 value to its TBSONVariant custom variant value

procedure AddText(W: TTextWriter);

Converts this Decimal128 value to its string representation

procedure FromCurr(const value: Currency);

Fills with a fixed decimal value, as stored in currency
- will store the content with explicitly four decimals, as in currency
- by design, this method is very fast and accurate

procedure FromInt32(value: integer);

Fills with a 32-bit signed value

procedure FromInt64(value: Int64);

Fills with a 64-bit signed value

procedure FromQWord(value: QWord);

Fills with a 64-bit unsigned value

procedure FromUInt32(value: cardinal);

Fills with a 32-bit unsigned value

procedure SetSpecial(special: TDecimal128SpecialValue);

Fills with a special value
- dsvError or dsvValue will set dsvNan binary content

procedure SetZero;

Fills with the Zero value
- note: under IEEE 754, Zero can have sign and exponents, so is not Hi=Lo=0
- is the same as Fill(dsvZero)

procedure ToCurr(**out** result: currency); overload;

Converts this Decimal128 value to a fixed decimal value

- by design, some information may be lost during conversion, unless the value has been stored previously via the FromCurr() method - in this case, conversion is immediate and accurate

procedure ToText(**var** result: RawUTF8); overload;

Converts this Decimal128 value to its string representation

procedure ToVariant(**out** result: variant); overload;

Convert this Decimal128 value to its BSONVariant custom variant value

EBSONException = **class**(ESynException)

Exception type used for BSON process

TBSON24 = **record**

24-bit storage, mapped as a 3 bytes buffer

- as used for TBSONObjectID.MachineID and TBSONObjectID.Counter

TBSONObjectID = **object**(TObject)

BSON ObjectID 12-byte internal binary representation

- in MongoDB, documents stored in a collection require a unique _id field that acts as a primary key: by default, it uses such a 12-byte ObjectID

- by design, sorting by _id: ObjectID is roughly equivalent to sorting by creation time, so ease sharding and BTREE storage

- in our ODM, we rather use 64-bit genuine integer identifiers (TID), as computed by an internal sequence or TSynUniqueIdentifierGenerator

- match betObjectID TBSONElementType

Counter: TBSON24;

3-byte counter, starting with a random value

- used to avoid collision

MachineID: TBSON24;

3-byte machine identifier

- ComputeNew will use a hash of ExeVersion.Host and ExeVersion.User

ProcessID: word;

2-byte process id

- ComputeNew will derivate it from MainThreadID

UnixCreateTime: cardinal;

Big-endian 4-byte value representing the seconds since the Unix epoch

- time is expressed in Coordinated Universal Time (UTC), not local time

function CreateDateTime: TDateTime;

Returns the timestamp portion of the ObjectId() object as a Delphi date

- time is expressed in Coordinated Universal Time (UTC), not local time so you can compare it to NowUTC returned time

function Equal(**const** Another: TBSONObjectID): boolean; overload;

Compare two Object IDs

function Equal(const Another: variant): boolean; overload;

Compare two Object IDs, the second being stored in a TBSONVariant

function FromText(Text: PUTF8Char): boolean; overload;

Convert an hexadecimal string value into one ObjectID

- returns TRUE if conversion was made, FALSE on any error

function FromText(const Text: RawUTF8): boolean; overload;

Convert an hexadecimal string value into one ObjectID

- returns TRUE if conversion was made, FALSE on any error

function FromVariant(const value: variant): boolean;

Convert a variant into one ObjectID

- will first check for a TBSONVariant containing a betObjectID

- then will try to convert the variant from its string value, expecting an hexadecimal text content

- returns TRUE if conversion was made, FALSE on any error

function ToText: RawUTF8; overload;

Convert this ObjectID to its hexadecimal string value

function ToVariant: variant; overload;

Convert this ObjectID to its TBSONVariant custom variant value

procedure ComputeNew;

ObjectID content be filled with some unique values

- this implementation is thread-safe

procedure Init;

Set all internal fields to zero

procedure ToText(var result: RawUTF8); overload;

Convert this ObjectID to its hexadecimal string value

procedure ToVariant(var result: variant); overload;

Convert this ObjectID to its TBSONVariant custom variant value

TBSONVariantData = packed record

Memory structure used for some special BSON storage as variant

- betObjectID kind will store a TBSONObjectID

- betBinary kind will store a BLOB content as RawByteString

- betDoc and betArray kind will store a BSON document, in its original binary format as RawByteString (TBSONDocument)

- betDeprecatedDbptr, betJSScope, betTimestamp and betRegEx will store the raw original BSON content as RawByteString

- betJS and betDeprecatedSymbol will store the UTF-8 encoded string as a RawUTF8

- betDeprecatedUndefined or betMinKey/betMaxKey do not contain any data

- betDecimal128 will store the TDecimal128 16 bytes binary buffer

- warning: VBlob/VText use should match BSON_ELEMENTVARIANTMANAGED constant

VBlob: pointer;

Store the raw binary content as a RawByteString (or TBSONDocument for betDoc/betArray, i.e. the "int32 e_list #0" standard layout)

- you have to use RawByteString(VBlob) when accessing this field
- e.g. for betRegEx, it will contain raw [cstring cstring] content

VFiller: array[1..SizeOf(TVarData)-SizeOf(TVarType)-SizeOf(TBSONElementType)-SizeOf(TBSONObjectID)] of byte;

Does not complain if Filler is declared but never used

VKind: TBSONElementType

The kind of element stored

VText: pointer;

Store here a RawUTF8 with the associated text

- you have to use RawUTF8(VText) when accessing this field

VType: TVarType;

The variant type

TBSONVariant = class(TSynInvokeableVariantType)

Custom variant type used to store some special BSON elements

- internal layout will follow TBSONVariantData
- handled kind of item are complex BSON types, like betObjectID, betBinary or betDoc/betArray
- it will allow conversion to/from string (and to date for ObjectID)

function IsOfKind(const V: variant; Kind: TBSONElementType): boolean;

Returns TRUE if the supplied variant stores the supplied BSON kind of value

function ToBlob(const V: Variant; var Blob: RawByteString): boolean;

Retrieve a betBinary content stored in a TBSONVariant instance

- returns TRUE if the supplied variant is a betBinary, and set the binary value into the supplied Blob variable
- returns FALSE otherwise

function TryJSONToVariant(var JSON: PUTF8Char; var Value: variant; EndOfObject: PUTF8Char): boolean; override;

Customization of JSON conversion into TBSONVariant kind of variants

procedure Cast(var Dest: TVarData; const Source: TVarData); override;

Handle type conversion

- only types processed by now are string/OleStr/UnicodeString/date

procedure CastTo(var Dest: TVarData; const Source: TVarData; const AVarType: TVarType); override;

Handle type conversion

- only types processed by now are string/OleStr/UnicodeString/date

procedure Clear(var V: TVarData); override;

Clear the instance

```
procedure Compare(const Left, Right: TVarData; var Relationship:  
TVarCompareResult); override;
```

Compare two variant values

- handle comparison of any variant, including TBSONVariant, via a temporary JSON conversion, and case-sensitive comparison
- it uses case-sensitive text (hexadecimal) comparison for betObjectID

```
procedure Copy(var Dest: TVarData; const Source: TVarData; const Indirect: Boolean);  
override;
```

Copy one instance

```
procedure FromBinary(const Bin: RawByteString; BinType: TBSONElementBinaryType; var  
result: variant);
```

Convert a BLOB binary content into a TBSONVariant of kind betBinary

- if Bin is "", will store a NULL variant

```
procedure FromBSONDocument(const BSONDoc: TBSONDocument; var result: variant; Kind:  
TBSONElementType=betDoc);
```

Convert a TBSONDocument binary content into a TBSONVariant of kind betDoc or betArray

- see also all BSONVariant() overloaded functions, which also create a TBSONVariant betDoc instance

```
procedure FromJSON(json: PUTF8Char; var result: variant);
```

Convert a JSON content into a TBSONVariant of kind betDoc or betArray

- warning: the supplied JSON buffer will be modified in-place
- will create a plain variant value if the JSON doesn't start with [or {

```
procedure ToJSON(W: TTextWriter; const Value: variant; Escape: TTextWriterKind);  
override;
```

Variant serialization will use modMongoStrict JSON-compatible mode

```
property NewDoc[const BSONDoc: TBSONDocument]: variant read GetNewDoc;
```

Convert a TBSONDocument binary content into a TBSONVariant of kind betDoc

- is the default property, so that you can write:

```
BSONVariantType[BSON(['BSON',_Arr(['awesome',5.05, 1986]))]]
```

- see also all BSONVariant() overloaded functions, which also create a TBSONVariant betDoc instance

```
TBSONElement = object(TObject)
```

Data structure used during BSON binary decoding of one BSON element

- will be retrieved by FromVariant() or FromNext()
- see <http://bsonspec.org/#/specification>
- this structure has been optimized to map the BSON binary content, without any temporary memory allocation (the SAX way)

```
Data: record
```

Depending on the Kind, will point to parsed complex sub-data

- since variable records can't have properties, we nest this information within this main Data variable record
- not all Kind are handled here, only any complex data

Element: pointer;

Pointer to the BSON element value

- is the raw value, without any parsing, e.g. points to a double value or a document: "int32 e_list #0" standard layout (same as TBSONDocument)
- you may cast it for simple types:

PDouble(Element)^	PBoolean(Element)^	PInteger(Element)^
PInt64(Element)^	PBSONObjectID(Element)^	PDecimal128(Element)^
- or use the nested Data variant record to access more complex content
- warning: equals nil for betString/betJS after FromVariant()

ElementBytes: integer;

Number of bytes in the BSON element

- will include the trailing #0 for string element

Index: integer;

Index of this element in the original sequence list

- is correct only when the element has been reset before the parsing loop, e.g.:

```
item.Index := -1; // so item.Index will count starting at 0
while item.FromNext(elem.Document) do
  writeln(item.Index, ' ', Item.Name, ' ', Item.ValueBytes);
```

Kind: TBSONElementType;

The element type

Name: UTF8Char;

The UTF-8 encoded name of this element

NameLen: integer;

The name length (in chars) of this element

function DocItemToInteger(const aName: RawUTF8; const default: Int64=0): Int64;

Search an integer property value within the BSON element as document

- returns the value if aName has been found as property in the BSON element
- returns default if aName was not found, or if Kind is not betDoc or betArray

function DocItemToRawUTF8(const aName: RawUTF8): RawUTF8;

Search an UTF-8 property value within the BSON element as document

- returns the value if aName has been found as property in the BSON element
- returns "" if aName was not found, or if Kind is not betDoc or betArray

function DocItemToVariant(const aName: RawUTF8; var aValue: variant;
 DocArrayConversion: TBSONDocArrayConversion=asBSONVariant): boolean;

Search a variant property value within the BSON element as document

- returns true if aName has been found as property in the BSON element, and fills aValue with the corresponding value
- returns false if aName was not found, or if Kind is not betDoc or betArray

function FromDocument(**const** doc: TBSONDocument): boolean;

Fill a BSON Element structure from a BSON document

- will check the document length then set Kind := betDoc and Data.DocList
- will return TRUE if the supplied doc has a valid length, FALSE otherwise
- you can later on use DocItemToVariant, DocItemToRawUTF8 or DocItemToInteger methods
- the supplied "doc" variable should remain available until you are done with this TBSONElement wrapper

function FromNext(**var** BSON: PByte): boolean;

Fill a BSON Element structure from a BSON encoded binary buffer list

- parse the next BSON element: BSON parameter should point to the "e_list" of the "int32 e_list #0" BSON document
- will decode the supplied binary buffer into the BSON element structure, then it will let BSON point to the next element, and return TRUE
- returns FALSE when you reached betEOF, so that you can use it in a loop, and retrieve all the content as consecutive events, without any memory allocation (the SAX way):

```
var bson: PByte;
    item: TBSONElement;
...
BSONParseLength(bson);
while item.FromNext(bson) do
  writeln(item.Name);
```

- will raise an EBSONException if BSON content is not correct
- as an alternative, consider using TBSONIterator, which wrap both a PByte and a TBSONElement into one convenient item

function FromSearch(BSON: PByte; **const** aName: RawUTF8): boolean;

Search for a given name in a BSON encoded binary buffer list

- BSON parameter should point to the first "e_list" item of the "int32 e_list #0" BSON document
- returns false if the item was not found (with case-insensitive search)
- otherwise returns TRUE and the matching element content has been decoded within this TBSONElement structure

function ToInteger(**const** default: Int64=0): Int64;

Convert a BSON element into an integer value

- will work only for betBoolean/betInt32/betInt64 types
- any other kind of values will return the supplied default value

function ToRawUTF8: RawUTF8;

Convert a BSON element into an UTF-8 string

- any complex types (e.g. nested documents) will be converted via a variant

function ToVariant(DocArrayConversion: TBSONDocArrayConversion=asBSONVariant):
variant; overload;

Convert a BSON element, as retrieved by TBSONElement.FromNext(), into a variant

- it will return either standard variant values, or TBSONVariant custom type for most complex kind of elements (see TBSONVariantData type definition)
- note that betString types will be stored as RawUTF8 varString
- by default, it will return TBSONVariant custom variants for documents or arrays - but if storeDocArrayAsDocVariant is set, it will return a TDocVariant custom kind of variant, able to access to its nested properties via late-binding

procedure AddMongoJSON(W: TTextWriter; Mode: TMongoJSONMode=modMongoStrict);
overload;

Convert a BSON element, as retrieved by TBSONElement.FromNext(), into its JSON representation
- this method will use by default the MongoDB Extended JSON syntax for specific MongoDB objects but you may use modMongoShell if needed
- will raise an EBSONException if element is not correct

procedure FromVariant(const aName: RawUTF8; const aValue: Variant; var aTemp: RawByteString);

Fill a BSON Element structure from a variant content and associated name
- perform the reverse conversion as made with ToVariant()
- since the result won't store any data but points to the original binary content, the supplied Name/Value instances should remain available as long as you will access to the result content
- aName here is just for conveniency, and could be left void
- supplied aTemp variable will be used for temporary storage, private to this initialized TBSONElement

procedure ToVariant(var result: variant; DocArrayConversion: TBSONDocArrayConversion=asBSONVariant); overload;

Convert a BSON element, as retrieved by TBSONElement.FromNext(), into a variant
- same as the other ToVariant() overloaded function, but avoiding a copy of the resulting variant

TBSONIterator = **object**(TObject)

Data structure used for iterating over a BSON binary buffer
- is just a wrapper around a PByte value, to be used with a TBSONDocument

Item: TBSONElement;

Map the current item, after the Next method did return TRUE
- map the global document, after Init() but before the first Next call

function Init(const doc: TBSONDocument; kind: TBSONElementType=betArray): boolean;

Initialize the iteration on the supplied BSON document
- will check the document length and returns TRUE if it is correct
- only accepted kind are betDoc and betArray (but not used later)
- you can then use the Next method to iterate over the Item elements
- after this call, the Item property map to the global BSON document (note that after any call to the Next method, Item will map the current iterated value, and not the global BSON document any more)

function Next: boolean;

Will iterate on the BSON document
- returns TRUE if the item has been retrieved into the Item property
- returns FALSE if we reached the end of the supplied BSON buffer

TBSONWriter = **class**(TFileBufferWriter)

Used to write the BSON context

function BSONWriteDocFromJSON(JSON: PUTF8Char; aEndOfObject: PUTF8Char; out Kind: TBSONElementType; DoNotTryExtendedMongoSyntax: boolean=false): PUTF8Char;

Write some BSON document from a supplied (extended) JSON array or object

- warning: the incoming JSON buffer will be modified in-place: so you should make a private copy before running this method (see e.g. TSynTempBuffer)

- will handle only '{ ... }', '[...]' or 'null' input, with the standard strict JSON format, or BSON-like extensions, e.g. unquoted field names:

```
{id:10,doc:{name:"John",birthyear:1972}}
```

- if DoNotTryExtendedMongoSyntax is default FALSE, then the MongoDB Shell syntax will also be recognized to create BSON custom types, like

```
new Date() ObjectId() MinKey MaxKey /<jRegex>/<jOptions>
```

see @<http://docs.mongodb.org/manual/reference/mongodb-extended-json>

```
{id:new ObjectId(),doc:{name:"John",date:ISODate()}}
```

```
{name:"John",field:/acme.*corp/i}
```

- if DoNotTryExtendedMongoSyntax is TRUE, process may be slightly faster

- will create the BSON binary without any temporary TDocVariant storage

function BSONWriteQueryOperator(name: RawUTF8; inverted: boolean; operator: TSynTableStatementOperator; const Value: variant): boolean;

Write an object as query parameter

- will handle all SQL operators, including IN (), IS NULL or LIKE

- see @<http://docs.mongodb.org/manual/reference/operator/query>

- inverted should be TRUE e.g. for a NOT ... expression

- returns TRUE on success, FALSE if the operator is not implemented yet

procedure BSONAdjustDocumentsSize(BSON: PByteArray); virtual;

After all content has been written, call this method on the resulting memory buffer to store all document size as expected by the standard

procedure BSONDocumentBegin(const name: RawUTF8; kind: TBSONElementType=betDoc); overload;

To be called before a BSON document will be written

- each BSONDocumentBegin should be followed by its nested BSONDocumentEnd

- you could create a new BSON object by specifying a name and its type, i.e. either betDoc or betArray

procedure BSONDocumentBegin; overload;

To be called before a BSON document will be written

- each BSONDocumentBegin should be followed by its nested BSONDocumentEnd

procedure BSONDocumentBeginInArray(const name: RawUTF8; kind: TBSONElementType=betDoc);

To be called before a BSON document will be written in an array

- only one level of array should be used per TBSONWriter class

procedure BSONDocumentEnd(CloseNumber: integer=1; WriteEndingZero: boolean=true);

To be called when a BSON document has been written

- it will store the current stream position into an internal array, which will be written when you call AdjustDocumentsSize()

- you can optional specify how many nested documents should be closed, and/or if it should not write an ending betEof item

procedure BSONWrite(**const** name: RawUTF8; **const** bson: TBSONVariantData); overload;
Write a BSONVariant instance value

procedure BSONWrite(**const** name: RawUTF8; **const** elem: TBSONElement); overload;
Write an element with no value

procedure BSONWrite(**const** name: RawUTF8; **const** doc: TDocVariantData); overload;
Write a DocVariant instance value

procedure BSONWrite(**const** name: RawUTF8; **const** value: TVarRec); overload;
Write an open array (const Args: array of const) argument
- handle simple types (numbers, strings...) and custom types (TDocVariant)

procedure BSONWrite(**const** name: RawUTF8; **const** value: TDecimal128); overload;
Write a TDecimal128 value

procedure BSONWrite(**const** name: RawUTF8; elemtype: TBSONElementType); overload;
Write an element with no value
- elemType can be either betNull, betMinKey or betMaxKey

procedure BSONWrite(**const** name: RawUTF8; **const** value: Int64); overload;
Write a 64 bit integer value

procedure BSONWrite(**const** name: RawUTF8; value: PUTF8Char); overload;
Write a string (UTF-8) value from a memory buffer

procedure BSONWrite(**const** name: RawUTF8; **const** value: RawUTF8; isJavaScript: boolean=false); overload;
Write a string (UTF-8) value

procedure BSONWrite(**const** name: RawUTF8; **const** value: integer); overload;
Write a 32 bit integer value

procedure BSONWrite(**const** name: RawUTF8; **const** value: Double); overload;
Write a floating point value

procedure BSONWrite(**const** name: RawUTF8; **const** value: boolean); overload;
Write a boolean value

procedure BSONWrite(**const** name: RawUTF8; **const** value: TBSONObjectID); overload;
Write an ObjectID value

procedure BSONWrite(**const** name: RawUTF8; Data: pointer; DataLen: integer); overload;
Write a binary (BLOB) value

procedure BSONWriteArray(**const** Items: array of **const**); overload;

Write an array specified as a list of items as a BSON document

- data must be supplied as a list of values e.g.

aBSONWriter.BSONWriteArray(['John',1972]);

- this method will be faster than using a BSONWriteDoc(_ArrFast(...))

procedure BSONWriteArray(**const** kind: TBSONElementType); overload;

Write one array item, i.e. the ASCII index name as text

- only one level of array should be used per TBSONWriter class

procedure BSONWriteArrayOfInt64(**const** Integers: **array of** Int64);

Write an array of integers as a BSON Document

procedure BSONWriteArrayOfInteger(**const** Integers: **array of** integer);

Write an array of integers as a BSON Document

procedure BSONWriteDateTime(**const** name: RawUTF8; **const** value: TDateTime);

Write a data/time value

procedure BSONWriteDoc(**const** doc: TDocVariantData);

Recursive writing of a BSON document or value from a TDocVariant object or array, used e.g. by BSON(const doc: TDocVariantData) function

- caller should execute BSONAdjustDocumentsSize() on the resulting buffer
- this method will call BSONDocumentBegin/BSONDocumentEnd internally
- will raise an EBSONException if doc is not a valid TDocVariant or null or if the resulting binary content is bigger than BSON_MAXDOCUMENTSIZE

procedure BSONWriteFromJSON(**const** name: RawUTF8; **var** JSON: PUTF8Char; EndOfObject: PUTF8Char; DoNotTryExtendedMongoSyntax: **boolean**=false);

Write a value from the supplied JSON content

- is able to handle any kind of values, including nested documents or BSON extended syntax (if DoNotTryExtendedMongoSyntax=false)
- this method is used recursively by BSONWriteDocFromJSON(), and should not be called directly
- will return JSON=nil in case of unexpected error in the supplied JSON

procedure BSONWriteObject(**const** NameValuePairs: **array of const**);

Write an object specified as name/value pairs as a BSON document

- data must be supplied two by two, as Name,Value pairs, e.g.
aBSONWriter.BSONWriteObject(['name', 'John', 'year', 1972]);

- this method will be faster than using a BSONWriteDoc(_ObjFast(...))

procedure BSONWriteProjection(**const** FieldNamesCSV: RawUTF8);

Write a projection specified as fieldname:1 pairs as a BSON document

procedure BSONWriteRegEx(**const** name: RawUTF8; **const** RegEx,Options: RawByteString);

Write a RegEx value

procedure BSONWriteString(**const** name: RawUTF8; value: PUTF8Char; valueLen: integer);

Write a string (UTF-8) value from a memory buffer

procedure BSONWriteVariant(**const** name: RawUTF8; **const** value: **variant**); overload;

Write a variant value

- handle simple types (numbers, strings...) and custom types (TDocVariant and TBSONVariant, trying a translation to JSON for other custom types)

procedure CancelAll; **override**;

Rewind the Stream to the position when Create() was called

- this will also reset the internal document offset table

procedure ToBSONDocument(**var** result: TBSONDocument); **virtual**;

Flush the content and return the whole binary encoded stream

- call BSONAdjustDocumentsSize() to adjust all internal document sizes
- expect the TBSONWriter instance to have been created as such:
TBSONWriter.Create(TRawByteStringStream);

procedure ToBSONVariant(**var** result: **variant**; Kind: TBSONElementType=betDoc);

Flush the content and return the whole document as a TBSONVariant

- call ToBSONDocument() to adjust all internal document sizes
- expect the TBSONWriter instance to have been created as such:
TBSONWriter.Create(TRawByteStringStream);

EMongoException = **class**(ESynException)

Exception type used for MongoDB process

TMongoRequest = **class**(TBSONWriter)

Abstract class used to create MongoDB Wire Protocol client messages

- see <http://docs.mongodb.org/meta-driver/latest/legacy/mongodb-wire-protocol>
- this class is not tight to the connection class itself (which is one known limitation of TMongoWire for instance)

constructor Create(**const** FullCollectionName: RawUTF8; opCode: TMongoOperation; requestID, responseTo: integer); **reintroduce**;

Write a standard Message Header for MongoDB client

- opCode is the type of the message
- requestID is a client or database-generated identifier that uniquely identifies this message: in case of opQuery or opGetMore messages, it will be sent in the responseTo field from the database
- responseTo is the requestID taken from previous opQuery or opGetMore

function ToJSON(Mode: TMongoJSONMode): RawUTF8; **overload**;

Write the main parameters of the request as JSON

procedure BSONWriteParam(**const** paramDoc: **variant**);

Append a query parameter as a BSON document

- param can be a TDocVariant, e.g. created with:
_JsonFast(' {name:"John",age:{\$gt:21}} ');
_JsonFastFmt(' {name:?,age:{\$gt:??}} ', [], ['John', 21]);
_JsonFastFmt(' {name:?,field:/%/i}', ['acme.*corp'], ['John']);
- param can be a TBSONVariant containing a TBSONDocument raw binary block created e.g. from:

```
BSONVariant(['BSON',_Arr(['awesome',5.05, 1986])])
BSONVariantType[BSON(['BSON',_Arr(['awesome',5.05, 1986])])]
```

- if param is null, it will append a void document
- if param is a string, it will be converted as expected by most database commands, e.g.
TMongoRequestQuery.Create('admin.\$cmd','buildinfo',[],1)

will query { buildinfo: 1 } to the admin.\$cmd collection, i.e.
admin.\$cmd.findOne({ buildinfo: 1 })

procedure ToBSONDocument(**var** result: TBSONDocument); **override**;

Flush the content and return the whole binary encoded stream

- expect the TBSONWriter instance to have been created with reintroduced Create() specific constructors inheriting from this TMongoRequest class
- this overridden version will adjust the size in the message header

procedure ToJSON(W: TTextWriter; Mode: TMongoJSONMode); **overload**; **virtual**;

Write the main parameters of the request as JSON

property CollectionName: RawUTF8 **read** fCollectionName;

The associated full collection name, e.g. 'test'

property DatabaseName: RawUTF8 **read** fDatabaseName;

The associated full collection name, e.g. 'db'

property FullCollectionName: RawUTF8 **read** fFullCollectionName;

The associated full collection name, e.g. 'db.test'

property MongoRequestID: integer **read** fRequestID;

Identify the message, after call to any reintroduced Create() constructor

property MongoRequestOpCode: TMongoOperation **read** fRequestOpCode;

The message operation code

- should be either opUpdate, opInsert, opQuery, opGetMore, opDelete or opKillCursors, depending on the TMongoRequest* class instantiated

TMongoRequestWritable = **class**(TMongoRequest)

A MongoDB client abstract ancestor which is able to create a BULK command message for MongoDB >= 2.6 instead of older dedicated Wire messages

TMongoRequestUpdate = **class**(TMongoRequestWritable)

A MongoDB client message to update a document in a collection

constructor Create(**const** FullCollectionName: RawUTF8; **const** Selector, Update: **variant**; Flags: TMongoUpdateFlags=[]); **reintroduce**;

Initialize a MongoDB client message to update a document in a collection

- FullCollectionName is e.g. 'dbname.collectionname'
- how the update will be processed can be customized via Flags
- Selector is the BSON document query to select the document, supplied as TDocVariant - i.e. created via _JsonFast() or _JsonFastFmt() - or as TBSONVariant - i.e. created via BSONVariant() - or null if all documents are to be updated
- Update is the BSON document specification of the update to perform, supplied as TDocVariant or TBSONVariant
- there is no response to an opUpdate message

procedure ToJSON(W: TTextWriter; Mode: TMongoJSONMode); **override**;

Write the main parameters of the request as JSON

TMongoRequestInsert = **class**(TMongoRequestWritable)

A MongoDB client message to insert one or more documents in a collection

constructor Create(const FullCollectionName: RawUTF8; const JSONDocuments: array of PUTF8Char; Flags: TMongoInsertFlags=[]); reintroduce; overload;

Initialize a MongoDB client message to insert one or more documents in a collection, supplied as JSON objects

- FullCollectionName is e.g. 'dbname.collectionname'
- JSONDocuments is an array of JSON objects
- there is no response to an opInsert message
- warning: JSONDocuments[] buffer will be modified in-place during parsing, so a private copy may have to be made by the caller

constructor Create(const FullCollectionName: RawUTF8; const Documents: TBSONDocument; Flags: TMongoInsertFlags=[]); reintroduce; overload;

Initialize a MongoDB client message to insert one or more documents in a collection, supplied as raw BSON binary

- FullCollectionName is e.g. 'dbname.collectionname'
- Documents is the low-level concatenation of BSON documents, created e.g. with a TBSONWriter stream
- there is no response to an opInsert message

constructor Create(const FullCollectionName: RawUTF8; const Documents: array of variant; Flags: TMongoInsertFlags=[]); reintroduce; overload;

Initialize a MongoDB client message to insert one or more documents in a collection, supplied as variants

- FullCollectionName is e.g. 'dbname.collectionname'
- Documents is an array of TDocVariant or TBSONVariant - i.e. created via _JsonFast() _JsonFastFmt() or BSONVariant()
- there is no response to an opInsert message

TMongoRequestDelete = class(TMongoRequestWritable)

A MongoDB client message to delete one or more documents in a collection

constructor Create(const FullCollectionName: RawUTF8; const Selector: variant; Flags: TMongoDeleteFlags=[]); reintroduce;

Initialize a MongoDB client message to delete one or more documents in a collection

- FullCollectionName is e.g. 'dbname.collectionname'
- Selector is the BSON document query to select the document, supplied as TDocVariant - i.e. created via _JsonFast() or _JsonFastFmt() - or as TBSONVariant - i.e. created via BSONVariant() - or null if all documents are to be deleted
- warning: CreateDelete('db.coll',null) can be expensive so you should better drop the whole collection
- there is no response to an opDelete message

procedure ToJSON(W: TTextWriter; Mode: TMongoJSONMode); override;

Write the main parameters of the request as JSON

TMongoRequestQuery = class(TMongoRequest)

A MongoDB client message to query one or more documents in a collection

constructor Create(const FullCollectionName: RawUTF8; const Query, ReturnFieldsSelector: variant; NumberToReturn: integer; NumberToSkip: integer=0; Flags: TMongoQueryFlags=[]); **reintroduce**;

Initialize a MongoDB client message to query one or more documents in a collection from a specified Cursor identifier

- FullCollectionName is e.g. 'dbname.collectionname'
 - Query is the BSON document query to select the document, supplied as TDocVariant - i.e. created via _JsonFast() or _JsonFastFmt() - or null if all documents are to be retrieved - for instance:

```
_JsonFast('{name:"John",age:{$gt:21}}');
_JsonFastFmt('{name:?,age:{$gt:??}}',[,]['John',21]);
_JsonFastFmt('{name:?,field:/%/i}',[ 'acme.*corp' ],[ 'John' ]);
```

- if Query is a string, it will be converted as expected by most database commands, e.g.
 TMongoRequestQuery.Create('admin.\$cmd','buildinfo',[,],1)

will query { buildinfo: 1 } to the admin.\$cmd collection, i.e.
 admin.\$cmd.findOne({ buildinfo: 1 })

- Query can also be a TBSONVariant, e.g. created with:
 BSONVariant('{name:?,age:{\$gt:??}}',[,]['John',21])

- ReturnFieldsSelector is an optional selector (set to null if not applicable) as a BSON document that limits the fields in the returned documents, supplied as TDocVariant or TBSONVariant - e.g. created via:

```
BSONVariantFieldSelector('a,b,c');
BSONVariantFieldSelector(['a','b','c']);
BSONVariant('{a:1,b:1,c:1}');
_JsonFast('{a:1,b:1,c:1}');
```

- if ReturnFieldsSelector is a string, it will be converted into
 { ReturnFieldsSelector: 1 }

procedure ToJSON(W: TTextWriter; Mode: TMongoJSONMode); **override**;

Write the main parameters of the request as JSON

property NumberToReturn: integer **read** fNumberToReturn;

Retrieve the NumberToReturn parameter as set to the constructor

property NumberToSkip: integer **read** fNumberToSkip;

Retrieve the NumberToSkip parameter as set to the constructor

TMongoRequestGetMore = **class**(TMongoRequest)

A MongoDB client message to continue the query of one or more documents in a collection, after a TMongoRequestQuery message

constructor Create(const FullCollectionName: RawUTF8; NumberToReturn: integer; CursorID: Int64); **reintroduce**;

Initialize a MongoDB client message to continue the query of one or more documents in a collection, after a opQuery / TMongoRequestQuery message

- FullCollectionName is e.g. 'dbname.collectionname'
 - you can specify the number of documents to return (e.g. from previous opQuery response)
 - CursorID should have been retrieved within an opReply message from the database

TMongoRequestKillCursor = class(TMongoRequest)

A MongoDB client message to close one or more active cursors

constructor Create(const FullCollectionName: RawUTF8; const CursorIDs: array of Int64); reintroduce;

Initialize a MongoDB client message to close one or more active cursors in the database

- it is mandatory to ensure that database resources are reclaimed by the client at the end of the query
- if a cursor is read until exhausted (read until opQuery or opGetMore returns zero for the CursorId), there is no need to kill the cursor
- there is no response to an opKillCursor message

procedure ToJSON(W: TTextWriter; Mode: TMongoJSONMode); override;

Write the main parameters of the request as JSON

TMongoWireHeader = packed record

Internal low-level binary structure mapping all message headers

MessageLength: integer;

Total message length, including the header

OpCode: integer;

Low-level code of the message

- GetReply() will map it to a high-level TMongoOperation

RequestID: integer;

Identifier of this message

ResponseTo: integer;

Retrieve the RequestID from the original request

TMongoReplyHeader = packed record

Internal low-level binary structure mapping the TMongoReply header

- used e.g. by TMongoReplyCursor and TMongoConnection.GetReply()

CursorID: Int64;

Cursor identifier if the client may need to perform further opGetMore

Header: TMongoWireHeader;

Standard message header

NumberReturned: integer;

Number of documents in the reply

ResponseFlags: integer;

Response flags

StartingFrom: integer;

Where in the cursor this reply is starting

TMongoReplyCursor = object(TObject)

Map a MongoDB server reply message as sent by the database

- in response to TMongoRequestQuery / TMongoRequestGetMore messages
- you can use the record's methods to retrieve information about a given response, and navigate within all nested documents
- several TMongoReplyCursor instances may map the same TMongoReply content
- you can safely copy one TMongoReplyCursor instance to another

function AppendAllToDocVariant(**var** Dest: TDocVariantData): integer;

Append all documents content to a TDocVariant array instance

- if the supplied instance is not already a TDocVariant of kind dvArray, a new void instance will be created
- return the new size of the Dest array

function AppendAllToDocVariantDynArray(**var** Dest: TVariantDynArray): integer;

Append all documents content to a dynamic array of TDocVariant

- return the new size of the Dest[] array

function Next(**out** JSON: RawUTF8; Mode: TMongoJSONMode=modMongoStrict): boolean; overload;

Retrieve the next document in the list, as JSON content

- return TRUE if the supplied document has been retrieved
- return FALSE if there is no more document to get - you can use the Rewind method to restart from the first document
- could be used e.g. as:

```
var Reply: TMongoReply;
    json: RawUTF8;
...
Reply.Init(ResponseMessage);
while Reply.Next(json,modMongoShell) do
  writeln(json); // fast display
```

function Next(**out** BSON: TBSONDocument): boolean; overload;

Retrieve the next document in the list, as a BSON binary document

- return TRUE if the supplied document has been retrieved - then doc points to a "int32 e_list #0" BSON document
- return FALSE if there is no more document to get - you can use the Rewind method to restart from the first document
- this method is slightly slower than the one returning a PByte, since it will allocate a memory buffer to store the TBSONDocument binary
- could be used e.g. as:

```
var Reply: TMongoReply;
    doc: TBSONDocument;
...
Reply.Init(ResponseMessage);
while Reply.Next(doc) do
  writeln(BSONToJSON(doc,0,modMongoShell)); // fast display
```

```
function Next(out doc: variant; option:
TBSONDocArrayConversion=asDocVariantPerReference): boolean; overload;
```

Retrieve the next document in the list, as a TDocVariant instance

- return TRUE if the supplied document has been retrieved
- return FALSE if there is no more document to get - you can use the Rewind method to restart from the first document

- could be used e.g. as:

```
var Reply: TMongoReply;
    doc: variant;
...
Reply.Init(ResponseMessage);
while Reply.Next(doc) do
  writeln('Name: ',doc.Name, ' FirstName: ',doc.FirstName);
```

```
function Next(out doc: PByte): boolean; overload;
```

Retrieve the next document in the list, as BSON content

- return TRUE if the supplied document has been retrieved - then doc points to a "int32 e_list #0" BSON document
- return FALSE if there is no more document to get - you can use the Rewind method to restart from the first document
- this method is almost immediate, since the BSON raw binary is returned directly without any conversion

- could be used e.g. as:

```
var Reply: TMongoReply;
    doc: PByte;
...
Reply.Init(ResponseMessage);
while Reply.Next(doc) do
  writeln(BSONToJSON(doc,0,modMongoShell)); // fast display
```

```
function ToJSON(Mode: TMongoJSONMode=modMongoStrict; WithHeader: boolean=false;
MaxSize: Cardinal=0): RawUTF8;
```

Return all documents content as a JSON array, or one JSON object if there is only one document in this reply

- this method is very optimized and will convert the BSON binary content directly into JSON

```
procedure AppendAllToBSON(Dest: TBSONWriter);
```

Append all documents content to a BSON binary stream

- Dest.Tag will be used to count the current item number in the resulting BSON array

```
procedure FetchAllToJSON(W: TTextWriter; Mode: TMongoJSONMode=modMongoStrict;
WithHeader: boolean=false; MaxSize: Cardinal=0);
```

Return all documents content as a JSON array, or one JSON object if there is only one document in this reply

- this method is very optimized and will convert the BSON binary content directly into JSON

procedure GetDocument(index: integer; var result: variant);

Retrieve a given document as a TDocVariant instance

- this method won't use any cache (like Document[..] property), since it should be used with a local variant on stack as cache:

```
var Reply: TMongoReply;
doc: variant;
i: integer;
...
Reply.Init(ResponseMessage);
for i := 0 to Reply.DocumentCount-1 do begin
  GmrQueryFailureetDocument(i,doc);
  writeln('Name: ',doc.Name, ' FirstName: ',doc.FirstName);
end;
```

procedure Init(const ReplyMessage: TMongoReply);

Initialize the cursor with a supplied binary reply from the server

- will raise an EMongoException if the content is not valid
 - will populate all record fields with the supplied data

procedure Rewind;

Let Next() overloaded methods point to the first document of this message

property CursorID: Int64 read fCursorID;

Cursor identifier if the client may need to perform further TMongoRequestGetMore messages

- in the event that the result set of the query fits into one OP_REPLY message, CursorID will be 0

property Document[index: integer]: variant read GetOneDocument;

Retrieve a given document as a TDocVariant instance

- could be used e.g. as:

```
var Reply: TMongoReply;
i: integer;
...
Reply.Init(ResponseMessage);
for i := 0 to Reply.DocumentCount-1 do
  writeln('Name: ',Reply.Document[i].Name, ' FirstName: ',Reply.Document[i].FirstName);
```

- note that there is an internal cache for the latest retrieved document by this property, so that you can call Reply.Document[i] several times without any noticeable speed penalty

property DocumentBSON: TPointerDynArray read fDocuments;

Direct access to the low-level BSON binary content of each document

property DocumentCount: integer read fNumberReturned;

Number of documents in the reply

property FirstDocument: PAnsiChar read fFirstDocument;

Points to the first document binary

- i.e. just after the Reply header

property Position: integer read fCurrentPosition;

The current position of the Next() call, starting at 0

property Reply: TMongoReply read fReply;

Access to the low-level binary reply message

property RequestID: integer read fRequestID;

Identifier of this message

property ResponseFlags: TMongoReplyCursorFlags read fResponseFlags;

Retrieve the context execution of this message

property ResponseTo: integer read fResponseTo;

Retrieve the RequestID from the original request

property StartingFrom: integer read fStartingFrom;

Where in the cursor this reply is starting

TMongoConnection = **class**(TObject)

One TCP/IP connection to a MongoDB server

- all access will be protected by a mutex (critical section): it is thread safe but you may use one TMongoClient per thread or a connection pool, for better performance

constructor Create(const aClient: TMongoClient; const aServerAddress: RawByteString; aServerPort: integer=MONGODB_DEFAULTPORT); **reintroduce**;

Initialize the connection to the corresponding MongoDB server

- the server address is either a host name, or an IP address
- if no server address is specified, will try to connect to localhost
- this won't create the connection, until Open method is executed

destructor Destroy; **override**;

Release the connection, including the socket

function GetBSONAndFree(Query: TMongoRequestQuery): TBSONDocument;

Send a query to the server, returning a TBSONDocument instance containing all the incoming data, as raw binary BSON document containing an array of the returned items

- will send the Request message, and any needed TMongoRequestGetMore messages to retrieve all the data from the server
- the supplied Query instance will be released when not needed any more

function GetDocumentsAndFree(Query: TMongoRequestQuery): **variant**; **overload**;

Send a query to the server, returning a TDocVariant instance containing all the incoming data

- will send the Request message, and any needed TMongoRequestGetMore messages to retrieve all the data from the server
- the supplied Query instance will be released when not needed any more
- if Query.NumberToReturn<>1, it will return either null or a dvArray kind of TDocVariant containing all returned items
- if Query.NumberToReturn=1, then it will return either null or a single TDocVariant instance

function GetJSONAndFree(Query: TMongoRequestQuery; Mode: TMongoJSONMode): RawUTF8;

Send a query to the server, returning all the incoming data as JSON

- will send the Request message, and any needed TMongoRequestGetMore messages to retrieve all the data from the server
- this method is very optimized and will convert the BSON binary content directly into JSON, in either modMongoStrict or modMongoShell layout (modNoMongo will do the same as modMongoStrict)
- if Query.NumberToReturn<>1, it will return either 'null' or a '['..']' JSON array with all the incoming documents retrieved from the server
- if Query.NumberToReturn=1, it will return either 'null' or a single '{...}' JSON object
- the supplied Query instance will be released when not needed any more

function RunCommand(const aDatabaseName: RawUTF8; const command: variant; var returnedValue: variant; flags: TMongoQueryFlags=[]): RawUTF8; overload;

Run a database command, supplied as a TDocVariant, TBSONVariant or a string, and return the a TDocVariant instance

- see <http://docs.mongodb.org/manual/reference/command> for a list of all available commands
- for instance:

```
RunCommand('test',_ObjFast(['dbStats',1,'scale',1024],stats);  
RunCommand('test',BSONVariant(['dbStats',1,'scale',1024],stats);  
RunCommand('admin','buildinfo',fServerBuildInfo);
```

- the message will be returned by the server as a single TDocVariant instance (since the associated TMongoRequestQuery.NumberToSkip=1)
- in case of any error, the error message is returned as text
- in case of success, this method will return ''

function RunCommand(const aDatabaseName: RawUTF8; const command: variant; var returnedValue: TBSONDocument; flags: TMongoQueryFlags=[]): boolean; overload;

Run a database command, supplied as a TDocVariant, TBSONVariant or a string, and return the raw BSON document array of received items

- this overloaded method can be used on huge content to avoid the slower conversion to an array of TDocVariant instances
- in case of success, this method will return TRUE, or FALSE on error

function SendAndFree(Request: TMongoRequest; NoAcknowledge: boolean=false): variant;

Send a message to the MongoDB server

- will apply Client.WriteConcern policy, and run an EMongoException in case of any error
- the supplied Request instance will be released when not needed any more
- by default, it will follow Client.WriteConcern pattern - but you can set NoAcknowledge = TRUE to avoid calling the GetLastError command
- will return the GetLastError reply (if retrieved from server)

procedure Close;

Disconnect from MongoDB server

- will raise an EMongoException on error

procedure GetCursor(Request: TMongoRequest; var Result: TMongoReplyCursor);

Low-level method to send a request to the server, and return a cursor

- if Request is not either TMongoRequestQuery or TMongoRequestGetMore, will raise an EMongoException
- then will parse and return a cursor to the reply message as sent back by the database, with logging if necessary
- raise an EMongoException if mrfQueryFailure flag is set in the reply

procedure GetDocumentsAndFree(Query: TMongoRequestQuery; var result: variant); overload;

Send a query to the server, returning a TDocVariant instance containing all the incoming data

- will send the Request message, and any needed TMongoRequestGetMore messages to retrieve all the data from the server
- the supplied Query instance will be released when not needed any more
- if Query.NumberToReturn<>1, it will return either null or a dvArray kind of TDocVariant containing all returned items
- if Query.NumberToReturn=1, then it will return either null or a single TDocVariant instance

procedure GetDocumentsAndFree(Query: TMongoRequestQuery; var result: TVariantDynArray); overload;

Send a query to the server, returning a dynamic array of TDocVariant instance containing all the incoming data

- will send the Request message, and any needed TMongoRequestGetMore messages to retrieve all the data from the server
- the supplied Query instance will be released when not needed any more

procedure GetRepliesAndFree(Query: TMongoRequestQuery; OnEachReply: TOnMongoConnectionReply; var Opaque);

Low-level method to send a query to the server, calling a callback event on each reply

- is used by GetDocumentsAndFree, GetBSONAndFree and GetJSONAndFree methods to receive the whole document (you should better call those)
- the supplied Query instance will be released when not needed any more

procedure GetReply(Request: TMongoRequest; out result: TMongoReply);

Low-level method to send a request to the server

- if Request is not either TMongoRequestQuery or TMongoRequestGetMore, will raise an EMongoException
- then will return the reply message as sent back by the database, ready to be accessed using a TMongoReplyCursor wrapper

procedure Open;

Connect to the MongoDB server

- will raise an EMongoException on error

property Client: TMongoClient read fClient;

Access to the corresponding MongoDB server

property Locked: boolean read GetLocked;

Is TRUE when the connection is busy

property Opened: boolean read GetOpened;

Return TRUE if the Open method has successfully been called

property ServerAddress: RawUTF8 **read** fServerAddress;

Read-only access to the supplied server address

- the server address is either a host name, or an IP address

property ServerPort: integer **read** fServerPort;

Read-only access to the supplied server port

- the server Port is MONGODB_DEFAULTPORT (27017) by default

property Socket: TCrtSocket **read** fSocket;

Direct access to the low-level TCP/IP communication socket

TMongoClient = **class**(TObject)

Remote access to a MongoDB server

- a single server can have several active connections, if some secondary hosts were defined

constructor Create(**const** Host: RawUTF8; Port: integer=MONGODB_DEFAULTPORT; aTLS: boolean=false; **const** SecondaryHostCSV: RawUTF8=''; **const** SecondaryPortCSV: RawUTF8=''); overload;

Prepare a connection to a MongoDB server or Replica Set

- this constructor won't create the connection until the Open method is called

- you can specify multiple hosts, as CSV values, if necessary

- depending on the platform, you may request for a TLS secured connection

destructor Destroy; **override**;

Close the connection and release all associated TMongoDatabase, TMongoCollection and TMongoConnection instances

function GetOneReadConnection: TMongoConnection;

Select Connection in dependence of ReadPreference

function Open(**const** DatabaseName: RawUTF8): TMongoDatabase;

Connect to a database on a remote MongoDB primary server

- this method won't use authentication, and will return the corresponding MongoDB database instance

- this method is an alias to the Database[] property

function OpenAuth(**const** DatabaseName,UserName,PassWord: RawUTF8; ForceMongoDBCR: boolean=false): TMongoDatabase;

Secure connection to a database on a remote MongoDB server

- this method will use authentication and will return the corresponding MongoDB database instance, with a dedicated secured connection

- will use MONGODB-CR for MongoDB engines up to 2.6 (or if ForceMongoDBCR is TRUE), and SCRAM-SHA-1 since MongoDB 3.x

- see <http://docs.mongodb.org/manual/administration/security-access-control>

function ServerBuildInfoText: RawUTF8;

Retrieve extended server version and build information, as text

- will create a string from ServerBuildInfo object, e.g. as

'MongoDB 3.2.0 mozjs mmapv1,wiredTiger'

```
procedure SetLog(LogClass: TSynLogClass; RequestEvent: TSynLogInfo=sllSQL;  
ReplyEvent: TSynLogInfo=sllDB; ReplyEventMaxSize: cardinal=1024);
```

Define an optional logging instance to be used

- you can also specify the event types to be used for requests or replay: by default, a verbose log with sllSQL and sllDB will be set
- e.g. mORMotMongoDB.pas will call Client.SetLog(SQLite3Log) for you

```
property BytesReceived: Int64 read GetBytesReceived;
```

How may bytes this client did received, among all its connections

```
property BytesSent: Int64 read GetBytesSent;
```

How may bytes this client did received, among all its connections

```
property BytesTransmitted: Int64 read GetBytesTransmitted;
```

How may bytes this client did transmit, adding both input and output

```
property Connections: TMongoConnectionDynArray read fConnections;
```

Low-level access to the TCP/IP connections of this MongoDB replica set

- first item [0] is the Primary member
- other items [1..] are the Secondary members

```
property ConnectionString: RawUTF8 read fConnectionString;
```

The connection definition used to connect to this MongoDB server

```
property ConnectionTimeout: Cardinal read fConnectionTimeout write  
fConnectionTimeout;
```

The connection time out, in milliseconds

- default value is 30000, i.e. 30 seconds

```
property ConnectionTLS: boolean read fConnectionTLS;
```

If the socket connection is secured over TLS

```
property Database[const DatabaseName: RawUTF8]: TMongoDatabase read Open;
```

Access to a given MongoDB database

- try to open it via a non-authenticated connection if not already: will raise an exception on error, or will return an instance
- will return an existing instance if has already been opened

```
property GracefulReconnect: boolean read fGracefulReconnect.Enabled write  
fGracefulReconnect.Enabled;
```

Allow automatic reconnection (with authentication, if applying), if the socket is closed (e.g. was dropped from the server)

```
property Log: TSynLog read fLog write fLog;
```

Define the logging instance to be used for LogRequestEvent/LogReplyEvent

- you may also call the SetLog() method to set all options at once

property LogReplyEvent: TSynLogInfo read fLogReplyEvent write fLogReplyEvent;

If set to something else than default sllNone, will log each reply with the corresponding logging event kind

- WARNING: logging all incoming data may be very verbose, e.g. when retrieving a document list
- use it with care, not on production, but only for debugging purposes - or set LogReplyEventMaxSize to a low value
- will use the Log property for the destination log
- you may also call the SetLog() method to set all options at once

property LogReplyEventMaxSize: cardinal read fLogReplyEventMaxSize write fLogReplyEventMaxSize;

Defines how many characters a LogReplyEvent entry may append in the log

- is set by default to 1024, which sounds somewhat good for debugging

property LogRequestEvent: TSynLogInfo read fLogRequestEvent write fLogRequestEvent;

If set to something else than default sllNone, will log each request with the corresponding logging event kind

- will use the Log property for the destination log
- you may also call the SetLog() method to set all options at once

property ReadPreference: TMongoClientReplicaSetReadPreference read fReadPreference write fReadPreference;

Define Read Preference mode to a MongoDB replica set

- see <http://docs.mongodb.org/manual/core/read-preference>
- default is rpPrimary, i.e. reading from the main primary instance
- Important: All read preference modes except rpPrimary may return stale data because secondaries replicate operations from the primary with some delay - ensure that your application can tolerate stale data if you choose to use a non-primary mode

property ServerBuildInfo: variant read fServerBuildInfo;

Retrieve the server version and build information

- return the content as a TDocVariant document, e.g.

ServerBuildInfo.version = '2.4.9'

ServerBuildInfo.versionArray = [2,4,9,0]

- this property is cached, so request is sent only once
- you may rather use ServerBuildInfoNumber to check for available features at runtime, for easy comparison of the server version

property ServerBuildInfoNumber: cardinal read fServerBuildInfoNumber;

Retrieve the server version and build information

- return the content as a TDocVariant document, e.g.

2040900 for MongoDB 2.4.9, or 2060000 for MongoDB 2.6, or

3000300 for MongoDB 3.0.3

- this property is cached, so can be used to check for available features at runtime, without any performance penalty

property WriteConcern: TMongoClientWriteConcern read fWriteConcern write fWriteConcern;

Define Write Concern mode to a MongoDB replica set

- see <http://docs.mongodb.org/manual/core/write-concern>
- default is wcAcknowledged, i.e. to acknowledge all write operations

TMongoDatabase = class(TObject)

Remote access to a MongoDB database

constructor Create(aClient: TMongoClient; **const** aDatabaseName: RawUTF8);

Initialize a reference to a given MongoDB Database

- you should not use this constructor directly, but rather use the TMongoClient.Database[] property
- it will connect to the Client's primary host, then retrieve all collection names of this database

destructor Destroy; **override**;

Release all associated TMongoCollection instances

function CreateUser(**const** UserName, Password: RawUTF8; **const** roles: **variant**): RawUTF8;

Create the user in the database to which the user will belong

- you could specify the roles to use, for this database or others:
reportingDB.CreateUser('reportsUser','12345678',BSONVariant(['{ role: "readWrite", db: "reporting" }, { role: "read", db: "products" }]));
- returns "" on success, an error message otherwise

function CreateUserForThisDatabase(**const** UserName, Password: RawUTF8; allowWrite: Boolean=true): RawUTF8;

Create the user with a read or read/write role on the current database

- returns "" on success, an error message otherwise

function DropUser(**const** UserName: RawUTF8): RawUTF8;

Deletes the supplied user on the current database

- returns "" on success, an error message otherwise

function RunCommand(**const** command: **variant**; **var** returnedValue: **variant**): RawUTF8; overload;

Run a database command, supplied as a TDocVariant, TBSONVariant or a string, and return a TDocVariant instance

- this is the preferred method to issue database commands, as it provides a consistent interface between the MongoDB shell and this driver
- see <http://docs.mongodb.org/manual/reference/command> for a list of all available commands
- for instance:
RunCommand(_ObjFast(['dbStats',1,'scale',1024],stats);
RunCommand(BSONVariant(['dbStats',1,'scale',1024],stats);
RunCommand('dbStats',stats);
RunCommand('hostInfo',host);

- the message will be returned by the server as a TDocVariant instance (since the associated TMongoRequestQuery.NumberToSkip=1)
- in case of any error, the error message is returned as text
- in case of success, this method will return ""

function RunCommand(**const** command: **variant**; **var** returnedValue: TBSONDocument): boolean; overload;

Run a database command, supplied as a TDocVariant, TBSONVariant or a string, and return the raw BSON document array of received items

- this overloaded method can be used on huge content to avoid the slower conversion to an array of TDocVariant instances
- in case of success, this method will return TRUE, or FALSE on error

property Client: TMongoClient **read** fClient;

The associated MongoDB client instance

property Collection[**const** Name: RawUTF8]: TMongoCollection **read** GetCollection;

Access to a given MongoDB collection

- raise an EMongoDatabaseException if the collection name does not exist

property CollectionOrCreate[**const** Name: RawUTF8]: TMongoCollection **read** GetCollectionOrCreate;

Access to a given MongoDB collection

- if the collection name does not exist, it will add use the name to create a TMongoCollection instance and register it to the internal list

property CollectionOrNil[**const** Name: RawUTF8]: TMongoCollection **read** GetCollectionOrNil;

Access to a given MongoDB collection

- if the collection name does not exist, it will return nil

property Name: RawUTF8 **read** fName;

The database name

TMongoCollection = **class**(TObject)

Remote access to a MongoDB collection

constructor Create(aDatabase: TMongoDatabase; **const** aCollectionName: RawUTF8);

Initialize a reference to a given MongoDB Collection

- you should not use this constructor directly, but rather use TMongoClient.Database[].Collection[] property

function AggregateDoc(Operators: PUTF8Char; **const** Params: array of **const**): **variant**; overload;

Calculate aggregate values using the MongoDB aggregation framework and return the result as a TDocVariant instance

- the Aggregation Framework was designed to be more efficient than the alternative map-reduce pattern, and is available since MongoDB 2.2 - see <http://docs.mongodb.org/manual/reference/command/aggregate>
- you should specify the aggregation pipeline as a list of JSON object operators (without the [...]) - for reference of all available phases, see <http://docs.mongodb.org/manual/core/aggregation-pipeline>
- if the server sent back no {result:...} member, will return null
- if the server sent back one item as {result:[{..}]}, will return this single item as a TDocVariant
- if the server sent back several items as {result:[{..},{..}]}, will return a dvArray kind of TDocVariant

function AggregateDocFromJson(**const** PipelineJSON: RawUTF8): **variant**;

Calculate aggregate values using the MongoDB aggregation framework and return the result as a TDocVariant instance

- overloaded method to specify the pipeline as a JSON text object as detailed by <http://docs.mongodb.org/manual/core/aggregation-pipeline>
- for instance, the following will return the maximum `_id` value of the collection:
`AggregateDoc('{$group:{_id:null,max:{$max:"$_id"}}}').max`

function AggregateDocFromVariant(**const** pipelineArray: **variant**): **variant**;

Calculate aggregate values using the MongoDB aggregation framework and return the result as a TDocVariant instance

- overloaded method to specify the pipeline as a BSON raw document as detailed by <http://docs.mongodb.org/manual/core/aggregation-pipeline>

function AggregateJSON(Operators: PUTF8Char; **const** Params: **array of const**; Mode: TMongoJSONMode=modMongoStrict): RawUTF8; overload;

Calculate JSON aggregate values using the MongoDB aggregation framework

- the Aggregation Framework was designed to be more efficient than the alternative map-reduce pattern, and is available since MongoDB 2.2 - see <http://docs.mongodb.org/manual/reference/command/aggregate>
- you should specify the aggregation pipeline as a list of JSON object operators (without the [...]) - for reference of all available phases, see <http://docs.mongodb.org/manual/core/aggregation-pipeline>
- for instance, the following will return as JSON a collection sorted in descending order according by the age field and then in ascending order according to the value in the posts field
`AggregateJSON('{ $sort : { age : -1, posts: 1 } }',[])`

function AggregateJSONFromJson(**const** PipelineJSON: RawUTF8; Mode: TMongoJSONMode=modMongoStrict): RawUTF8; overload;

Calculate JSON aggregate values using the MongoDB aggregation framework

- overloaded method to specify the pipeline as a JSON text object as detailed by <http://docs.mongodb.org/manual/core/aggregation-pipeline>

function AggregateJSONFromVariant(**const** pipelineArray: **variant**; Mode: TMongoJSONMode=modMongoStrict): RawUTF8; overload;

Calculate JSON aggregate values using the MongoDB aggregation framework

- overloaded method to specify the pipeline as a BSON raw document as detailed by <http://docs.mongodb.org/manual/core/aggregation-pipeline>

function Count: Int64;

Calculate the number of documents in the collection

- be aware that this method may be somewhat slow for huge collections, since a full scan of an index is to be performed: if your purpose is to ensure that a collection contains items, use rather `IsEmpty` method

function Drop: RawUTF8;

Drops the entire collection from the database

- once dropped, this TMongoCollection instance will be freed: never use this instance again after success (i.e. returned "")
- in case of error, a textual message will be returned as result
- once dropped, this collection will be removed from the parent Database.Collection[] internal list
- Warning: this method obtains a write lock on the affected database and will block other operations until it has completed

function FindBSON(const Criteria, Projection: Variant; NumberToReturn: integer=maxInt; NumberToSkip: integer=0; Flags: TMongoQueryFlags=[]): TBSONDocument;

Select documents in a collection and returns a TBSONDocument instance containing the selected documents as a raw binary BSON array document

- Criteria can be null (to retrieve all documents) or a TDocVariant / TBSONVariant query selector:
 FindBSON(BSONVariant('{name:"John",age:{\$gt:21}}'),null);
 FindBSON(BSONVariant('{name:?,age:{\$gt:?}}' ,[],['John',21]),null);
- Projection can be null (to retrieve all fields) or a CSV string to set the field names to retrieve, or a TDocVariant or TBSONVariant - e.g.:
 FindBSON(BSONVariant(['name','John']),null);
 FindBSON(BSONVariant(['name','John']),'_id');
 FindBSON(BSONVariant(['name','John']),BSONVariantFieldSelector('name,_id'));
- NumberToReturn can be left to its default maxInt value to return all matching documents, or specify a limit (e.g. 1 for one document)

function FindCount(Criteria: PUTF8Char; const Args,Params: array of const; MaxNumberToReturn: integer=0; NumberToSkip: integer=0): Int64; overload;

Calculate the number of documents in the collection that match a specific query

- Criteria can specify the query selector as (extended) JSON and parameters:
 FindCount('{name:?,age:{\$gt:?}}' ,[],['John',21]);
 FindCount('{ ord_dt: { \$gt: new Date(?) } }' ,[],[trunc(Now)-7]);
- optional MaxNumberToReturn can specify a limit for the search (e.g. if you do not want an exact count, but only check for a specific limit)
- optional NumberToSkip can specify the number of matching documents to skip before counting

function FindCount(const Query: variant): Int64; overload;

Calculate the number of documents in the collection that match a specific query

- Criteria can specify the query selector as a BSONVariant/TDocVariant

function FindDoc(const Criteria, Projection: Variant; NumberToReturn: integer=1; NumberToSkip: integer=0; Flags: TMongoQueryFlags=[]): variant; overload;

Select documents in a collection and returns a dvArray TDocVariant instance containing the selected documents

- Criteria can be null (to retrieve all documents) or a TDocVariant / TBSONVariant query selector:

```
FindDoc(BSONVariant(' {name:"John",age:{$gt:21}}'),null);
FindDoc(BSONVariant(' {name:?,age:{$gt:??}}',[,['John',21]],null);
```

see <http://docs.mongodb.org/manual/reference/operator> for reference

- Projection can be null (to retrieve all fields) or a CSV string to set field names to retrieve, or a TDocVariant or TBSONVariant - e.g.:

```
FindDoc(BSONVariant(['name','John']),null);
FindDoc(BSONVariant(['name','John'],'_id,name');
FindDoc(BSONVariant(['name','John'],BSONVariantFieldSelector('name,_id'));
```

- NumberToReturn can be left to its default maxInt value to return all matching documents, or specify a limit (e.g. 1 for one document - in this case, the returned instance won't be a dvArray kind of TDocVariant, but either null or the single returned document)

- if the query does not have any matching record, it will return null

function FindDoc(Criteria: PUTF8Char; const Params: array of const; NumberToReturn: integer=maxInt; NumberToSkip: integer=0; Flags: TMongoQueryFlags=[]): variant; overload;

Select documents in a collection and returns a dvArray TDocVariant instance containing the selected documents

- Criteria can specify the query selector as (extended) JSON and parameters:

```
FindDoc(' {name:"John",age:{$gt:21}}',[,]);
FindDoc(' {name:?,age:{$gt:??}}',[,['John',21]]);
```

see <http://docs.mongodb.org/manual/reference/operator> for reference

- this overloaded method will use a null Projection, i.e. will retrieve all fields

- NumberToReturn can be left to its default maxInt value to return all matching documents, or specify a limit (e.g. 1 for one document - in this case, the returned instance won't be a dvArray kind of TDocVariant, but either null or the single returned document)

- if the query does not have any matching record, it will return null

function FindDocs(Criteria: PUTF8Char; const Params: array of const; const Projection: variant; NumberToReturn: integer=maxInt; NumberToSkip: integer=0; Flags: TMongoQueryFlags=[]): TVariantDynArray; overload;

Select documents in a collection and returns a dynamic array of TDocVariant instance containing the selected documents

- could be used to fill a VCL grid using a TDocVariantArrayDataSet as defined in

SynVirtualDataSet.pas:

```
ds1.DataSet := ToDataSet(self,FindDocs(' {name:?,age:{$gt:??}}',[,['John',21],null));
```

- Projection can be null (to retrieve all fields) or a CSV string to set field names to retrieve, or a TDocVariant or TBSONVariant with projection operators

```
function FindJSON(Criteria: PUTF8Char; const Params: array of const; NumberToReturn:
integer=maxInt; NumberToSkip: integer=0; Flags: TMongoQueryFlags=[]; Mode:
TMongoJSONMode=modMongoStrict): RawUTF8; overload;
```

Select documents in a collection and returns a JSON array of documents containing the selected documents

- Criteria can specify the query selector as (extended) JSON and parameters:

```
FindJSON('{"name":"John",age:{$gt:21}}',[]);
FindJSON('{"name:?,age:{$gt:?}",["John",21]}');
```

see <http://docs.mongodb.org/manual/reference/operator> for reference

- this overloaded method will use a null Projection, i.e. will retrieve all fields
 - NumberToReturn can be left to its default maxInt value to return all matching documents as a '[]' JSON array, or specify a limit (e.g. 1 for one document - in this case, the returned instance won't be a '[]' JSON array, but either 'null' or a single '{..}' JSON object)

```
function FindJSON(const Criteria, Projection: Variant; NumberToReturn:
integer=maxInt; NumberToSkip: integer=0; Flags: TMongoQueryFlags=[]; Mode:
TMongoJSONMode=modMongoStrict): RawUTF8; overload;
```

Select documents in a collection and returns a JSON array of documents containing the selected documents

- Criteria can be null (to retrieve all documents) or a TDocVariant / TBSONVariant query selector:

```
FindJSON(BSONVariant('{"name":"John",age:{$gt:21}}'),null);
FindJSON(BSONVariant('{"name:?,age:{$gt:?}",["John",21]}'),null);
```

see <http://docs.mongodb.org/manual/reference/operator> for reference

- Projection can be null (to retrieve all fields) or a CSV string to set the field names to retrieve, or a TDocVariant or TBSONVariant - e.g.:

```
FindJSON(BSONVariant(['name','John']),null);
FindJSON(BSONVariant(['name','John'],'_id'));
FindJSON(BSONVariant(['name','John']),BSONVariantFieldSelector('name,_id'));
```

- NumberToReturn can be left to its default maxInt value to return all matching documents as a '[]' JSON array, or specify a limit (e.g. 1 for one document - in this case, the returned instance won't be a '[]' JSON array, but either 'null' or a single '{..}' JSON object)
 - this method is very optimized and will convert the BSON binary content directly into JSON, in either modMongoStrict or modMongoShell layout (modNoMongo will do the same as modMongoStrict)

```
function FindJSON(Criteria: PUTF8Char; const CriteriaParams: array of const; const
Projection: variant; NumberToReturn: integer=maxInt; NumberToSkip: integer=0;
Flags: TMongoQueryFlags=[]; Mode: TMongoJSONMode=modMongoStrict): RawUTF8;
overload;
```

Select documents in a collection and returns a JSON array of documents containing the selected documents

- Criteria and Projection can specify the query selector as (extended) JSON and parameters

```
function FindOne(const _id: variant): variant; overload;
```

Find an existing document in a collection, by its _id field

- _id will identify the unique document to be retrieved
 - returns null, or a TDocVariant instance

```
function FindOne(const _id: TBSONObjectID): variant; overload;
```

Find an existing document in a collection, by its _id field

- _id will identify the unique document to be retrieved
 - returns null, or a TDocVariant instance

function FindOne(**const** NameValuePairs: **array of const**; ReturnNewObjectIfNotFound: **boolean**=false): **variant**; overload;

Find an existing document in a collection, by a custom Criteria value

- Criteria object, specified as name/value pairs, will identify the unique document to be retrieved
- returns the found TDocVariant instance
- if the Criteria has no match, return either null or a new object with default values as NameValuePairs if ReturnNewObjectIfNotFound is true

function IsEmpty: **boolean**;

Returns TRUE if the collection has no document, FALSE otherwise

- is much faster than Count, especially for huge collections

function Save(**var** Document: **variant**; DocumentObjectID: PBSONObjectID=nil): **boolean**; overload;

Updates an existing document or inserts a new document, depending on its document parameter

- this document should be a TDocVariant (i.e. created via _JsonFast() or _JsonFastFmt()) since we need to check for the _id field, other types will be converted to a TDocVariant instance (via its JSON representation) so it is pointless to use BSONVariant() here
- if the document does not contain an _id field, then the Save() method performs an insert; during the operation, the client will add to the Document variant the _id field and assign it a unique ObjectId - and the method returns FALSE
- if the document contains an _id field, then the save() method performs an upsert, querying the collection on the _id field: if a document does not exist with the specified _id value, the save() method performs an insert; if a document exists with the specified _id value, the save() method performs an update that replaces ALL fields in the existing document with the fields from the document - and the method returns TRUE
- you can optionally retrieve the _id value with the DocumentObjectID pointer

procedure EnsureIndex(**const** Keys: **array of RawUTF8**; Ascending: **boolean**=true; Unique: **boolean**=false); overload;

Creates an index on the specified field(s) if the index does not already exist

- Keys are the corresponding field names
- you can write e.g. to create an ascending index on a given field:
book.EnsureIndex(['orderDate']);

procedure EnsureIndex(**const** Keys, Options: **variant**); overload;

Creates an index on the specified field(s) if the index does not already exist

- Keys and Options parameters should be TDocVariant (e.g. created via _JsonFast() or _JsonFastFmt()) - and not TBSONVariant values
- for ascending/descending indexes, Keys is a document that contains pairs with the name of the field or fields to index and order of the index: value of 1 specifies ascending and of -1 specifies descending
- options is a non-mandatory document that controls the creation of the index -
- you can write e.g.
book.EnsureIndex(_JsonFast('{ orderDate: 1 }'),null)
book.EnsureIndex(_ObjFast(['orderDate',1]),null)

```
procedure FindDocs(Criteria: PUTF8Char; const Params: array of const; var result:
TVariantDynArray; const Projection: variant; NumberToReturn: integer=maxInt;
NumberToSkip: integer=0; Flags: TMongoQueryFlags=[]); overload;
```

Select documents in a collection and returns a dynamic array of TDocVariant instance containing the selected documents

- you can e.g. fill a res: TVariantDynArray with the following query:

```
FindDocs('{name:?,age:{$gt:??}','[ 'John',21],res,null);
```

- Projection can be null (to retrieve all fields) or a CSV string to set field names to retrieve, or a TDocVariant or TBSONVariant with projection operators

```
procedure FindDocs(var result: TVariantDynArray; const Projection: variant;
NumberToReturn: integer=maxInt; NumberToSkip: integer=0; Flags:
TMongoQueryFlags=[]); overload;
```

Returns a dynamic array of TDocVariant instance containing all documents of a collection

- Projection can be null (to retrieve all fields) or a CSV string to set field names to retrieve, or a TDocVariant or TBSONVariant with projection operators

```
procedure Insert(const Documents: TBSONDocument; Flags: TMongoInsertFlags=[];
NoAcknowledge: boolean=false); overload;
```

Insert one or more documents in the collection

- Documents is the low-level concatenation of BSON documents, created e.g. with a TBSONWriter stream

- by default, it will follow Client.WriteConcern pattern - but you can set NoAcknowledge = TRUE to avoid calling the GetLastError command and increase the execution speed, at the expense of a unsafe process

```
procedure Insert(const Documents: array of variant; Flags: TMongoInsertFlags=[];
NoAcknowledge: boolean=false); overload;
```

Insert one or more documents in the collection

- Documents is an array of TDocVariant (i.e. created via _JsonFast() or _JsonFastFmt()) - or of TBSONVariant (created via BSONVariant())

- by default, it will follow Client.WriteConcern pattern - but you can set NoAcknowledge = TRUE to avoid calling the GetLastError command and increase the execution speed, at the expense of a unsafe process

```
procedure Insert(const Document: RawUTF8; const Params: array of const;
DocumentObjectID: PBSONObjectID=nil); overload;
```

Insert one document, supplied as (extended) JSON and parameters, in the collection

- supplied JSON could be either strict or in MongoDB Shell syntax:

```
products.insert('{ _id: ?, item: ?, qty: ? }',[1,'card',15]);
// here _id is forced on the client side
products.insert('{ item: ?, qty: ? }',[1,'card',15]);
// here the _id will be created on the client side as an ObjectID
```

- you can retrieve the associated ObjectID, as such:

```
var oid: TBSONObjectID;
...
products.insert('{ item: ?, qty: ? }',['card',15],@oid);
writeln(oid.ToText);
```

```
procedure InsertJSON(const JSONDocuments: array of UTF8Char; Flags:
TMongoInsertFlags=[]; NoAcknowledge: boolean=false);
```

Insert one or more documents in the collection

- JSONDocuments is an array of JSON objects
- by default, it will follow Client.WriteConcern pattern - but you can set NoAcknowledge = TRUE to avoid calling the GetLastError command and increase the execution speed, at the expense of a unsafe process

```
procedure Remove(const Query: variant; Flags: TMongoDeleteFlags=[]; overload;
```

Delete an existing document or several documents in a collection

- Query parameter should be TDocVariant (i.e. created via _JsonFast() or _JsonFastFmt()) or TBSONVariant (created via BSONVariant())
- Query is the selection criteria for the deletion; use the same query selectors as used in the Find() method
- to limit the deletion to just one document, set Flags to [mdfSingleRemove]
- to delete all documents matching the deletion criteria, leave it to []

```
procedure RemoveFmt(Query: UTF8Char; const QueryParams: array of const; Flags:
TMongoDeleteFlags=[]);
```

Delete an existing document or several documents in a collection

- Query parameter can be specified as JSON objects with parameters
- Query is the selection criteria for the deletion; use the same query selectors as used in the Find() method
- to limit the deletion to just one document, set Flags to [mdfSingleRemove]
- to delete all documents matching the deletion criteria, leave it to []

```
procedure RemoveOne(const _id: TBSONObjectID); overload;
```

Delete an existing document in a collection, by its _id field

- _id will identify the unique document to be deleted

```
procedure RemoveOne(const _id: variant); overload;
```

Delete an existing document in a collection, by its _id field

- _id will identify the unique document to be deleted

```
procedure Save(const Document: RawUTF8; const Params: array of const;
DocumentObjectID: PBSONObjectID=nil); overload;
```

Updates an existing document or inserts a new document, depending on its document parameter, supplied as (extended) JSON and parameters

- supplied JSON could be either strict or in MongoDB Shell syntax:
- will perform either an insert or an update, depending of the presence of the _id field, as overloaded Save(const Document: variant)

procedure Update(const Query, Update: variant; Flags: TMongoUpdateFlags=[]); overload;

Modifies an existing document or several documents in a collection

- the method can modify specific fields of existing document or documents or replace an existing document entirely, depending on the update parameter
- Query and Update parameters should be TDocVariant (i.e. created via _JsonFast() or _JsonFastFmt()) or TBSONVariant (created via BSONVariant())
- Query is the selection criteria for the update; use the same query selectors as used in the Find() method
- if Update contains a plain document, it will replace any existing data
- if Update contains update operators (like \$set), it will update the corresponding fields in the document

procedure Update(Query: PUTF8Char; const QueryParams: array of const; const Update: RawUTF8; const UpdateParams: array of const; Flags: TMongoUpdateFlags=[]); overload;

Modifies an existing document or several documents in a collection

- the method can modify specific fields of existing document or documents or replace an existing document entirely, depending on the update parameter
- since all content will be transformed into JSON internally, use this method only if the supplied parameters are simple types: any complex value (e.g. a TDateTime or a BSONVariant binary) won't be handled as expected - use the overloaded Update() with explicit BSONVariant() values instead
- Query and Update parameters can be specified as JSON objects with parameters
- Query is the selection criteria for the update; use the same query selectors as used in the Find() method
- if Update contains a plain document, it will replace any existing data:
 people.update('{name:?}', ['Andy'], '{name:?,age:? }', ['Andy',25], [mufUpsert]);

Warning: to avoid inserting the same document more than once, only use mufUpsert if the query field is uniquely indexed

- if Update contains update operators (like \$set), it will update the corresponding fields in the document:

```
book.insert('{_id:?,item:?,stock:?}',[11,'Divine Comedy',2]);
book.update('{item:?}','Divine Comedy','{$set:{price:?,$inc:{stock:??}},[18,5]);
// the updated document is now:
{ "_id" : 11, "item" : "Divine Comedy", "price" : 18, "stock" : 7 }
```

procedure UpdateOne(const _id, UpdatedFields: variant);

Modifies some fields of an existing document in a collection

- by default, Update() or Save() will replace the whole document
- this method will expect the identifier to be supplied as a variant - may be via the ObjectID() function
- and will replace the specified fields, i.e. it will execute a \$set: with the supplied UpdatedFields value

property Database: TMongoDatabase read fDatabase;

The associated MongoDB database instance

property FullCollectionName: RawUTF8 read fFullCollectionName;

The full collection name, e.g. 'dbname.collectionname'

property Name: RawUTF8 read fName;

The collection name

EMongoConnectionException = **class**(EMongoException)

Exception type used for MongoDB process, once connected

constructor Create(const aMsg: string; aConnection: TMongoConnection); reintroduce; overload;

Initialize the Exception for a given request

constructor CreateUTF8(const Format: RawUTF8; const Args: array of const; aConnection: TMongoConnection); reintroduce;

Initialize the Exception for a given request

property Connection: TMongoConnection read fConnection;

The associated connection

EMongoRequestException = **class**(EMongoConnectionException)

Exception type used for MongoDB query process

constructor Create(const aMsg: string; aConnection: TMongoConnection; aRequest: TMongoRequest; const aError: TMongoReplyCursor); reintroduce; overload;

Initialize the Exception for a given request

constructor Create(const aMsg: string; aConnection: TMongoConnection; aRequest: TMongoRequest; const aErrorDoc: TDocVariantData); reintroduce; overload;

Initialize the Exception for a given request

constructor Create(const aMsg: string; aConnection: TMongoConnection; aRequest: TMongoRequest=nil); reintroduce; overload;

Initialize the Exception for a given request

constructor CreateUTF8(const Format: RawUTF8; const Args: array of const; aConnection: TMongoConnection; aRequest: TMongoRequest); reintroduce;

Initialize the Exception for a given request

function CustomLog(WR: TTextWriter; const Context: TSynLogExceptionContext): boolean; override;

Used to customize the exception log to contain information about the Query

- it will log both the failing request and the returned error message

property ErrorDoc: Variant read GetErrorDoc;

The associated error reply document, as a TDocVariant instance

- will return the first document available in ErrorReply, or the supplied aErrorDoc: TDocVariantData instance

property ErrorReply: TMongoReplyCursor read fError;

The associated error reply document

EMongoRequestOSException = class(EMongoRequestException)

Exception type used for MongoDB query process after an Operating System error (e.g. in case of socket error)

constructor Create(const aMsg: string; aConnection: TMongoConnection; aRequest: TMongoRequest=nil); reintroduce;

Initialize the Exception for a given request, including the last error message retrieved from the operating system

- if such an exception is raised, you can use SystemLastError property to retrieve the corresponding Operating System error code

property SystemLastError: cardinal read fSystemLastError;

Contain the associated Operating System last error code

- will specify e.g. the kind of communication/socket error

Types implemented in the SynMongoDB unit

PBSON24 = ^TBSON24;

Points to 24-bit storage, mapped as a 3 bytes buffer

PBSONElementType = ^TBSONElementType;

Points to an element type for BSON internal representation

PBSONObjectID = ^TBSONObjectID;

Points to a BSON ObjectID internal binary representation

PBSONVariantData = ^TBSONVariantData;

Points to memory structure used for some special BSON storage as variant

PDecimal128 = ^TDecimal128;

Points to a 128-bit decimal value

PDecimal128Bits = ^TDecimal128Bits;

Points to a 128-bit decimal binary

PMongoReplyHeader = ^TMongoReplyHeader;

Points to an low-level binary structure mapping the TMongoReply header

- so that you can write e.g.

PMongoReplyHeader(aMongoReply)^.RequestID

TBSONDocArrayConversion = (asBSONVariant, asDocVariantPerValue, asDocVariantPerReference, asDocVariantInternNamesPerValue, asDocVariantInternNamesPerReference);

Define how betDoc/betArray BSON elements will be converted as variants

- by default a TBSONVariant custom type will be returned, containing the raw BSON binary content of the embedded document or array

- asDocVariantPerValue or asDocVariantPerReference could be used to create a tree of TDocVariant custom kind of variant, able to access to its nested properties via late-binding (asDocVariantPerReference being also much faster in some cases - but less safe - than asDocVariantPerValue)

- asDocVariantPerValue will set JSON_OPTIONS[false] settings:

```
[dvoReturnNullForUnknownProperty]
```

- asDocVariantPerReference will set JSON_OPTIONS[true]/JSON_OPTIONS_FAST settings: [dvoValueCopiedByReference, dvoReturnNullForUnknownProperty]
- asDocVariantInternNamesPerValue and asDocVariantInternNamesPerReference will include dvoInternalNames to the TDocVariant.Options

```
TBSONDocument = RawByteString;
```

Storage of a BSON binary document

- a specific type is defined for consistency with this unit classes
- binary content should follow the "int32 e_list #0" standard layout

```
TBSONDocumentDynArray = array of TBSONDocument;
```

Dynamic array of BSON binary document storage

```
TBSONElementBinaryType = ( bbtGeneric, bbtFunction, bbtOldBinary, bbtOldUUID, bbtUUID, bbtMD5, bbtUser );
```

Sub-types for betBinary element BSON internal representation

```
TBSONElementType = ( betEOF, betFloat, betString, betDoc, betArray, betBinary, betDeprecatedUndefined, betObjectID, betBoolean, betDateTime, betNull, betRegex, betDeprecatedDbptr, betJS, betDeprecatedSymbol, betJSScope, betInt32, betTimestamp, betInt64, betDecimal128 );
```

Element types for BSON internal representation

```
TDecimal128SpecialValue = ( dsvError, dsvValue, dsvNan, dsvZero, dsvPosInf, dsvNegInf, dsvMin, dsvMax );
```

Some special 128-bit decimal values

- see TDecimal128.SetSpecial to set the corresponding value
- dsvError is returned by TDecimal128.FromText() on parsing error
- dsvValue indicates that this is not a known "special" value, but some valid decimal number

```
TDecimal128Str = array[0..42] of AnsiChar;
```

Enough characters to contain any TDecimal128 text representation

```
TMongoClientReplicaSetReadPreference = ( rpPrimary, rpPrimaryPreferred, rpSecondary, rpSecondaryPreferred, rpNearest );
```

Define Read Preference Modes to a MongoDB replica set

- Important: All read preference modes except rpPrimary may return stale data because secondaries replicate operations from the primary with some delay - ensure that your application can tolerate stale data if you choose to use a non-primary mode
- rpPrimary: Default mode - all operations read from the current replica set primary
- rpPrimaryPreferred: in most situations, operations read from the primary but if it is unavailable, operations read from secondary members.
- rpPsecondary: all operations read from the secondary members of the replica set
- rpPsecondaryPreferred: in most situations, operations read from secondary members but if no secondary members are available, operations read from the primary rpNearest: read from the member of the replica set with the least network latency, irrespective of whether that member is a primary or secondary (in practice, we won't use latency, just a random distribution)

```
TMongoClientWriteConcern = ( wcAcknowledged, wcJournalled, wcReplicaAcknowledged, wcUnacknowledged, wcErrorsIgnored );
```

Define Write Concern property of a MongoDB connection

- Write concern describes the guarantee that MongoDB provides when reporting on the success of a write operation. The strength of the write concerns determine the level of guarantee. When inserts,

updates and deletes have a weak write concern, write operations return quickly. In some failure cases, write operations issued with weak write concerns may not persist. With stronger write concerns, clients wait after sending a write operation for MongoDB to confirm the write operations. MongoDB provides different levels of write concern to better address the specific needs of applications. Clients may adjust write concern to ensure that the most important operations persist successfully to an entire MongoDB deployment. For other less critical operations, clients can adjust the write concern to ensure faster performance rather than ensure persistence to the entire deployment.

- `wcAcknowledged` is the default safe mode: the mongod confirms the receipt of the write operation. Acknowledged write concern allows clients to catch network, duplicate key, and other errors.
- with `wcJournalled`, the mongod acknowledges the write operation only after committing the data to the journal. This write concern ensures that MongoDB can recover the data following a shutdown or power interruption.
- `wcReplicaAcknowledged` will guarantee that the write operation propagates to at least one member of a replica set
- with `wcUnacknowledged`, MongoDB does not acknowledge the receipt of write operation. Unacknowledged is similar to errors ignored; however, drivers attempt to receive and handle network errors when possible. The driver's ability to detect network errors depends on the system's networking configuration.
- with `wcErrorsIgnored`, MongoDB does not acknowledge write operations. With this level of write concern, the client cannot detect failed write operations. These errors include connection errors and mongod exceptions such as duplicate key exceptions for unique indexes. Although the errors ignored write concern provides fast performance, this performance gain comes at the cost of significant risks for data persistence and durability. **WARNING:** Do not use `wcErrorsIgnored` write concern in normal operation.

```
TMongoConnectionDynArray = array of TMongoConnection;
```

Array of TCP connection to a MongoDB Replica Set

- first item [0] is the Primary member
- other items [1..] are the Secondary members

```
TMongoDeleteFlag = ( mdfSingleRemove );
```

Define how an opDelete operation will behave

- if `mdfSingleRemove` is set, the database will remove only the first matching document in the collection. Otherwise (by default) all matching documents will be removed

```
TMongoDeleteFlags = set of TMongoDeleteFlag;
```

Define how a TMongoRequestDelete message will behave

```
TMongoInsertFlag = ( mifContinueOnError );
```

Define how an opInsert operation will behave

- if `mifContinueOnError` is set, the database will not stop processing a bulk insert if one fails (e.g. due to duplicate IDs); this makes bulk insert behave similarly to a series of single inserts, except `lastError` will be set if any insert fails, not just the last one - if multiple errors occur, only the most recent will be reported by `getLastError`

```
TMongoInsertFlags = set of TMongoInsertFlag;
```

Define how a TMongoRequestInsert message will behave

```
TMongoJSONMode = ( modNoMongo, modMongoStrict, modMongoShell );
```

How `TBSONElement.AddMongoJSON()` method and `AddMongoJSON()` and `VariantSaveMongoJSON()`

functions will render their JSON content

- modMongoStrict and modNoMongo will follow the JSON RFC specifications
- modMongoShell will use a syntax incompatible with JSON RFC, but more common to MongoDB daily use - as 'ObjectId()' or '{ field: /acme.*corp/i }'
- modMongoStrict will use the MongoDB Extended JSON syntax
- modNoMongo will serialize dates as ISO-8601 strings, ObjectId as hexadecimal string and other MongoDB special objects in WrBase64() format
- see <http://docs.mongodb.org/manual/reference/mongodb-extended-json>

```
TMongoOperation = ( opReply, opMsgOld, opUpdate, opInsert, opQuery, opGetMore, opDelete, opKillCursors, opMsg );
```

The available MongoDB driver Request Opcodes

- opReply: database reply to a client request - ResponseTo shall be set
- opMsgOld: generic msg command followed by a string (deprecated)
- opUpdate: update document
- opInsert: insert new document
- opQuery: query a collection
- opGetMore: get more data from a previous query
- opDelete: delete documents
- opKillCursors: notify database client is done with a cursor
- opMsg: new OP_MSG layout introduced in MongoDB 3.6

```
TMongoQueryFlag = ( mqfTailableCursor, mqfSlaveOk, mqfOplogReplay, mqfNoCursorTimeout, mqfAwaitData, mqfExhaust, mqfPartial );
```

Define how an opQuery operation will behave

- if mqfTailableCursor is set, cursor is not closed when the last data is retrieved
- if mqfSlaveOk is set, it will allow query of replica slave; normally this returns an error except for namespace "local"
- mqfOplogReplay is internal replication use only - driver should not set
- if mqfNoCursorTimeout is set, the server normally does not times out idle cursors after an inactivity period (10 minutes) to prevent excess memory use
- if mqfAwaitData is to use with TailableCursor. If we are at the end of the data, block for a while rather than returning no data. After a timeout period, we do return as normal
- if mqfExhaust is set, stream the data down full blast in multiple "more" packages, on the assumption that the client will fully read all data queried
- if mqfPartial is set, it will get partial results from a mongos if some shards are down (instead of throwing an error)

```
TMongoQueryFlags = set of TMongoQueryFlag;
```

Define how a TMongoRequestQuery message will behave

```
TMongoReply = RawByteString;
```

Used to store the binary raw data a database response to a TMongoRequestQuery / TMongoRequestGetMore client message

```
TMongoReplyCursorFlag = ( mrfCursorNotFound, mrfQueryFailure, mrfShardConfigStale, mrfAwaitCapable );
```

Define an opReply message execution content

- mrfCursorNotFound will be set when getMore is called but the cursor id is not valid at the server; returned with zero results
- mrfQueryFailure is set when the query failed - results consist of one document containing an "\$err" field describing the failure

- mrfShardConfigStale should not be used by client, just by Mongos
- mrfAwaitCapable is set when the server supports the AwaitData Query option (always set since Mongod version 1.6)

TMongoReplyCursorFlags = set of TMongoReplyCursorFlag;

Define a TMongoReplyCursor message execution content

TMongoUpdateFlag = (mufUpsert, mufMultiUpdate);

Define how an opUpdate operation will behave

- if mufUpsert is set, the database will insert the supplied object into the collection if no matching document is found
- if mufMultiUpdate is set, the database will update all matching objects in the collection; otherwise (by default) only updates first matching doc

TMongoUpdateFlags = set of TMongoUpdateFlag;

Define how a TMongoRequestUpdate message will behave

TOmongoConnectionReply = procedure(Request: TMongoRequest; const Reply: TMongoReplyCursor; var Opaque) of object;

Event callback signature for iterative process of TMongoConnection

Constants implemented in the SynMongoDB unit

betMaxKey = \$7f;

Fake BSON element type which compares higher than all other possible values

- element type sounds to be stored as shortint, so here betInt64=\$12<\$7f
- defined as an integer to circumvent a compilation issue with FPC trunk

betMinKey = \$ff;

Fake BSON element type which compares lower than all other possible values

- element type sounds to be stored as shortint, so here \$ff=-1<0=betEOF
- defined as an integer to circumvent a compilation issue with FPC trunk

BSON_DECIMAL128_HI_CURRNEG = \$b038000000000000;

4 fixed decimals

BSON_DECIMAL128_HI_INT64NEG = \$b040000000000000;

0 fixed decimals

BSON_DECIMAL128_HI_NAN = \$7c00000000000000;

DsvError, dsvValue, dsvNan, dsvZero, dsvPosInf, dsvNegInf, dsvMin, dsvMax

BSON_ELEMENTVARIANTMANAGED = [betBinary, betDoc, betArray, betRegEx, betDeprecatedDbptr, betTimestamp, betJSScope, betJS, betDeprecatedSymbol, betDecimal128];

Kind of elements which will store a RawByteString/RawUTF8 content within its TBSONVariant kind
- i.e. TBSONVariantData.VBlob/VText field is to be managed

BSON_JSON_BINARY: array[boolean,boolean] of string[15] = (('{"\$binary":"","","\$type":""}'),('BinData(','','"'));

Special JSON patterns which will be used to format a betBinary item

- *[false,*] is for strict JSON, *[true,*] for MongoDB Extended JSON

BSON_JSON_DATE: array[TMongoJSONMode,boolean] of string[15] = (('',''), ('{"\$date":"",""}'),('ISODate(','','"'));

- `*[,false]` is to be written before the date value, `*[,true]` after

- *[false,*] is for strict JSON, *[true,*] for MongoDB Extended JSON
- (not used by now for this deprecated content)

- `*[false,*]` is to be written before the decimal value, `*[true,*]` after

- `*[false]` is for strict JSON, `*[true]` for MongoDB Extended JSON

- `*[false]` is for strict JSON, `*[true]` for MongoDB Extended JSON

- `*[false,*]` is to be written before the hexadecimal ID, `*[true,*]` after

Special JSON string content which will be used to store a betReqEx

- `*[false]` is for strict JSON, `*[true]` for MongoDB Extended JSON

By definition, maximum MongoDB document size is 16 MB

The textual representation of the TDecimal128 special values

MongoDB server default IP port

Functions or procedures	Description	Page
AddMongoJSON	Convert any kind of BSON/JSON element, encoded as variant, into JSON	1449
BSON	Store some object content, supplied as (extended) JSON and parameters, into BSON encoded binary	1451

Functions or procedures	Description	Page
BSON	Store some TDocVariant custom variant content into BSON encoded binary	1451
BSON	Store some object content, supplied as (extended) JSON, into BSON encoded binary	1451
BSON	Store some object content into BSON encoded binary	1451
BSONDocumentToDoc	Convert a TBSONDocument into a TDocVariant variant instance	1451
BSONDocumentToJSON	Convert a TBSONDocument into its JSON representation	1451
BSONFieldSelector	Create a fields selector BSON document from a CSV field names list	1451
BSONFieldSelector	Create a fields selector BSON document from a field names list	1451
BSONFromInt64s	Store an array of 64 bit integer into BSON encoded binary	1451
BSONFromIntegers	Store an array of integer into BSON encoded binary	1451
BSONListToJSON	Convert a BSON list of elements into its JSON representation	1451
BSONObjectID	Convert a TBSONVariant Object ID custom variant into a TBSONObjectID	1452
BSONParseLength	Parse the header of a BSON encoded binary buffer, and return its length	1452
BSONParseNextElement	Parse the next element in supplied BSON encoded binary buffer list	1452
BSONPerIndexElement	Search for a property by number in a a supplied BSON encoded binary buffer	1452
BSONToDoc	Convert a BSON document into a TDocVariant variant instance	1452
BSONToJSON	Convert a BSON document into its JSON representation	1453
BSONVariant	Convert a TDocVariant variant into a TBSONVariant betDoc type instance	1453
BSONVariant	Store some object content into a TBSONVariant betDoc type instance	1453
BSONVariant	Store some object content, supplied as (extended) JSON and parameters, into a TBSONVariant betDoc type instance	1453
BSONVariant	Store some object content, supplied as (extended) JSON, into a TBSONVariant betDoc type instance	1453
BSONVariant	Store some object content, supplied as (extended) JSON, into a TBSONVariant betDoc type instance	1453
BSONVariantFieldSelector	Create a fields selector BSON document from a CSV field names list	1453
BSONVariantFieldSelector	Create a fields selector BSON document from a field names list	1453

Functions or procedures	Description	Page
BSONVariantFromInt64s	Store an array of 64 bit integer into a TBSONVariant betArray type instance	1454
BSONVariantFromIntegers	Store an array of integer into a TBSONVariant betArray type instance	1454
JavaScript	Create a TBSONVariant JavaScript custom variant type from a supplied code	1454
JavaScript	Create a TBSONVariant JavaScript and associated scope custom variant type from a supplied code and document	1454
JSONBufferToBSONArray	Store one JSON array into an array of BSON binary	1454
JSONBufferToBSONDocument	Store some object content, supplied as (extended) JSON into BSON binary	1454
NumberDecimal	Create a TBSONVariant Decimal128 from some text corresponding to a floating-point number	1454
NumberDecimal	Create a TBSONVariant Decimal128 from a currency fixed decimal	1454
ObjectID	Create a TBSONVariant Object ID custom variant type from a supplied text	1455
ObjectID	Create a TBSONVariant custom variant type containing a BSON Object ID	1455
ToText	Ready-to-be displayed text of a TBSONElementType value	1455
ToText	Ready-to-be displayed text of a TDecimal128SpecialValue	1455
ToText	Ready-to-be displayed text of a TMongoClientReplicaSetReadPreference item	1455
ToText	Ready-to-be displayed text of a TMongoOperation item	1455
ToText	Ready-to-be displayed text of a TMongoClientWriteConcern item	1455
VariantSaveMongoJSON	Convert any kind of BSON/JSON element, encoded as variant, into JSON	1455

procedure AddMongoJSON(const Value: variant; W: TTextWriter; Mode: TMongoJSONMode=modMongoStrict); overload;

Convert any kind of BSON/JSON element, encoded as variant, into JSON

- this function will use by default the MongoDB Extended JSON syntax for specific MongoDB objects but you may use modMongoShell if needed

```
function BSON(const JSON: RawUTF8; kind: PBSONElementType=nil): TBSONDocument;  
overload;
```

Store some object content, supplied as (extended) JSON, into BSON encoded binary
- in addition to the JSON RFC specification strict mode, this method will handle some BSON-like extensions, e.g. unquoted field names:

```
BSON(' {id:10,doc:{name:"John",birthyear:1972}}');
```

- MongoDB Shell syntax will also be recognized to create TBSONVariant, like
new Date() ObjectId() MinKey MaxKey /<jRegex>/<jOptions>

see @<http://docs.mongodb.org/manual/reference/mongodb-extended-json>

```
BSON(' {id:new ObjectId(),doc:{name:"John",date:ISODate()}}');
```

```
BSON(' {name:"John",field:/acme.*corp/i}');
```

- will create the BSON binary without any temporary TDocVariant storage, by calling
JSONBufferToBSONDocument() on a temporary copy of the supplied JSON

```
function BSON(const NameValuePairs: array of const): TBSONDocument; overload;
```

Store some object content into BSON encoded binary

- object will be initialized with data supplied two by two, as Name,Value pairs, e.g.:

```
abson := BSON(['name','John','year',1972]);
```

- you can define nested arrays or objects as TDocVariant, e.g:

```
abson := BSON(['bsonDat',_Arr(['awesome',5.05, 1986])]);
```

- or you can specify nested arrays or objects with '['..'']' or '{'..'}':

```
abson := BSON(['BSON',['','awesome',5.05,1986,']]);
```

```
u := BSONTJSON(BSON(['doc',{'name','John','year',1982},'','id',123]));
```

```
assert(u="{\"doc\":{\"name\":\"John\",\"year\":1982},\"id\":123}");
```

```
u := BSONTJSON(BSON(['doc',{'name','John','abc','[','a','b','c',']','}','id',123]));
```

```
assert(u="{\"doc\":{\"name\":\"John\",\"abc\":\"a\",\"b\",\"c\"},\"id\":123}");
```

- will create the BSON binary without any temporary TDocVariant storage

```
function BSON(const Format: RawUTF8; const Args,Params: array of const; kind:  
PBSONElementType=nil): TBSONDocument; overload;
```

Store some object content, supplied as (extended) JSON and parameters, into BSON encoded binary

- in addition to the JSON RFC specification strict mode, this method will handle some BSON-like extensions, e.g. unquoted field names

- MongoDB Shell syntax will also be recognized to create TBSONVariant, like
new Date() ObjectId() MinKey MaxKey /<jRegex>/<jOptions>

see @<http://docs.mongodb.org/manual/reference/mongodb-extended-json>

- typical use could be:

```
BSON(' {in:{in:[?]} },['type'],['food','snack']);
```

```
BSON(' {type:{in:[]}} ',[],[_Arr(['food','snack'])]);
```

```
BSON(' {:[?]} ',['BSON'],['awesome',5.05,1986])
```

```
BSON(' {:[?]} ',['BSON'],[_Arr(['awesome',5.05,1986)])
```

```
BSON(' {name:?,field:/%/i}', ['acme.*corp'], ['John']);
```

```
BSON(' {id:new ObjectId(),doc:{name:?,date:ISODate(?)}} ',[],['John',NowUTC]);
```

- will create the BSON binary without any temporary TDocVariant storage, by calling
JSONBufferToBSONDocument() on the generated JSON content

- since all content will be transformed into JSON internally, use this method only if the supplied parameters are simple types, and identified explicitly via BSON-like extensions: any complex value (e.g. a TDateTime or a BSONVariant binary) won't be handled as expected - use the overloaded BSON() with explicit BSONVariant() name/value pairs instead

function BSON(const doc: TDocVariantData): TBSONDocument; overload;

Store some TDocVariant custom variant content into BSON encoded binary

- will write either a BSON object or array, depending of the internal layout of this TDocVariantData instance (i.e. Kind property value)
- if supplied variant is not a TDocVariant, raise an EBSONException

function BSONDocumentToDoc(const BSON: TBSONDocument; Option: TBSONDocArrayConversion=asDocVariantPerReference): variant;

Convert a TBSONDocument into a TDocVariant variant instance

- BSON should be valid BSON document (length will be checked against expected "int32 e_list #0" binary layout)
- by definition, asBSONVariant is not allowed as Option value

function BSONDocumentToJSON(const BSON: TBSONDocument; Mode: TMongoJSONMode=modMongoStrict): RawUTF8;

Convert a TBSONDocument into its JSON representation

- BSON should be valid BSON document (length will be checked against expected "int32 e_list #0" binary layout)
- this function will use by default the MongoDB Extended JSON syntax for specific MongoDB objects but you may use modMongoShell if needed

function BSONFieldSelector(const FieldNames: array of RawUTF8): TBSONDocument; overload;

Create a fields selector BSON document from a field names list

- can be used via a TBSONVariant instance for the projection parameter of a TMongoRequestQuery, e.g.:

BSONToJSON(BSONFieldSelector(['a', 'b', 'c']))='{"a":1,"b":1,"c":1}'

function BSONFieldSelector(const FieldNamesCSV: RawUTF8): TBSONDocument; overload;

Create a fields selector BSON document from a CSV field names list

- can be used via a TBSONVariant instance for the projection parameter of a TMongoRequestQuery, e.g.:

BSONToJSON(BSONFieldSelector('a,b,c'))='{"a":1,"b":1,"c":1}'

function BSONFromInt64s(const Integers: array of Int64): TBSONDocument;

Store an array of 64 bit integer into BSON encoded binary

- object will be initialized with data supplied e.g. as a TIntegerDynArray

function BSONFromIntegers(const Integers: array of integer): TBSONDocument;

Store an array of integer into BSON encoded binary

- object will be initialized with data supplied e.g. as a TIntegerDynArray

procedure BSONListToJSON(BSONList: PByte; Kind: TBSONElementType; W: TTextWriter; Mode: TMongoJSONMode=modMongoStrict);

Convert a BSON list of elements into its JSON representation

- BSON should point to the "e_list" of the "int32 e_list #0" BSON document, i.e. the item data as expected by TBSONElement.FromNext()
- this function will use by default the MongoDB Extended JSON syntax for specific MongoDB objects but you may use modMongoShell if needed

function BSONObjectID(const aObjectID: variant): TBSONObjectID;

Convert a TBSONVariant Object ID custom variant into a TBSONObjectID

- raise an exception if the supplied variant is not a TBSONVariant Object ID

function BSONParseLength(var BSON: PByte; ExpectedBSONLen: integer=0): integer;

Parse the header of a BSON encoded binary buffer, and return its length

- BSON should point to a "int32 e_list #0" BSON document (like TBSONDocument)
 - if ExpectedBSONLen is set, this function will check that the supplied BSON content "int32" length matches the supplied value, and raise an EBSNException if this comparison fails
 - as an alternative, consider using TBSONIterator, which wrap both a PByte and a TBSONElement into one convenient item

function BSONParseNextElement(var BSON: PByte; var name: RawUTF8; var element: variant; DocArrayConversion: TBSONDocArrayConversion=asBSONVariant): boolean;

Parse the next element in supplied BSON encoded binary buffer list

- BSON should point to the "e_list" of the "int32 e_list #0" BSON document
 - will decode the supplied binary buffer as a variant, then it will let BSON point to the next element, and return TRUE
 - returns FALSE when you reached betEOF, so that you can use it in a loop:

```
var bson: PByte;
    name: RawUTF8;
    value: variant;
...
BSONParseLength(bson);
while BSONParseNextElement(bson,name,value) do
  writeln(name,':',value);
```

- by default, it will return TBSONVariant custom variants for documents or arrays - but if storeDocArrayAsDocVariant is set, it will return a TDocVariant custom kind of variant, able to access to its nested properties via late-binding
 - if you want to parse a BSON list as fast as possible, you should better use TBSONElement.FromNext() which avoid any memory allocation (the SAX way) - in fact, this function is just a wrapper around TBSONElement.FromNext + ToVariant
 - as an alternative, consider using TBSONIterator, which wrap both a PByte and a TBSONElement into one convenient item

function BSONPerIndexElement(BSON: PByte; index: integer; var item: TBSONElement): boolean;

Search for a property by number in a a supplied BSON encoded binary buffer

- BSON should point to a "int32 e_list #0" BSON document (like TBSONDocument)
 - returns FALSE if the list has too few elements (starting at index 0)
 - otherwise, returns TRUE then let item point to the corresponding element

procedure BSONToDoc(BSON: PByte; var Result: Variant; ExpectedBSONLen: integer=0; Option: TBSONDocArrayConversion=asDocVariantPerReference);

Convert a BSON document into a TDocVariant variant instance

- BSON should point to a "int32 e_list #0" BSON document
 - if ExpectedBSONLen is set, this function will check that the supplied BSON content "int32" length matches the supplied value
 - by definition, asBSONVariant is not allowed as Option value

function BSONToJSON(BSON: PByte; Kind: TBSONElementType; ExpectedBSONLen: integer=0; Mode: TMongoJSONMode=modMongoStrict): RawUTF8;

Convert a BSON document into its JSON representation

- BSON should point to a "int32 e_list #0" BSON document
- Kind should be either betDoc or betArray
- if ExpectedBSONLen is set, this function will check that the supplied BSON content "int32" length matches the supplied value
- this function will use by default the MongoDB Extended JSON syntax for specific MongoDB objects but you may use modMongoShell if needed

procedure BSONVariant(JSON: PUTF8Char; var result: variant); overload;

Store some object content, supplied as (extended) JSON, into a TBSONVariant betDoc type instance

- in addition to the JSON RFC specification strict mode, this method will handle some BSON-like extensions, as with the overloaded BSON() function
- warning: this overloaded method will modify the supplied JSON buffer in-place: you can use the overloaded BSONVariant(const JSON: RawUTF8) function instead if you do not want to modify the input buffer content

function BSONVariant(const JSON: RawUTF8): variant; overload;

Store some object content, supplied as (extended) JSON, into a TBSONVariant betDoc type instance

- in addition to the JSON RFC specification strict mode, this method will handle some BSON-like extensions, as with the overloaded BSON() function

function BSONVariant(const Format: RawUTF8; const Args,Params: array of const): variant; overload;

Store some object content, supplied as (extended) JSON and parameters, into a TBSONVariant betDoc type instance

- in addition to the JSON RFC specification strict mode, this method will handle some BSON-like extensions, as with the overloaded BSON() function

function BSONVariant(doc: TDocVariantData): variant; overload;

Convert a TDocVariant variant into a TBSONVariant betDoc type instance

function BSONVariant(const NameValuePairs: array of const): variant; overload;

Store some object content into a TBSONVariant betDoc type instance

- object will be initialized with data supplied two by two, as Name,Value pairs, as expected by the corresponding overloaded BSON() function

function BSONVariantFieldSelector(const FieldNames: array of RawUTF8): variant; overload;

Create a fields selector BSON document from a field names list

- can be used for the projection parameter of a TMongoRequestQuery, e.g.:
 VariantToJSON(BSONVariantFieldSelector(['a','b','c']))='{"a":1,"b":1,"c":1}'

function BSONVariantFieldSelector(const FieldNamesCSV: RawUTF8): variant; overload;

Create a fields selector BSON document from a CSV field names list

- can be used for the projection parameter of a TMongoRequestQuery, e.g.:
 VariantToJSON(BSONVariantFieldSelector('a,b,c'))='{"a":1,"b":1,"c":1}'

function BSONVariantFromInt64s(const Integers: array of Int64): variant;

Store an array of 64 bit integer into a TBSONVariant betArray type instance
 - object will be initialized with data supplied e.g. as a TIntegerDynArray

function BSONVariantFromIntegers(const Integers: array of integer): variant;

Store an array of integer into a TBSONVariant betArray type instance
 - object will be initialized with data supplied e.g. as a TIntegerDynArray

function JavaScript(const JS: RawUTF8; const Scope: TBSONDocument): variant;
 overload;

Create a TBSONVariant JavaScript and associated scope custom variant type from a supplied code and document
 - will set a BSON element of betJSScope kind

function JavaScript(const JS: RawUTF8): variant; overload;

Create a TBSONVariant JavaScript custom variant type from a supplied code
 - will set a BSON element of betJS kind

function JSONBufferToBSONArray(JSON: PUTF8Char; out docs: TBSONDocumentDynArray;
 DoNotTryExtendedMongoSyntax: boolean=false): boolean;

Store one JSON array into an array of BSON binary
 - since BSON documents are limited to 16 MB by design, this function will allow to process huge data content, as soon as it is provided as array
 - in addition to the JSON RFC specification strict mode, this method will handle some BSON-like extensions, e.g. unquoted field names
 - if DoNotTryExtendedMongoSyntax is FALSE, then MongoDB Shell syntax will be recognized to create BSON custom values - but it will be slightly slower

function JSONBufferToBSONDocument(JSON: PUTF8Char; var doc: TBSONDocument;
 DoNotTryExtendedMongoSyntax: boolean=false): TBSONElementType;

Store some object content, supplied as (extended) JSON into BSON binary
 - warning: the supplied JSON buffer will be modified in-place, if necessary: so you should create a temporary copy before calling this function, or call BSON(const JSON: RawUTF8) function instead
 - in addition to the JSON RFC specification strict mode, this method will handle some BSON-like extensions, e.g. unquoted field names
 - if DoNotTryExtendedMongoSyntax is FALSE, then MongoDB Shell syntax will also be recognized to create BSON custom values, like

`new Date() ObjectId() MinKey MaxKey /<jRegex>/<jOptions>`

see @<http://docs.mongodb.org/manual/reference/mongodb-extended-json>

`BSON('{id:new ObjectId(),doc:{name:"John",date:ISODate()}}');`

`BSON('{name:"John",field:/acme.*corp/i}');`

- will create the BSON binary without any temporary TDocVariant storage
 - will return the kind of BSON document created, i.e. either betDoc or betArray

function NumberDecimal(const Value: currency): variant; overload;

Create a TBSONVariant Decimal128 from a currency fixed decimal
 - will store internally a TDecimal128 storage, with explicitly 4 decimals
 - if you want to store some floating-point value, use plain BSON double format

function NumberDecimal(const Value: RawUTF8): variant; overload;

Create a TBSONVariant Decimal128 from some text corresponding to a floating-point number
 - will store internally a TDecimal128 storage

function ObjectID: **variant**; overload;

Create a TBSONVariant custom variant type containing a BSON Object ID

- will be filled with some unique values, ready to create a new document key
- will store a BSON element of betObjectID kind

function ObjectID(const Hexa: RawUTF8): **variant**; overload;

Create a TBSONVariant Object ID custom variant type from a supplied text

- will raise an EBSONException if the supplied text is not valid hexadecimal
- will set a BSON element of betObjectID kind

function ToText(op: TMongoOperation): PShortString; overload;

Ready-to-be displayed text of a TMongoOperation item

function ToText(wc: TMongoClientWriteConcern): PShortString; overload;

Ready-to-be displayed text of a TMongoClientWriteConcern item

function ToText(pref: TMongoClientReplicaSetReadPreference): PShortString;
overload;

Ready-to-be displayed text of a TMongoClientReplicaSetReadPreference item

function ToText(kind: TBSONElementType): PShortString; overload;

Ready-to-be displayed text of a TBSONElementType value

function ToText(spec: TDecimal128SpecialValue): PShortString; overload;

Ready-to-be displayed text of a TDecimal128SpecialValue

function VariantSaveMongoJSON(const Value: **variant**; Mode: TMongoJSONMode): RawUTF8;

Convert any kind of BSON/JSON element, encoded as variant, into JSON

- in addition to default modMongoStrict as rendered by VariantSaveJSON(), this function can render the supplied variant with the Mongo Shell syntax or even raw JSON content

Variables implemented in the SynMongoDB unit

BSONVariantType: TBSONVariant;

Global TCustomVariantType used to register BSON variant types

- if you use this unit, both TDocVariant and TBSONVariant custom types will be registered, since they are needed for any MongoDB / BSON process

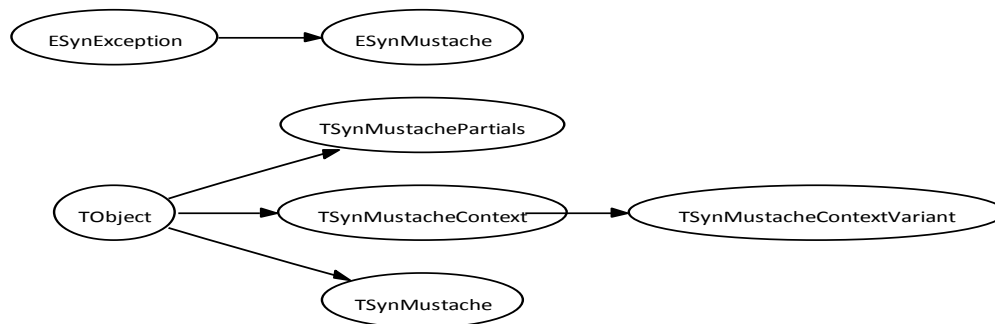

27.27. SynMustache.pas unit

Purpose: Logic-less mustache template rendering

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the *SynMustache* unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynTable</i>	Filter/database/cache/buffer/security/search/multithread/OS features - as a complement to SynCommons, which tended to increase too much - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1728

SynMustache class hierarchy

Objects implemented in the *SynMustache* unit

Objects	Description	Page
ESynMustache	Exception raised during process of a {{mustache}} template	1456
TSynMustache	Stores one {{mustache}} pre-rendered template	1459
TSynMustacheContext	Handle {{mustache}} template rendering context, i.e. all values	1457
TSynMustacheContextVariant	Handle {{mustache}} template rendering context from a custom variant	1458
TSynMustacheHelper	Used to store a registered Expression Helper implementation	1457
TSynMustachePartials	Maintain a list of {{mustache}} partials	1458
TSynMustacheTag	Store a {{mustache}} tag	1457

ESynMustache = class(ESynException)

Exception raised during process of a {{mustache}} template

TSynMustacheTag = record

Store a {{mustache}} tag

Kind: TSynMustacheTagKind;

The kind of the tag

SectionOppositeIndex: integer;

The index in Tags[] of the other end of this section

- either the index of mtSectionEnd for mtSection/mtInvertedSection
- or the index of mtSection/mtInvertedSection for mtSectionEnd

TextLen: integer;

Stores the mtText buffer length

TextStart: PUTF8Char;

Points to the mtText buffer start

- main template's text is not allocated as a separate string during parsing, but will rather be copied directly from the template memory

Value: RawUTF8;

The tag content, excluding trailing {{ }} and corresponding symbol

- is not set for mtText nor mtSetDelimiter

TSynMustacheHelper = record

Used to store a registered Expression Helper implementation

Event: TSynMustacheHelperEvent;

The corresponding callback to process the tag

Name: RawUTF8;

The Expression Helper name

TSynMustacheContext = class(TObject)

Handle {{mustache}} template rendering context, i.e. all values

- this abstract class should not be used directly, but rather any other overridden class

constructor Create(Owner: TSynMustache; WR: TTextWriter);

Initialize the rendering context for the given text writer

property EscapeInvert: boolean **read** fEscapeInvert **write** fEscapeInvert;

Invert the HTML characters escaping process

- by default, {{value}} will escape value chars, and {{{value}}} won't
- set this property to true to force {{value}} NOT to escape HTML chars and {{{value}}} escaping chars (may be useful e.g. for code generation)

property Helpers: TSynMustacheHelpers **read** fHelpers **write** fHelpers;

The registered Expression Helpers, to handle {{helperName value}} tags

- use TSynMustache.HelperAdd/HelperDelete class methods to manage the list or retrieve standard helpers via TSynMustache.HelpersGetStandardList

property OnStringTranslate: TOnStringTranslate **read** fOnStringTranslate **write** fOnStringTranslate;

Access to the `{{"English text"}}` translation callback

property Writer: TTextWriter **read** fWriter;

Read-only access to the associated text writer instance

TSynMustacheContextVariant = **class**(TSynMustacheContext)

Handle `{{mustache}}` template rendering context from a custom variant

- the context is given via a custom variant type implementing TSynInvokeableVariantType.Lookup, e.g. TDocVariant or TSMVariant

constructor Create(Owner: TSynMustache; WR: TTextWriter; SectionMaxCount: integer; **const** aDocument: **variant**);

Initialize the context from a custom variant document

- note that the aDocument instance shall be available during all lifetime of this TSynMustacheContextVariant instance

- you should not use this constructor directly, but the corresponding TSynMustache.Render*() methods

TSynMustachePartials = **class**(TObject)

Maintain a list of `{{mustache}}` partials

- this list of partials template could be supplied to TSynMustache.Render() method, to render `{{>partials}}` as expected

- using a dedicated class allows to share the partials between execution context, without recurring to non SOLID global variables

- you may also define "internal" partials, e.g. `{{<foo}}`This is foo`{{/foo}}`

constructor Create; **overload**;

Initialize the template partials storage

- after creation, the partials should be registered via the Add() method

- you shall manage this instance life time with a try..finally Free block

constructor CreateOwned(**const** NameTemplatePairs: **array of** RawUTF8); **overload**;

Initialize a template partials storage with the supplied templates

- partials list is expected to be supplied in Name / Template pairs

- this instance can be supplied as parameter to the TSynMustache.Render() method, which will free the instances as soon as it finishes

destructor Destroy; **override**;

Delete the partials

function Add(**const** aName: RawUTF8; aTemplateStart, aTemplateEnd: PUTF8Char): TSynMustache; **overload**;

Register a `{{>partialName}}` template

- returns the parsed template

function Add(**const** aName, aTemplate: RawUTF8): TSynMustache; **overload**;

Register a `{{>partialName}}` template

- returns the parsed template

```
class function CreateOwned(const Partials: variant): TSynMustachePartials;  
overload;
```

Initialize a template partials storage with the supplied templates

- partials list is expected to be supplied as a dvObject TDocVariant, each member being the name/template string pairs
- if the supplied variant is not a matching TDocVariant, will return nil
- this instance can be supplied as parameter to the TSynMustache.Render() method, which will free the instances as soon as it finishes

```
function FoundInTemplate(const text: RawUTF8): PtrInt;
```

Search some text withing the {{mustache}} partial

```
property List: TRawUTF8List read fList;
```

Low-level access to the internal partials list

```
TSynMustache = class(TObject)
```

Stores one {{mustache}} pre-rendered template

- once parsed, a template will be stored in this class instance, to be rendered later via the Render() method
- you can use the Parse() class function to maintain a shared cache of parsed templates
- implements all official mustache specifications, and some extensions
- handles {{.}} pseudo-variable for the current context object (very handy when looping through a simple list, for instance)
- handles {{-index}} pseudo-variable for the current context array index (1-based value) so that e.g. "My favorite things:\n{{#things}}{{-index}}. {{.}}\n{{/things}}" over {things:["Peanut butter", "Pen spinning", "Handstands"]} renders as "My favorite things:\n1. Peanut butter\n2. Pen spinning\n3. Handstands\n"
- you could use {{-index0}} for 0-based index value
- handles -first -last and -odd pseudo-section keys, e.g. "{{#things}}{{^-first}}, {{/-first}}{{.}}\n{{/things}}" over {things:["one", "two", "three"]} renders as 'one, two, three'
- allows inlined partial templates, to be defined e.g. as {{<foo}}This is the foo partial {{myValue}} template{{/foo}}
- features {"English text"} translation, via a custom callback
- this implementation is thread-safe and re-entrant (i.e. the same TSynMustache instance can be used by several threads at once)

```
constructor Create(const aTemplate: RawUTF8); overload;
```

Initialize and parse a pre-rendered {{mustache}} template

- you should better use the Parse() class function instead, which features an internal thread-safe cache

```
constructor Create(aTemplate: PUTF8Char; aTemplateLen: integer); overload; virtual;
```

Initialize and parse a pre-rendered {{mustache}} template

- you should better use the Parse() class function instead, which features an internal thread-safe cache

```
destructor Destroy; override;
```

Finalize internal memory

```
function FoundInTemplate(const text: RawUTF8): boolean;
```

Search some text within the {{mustache}} template text

```
class function HelperFind(const Helpers: TSynMustacheHelpers; aName: PUTF8Char;
aNameLen: integer): integer;
```

Search for one Expression Helper event by name

```
class function HelpersGetStandardList: TSynMustacheHelpers; overload;
```

Returns a list of most used static Expression Helpers

- registered helpers are DateTimeToText, DateToText, DateFmt, TimeLogToText, BlobToBase64, JSONQuote, JSONQuoteURI, ToJSON, EnumTrim, EnumTrimRight, Lower, Upper, PowerOfTwo, Equals (expecting two parameters), MarkdownToHtml, SimpleToHtml (Markdown with no HTML pass-through) and WikiToHtml (following TTextWriter.AddHtmlEscapeWiki syntax)
- an additional #if helper is also registered, which would allow runtime view logic, via = < > <= >= <> operators over two values:

```
{{#if .,"=",123}} {{#if Total,">",1000}} {{#if info,"<>",""}}
```

which may be shortened as such:

```
{{#if .=123}} {{#if Total>1000}} {{#if info<>""}}
```

```
class function HelpersGetStandardList(const aNames: array of RawUTF8; const aEvents:
array of TSynMustacheHelperEvent): TSynMustacheHelpers; overload;
```

Returns a list of most used static Expression Helpers, adding some custom callbacks

- is just a wrapper around HelpersGetStandardList and HelperAdd()

```
class function Parse(const aTemplate: RawUTF8): TSynMustache;
```

Parse a {{mustache}} template, and returns the corresponding TSynMustache instance

- an internal cache is maintained by this class function
- this implementation is thread-safe and re-entrant: i.e. the same TSynMustache returned instance can be used by several threads at once
- will raise an ESynMustache exception on error

```
function Render(const Context: variant; Partial: TSynMustachePartials=nil;  

  Helpers: TSynMustacheHelpers=nil; OnTranslate: TOnStringTranslate=nil;  

  EscapeInvert: boolean=false): RawUTF8;
```

Renders the {{mustache}} template from a variant defined context

- the context is given via a custom variant type implementing TSynInvokeableVariantType.Lookup, e.g. TDocVariant or TSMVariant
- you can specify a list of partials via TSynMustachePartials.CreateOwned, a list of Expression Helpers, or a custom {"English text"} callback
- can be used e.g. via a TDocVariant:

```
var mustache := TSynMustache;  

  doc: variant;  

  html: RawUTF8;  

begin  

  mustache := TSynMustache.Parse(  

    'Hello {{name}}'#13#10'You have just won {{value}} dollars!');  

  TDocVariant.New(doc);  

  doc.name := 'Chris';  

  doc.value := 10000;  

  html := mustache.Render(doc);  

  // here html='Hello Chris'#13#10'You have just won 10000 dollars!'
```

- you can also retrieve the context from an ORM query of mORMot.pas:

```
dummy := TSynMustache.Parse(  

  '{{#items}}'#13#10'{{Int}}={{Test}}'#13#10'{{/items}}').Render(  

  aClient.RetrieveDocVariantArray(TSQLRecordTest, 'items', 'Int,Test');
```

- set EscapeInvert = true to force {{value}} NOT to escape HTML chars and {{value}} escaping chars (may be useful e.g. for code generation)

```
function RenderJSON(const JSON: RawUTF8; const Args,Params: array of const;  

  Partial: TSynMustachePartials=nil; Helpers: TSynMustacheHelpers=nil; OnTranslate:  

  TOnStringTranslate=nil; EscapeInvert: boolean=false): RawUTF8; overload;
```

Renders the {{mustache}} template from JSON defined context

- the context is given via a JSON object, defined with parameters
- you can specify a list of partials via TSynMustachePartials.CreateOwned, a list of Expression Helpers, or a custom {"English text"} callback
- is just a wrapper around Render(_JsonFastFmt())
- you can write e.g. with the extended JSON syntax:

```
html := mustache.RenderJSON('{{name:?,value:??}}',[],['Chris',10000]);
```

- set EscapeInvert = true to force {{value}} NOT to escape HTML chars and {{value}} escaping chars (may be useful e.g. for code generation)

```
function RenderJSON(const JSON: RawUTF8; Partial: TSynMustachePartials=nil;  

  Helpers: TSynMustacheHelpers=nil; OnTranslate: TOnStringTranslate=nil;  

  EscapeInvert: boolean=false): RawUTF8; overload;
```

Renders the {{mustache}} template from JSON defined context

- the context is given via a JSON object, defined from UTF-8 buffer
- you can specify a list of partials via TSynMustachePartials.CreateOwned, a list of Expression Helpers, or a custom {"English text"} callback
- is just a wrapper around Render(_JsonFast())
- you can write e.g. with the extended JSON syntax:

```
html := mustache.RenderJSON('{{things:["one", "two", "three"]}}');
```

- set EscapeInvert = true to force {{value}} NOT to escape HTML chars and {{value}} escaping chars (may be useful e.g. for code generation)

```
class function TryRenderJson(const aTemplate,aJSON: RawUTF8; out aContent: RawUTF8): boolean;
```

Parse and render a {{mustache}} template over the supplied JSON
 - an internal templates cache is maintained by this class function
 - returns TRUE and set aContent the rendered content on success
 - returns FALSE if the template is not correct

```
class function UnParse(const aTemplate: RawUTF8): boolean;
```

Remove the specified {{mustache}} template from the internal cache
 - returns TRUE on success, or FALSE if the template was not cached by a previous call to Parse() class function

```
class procedure HelperAdd(var Helpers: TSynMustacheHelpers; const aName: RawUTF8; aEvent: TSynMustacheHelperEvent); overload;
```

Register one Expression Helper callback for a given list of helpers
 - i.e. to let aEvent process {{aName value}} tags
 - the supplied name will be checked against the current list, and replace any existing entry

```
class procedure HelperAdd(var Helpers: TSynMustacheHelpers; const aNames: array of RawUTF8; const aEvents: array of TSynMustacheHelperEvent); overload;
```

Register several Expression Helper callbacks for a given list of helpers
 - the supplied names will be checked against the current list, and replace any existing entry

```
class procedure HelperDelete(var Helpers: TSynMustacheHelpers; const aName: RawUTF8);
```

Unregister one Expression Helper callback for a given list of helpers

```
procedure RenderContext(Context: TSynMustacheContext; TagStart,TagEnd: integer; Partial: TSynMustachePartial; NeverFreePartial: boolean);
```

Renders the {{mustache}} template into a destination text buffer
 - the context is given via our abstract TSynMustacheContext wrapper
 - the rendering extended in fTags[] is supplied as parameters
 - you can specify a list of partials via TSynMustachePartial.CreateOwned

```
property SectionMaxCount: Integer read fSectionMaxCount;
```

The maximum possible number of nested contexts

```
property Template: RawUTF8 read fTemplate;
```

Read-only access to the raw {{mustache}} template content

Types implemented in the *SynMustache* unit

```
TSynMustacheHelperEvent = procedure(const Value: variant; out result: variant) of object;
```

Callback signature used to process an Expression Helper variable
 - i.e. {{helperName value}} tags
 - returned value will be used to process as replacement of a single {{tag}}

```
TSynMustacheHelpers = array of TSynMustacheHelper;
```

Used to store all registered Expression Helpers
 - i.e. {{helperName value}} tags
 - use TSynMustache.HelperAdd/HelperDelete class methods to manage the list or retrieve standard helpers via TSynMustache.HelpersGetStandardList

```
TSynMustacheSectionType = ( msNothing, msSingle, msSinglePseudo, msList );
```

States the section content according to a given value

- msNothing for false values or empty lists
- msSingle for non-false values but not a list
- msSinglePseudo is for *-first *-last *-odd and helper values
- msList for non-empty lists

```
TSynMustacheTagDynArray = array of TSynMustacheTag;
```

Store all {{mustache}} tags of a given template

```
TSynMustacheTagKind = ( mtVariable, mtVariableUnescape, mtVariableUnescapeAmp,  
mtSection, mtInvertedSection, mtSectionEnd, mtComment, mtPartial, mtSetPartial,  
mtSetDelimiter, mtTranslate, mtText );
```

Identify the {{mustache}} tag kind

- mtVariable if the tag is a variable - e.g. {{myValue}} - or an Expression Helper - e.g. {{helperName valueName}}
- mtVariableUnescape, mtVariableUnescapeAmp to unescape the variable HTML - e.g. {{{myRawValue}}} or {{& name}}
- mtSection and mtInvertedSection for sections beginning - e.g. {{#person}} or {{^person}}
- mtSectionEnd for sections ending - e.g. {{/person}}
- mtComment for comments - e.g. {{! ignore me}}
- mtPartial for partials - e.g. {{> next_more}}
- mtSetPartial for setting an internal partial - e.g. {{<foo}}This is the foo partial {{myValue}} template{{/foo}}
- mtSetDelimiter for setting custom delimiter symbols - e.g. {{=<% %>=}} - Warning: current implementation only supports two character delimiters
- mtTranslate for content i18n via a callback - e.g. {{"English text"}}
- mtText for all text that appears outside a symbol

Constants implemented in the *SynMustache* unit

```
NULL_OR_COMMA: array[boolean] of RawUTF8 = ('null', ',', '');
```

This constant can be used to define as JSON a tag value as separator

```
NULL_OR_TRUE: array[boolean] of RawUTF8 = ('null', 'true');
```

This constant can be used to define as JSON a tag value

27.28. SynOleDB.pas unit

Purpose: Fast OleDB direct access classes

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the *SynOleDB* unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynDB</i>	Abstract database direct access classes - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1208
<i>SynLog</i>	Logging functions used by Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1368
<i>SynTable</i>	Filter/database/cache/buffer/security/search/multithread/OS features - as a complement to SynCommons, which tended to increase too much - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1728

SynOleDB class hierarchy

Objects implemented in the *SynOleDB* unit

Objects	Description	Page
EOleDBException	Generic Exception type, generated for OleDB connection	1468
IAccessor	Provides methods for accessor management, to access OleDB data	1468
IColumnsInfo	Expose information about columns of an OleDB rowset or prepared command	1468
ICommand	Provide methods to execute commands	1467

Objects	Description	Page
ICommandText	Methods to access the ICommand text to be executed	1467
IDataInitialize	Create an Oledb data source object using a connection string	1467
IDBCreateCommand	Used on an Oledb session to obtain a new command	1468
IDBCreateSession	Obtain a new session to a given Oledb data source	1467
IDBInitialize	Packed records initialize and uninitialize Oledb data source objects and enumerators	1467
IDBPromptInitialize	Allows the display of the data link dialog boxes programmatically	1468
IDBSchemaRowset	Used to retrieve the database metadata (e.g. tables and fields layout)	1468
IErrorRecords	Interface used to retrieve enhanced custom error information	1468
IRowset	Provides methods for fetching rows sequentially, getting the data from those rows, and managing rows	1467
ITransaction	Commit, abort, and obtain status information about Oledb transactions	1467
ITransactionLocal	Optional interface on Oledb sessions, used to start, commit, and abort transactions on the session	1467
ITransactionOptions	Gets and sets a suite of options associated with an Oledb transaction	1467
TBoId	Packed records	1467
TOleDBACEConnectionProperties	Oledb connection properties to Microsoft Access Database	1470
TOleDBAS400ConnectionProperties	Oledb connection properties to IBM AS/400	1470
TOleDBConnection	Implements an Oledb connection	1471
TOleDBConnectionProperties	Will implement properties shared by Oledb connections	1468
TOleDBInformixConnectionProperties	Oledb connection properties to Informix Server	1471
TOleDBJetConnectionProperties	Jet is not available on Win64 Oledb connection properties to Jet/MSAccess .mdb files	1470
TOleDBMSOracleConnectionProperties	Oledb connection properties to an Oracle database using Microsoft's Provider	1469
TOleDBMSSQL2005ConnectionProperties	Oledb connection properties to Microsoft SQL Server 2005, via SQL Server Native Client (SQL Server 2005)	1470
TOleDBMSSQL2012ConnectionProperties	Oledb connection properties to Microsoft SQL Server 2008/2012, via SQL Server Native Client 11.0 (Microsoft SQL Server 2012 Native Client)	1470
TOleDBMSSQLConnectionProperties	Oledb connection properties to Microsoft SQL Server 2008-2012, via SQL Server Native Client 10.0 (SQL Server 2008)	1470

Objects	Description	Page
TOleDBMySQLConnectionProperties	OleDB connection properties to MySQL Server	1470
TOleDBODBCSQLConnectionProperties	OleDB connection properties via Microsoft Provider for ODBC	1471
TOleDBOracleConnectionProperties	OleDB connection properties to an Oracle database using Oracle's Provider	1469
TOleDBStatement	Implements an OleDB SQL query statement	1473
TOleDBStatementParam	Used to store properties and value about one TOleDBStatement Param	1472

TBoid = record

Packed records

IDBInitialize = interface(IUnknown)

Packed records initialize and uninitialize OleDB data source objects and enumerators

IDataInitialize = interface(IUnknown)

Create an OleDB data source object using a connection string

IDBCreateSession = interface(IUnknown)

Obtain a new session to a given OleDB data source

ITransaction = interface(IUnknown)

Commit, abort, and obtain status information about OleDB transactions

ITransactionOptions = interface(IUnknown)

Gets and sets a suite of options associated with an OleDB transaction

ITransactionLocal = interface(ITransaction)

Optional interface on OleDB sessions, used to start, commit, and abort transactions on the session

ICommand = interface(IUnknown)

Provide methods to execute commands

ICommandText = interface(ICommand)

Methods to access the ICommand text to be executed

IRowset = interface(IUnknown)

Provides methods for fetching rows sequentially, getting the data from those rows, and managing rows

function AddRefRows(cRows: PtrUInt; rghRows: PPtrUIntArray; rgRefCounts, rgRowStatus: PCardinalArray): HRESULT; **stdcall**;

Adds a reference count to an existing row handle

function GetData(HROW: HROW; HACCESSOR: HACCESSOR; pData: Pointer): HRESULT; **stdcall**;

Retrieves data from the rowset's copy of the row

function GetNextRows(hReserved: HCHAPTER; lRowsOffset: PtrInt; cRows: PtrInt; out pcRowsObtained: PtrUInt; var prghRows: pointer): HResult; **stdcall**;

Fetches rows sequentially, remembering the previous position

- this method has been modified from original OleDB.pas to allow direct typecast of prghRows parameter to pointer(fRowStepHandles)

function ReleaseRows(cRows: UInt; rghRows: PPtrUIntArray; rgRowOptions, rgRefCounts, rgRowStatus: PCardinalArray): HResult; **stdcall**;

Releases rows

function RestartPosition(hReserved: HCHAPTER): HResult; **stdcall**;

Repositions the next fetch position to its initial position

- that is, its position when the rowset was first created

IErrorsRecords = **interface**(IUnknown)

Interface used to retrieve enhanced custom error information

IDBCreateCommand = **interface**(IUnknown)

Used on an OleDB session to obtain a new command

IAccessor = **interface**(IUnknown)

Provides methods for accessor management, to access OleDB data

- An accessor is a data structure created by the consumer that describes how row or parameter data from the data store is to be laid out in the consumer's data buffer.

- For each column in a row (or parameter in a set of parameters), the accessor contains a binding. A binding is a DBBinding data structure that holds information about a column or parameter value, such as its ordinal value, data type, and destination in the consumer's buffer.

IColumnsInfo = **interface**(IUnknown)

Expose information about columns of an OleDB rowset or prepared command

IDBPromptInitialize = **interface**(IUnknown)

Allows the display of the data link dialog boxes programmatically

IDBSchemaRowset = **interface**(IUnknown)

Used to retrieve the database metadata (e.g. tables and fields layout)

EOleDBException = **class**(ESQLDBException)

Generic Exception type, generated for OleDB connection

TOleDBConnectionProperties = **class**(TSQLDBConnectionPropertiesThreadSafe)

Will implement properties shared by OleDB connections

function ColumnTypeNativeToDB(const aNativeType: RawUTF8; aScale: integer): TSQLDBFieldType; **override**;

Convert a textual column data type, as retrieved e.g. from SQLGetField, into our internal primitive types

function ConnectionStringDialogExecute(Parent: HWND=0): boolean;

Display the OleDB/ADO Connection Settings dialog to customize the OleDB connection string

- returns TRUE if the connection string has been modified

- Parent is an optional GDI Window Handle for modal display

function NewConnection: TSQLDBConnection; **override**;

Create a new connection

- call this method if the shared MainConnection is not enough (e.g. for multi-thread access)
- the caller is responsible of freeing this instance
- this overridden method will create an TOleDBConnection instance

procedure GetFields(**const** aTableName: RawUTF8; **out** Fields: TSQLDBColumnDefineDynArray); **override**;

Retrieve the column/field layout of a specified table

- will retrieve the corresponding metadata from OleDB interfaces if SQL direct access was not defined

procedure GetTableNames(**out** Tables: TRawUTF8DynArray); **override**;

Get all table names

- will retrieve the corresponding metadata from OleDB interfaces if SQL direct access was not defined

property ConnectionString: SynUnicode **read** fConnectionString **write** fConnectionString;

The associated OleDB connection string

- is set by the Create() constructor most of the time from the supplied server name, user id and password, according to the database provider corresponding to the class
- you may want to customize it via the ConnectionStringDialogExecute method, or to provide some additional parameters

property OnCustomError: TOleDBOnCustomError **read** fOnCustomError **write** fOnCustomError;

Custom Error handler for OleDB COM objects

- returns TRUE if specific error was retrieved and has updated ErrorMessage and InfoMessage
- default implementation just returns false

property ProviderName: RawUTF8 **read** fProviderName;

The associated OleDB provider name, as set for each class

TOleDBOracleConnectionProperties = **class**(TOleDBConnectionProperties)

OleDB connection properties to an Oracle database using Oracle's Provider

- this will use the native OleDB provider supplied by Oracle see
[@http://download.oracle.com/docs/cd/E11882_01/win.112/e17726/toc.htm](http://download.oracle.com/docs/cd/E11882_01/win.112/e17726/toc.htm)

TOleDBMSOracleConnectionProperties = **class**(TOleDBOracleConnectionProperties)

OleDB connection properties to an Oracle database using Microsoft's Provider

- this will use the generic (older) OleDB provider supplied by Microsoft which would not be used any more: "This feature will be removed in a future version of Windows. Avoid using this feature in new development work, and plan to modify applications that currently use this feature. Instead, use Oracle's OLE DB provider." see <http://msdn.microsoft.com/en-us/library/ms675851>

TOleDBMSSQLConnectionProperties = class(TOleDBConnectionProperties)

OleDB connection properties to Microsoft SQL Server 2008-2012, via SQL Server Native Client 10.0 (SQL Server 2008)

- this will use the native OleDB provider supplied by Microsoft see <http://msdn.microsoft.com/en-us/library/ms677227>
- is aUserID="" at Create, it will use Windows Integrated Security for the connection
- will use the SQLNCLI10 provider, which will work on Windows XP; if you want all features, especially under MS SQL 2012, use the inherited class TOleDBMSSQL2012ConnectionProperties; if, on the other hand, you need to connect to a old MS SQL Server 2005, use TOleDBMSSQL2005ConnectionProperties, or set your own provider string

TOleDBMSSQL2005ConnectionProperties = class(TOleDBMSSQLConnectionProperties)

OleDB connection properties to Microsoft SQL Server 2005, via SQL Server Native Client (SQL Server 2005)

- this overridden version will use the SQLNCLI provider, which is deprecated but may be an alternative with MS SQL Server 2005
- is aUserID="" at Create, it will use Windows Integrated Security for the connection

constructor Create(const aServerName, aDatabaseName, aUserID, aPassword: RawUTF8);
override;

Initialize the connection properties

- this overridden version will disable the MultipleValuesInsert() optimization as defined in TSQLDBConnectionProperties.Create(), since INSERT with multiple VALUES (..),(..),(..) is available only since SQL Server 2008

TOleDBMSSQL2012ConnectionProperties = class(TOleDBMSSQLConnectionProperties)

OleDB connection properties to Microsoft SQL Server 2008/2012, via SQL Server Native Client 11.0 (Microsoft SQL Server 2012 Native Client)

- from <http://www.microsoft.com/en-us/download/details.aspx?id=29065> get the sqlncli.msi package corresponding to your Operating System: note that the "X64 Package" will also install the 32-bit version of the client
- this overridden version will use newer SQLNCLI11 provider, but won't work under Windows XP - in this case, it will fall back to SQLNCLI10 - see <http://msdn.microsoft.com/en-us/library/ms131291>
- if aUserID="" at Create, it will use Windows Integrated Security for the connection
- for SQL Express LocalDB edition, just use aServerName='(localdb)\v11.0'

TOleDBMySQLConnectionProperties = class(TOleDBConnectionProperties)

OleDB connection properties to MySQL Server

TOleDBJetConnectionProperties = class(TOleDBConnectionProperties)

Jet is not available on Win64 OleDB connection properties to Jet/MSAccess .mdb files

- the server name should be the .mdb file name
- note that the Jet OleDB driver is not available under Win64 platform

TOleDBACEConnectionProperties = class(TOleDBConnectionProperties)

OleDB connection properties to Microsoft Access Database

TOleDBAS400ConnectionProperties = class(TOleDBConnectionProperties)

OleDB connection properties to IBM AS/400

```
TleDBInformixConnectionProperties = class(TleDBConnectionProperties)
```

OleDB connection properties to Informix Server

```
TleDBODBCSQLConnectionProperties = class(TleDBConnectionProperties)
```

OleDB connection properties via Microsoft Provider for ODBC

- this will use the ODBC provider supplied by Microsoft see [http://msdn.microsoft.com/en-us/library/ms675326\(v=VS.85\).aspx](http://msdn.microsoft.com/en-us/library/ms675326(v=VS.85).aspx)
- an ODBC Driver should be specified at creation
- you should better use direct connection classes, like TleDBMSSQLConnectionProperties or TleDBOracleConnectionProperties as defined in SynDBODBC.pas

```
constructor Create(const aDriver, aServerName, aDatabaseName, aUserID, aPassword: RawUTF8); reintroduce;
```

Initialize the properties

- an additional parameter is available to set the ODBC driver to use
- you may also set aDriver=" and modify the connection string directly, e.g. adding '{ DSN=name | FileDSN=filename }';

```
property Driver: RawUTF8 read fDriver;
```

The associated ODBC Driver name, as specified at creation

```
TleDBConnection = class(TSQLDBConnectionThreadSafe)
```

Implements an OleDB connection

- will retrieve the remote DataBase behavior from a supplied TSQLDBConnectionProperties class, shared among connections

```
constructor Create(aProperties: TSQLDBConnectionProperties); override;
```

Connect to a specified OleDB database

```
destructor Destroy; override;
```

Release all associated memory and OleDB COM objects

```
function IsConnected: boolean; override;
```

Return TRUE if Connect has been already successfully called

```
function NewStatement: TSQLDBStatement; override;
```

Initialize a new SQL query statement for the given connection

- the caller should free the instance after use

```
procedure Commit; override;
```

Commit changes of a Transaction for this connection

- StartTransaction method must have been called before

```
procedure Connect; override;
```

Connect to the specified database

- should raise an EOleDBException on error

```
procedure Disconnect; override;
```

Stop connection to the specified database

- should raise an EOleDBException on error

procedure Rollback; override;

Discard changes of a Transaction for this connection
- StartTransaction method must have been called before

procedure StartTransaction; override;

Begin a Transaction for this connection
- be aware that not all OleDB provider support nested transactions see
[http://msdn.microsoft.com/en-us/library/ms716985\(v=vs.85\).aspx](http://msdn.microsoft.com/en-us/library/ms716985(v=vs.85).aspx)

property OleDBErrorMessage: string read fOleDBErrorMessage;

Internal error message, as retrieved from the OleDB provider

property OleDBInfoMessage: string read fOleDBInfoMessage;

Internal information message, as retrieved from the OleDB provider

property OleDBProperties: TOleDBConnectionProperties read fOleDBProperties;

The associated OleDB database properties

TOleDBStatementParam = record

Used to store properties and value about one TOleDBStatement Param
- we don't use a Variant, not the standard TSQLDBParam record type, but manual storage for better performance
- whole memory block of a TOleDBStatementParamDynArray will be used as the source Data for the OleDB parameters - so we should align data carefully packed records

VArray: TRawUTF8DynArray;

Storage used for table variables

VBlob: RawByteString;

Storage used for BLOB (ftBlob) values
- will be referred as DBTYPE_BYREF when sent as OleDB parameters, to avoid unnecessary memory copy

VFill:

array[sizeof(TSQLDBFieldType)+sizeof(TSQLDBParamInOutType)+sizeof(integer)..
SizeOf(Int64)-1] **of** byte;

So that VInt64 will be 8 bytes aligned

VInOut: TSQLDBParamInOutType;

Define if parameter can be retrieved after a stored procedure execution

VInt64: Int64;

Storage used for ftInt64, ftDouble, ftDate and ftCurrency value

VIUnknown: IUnknown;

Storage used for table variables

VStatus: integer;

Storage used for the OleDB status field
- if VStatus=ord(stIsNull), then it will bind a NULL with the type as set by VType (to avoid conversion error like in [e8c211062e])

VText: WideString;

Storage used for TEXT (ftUTF8) values

- we store TEXT here as WideString, and not RawUTF8, since OleDb expects the text to be provided with Unicode encoding
- for some providers (like Microsoft SQL Server 2008 R2, AFAIK), using DBTYPE_WSTR value (i.e. what the doc. says) will raise an OleDb Error 80040E1D (DB_E_UNSUPPORTEDCONVERSION, i.e. 'Requested conversion is not supported'): we found out that only DBTYPE_BSTR type (i.e. OLE WideString) does work... so we'll use it here! Shame on Microsoft!
- what's fine with DBTYPE_BSTR is that it can be resized by the provider in case of VInOut in [paramOut, paramInOut] - so let it be

VType: TSQLDBFieldType;

The column/parameter Value type

TOleDbStatement = class(TSQLDBStatement)

Implements an OleDb SQL query statement

- this statement won't retrieve all rows of data, but will allow direct per-row access using the Step() and Column*() methods

constructor Create(aConnection: TSQLDBConnection); **override;**

Create an OleDb statement instance, from an OleDb connection

- the Execute method can be called only once per TOleDbStatement instance
- if the supplied connection is not of TOleDbConnection type, will raise an exception

destructor Destroy; **override;**

Release all associated memory and COM objects

function ColumnBlob(Col: integer): RawByteString; **override;**

Return a Column as a blob value of the current Row, first Col is 0

- ColumnBlob() will return the binary content of the field if it was not ftBlob, e.g. a 8 bytes RawByteString for a vtInt64/vtDouble/vtDate/vtCurrency, or a direct mapping of the RawUnicode

function ColumnCurrency(Col: integer): currency; **override;**

Return a Column currency value of the current Row, first Col is 0

- should retrieve directly the 64 bit Currency content, to avoid any rounding/conversion error from floating-point types

function ColumnDateTime(Col: integer): TDateTime; **override;**

Return a Column date and time value of the current Row, first Col is 0

function ColumnDouble(Col: integer): double; **override;**

Return a Column floating point value of the current Row, first Col is 0

function ColumnIndex(const aColumnName: RawUTF8): integer; **override;**

Returns the Column index of a given Column name

- Columns numeration (i.e. Col value) starts with 0
- returns -1 if the Column name is not found (via case insensitive search)

function ColumnInt(Col: integer): Int64; **override;**

Return a Column integer value of the current Row, first Col is 0

function ColumnName(Col: integer): RawUTF8; **override;**

Retrieve a column name of the current Row

- Columns numeration (i.e. Col value) starts with 0
- it's up to the implementation to ensure that all column names are unique

function ColumnNull(Col: integer): boolean; **override;**

Returns TRUE if the column contains NULL

function ColumnString(Col: integer): string; **override;**

Return a Column text generic VCL string value of the current Row, first Col is 0

function ColumnToVariant(Col: integer; var Value: Variant): TSQLDBFieldType; **override;**

Return a Column as a variant

- this implementation will retrieve the data with no temporary variable (since TQuery calls this method a lot, we tried to optimize it)
- a ftUTF8 content will be mapped into a generic WideString variant for pre-Unicode version of Delphi, and a generic UnicodeString (=string) since Delphi 2009: you may not lose any data during charset conversion
- a ftBlob content will be mapped into a TBlobData AnsiString variant

function ColumnType(Col: integer; FieldSize: PInteger=nil): TSQLDBFieldType; **override;**

The Column type of the current Row

- ftCurrency type should be handled specifically, for faster process and avoid any rounding issue, since currency is a standard OleDB type
- FieldSize can be set to store the size in chars of a ftUTF8 column (0 means BLOB kind of TEXT column)

function ColumnUTF8(Col: integer): RawUTF8; **override;**

Return a Column UTF-8 encoded text value of the current Row, first Col is 0

function ParamToVariant(Param: Integer; var Value: Variant; CheckIsOutParameter: boolean=true): TSQLDBFieldType; **override;**

Retrieve the parameter content, after SQL execution

- the leftmost SQL parameter has an index of 1
- to be used e.g. with stored procedures
- any TEXT parameter will be retrieved as WideString Variant (i.e. as stored in TOleDBStatementParam)

function Step(SeekFirst: boolean=false): boolean; **override;**

After a statement has been prepared via Prepare() + ExecutePrepared() or Execute(), this method must be called one or more times to evaluate it

- you shall call this method before calling any Column*() methods
- return TRUE on success, with data ready to be retrieved by Column*()
- return FALSE if no more row is available (e.g. if the SQL statement is not a SELECT but an UPDATE or INSERT command)
- access the first or next row of data from the SQL Statement result: if SeekFirst is TRUE, will put the cursor on the first row of results, otherwise, it will fetch one row of data, to be called within a loop
- raise an ESQLEOLEDBException on any error

function UpdateCount: integer; **override**;

Gets a number of updates made by latest executed statement

procedure Bind(Param: Integer; Value: Int64; IO: TSQLEDBParamInOutType=paramIn);
overload; **override**;

Bind an integer value to a parameter

- the leftmost SQL parameter has an index of 1
- raise an EOleDBException on any error

procedure Bind(Param: Integer; Value: double; IO: TSQLEDBParamInOutType=paramIn);
overload; **override**;

Bind a double value to a parameter

- the leftmost SQL parameter has an index of 1
- raise an EOleDBException on any error

procedure BindArray(Param: Integer; **const** Values: array of RawUTF8); **overload**;
override;

Bind a array of RawUTF8 (255 length max) values to a parameter

- using TABLE variable (MSSQL 2008 & UP). Must be created in the database as:
CREATE TYPE dbo.StrList AS TABLE(id nvarchar(255) NULL)
- must be declared in the database

procedure BindArray(Param: Integer; **const** Values: array of Int64); **overload**;
override;

Bind an array of Int64 values to a parameter

- using TABLE variable (MSSQL 2008 & UP). Must be created in the database as:
CREATE TYPE dbo.IDList AS TABLE(id bigint NULL)
- Internally BindArray(0, [1, 2,3]) is the same as:
declare @a dbo.IDList;
insert into @a (id) values (1), (2), (3);
SELECT usr.ID FROM user usr WHERE usr.ID IN (select id from @a)

procedure BindBlob(Param: Integer; Data: pointer; Size: integer; IO:
TSQLEDBParamInOutType=paramIn); **overload**; **override**;

Bind a Blob buffer to a parameter

- the leftmost SQL parameter has an index of 1
- raise an EOleDBException on any error

procedure BindBlob(Param: Integer; **const** Data: RawByteString; IO:
TSQLEDBParamInOutType=paramIn); **overload**; **override**;

Bind a Blob buffer to a parameter

- the leftmost SQL parameter has an index of 1
- raise an EOleDBException on any error

procedure BindCurrency(Param: Integer; Value: currency; IO:
TSQLEDBParamInOutType=paramIn); **overload**; **override**;

Bind a currency value to a parameter

- the leftmost SQL parameter has an index of 1
- raise an EOleDBException on any error

```
procedure BindDateTime(Param: Integer; Value: TDateTime; IO:  
TSQLDBParamInOutType=paramIn); overload; override;
```

Bind a TDateTime value to a parameter

- the leftmost SQL parameter has an index of 1
- raise an EOleDBException on any error

```
procedure BindNull(Param: Integer; IO: TSQLDBParamInOutType=paramIn; BoundType:  
TSQLDBFieldType=ftNull); override;
```

Bind a NULL value to a parameter

- the leftmost SQL parameter has an index of 1
- OleDB during MULTI INSERT statements expect BoundType to be set in ToleDBStatementParam, and its VStatus set to ord(stIsNull)
- raise an EOleDBException on any error

```
procedure BindTextP(Param: Integer; Value: PUTF8Char; IO:  
TSQLDBParamInOutType=paramIn); overload; override;
```

Bind a UTF-8 encoded buffer text (#0 ended) to a parameter

- the leftmost SQL parameter has an index of 1
- raise an EOleDBException on any error

```
procedure BindTextS(Param: Integer; const Value: string; IO:  
TSQLDBParamInOutType=paramIn); overload; override;
```

Bind a VCL string to a parameter

- the leftmost SQL parameter has an index of 1
- raise an EOleDBException on any error

```
procedure BindTextU(Param: Integer; const Value: RawUTF8; IO:  
TSQLDBParamInOutType=paramIn); overload; override;
```

Bind a UTF-8 encoded string to a parameter

- the leftmost SQL parameter has an index of 1
- raise an EOleDBException on any error

```
procedure BindTextW(Param: Integer; const Value: WideString; IO:  
TSQLDBParamInOutType=paramIn); overload; override;
```

Bind an OLE WideString to a parameter

- the leftmost SQL parameter has an index of 1
- raise an EOleDBException on any error

```
procedure ColumnsToJSON(WR: TJSONWriter); override;
```

Append all columns values of the current Row to a JSON stream

- will use WR.Expand to guess the expected output format
- fast overridden implementation with no temporary variable
- BLOB field value is saved as Base64, in the '"\uFFFF0base64encodedbinary"' format and contains true BLOB data

```
procedure ExecutePrepared; override;
```

Execute an UTF-8 encoded SQL statement

- parameters marked as ? should have been already bound with Bind*() functions above
- raise an EOleDBException on any error

procedure FromRowSet(RowSet: IRowSet);

Retrieve column information from a supplied IRowSet

- is used e.g. by TOleDBStatement.Execute or to retrieve metadata columns
- raise an exception on error

procedure Prepare(const aSQL: RawUTF8; ExpectResults: Boolean=false); overload;
override;

Prepare an UTF-8 encoded SQL statement

- parameters marked as ? will be bound later, before ExecutePrepared call
- if ExpectResults is TRUE, then Step() and Column*() methods are available to retrieve the data rows
- raise an EOleDBException on any error

procedure ReleaseRows; **override;**

Clear result rowset when ISQLDBStatement is back in cache

procedure Reset; **override;**

Reset the previous prepared statement

- this overridden implementation will reset all bindings and the cursor state
- raise an EOleDBException on any error

property AlignDataInternalBuffer: boolean **read** fAlignBuffer **write** fAlignBuffer;

If TRUE, the data will be 8 bytes aligned in OleDB internal buffers

- it's recommended by official OleDB documentation for faster process
- is enabled by default, and should not be modified in most cases

property OleDBConnection: TOleDBConnection **read** fOleDBConnection;

Just map the original Collection into a TOleDBConnection class

property RowBufferSize: integer **read** fRowBufferSize **write** SetRowBufferSize;

Size in bytes of the internal OleDB buffer used to fetch rows

- several rows are retrieved at once into the internal buffer
- default value is 16384 bytes, minimal allowed size is 8192

Types implemented in the SynOleDB unit

TOleDBBindStatus = (bsOK, bsBadOrdinal, bsUnsupportedConversion, bsBadBindInfo, bsBadStorageFlags, bsNoInterface, bsMultipleStorage);

Binding status of a given column

- see <http://msdn.microsoft.com/en-us/library/windows/desktop/ms720969> and <http://msdn.microsoft.com/en-us/library/windows/desktop/ms716934>

TOleDBMSSQL2008ConnectionProperties = TOleDBMSSQLConnectionProperties;

OleDB connection properties to Microsoft SQL Server 2008, via SQL Server Native Client 10.0 (SQL Server 2008)

- just maps default TOleDBMSSQLConnectionProperties type

TOleDBStatementParamDynArray = **array of** TOleDBStatementParam;

Used to store properties about TOleDBStatement Parameters

- whole memory block of a TOleDBStatementParamDynArray will be used as the source Data for the OleDB parameters

TOleDBStatus = (stOK, stBadAccessor, stCanNotConvertValue, stIsNull, stTruncated, stSignMismatch, stDataoverflow, stCanNotCreateValue, stUnavailable,

```
stPermissionDenied, stIntegrityViolation, stSchemaViolation, stBadStatus, stDefault,
stCellEmpty, stIgnoreColumn, stDoesNotExist, stInvalidURL, stResourceLocked,
stResoruceExists, stCannotComplete, stVolumeNotFound, stOutOfSpace,
stCannotDeleteSource, stAlreadyExists, stCanceled, stNotCollection, stRowSetColumn );
```

Indicates whether the data value or some other value, such as a NULL, is to be used as the value of the column or parameter

- see <http://msdn.microsoft.com/en-us/library/ms722617> and <http://msdn.microsoft.com/en-us/library/windows/desktop/ms716934>

Functions or procedures implemented in the *SynOleDB* unit

Functions or procedures	Description	Page
CoInit	This global procedure should be called for each thread needing to use OLE	1478
CoUninit	This global procedure should be called at thread termination	1478
IsJetFile	Check from the file beginning if sounds like a valid Jet / MSAccess file	1478

procedure CoInit;

This global procedure should be called for each thread needing to use OLE

- it is already called by TOleDBConnection.Create when an OleDb connection is instantiated for a new thread
- every call of CoInit shall be followed by a call to CoUninit
- implementation will maintain some global counting, to call the CoInitialize API only once per thread
- only made public for user convenience, e.g. when using custom COM objects

procedure CoUninit;

This global procedure should be called at thread termination

- it is already called by TOleDBConnection.Destroy, e.g. when thread associated to an OleDb connection is terminated
- every call of CoInit shall be followed by a call to CoUninit
- only made public for user convenience, e.g. when using custom COM objects

function IsJetFile(const FileName: TFileName): boolean;

Check from the file beginning if sounds like a valid Jet / MSAccess file

27.29. SynPdf.pas unit

Purpose: PDF file generation

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

The *SynPdf* unit is quoted in the following items

SWRS #	Description	Page
DI-2.3.2	A reporting feature, with full preview and export as PDF or TXT files, shall be integrated	2560

Units used in the *SynPdf* unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynCrypto</i>	Fast cryptographic routines (hashing and cypher) - implements AES,XOR,ADLER32,MD5,RC4,SHA1,SHA256,SHA384,SHA512,SHA3 and JWT - optimized for speed (tuned assembler and SSE3/SSE4/AES-NI/PADLOCK support) - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1143
<i>SynGdiPlus</i>	GDI+ library API access - adds GIF, TIF, PNG and JPG pictures read/write support as standard TGraphic - make available most useful GDI+ drawing methods - allows Antialiased rendering of any EMF file using GDI+ - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1355
<i>SynLZ</i>	SynLZ Compression routines - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1399
<i>SynZip</i>	Low-level access to ZLib compression (1.2.5 engine version) - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1853

SynPdf class hierarchy

Objects implemented in the *SynPdf* unit

Objects	Description	Page
EPdfInvalidOperation	PDF exception, raised when an invalid operation is triggered	1483
EPdfInvalidValue	PDF exception, raised when an invalid value is given to a constructor	1483
TCmapFmt4	Header for the 'cmap' Format 4 table	1483
TCmapHEAD	'head' table contains global information about the font	1483
TCmapHeader	The 'cmap' table begins with an index containing the table version number followed by the number of encoding tables. The encoding subtables follow.	1483

Objects	Description	Page
TCmapHHEA	Platform identifier Platform-specific encoding identifier Offset of the mapping table 'hhea' table contains information needed to layout fonts whose characters are written horizontally, that is, either left to right or right to left	1483
TPdfArray	Used to store an array of PDF objects	1488
TPdfBinary	Used to handle object which are not defined in this library	1492
TPdfBoolean	A PDF object, storing a boolean value	1487
TPdfBox	A PDF coordinates box	1483
TPdfCanvas	Access to the PDF Canvas, used to draw on the page	1500
TPdfCatalog	A dictionary wrapper class for the PDF document catalog fields	1509
TPdfClearText	A PDF object, storing a textual value with no encryption	1488
TPdfDestination	A destination defines a particular view of a document, consisting of the following:	1512
TPdfDictionary	A PDF Dictionary is used to manage Key / Value pairs	1490
TPdfDictionaryElement	PDF dictionary element definition	1489
TPdfDictionaryWrapper	Common ancestor to all dictionary wrapper classes	1508
TPdfDocument	The main class of the PDF engine, processing the whole PDF document	1493
TPdfDocumentGDI	Class handling PDF document creation using GDI commands	1514
TPdfEncryption	Abstract class to handle PDF security	1483
TPdfEncryptionRC4MD5	Handle PDF security with RC4+MD5 scheme in 40-bit and 128-bit	1484
TPdfFont	A generic PDF font object	1509
TPdfFontCIDFontType2	An embedded Composite CIDFontType2	1510
TPdfFontTrueType	Handle TrueType Font	1511
TPdfFontType1	An embedded WinAnsi-Encoded standard Type 1 font	1510
TPdfFontWinAnsi	A generic PDF font object, handling at least WinAnsi encoding	1510
TPdfForm	Handle any form XObject	1516
TPdfFormWithCanvas	A form XObject with a Canvas for drawing	1517
TPdfImage	Generic image object	1516
TPdfInfo	A dictionary wrapper class for the PDF document information fields	1508
TPdfName	A PDF object, storing a PDF name	1488
TPdfNull	A PDF object, storing a NULL value	1487

Objects	Description	Page
TPdfNumber	A PDF object, storing a numerical (integer) value	1487
TPdfObject	Master class for most PDF objects declaration	1487
TPdfObjectMgr	Object manager is a virtual class to manage instance of indirect PDF objects	1487
TPdfObjectStream	Used to handle compressed object stream (in PDF 1.5 format)	1517
TPdfOptionalContentGroup	Generic PDF Optional Content entry	1493
TPdfOutlineEntry	An Outline entry in the PDF document	1513
TPdfOutlineRoot	Root entry for all Outlines of the PDF document	1514
TPdfOutlines	Generic PDF Outlines entries, stored as a PDF dictionary	1493
TPdfPage	A PDF page	1500
TPdfPageGDI	A PDF page, with its corresponding Meta File and Canvas	1514
TPdfRawText	A PDF object, storing a raw PDF content	1488
TPdfReal	A PDF object, storing a numerical (floating point) value	1487
TPdfRect	A PDF coordinates rectangle	1483
TPdfStream	A temporary memory stream, to be stored into the PDF content	1491
TPdfText	A PDF object, storing a textual value	1488
TPdfTextString	A PDF object, storing a textual value	1488
TPdfTextUTF8	A PDF object, storing a textual value	1488
TPdfTrailer	The Trailer of the PDF File	1492
TPdfTTF	Handle Unicode glyph description for a True Type Font	1510
TPdfVirtualObject	A virtual PDF object, with an associated PDF Object Number	1487
TPdfWrite	Buffered writer class, specialized for PDF encoding	1484
TPdfXObject	Any object stored to the PDF file	1493
TPdfXref	Store the XRef list of the PDF file	1493
TPdfXrefEntry	Store one entry in the XRef list of the PDF file	1492
TScriptAnalysis	An Uniscribe script analysis	1517
TScriptItem	A Uniscribe script item, after analysis of a unicode text	1517
TScriptProperties	Contains information about Uniscribe special processing for each script	1518
TScriptState	An UniScribe script state	1517

Objects	Description	Page
TScriptVisAttr	Contains the visual (glyph) attributes that identify clusters and justification points, as generated by ScriptShape	1518

TCmapHeader = **packed record**

The 'cmap' table begins with an index containing the table version number followed by the number of encoding tables. The encoding subtables follow.

numberSubtables: word;

Number of encoding subtables

version: word;

Version number (Set to zero)

TCmapHHEA = **packed record**

Platform identifier Platform-specific encoding identifier Offset of the mapping table 'hhea' table contains information needed to layout fonts whose characters are written horizontally, that is, either left to right or right to left

TCmapHEAD = **packed record**

'head' table contains global information about the font

TCmapFmt4 = **packed record**

*Header for the 'cmap' Format 4 table
- this is a two-byte encoding format*

EPdfInvalidValue = **class**(Exception)

PDF exception, raised when an invalid value is given to a constructor

EPdfInvalidOperation = **class**(Exception)

PDF exception, raised when an invalid operation is triggered

TPdfRect = **record**

A PDF coordinates rectangle

TPdfBox = **record**

A PDF coordinates box

TPdfEncryption = **class**(TObject)

Abstract class to handle PDF security

constructor Create(aLevel: TPdfEncryptionLevel; aPermissions: TPdfEncryptionPermissions; **const** aUserPassword, aOwnerPassword: **string**); **virtual**;
*Initialize the internal structures with the proper classes
- do not call this method directly, but class function TPdfEncryption.New()*

```
class function New(aLevel: TPdfEncryptionLevel; const aUserPassword,
aOwnerPassword: string; aPermissions: TPdfEncryptionPermissions): TPdfEncryption;
```

Will create the expected TPdfEncryption instance, depending on aLevel

- to be called as parameter of TPdfDocument/TPdfDocumentGDI.Create()
- currently, only eIRC4_40 and eIRC4_128 levels are implemented
- both passwords are expected to be ASCII-7 characters only
- aUserPassword will be asked at file opening: to be set to "" for not blocking display, but optional permission
- aOwnerPassword shall not be "", and will be used internally to cypher the pdf file content
- aPermissions can be either one of the PDF_PERMISSION_ALL / PDF_PERMISSION_NOMODIF / PDF_PERMISSION_NOPRINT / PDF_PERMISSION_NOCOPY / PDF_PERMISSION_NOCOPYNOPRINT set of options
- typical use may be:

```
Doc := TPdfDocument.Create(false,0,false,
  TPdfEncryption.New(eIRC4_40,'','toto',PDF_PERMISSION_NOMODIF));
Doc := TPdfDocument.Create(false,0,false,
  TPdfEncryption.New(eIRC4_128,'','toto',PDF_PERMISSION_NOCOPYNOPRINT));
```

```
procedure AttachDocument(aDoc: TPdfDocument); virtual;
```

Prepare a specific document to be encrypted

- internally used by TPdfDocument.NewDoc method

```
TPdfEncryptionRC4MD5 = class(TPdfEncryption)
```

Handle PDF security with RC4+MD5 scheme in 40-bit and 128-bit

- allowed aLevel parameters for Create() are only eIRC4_40 and eIRC4_128

```
procedure AttachDocument(aDoc: TPdfDocument); override;
```

Prepare a specific document to be encrypted

- will compute the internal keys

```
TPdfWrite = class(TObject)
```

Buffered writer class, specialized for PDF encoding

```
constructor Create(Destination: TPdfDocument; DestStream: TStream);
```

Create the buffered writer, for a specified destination stream

```
function Add(Value: TSynExtended): TPdfWrite; overload;
```

Add a floating point numerical value to the buffer

- up to 2 decimals are written

```
function Add(Text: PAnsiChar; Len: integer): TPdfWrite; overload;
```

Direct raw write of some data

- no conversion is made

```
function Add(const Text: RawByteString): TPdfWrite; overload;
```

Direct raw write of some data

- no conversion is made

function Add(Value, DigitCount: Integer): TPdfWrite; overload;

Add an integer numerical value to the buffer
- with a specified fixed number of digits (left filled by '0')

function Add(Value: Integer): TPdfWrite; overload;

Add an integer numerical value to the buffer

function Add(c: AnsiChar): TPdfWrite; overload;

Add a character to the buffer

function AddColorStr(Color: TPdfColorRGB): TPdfWrite;

Add a PDF color, from its TPdfColorRGB RGB value

function AddEscape(Text: PAnsiChar; TextLen: integer): TPdfWrite;

Add some WinAnsi text as PDF text
- used by TPdfText object

function AddEscapeContent(const Text: RawByteString): TPdfWrite;

Add some WinAnsi text as PDF text
- used by TPdfText object
- will optionally encrypt the content

function AddEscapeName(Text: PAnsiChar): TPdfWrite;

Add some PDF /property value

function AddEscapeText(Text: PAnsiChar; Font: TPdfFont): TPdfWrite;

Add some WinAnsi text as PDF text
- used by TPdfCanvas.ShowText method for WinAnsi text

function AddGlyphs(Glyphs: PWord; GlyphsCount: integer; Canvas: TPdfCanvas;
AVisAttrsPtr: Pointer=nil): TPdfWrite;

Write some Unicode text, encoded as Glyphs indexes, corresponding to the current font

function AddHex(const Bin: PDFString): TPdfWrite;

Hexadecimal write of some row data
- row data is written as hexadecimal byte values, one by one

function AddHex4(aWordValue: cardinal): TPdfWrite;

Add a word value, as Big-Endian 4 hexadecimal characters

function AddIntegerBin(value: integer; bytesize: cardinal): TPdfWrite;

Add an integer value as binary, specifying a storage size in bytes

function AddIso8601(DateTime: TDateTime): TPdfWrite;

Add an ISO 8601 encoded date time (e.g. '2010-06-16T15:06:59-07:00')

function AddToUnicodeHex(const Text: PDFString): TPdfWrite;

Convert some text into unicode characters, then write it as as Big-Endian 4 hexadecimal characters
- Ansi to Unicode conversion uses the CodePage set by Create() constructor

function AddToUnicodeHexText(**const** Text: PDFString; NextLine: boolean; Canvas: TPdfCanvas): TPdfWrite;

Convert some text into unicode characters, then write it as PDF Text

- Ansi to Unicode conversion uses the CodePage set by Create() constructor
- use (...) for all WinAnsi characters, or <..hexa..> for Unicode characters
- if NextLine is TRUE, the first written PDF Text command is not Tj but '
- during the text process, corresponding TPdfTrueTypeFont properties are updated (Unicode version created if necessary, indicate used glyphs for further Font properties writing to the PDF file content...)
- if the current font is not True Type, all Unicode characters are drawn as '?'

function AddUnicodeHex(PW: PWideChar; WideCharCount: integer): TPdfWrite;

Write some unicode text as as Big-Endian 4 hexadecimal characters

function AddUnicodeHexText(PW: PWideChar; NextLine: boolean; Canvas: TPdfCanvas): TPdfWrite;

Write some Unicode text, as PDF text

- incoming unicode text must end with a #0
- use (...) for all WinAnsi characters, or <..hexa..> for Unicode characters
- if NextLine is TRUE, the first written PDF Text command is not Tj but '
- during the text process, corresponding TPdfTrueTypeFont properties are updated (Unicode version created if necessary, indicate used glyphs for further Font properties writing to the PDF file content...)
- if the current font is not True Type, all Unicode characters are drawn as '?'

function AddWithSpace(Value: TSynExtended): TPdfWrite; overload;

Add a floating point numerical value to the buffer

- up to 2 decimals are written, together with a trailing space

function AddWithSpace(Value: Integer): TPdfWrite; overload;

Add an integer numerical value to the buffer

- and append a trailing space

function AddWithSpace(Value: TSynExtended; Decimals: cardinal): TPdfWrite; overload;

Add a floating point numerical value to the buffer

- this version handles a variable number of decimals, together with a trailing space - this is used by ConcatToCTM e.g. or enhanced precision

function Position: Integer;

Return the current position

- add the current internal buffer stream position to the destination stream position

function ToPDFString: PDFString;

Get the data written to the Writer as a PDFString

- this method could not use Save to flush the data, if all input was inside the internal buffer (save some CPU and memory): so don't intend the destination stream to be flushed after having called this method

procedure AddRGB(P: PAnsiChar; PInc, Count: integer);

Add a TBitmap.Scanline[] content into the stream

procedure Save;

Flush the internal buffer to the destination stream

TPdfObjectMgr = **class**(TObject)

Object manager is a virtual class to manage instance of indirect PDF objects

TPdfObject = **class**(TObject)

Master class for most PDF objects declaration

constructor Create; **virtual**;

Create the PDF object instance

procedure ForceSaveNow;

Low-level force the object to be saved now

- you should not use this low-level method, unless you want to force the FSaveAtTheEnd internal flag to be set to force, so that TPdfDocument.SaveToStreamDirectPageFlush would flush the object content

procedure WriteTo(**var** W: TPdfWrite);

Write object to specified stream

- If object is indirect object then write references to stream

procedure WriteValueTo(**var** W: TPdfWrite);

Write indirect object to specified stream

- this method called by parent object

property GenerationNumber: integer **read** FGenerationNumber;

The associated PDF Generation Number

property ObjectNumber: integer **read** FObjectNumber **write** SetObjectNumber;

The associated PDF Object Number

- If you set an object number higher than zero, the object is considered as indirect. Otherwise, the object is considered as direct object.

property ObjectType: TPdfObjectType **read** FObjectType;

The corresponding type of this PDF object

TPdfVirtualObject = **class**(TPdfObject)

A virtual PDF object, with an associated PDF Object Number

TPdfBoolean = **class**(TPdfObject)

A PDF object, storing a boolean value

TPdfNull = **class**(TPdfObject)

A PDF object, storing a NULL value

TPdfNumber = **class**(TPdfObject)

A PDF object, storing a numerical (integer) value

TPdfReal = **class**(TPdfObject)

A PDF object, storing a numerical (floating point) value

TPdfText = class(TPdfObject)

A PDF object, storing a textual value

- the value is specified as a PDFString
- this object is stored as '(escapedValue)'
- in case of MBCS, conversion is made into Unicode before writing, and stored as '<FEFFHexUnicodeEncodedValue>'

TPdfTextUTF8 = class(TPdfObject)

A PDF object, storing a textual value

- the value is specified as an UTF-8 encoded string
- this object is stored as '(escapedValue)'
- in case characters with ANSI code higher than 8 Bits, conversion is made into Unicode before writing, and '<FEFFHexUnicodeEncodedValue>'

TPdfTextString = class(TPdfTextUTF8)

A PDF object, storing a textual value

- the value is specified as a generic VCL string
- this object is stored as '(escapedValue)'
- in case characters with ANSI code higher than 8 Bits, conversion is made into Unicode before writing, and '<FEFFHexUnicodeEncodedValue>'

TPdfRawText = class(TPdfText)

A PDF object, storing a raw PDF content

- this object is stored into the PDF stream as the defined Value

TPdfClearText = class(TPdfText)

A PDF object, storing a textual value with no encryption

- the value is specified as a memory buffer
- this object is stored as '(escapedValue)'

TPdfName = class(TPdfText)

A PDF object, storing a PDF name

- this object is stored as '/Value'

function AppendPrefix: RawUtf8;

Append the 'SUBSET+' prefix to the Value

- used e.g. to notify that a font is included as a subset

TPdfArray = class(TPdfObject)

Used to store an array of PDF objects

constructor Create(AObjectMgr: TPdfObjectMgr; AArray: PWordArray; AArrayCount: integer); **reintroduce**; overload;

Create an array of PDF objects, with some specified TPdfNumber values

constructor Create(AObjectMgr: TPdfObjectMgr; **const** AArray: array of Integer); **reintroduce**; overload;

Create an array of PDF objects, with some specified TPdfNumber values

constructor Create(AObjectMgr: TPdfObjectMgr); reintroduce; overload;

Create an array of PDF objects

constructor CreateNames(AObjectMgr: TPdfObjectMgr; const AArray: array of PDFString); reintroduce; overload;

Create an array of PDF objects, with some specified TPdfName values

constructor CreateReals(AObjectMgr: TPdfObjectMgr; const AArray: array of double); reintroduce; overload;

Create an array of PDF objects, with some specified TPdfReal values

destructor Destroy; override;

Release the instance memory, and all embedded objects instances

function AddItem(AItem: TPdfObject): integer;

Add a PDF object to the array

- if AItem already exists, do nothing

function FindName(const AName: PDFString): TPdfName;

Retrieve a TPdfName object stored in the array

function RemoveName(const AName: PDFString): boolean;

Remove a specified TPdfName object stored in the array

procedure InsertItem(Index: Integer; AItem: TPdfObject);

Insert a PDF object to the array

- if AItem already exists, do nothing

property ItemCount: integer read GetItemCount;

Retrieve the array size

property Items[Index: integer]: TPdfObject read GetItems;

Retrieve an object instance, stored in the array

property List: TList read FArray;

Direct access to the internal TList instance

- not to be used normally

property ObjectMgr: TPdfObjectMgr read FObjectMgr;

The associated PDF Object Manager

TPdfDictionaryElement = **class**(TObject)

PDF dictionary element definition

constructor Create(const AKey: PDFString; AValue: TPdfObject; AInternal: Boolean=false);

Create the corresponding Key / Value pair

destructor Destroy; override;

Release the element instance, and both associated Key and Value

property IsInternal: boolean read FIsInternal;

If this element was created as internal, i.e. not to be saved to the PDF content

property Key: PDFString **read** GetKey;

The associated Key Name

property Value: TPdfObject **read** FValue;

The associated Value stored in this element

TPdfDictionary = **class**(TPdfObject)

A PDF Dictionary is used to manage Key / Value pairs

constructor Create(AObjectMgr: TPdfObjectMgr); **reintroduce**;

Create the PDF dictionary

destructor Destroy; **override**;

Release the dictionary instance, and all associated elements

function PdfArrayByName(**const** AKey: PDFString): TPdfArray;

Fast find an array value by its name

function PdfBooleanByName(**const** AKey: PDFString): TPdfBoolean;

Fast find a boolean value by its name

function PdfDictionaryByName(**const** AKey: PDFString): TPdfDictionary;

Fast find a dictionary value by its name

function PdfNameByName(**const** AKey: PDFString): TPdfName;

Fast find a name value by its name

function PdfNumberByName(**const** AKey: PDFString): TPdfNumber;

Fast find a numerical (integer) value by its name

function PdfRealByName(**const** AKey: PDFString): TPdfReal;

Fast find a numerical (floating-point) value by its name

function PdfTextByName(**const** AKey: PDFString): TPdfText;

Fast find a textual value by its name

function PdfTextStringValueByName(**const** AKey: PDFString): **string**;

Fast find a textual value by its name

- return '' if not found, the TPdfTextString.Value otherwise

function PdfTextUTF8ValueByName(**const** AKey: PDFString): RawUTF8;

Fast find a textual value by its name

- return '' if not found, the TPdfTextUTF8.Value otherwise

function PdfTextValueByName(**const** AKey: PDFString): PDFString;

Fast find a textual value by its name

- return '' if not found, the TPdfText.Value otherwise

function ValueByName(**const** AKey: PDFString): TPdfObject;

Fast find a value by its name

procedure AddItem(**const** AKey: PDFString; AValue: integer); **overload**;

Add a specified Key / Value pair (of type TPdfNumber) to the dictionary

procedure AddItem(**const** AKey, AValue: PDFString); overload;

Add a specified Key / Value pair (of type TPdfName) to the dictionary

procedure AddItem(**const** AKey: PDFString; AValue: TPdfObject; AInternal: Boolean=false); overload;

Add a specified Key / Value pair to the dictionary

- create PdfDictionaryElement with given key and value, and add it to list
- if the element exists, replace value of element by given value
- internal items are local to the framework, and not to be saved to the PDF content

procedure AddItemText(**const** AKey, AValue: PDFString); overload;

Add a specified Key / Value pair (of type TPdfText) to the dictionary

procedure AddItemTextString(**const** AKey: PDFString; **const** AValue: string); overload;

Add a specified Key / Value pair (of type TPdfTextUTF8) to the dictionary

- the value is a generic VCL string: it will be written as Unicode hexadecimal to the PDF stream, if necessary

procedure AddItemTextUTF8(**const** AKey: PDFString; **const** AValue: RawUTF8); overload;

Add a specified Key / Value pair (of type TPdfTextUTF8) to the dictionary

- the value can be any UTF-8 encoded text: it will be written as Unicode hexadecimal to the PDF stream, if necessary

procedure RemoveItem(**const** AKey: PDFString);

Remove the element specified by its Key from the dictionary

- if the element does not exist, do nothing

property ItemCount: integer **read** GetItemCount;

Retrieve the dictionary element count

property Items[Index: integer]: TPdfDictionaryElement **read** GetItems;

Retrieve any dictionary element

property List: TList **read** FArray;

Direct access to the internal TList instance

- not to be used normally

property ObjectMgr: TPdfObjectMgr **read** FObjectMgr;

Retrieve the associated Object Manager

property TypeOf: PDFString **read** GetTypeOf;

Retrieve the type of the pdfdictionary object, i.e. the 'Type' property name

TPdfStream = class(TPdfObject)

A temporary memory stream, to be stored into the PDF content

- typically used for the page content
- can be compressed, if the FlateDecode filter is set

constructor Create(ADoc: TPdfDocument; DontAddToFXref: boolean=false);
reintroduce;

Create the temporary memory stream

- an optional DontAddToFXref is available, if you don't want to add this object to the main XRef list of the PDF file

destructor Destroy; **override**;

Release the memory stream

property Attributes: TPdfDictionary **read** FAttributes;

Retrieve the associated attributes, e.g. the stream Length

property Filter: PDFString **read** FFilter **write** FFilter;

Retrieve the associated filter name

property Writer: TPdfWrite **read** FWriter;

Retrieve the associated buffered writer

- use this TPdfWrite instance to write some data into the stream

TPdfBinary = **class**(TPdfObject)

Used to handle object which are not defined in this library

constructor Create; **override**;

Create the instance, i.e. its associated stream

destructor Destroy; **override**;

Release the instance

property Stream: TMemoryStream **read** FStream;

The associated memory stream, used to store the corresponding data

- the content of this stream will be written to the resulting

TPdfTrailer = **class**(TObject)

The Trailer of the PDF File

TPdfXrefEntry = **class**(TObject)

Store one entry in the XRef list of the PDF file

constructor Create(AValue: TPdfObject);

Create the entry, with the specified value

- if the value is nil (e.g. root entry), the type is 'f' (PDF_FREE_ENTRY), otherwise the entry type is 'n' (PDF_IN_USE_ENTRY)

destructor Destroy; **override**;

Release the memory, and the associated value, if any

procedure SaveToPdfWrite(**var** W: TPdfWrite);

Write the XRef list entry

property ByteOffset: integer **read** FByteOffset;

The position (in bytes) in the PDF file content stream

- to be ignored if ObjectStreamIndex>=0

property EntryType: PDFString **read** FEntryType **write** FEntryType;

Return either 'f' (PDF_FREE_ENTRY), either 'n' (PDF_IN_USE_ENTRY)

property GenerationNumber: integer **read** FGenerationNumber **write** FGenerationNumber;

The associated Generation Number

- mostly 0, or 65535 (PDF_MAX_GENERATION_NUM) for the root 'f' entry

property ObjectStreamIndex: Integer **read** FObjectStreamIndex;

The index of this object in the global compressed /ObjStm object stream

- equals -1 by default, i.e. if stored within the main file content stream

property Value: TPdfObject **read** FValue;

The associated PDF object

TPdfXref = class(TPdfObjectMgr)

Store the XRef list of the PDF file

constructor Create;

Initialize the XRef object list

- create first a void 'f' (PDF_FREE_ENTRY) as root

destructor Destroy; **override**;

Release instance memory and all associated XRef objects

function GetObject(ObjectID: integer): TPdfObject; **override**;

Retrieve an object from its object ID

procedure AddObject(AObject: TPdfObject); **override**;

Register object to the xref table, and set corresponding object ID

property ItemCount: integer **read** GetItemCount;

Retrieve the XRef object count

property Items[ObjectID: integer]: TPdfXrefEntry **read** GetItem;

Retrieve a XRef object instance, from its object ID

TPdfXObject = class(TPdfStream)

Any object stored to the PDF file

- these objects are the main unit of the PDF file content

- these objects are written in the PDF file, followed by a "xref" table

TPdfOutlines = class(TPdfDictionary)

Generic PDF Outlines entries, stored as a PDF dictionary

TPdfOptionalContentGroup = class(TPdfDictionary)

Generic PDF Optional Content entry

TPdfDocument = class(TObject)

The main class of the PDF engine, processing the whole PDF document

Used for DI-2.3.2 (page 2560).

constructor Create(AUseOutlines: Boolean=false; ACodePage: integer=0; APDFA1: boolean=false ; AEncryption: TPdfEncryption=nil); **reintroduce**;

Create the PDF document instance, with a Canvas and a default A4 paper size

- the current charset and code page are retrieved from the SysLocale value, so the PDF engine is MBCS ready
- note that only Win-Ansi encoding allows use of embedded standard fonts
- you can specify a Code Page to be used for the PDFString encoding; by default (ACodePage left to 0), the current system code page is used
- you can create a PDF/A compliant document by setting APDFA to PDF/A Level or APDFA1 to true
- you can set an encryption instance, by using TPdfEncryption.New()

destructor Destroy; **override**;

Release the PDF document instance

function AddPage: TPdfPage; **virtual**;

Add a Page to the current PDF document

function AddTrueTypeFont(const TTFName: RawUtf8): boolean;

Register a font to the internal TTF font list

- some fonts may not be enumerated in the system, e.g. after calling AddFontMemResourceEx, so could be registered by this method
- to be called just after Create(), before anything is written

function AddXObject(const AName: PDFString; AXObject: TPdfXObject): integer;

Add then register an object (typically a TPdfImage) to the PDF document

- returns the internal index as added in FXObjectList[]

function CreateAnnotation(AType: TPdfAnnotationSubType; const ARect: TPdfRect; BorderStyle: TPdfAnnotationBorder=abSolid; BorderWidth: integer=1): TPdfDictionary;

Wrapper to create an annotation

- the annotation is set to a specified position of the current page

function CreateDestination: TPdfDestination;

Create a Destination

- the current PDF Canvas page is associated with this destination object

function CreateHyperLink(const ARect: TPdfRect; const url: RawUTF8; BorderStyle: TPdfAnnotationBorder=abSolid; BorderWidth: integer=0): TPdfDictionary;

Wrapper to create a hyper-link, with a specific URL value

function CreateLink(const ARect: TPdfRect; const aBookmarkName: RawUTF8; BorderStyle: TPdfAnnotationBorder=abSolid; BorderWidth: integer=1): TPdfDictionary;

Wrapper to create a Link annotation, specified by a bookmark

- the link is set to a specified rectangular position of the current page
- if the bookmark name is not existing (i.e. if no such name has been defined yet via the CreateBookMark method), it's added to the internal fMissingBookmarks list, and will be linked at CreateBookMark method call

```
function CreateOptionalContentGroup(ParentContentGroup: TPdfOptionalContentGroup;  
const Title: string; Visible: Boolean=true): TPdfOptionalContentGroup;
```

Create a new optional content group (layer)

- returns a TPdfOptionalContentGroup needed for TPDFCanvas.BeginMarkedContent
- if ParentContentGroup is not nil, the new content group is a subgroup to ParentContentGroup
- Title is the string shown in the PDF Viewer
- Visible controls the initial state of the content group

```
function CreateOrGetImage(B: TBitmap; DrawAt: PPdfBox=nil; ClipRc: PPdfBox=nil):  
PDFString;
```

Create an image from a supplied bitmap

- returns the internal XObject name of the resulting TPDFImage
- if you specify a PPdfBox to draw the image at the given position/size
- if the same bitmap content is sent more than once, the TPDFImage will be reused (it will therefore spare resulting pdf file space) - if the ForceNoBitmapReuse is FALSE
- if ForceCompression property is set, the picture will be stored as a JPEG
- you can specify a clipping rectangle region as ClipRc parameter

```
function CreateOutline(const Title: string; Level: integer; TopPosition: Single):  
TPdfOutlineEntry;
```

Create an Outline entry at a specified position of the current page

- the outline tree is created from the specified numerical level (0=root), just after the item added via the previous CreateOutline call
- the title is a generic VCL string, to handle fully Unicode support

```
function CreatePages(Parent: TPdfDictionary): TPdfDictionary;
```

Create a Pages object

- Pages objects can be nested, to save memory used by the Viewer
- only necessary if you have more than 8000 pages (this method is called by TPdfDocument.NewDoc, so you shouldn't have to use it)

```
function GetXObject(const AName: PDFString): TPdfXObject;
```

Retrieve a XObject from its name

- this method will handle also the Virtual Objects

```
function GetXObjectImageName(const Hash: THash128Rec; Width, Height: Integer):  
PDFString;
```

Retrieve a XObject TPDFImage index from its picture attributes

- returns "" if this image is not already there
- uses 4 hash codes, created with 4 diverse seeds, in order to avoid false positives

```
function GetXObjectIndex(const AName: PDFString): integer;
```

Retrieve a XObject index from its name

- this method won't handle the Virtual Objects

```
function RegisterXObject(AObject: TPdfXObject; const AName: PDFString): integer;
```

Register an object (typically a TPDFImage) to the PDF document

- returns the internal index as added in FXObjectList[]

```
function SaveToFile(const aFileName: TFileName): boolean;
```

Save the PDF file content into a specified file

- return FALSE on any writing error (e.g. if the file is opened in the Acrobat Reader)

procedure CreateBookMark(TopPosition: Single; **const** aBookmarkName: RawUTF8);

Create an internal bookmark entry at a specified position of the current page

- the current PDF Canvas page is associated with the destination object
- a dtXYZ destination with the corresponding TopPosition Y value is defined
- the associated bookmark name must be unique, otherwise an exception is raised

procedure CreateOptionalContentRadioGroup(**const** ContentGroups: array of TPdfOptionalContentGroup);

Create a Radio Optional ContentGroup

- ContentGroups is a array of TPdfOptionalContentGroups which should behave like radiobuttons, i.e. only one active at a time
- visibility must be set with CreateOptionalContentGroup, only one group should be visible

procedure NewDoc;

Create a new document

- this method is called first, by the Create constructor
- you can call it multiple time if you want to reset the whole document content

procedure SaveToStream(AStream: TStream; ForceModDate: TDateTime=0); **virtual**;

Save the PDF file content into a specified Stream

procedure SaveToStreamDirectBegin(AStream: TStream; ForceModDate: TDateTime=0);

Prepare to save the PDF file content into a specified Stream

- is called by SaveToStream() method
- you can then append other individual pages with SaveToStreamCurrentPage to avoid most resource usage (e.g. for report creation)
- shall be finished by a SaveToStreamDirectEnd call

procedure SaveToStreamDirectEnd;

Prepare to save the PDF file content into a specified Stream

- shall be made once after a SaveToStreamDirectBegin() call
- is called by SaveToStream() method

procedure SaveToStreamDirectPageFlush(FlushCurrentPageNow: boolean=false); **virtual**;

Save the current page content to the PDF file

- shall be made one or several times after a SaveToStreamDirectBegin() call and before a final SaveToStreamDirectEnd call
- see TPdfDocumentGDI.SaveToStream() in this unit, and TGDIPages.ExportPDFStream() in mORMotReport.pas for real use cases
- you can set FlushCurrentPageNow=true to force the current page to be part of the flushed content

property Canvas: TPdfCanvas **read** fCanvas;

Retrieve the current PDF Canvas, associated to the current page

property CharSet: integer **read** FCharSet;

The current CharSet used for this PDF Document

property CodePage: cardinal **read** FCodePage;

The current Code Page encoding used for this PDF Document

property CompressionMethod: TPdfCompressionMethod **read** FCompressionMethod **write** FCompressionMethod;
SetCompressionMethod;

The compression method used for page content storage
- is set by default to cmFlateDecode when the class instance is created

property DefaultPageHeight: cardinal **read** FDefaultPageHeight **write** SetDefaultPageHeight;

The default page height, used for new every page creation (i.e. AddPage method call)

property DefaultPageLandscape: boolean **read** GetDefaultPageLandscape **write** SetDefaultPageLandscape;

The default page orientation
- a call to this property will swap default page width and height if the orientation is not correct

property DefaultPageWidth: cardinal **read** FDefaultPageWidth **write** SetDefaultPageWidth;

The default page width, used for new every page creation (i.e. AddPage method call)

property DefaultPaperSize: TPDFPaperSize **read** FDefaultPaperSize **write** SetDefaultPaperSize;

The default page size, used for every new page creation (i.e. AddPage method call)
- a write to this property this will reset the default paper orientation to Portrait: you must explicitly set DefaultPageLandscape to true, if needed

property EmbeddedTTF: boolean **read** fEmbeddedTTF **write** fEmbeddedTTF;

If set to TRUE, the used True Type fonts will be embedded to the PDF content
- not set by default, to save disk space and produce tiny PDF

property EmbeddedTTFIgnore: TRawUTF8List **read** GetEmbeddedTTFIgnore;

You can add some font names to this list, if you want these fonts NEVER to be embedded to the PDF file, even if the EmbeddedTTF property is set
- if you want to ignore all standard windows fonts, use:
EmbeddedTTFIgnore.Text := MSWINDOWS_DEFAULT_FONTS;

property EmbeddedWholeTTF: boolean **read** fEmbeddedWholeTTF **write** fEmbeddedWholeTTF;

If set to TRUE, the embedded True Type fonts will be totally Embedded
- by default, is set to FALSE, meaning that a subset of the TTF font is stored into the PDF file, i.e. only the used glyphs are stored
- this option is only available if running on Windows XP or later

property FontFallbackName: string **read** GetFontFallbackName **write** SetFontFallbackName;

Set the font name to be used for missing characters
- used only if UseFontFallback is TRUE
- default value is 'Lucida Sans Unicode' or 'Arial Unicode MS', if available - but you may also consider <https://fonts.google.com/noto/fonts>

property ForceJPEGCompression: integer **read** fForceJPEGCompression **write** fForceJPEGCompression;

This property can force saving all canvas bitmaps images as JPEG

- handle bitmaps added by VCLCanvas/TMetaFile and bitmaps added as TPdfImage
- by default, this property is set to 0 by the constructor of this class, meaning that the JPEG compression is not forced, and the engine will use the native resolution of the bitmap - in this case, the resulting PDF file content will be bigger in size (e.g. use this for printing)
- 60 is the preferred way e.g. for publishing PDF over the internet
- 80/90 is a good ratio if you want to have a nice PDF to see on screen
- of course, this doesn't affect vectorial (i.e. emf) pictures

property ForceNoBitmapReuse: boolean **read** fForceNoBitmapReuse **write** fForceNoBitmapReuse;

This property can force all canvas bitmaps to be stored directly

- by default, the library will try to match an existing same bitmap content, and reuse the existing pdf object - you can set this property for a faster process, if you do not want to use this feature

property GeneratePDF15File: boolean **read** GetGeneratePDF15File **write** SetGeneratePDF15File;

Set to TRUE to force PDF 1.5 format, which may produce smaller files

property Info: TPdfInfo **read** GetInfo;

Retrieve the PDF information, associated to the PDF document

property OutlineRoot: TPdfOutlineRoot **read** GetOutlineRoot;

Retrieve the PDF Outline, associated to the PDF document

- UseOutlines must be set to TRUE before any use of the OutlineRoot property

property PDFA: TPdfALevel **read** fPDFA **write** SetPDFA;

Is pdfaXXX if the file was created in order to be PDF/A compliant

- set APDFA parameter to a level for Create constructor in order to use it
- warning: setting a value to this property after creation will call the NewDoc method, therefore will erase all previous content and pages (including Info properties)

property PDFA1: boolean **read** GetPDFA1 **write** SetPDFA1;

Is TRUE if the file was created in order to be PDF/A-1 compliant

- set APDFA1 parameter to true for Create constructor in order to use it
- warning: setting a value to this property after creation will call the NewDoc method, therefore will erase all previous content and pages (including Info properties)

property RawPages: TList **read** fRawPages;

Direct read-only access to all corresponding TPdfPage

- can be useful in inherited classe

property Root: TPdfCatalog **read** fRoot;

Retrieve the PDF Document Catalog, as root of the document's object hierarchy

property ScreenLogPixels: Integer **read** FScreenLogPixels **write** FScreenLogPixels;

The resolution used for pixel to PDF coordinates conversion

- by default, contains the Number of pixels per logical inch along the screen width
- you can override this value if you really need additional resolution for your bitmaps and such - this is useful only with TPdfDocumentGDI and its associated TCanvas: all TPdfDocument native TPdfCanvas methods use the native resolution of the PDF, i.e. more than 7200 DPI (since we write coordinates with 2 decimals per point - which is 1/72 inch)

property StandardFontsReplace: boolean **read** FStandardFontsReplace **write** SetStandardFontsReplace;

Set if the PDF engine must use standard fonts substitution

- if TRUE, 'Arial', 'Times New Roman' and 'Courier New' will be replaced by the corresponding internal Type 1 fonts, defined in the Reader
- only works with current ANSI_CHARSET, i.e. if you want to display some other unicode characters, don't enable this property: all non WinAnsi glyphs would be replaced by a '?' sign
- default value is false (i.e. not embedded standard font)

property UseFontFallback: boolean **read** fUseFontFallback **write** fUseFontFallback;

Used to define if the PDF document will handle "font fallback" for characters not existing in the current font: it will avoid rendering block/square symbols instead of the correct characters (e.g. for Chinese text)

- will use the font specified by FontFallbackName property to add any Unicode glyph not existing in the currently selected font
- default value is TRUE

property UseOptionalContent: boolean **read** FUseOptionalContent **write** SetUseOptionalContent;

Used to define if the PDF document will use optional content (layers)

- will also force PDF 1.5 as minimal file format
- must be set to TRUE before calling NewDoc
- warning: setting a value to this property after creation will call the NewDoc method, therefore will erase all previous content and pages (including Info properties)

property UseOutlines: boolean **read** FUseoutlines **write** FUseoutlines;

Used to define if the PDF document will use outlines

- must be set to TRUE before any use of the OutlineRoot property

property UseUniscribe: boolean **read** fUseUniscribe **write** fUseUniscribe;

Set if the PDF engine must use the Windows Uniscribe API to render Ordering and/or Shaping of the text

- useful for Hebrew, Arabic and some Asiatic languages handling
- set to FALSE by default, for faster content generation
- you can set this property temporary to TRUE, when using the Canvas property, but this property must be set appropriately before the content generation if you use any TPdfDocumentGdi.VCLCanvas text output with such scripting (since the PDF rendering is done once just before the saving, e.g. before SaveToFile() or SaveToStream() methods calls)
- the PDF engine don't handle Font Fallback yet: the font you use must contain ALL glyphs necessary for the supplied unicode text - squares or blanks will be drawn for any missing glyph/character

TPdfPage = class(TPdfDictionary)

A PDF page

constructor Create(ADoc: TPdfDocument); **reintroduce**; **virtual**;

Create the page with its internal VCL Canvas

function MeasureText(**const** Text: PDFString; Width: Single): integer;

Calculate the number of chars which can be displayed in the specified width, according to current attributes

- this function is compatible with MBCS strings, and returns the index in Text, not the glyphs index

function TextWidth(**const** Text: PDFString): Single;

Calculate width of specified text according to current attributes

- this function is compatible with MBCS strings

property CharSpace: Single **read** FCharSpace **write** SetCharSpace;

Retrieve or set the Char Space attribute, in PDF coordinates of 1/72 inch

property Font: TPdfFont **read** FFont **write** FFont;

Retrieve the current used font

- for TPdfFontTrueType, this points not always to the WinAnsi version of the Font, but can also point to the Unicode Version, if the last drawn character by ShowText() was unicode - see TPdfWrite.AddUnicodeHexText

property FontSize: Single **read** FFontSize **write** SetFontSize;

Retrieve or set the font Size attribute, in system TFont.Size units

property HorizontalScaling: Single **read** FHorizontalScaling **write** SetHorizontalScaling;

Retrieve or set the Horizontal Scaling attribute, in PDF coordinates of 1/72 inch

property Leading: Single **read** FLeading **write** SetLeading;

Retrieve or set the text Leading attribute, in PDF coordinates of 1/72 inch

property PageHeight: integer **read** GetPageHeight **write** SetPageHeight;

Retrieve or set the current page height, in PDF coordinates of 1/72 inch

property PageLandscape: Boolean **read** GetPageLandscape **write** SetPageLandscape;

Retrieve or set the paper orientation

property PageWidth: integer **read** GetPageWidth **write** SetPageWidth;

Retrieve or set the current page width, in PDF coordinates of 1/72 inch

property WordSpace: Single **read** FWordSpace **write** SetWordSpace;

Retrieve or set the word Space attribute, in PDF coordinates of 1/72 inch

TPdfCanvas = class(TObject)

Access to the PDF Canvas, used to draw on the page

Used for DI-2.3.2 (page 2560).

constructor Create(APdfDoc: TPdfDocument);

Create the PDF canvas instance

function GetNextWord(const S: PDFString; var Index: integer): PDFString;

Get the index of the next word in the supplied text

- this function is compatible with MBCS strings, and returns the index in Text, not the glyphs index

function MeasureText(const Text: PDFString; AWidth: Single): integer;

Calculate the number of chars which can be displayed in the specified width, according to current attributes

- this function is compatible with MBCS strings, and returns the index in Text, not the glyphs index

- note: this method only work with embedded fonts by now, not true type fonts (because text width measuring is not yet implemented for them)

function SetFont(const AName: RawUTF8; ASize: Single; AStyle: TPdfFontStyles; ACharSet: integer=-1; AForceTTF: integer=-1; AIsFixedWidth: boolean=false): TPdfFont; overload;

Set the current font for the PDF Canvas

- expect the font name to be either a standard embedded font ('Helvetica','Courier','Times') or its Windows equivalency (i.e. 'Arial','Courier New','Times New Roman'), either a UTF-8 encoded True Type font name available on the system

- if no CharSet is specified (i.e. if it remains -1), the current document CharSet parameter is used

function SetFont(ADC: HDC; const ALogFont: TLogFontW; ASize: single): TPdfFont; overload;

Set the current font for the PDF Canvas

- this method use the Win32 structure that defines the characteristics of the logical font

function TextWidth(const Text: PDFString): Single;

Calculate width of specified text according to current Canvas attributes

- works with MBCS strings

function UnicodeTextWidth(PW: PWideChar): Single;

Calculate width of specified text according to current Canvas attributes

- this function compute the raw width of the specified text, and won't use HorizontalScaling, CharSpace nor WordSpace in its calculation

procedure BeginMarkedContent(Group: TPdfOptionalContentGroup);

Starts optional content (layer)

- Group must be registered with TPdfDocument.CreateOptionalContentGroup

- each BeginMarkedContent must have a corresponding EndMarkedContent

- nested BeginMarkedContent/EndMarkedContent are possible

procedure BeginText;

Begin a text object

- Text objects cannot be nested

procedure Clip;

Nonzero winding clipping path set

- Modify the current clipping path by intersecting it with the current path, using the nonzero winding number rule to determine which regions lie inside the clipping path
- The graphics state contains a clipping path that limits the regions of the page affected by painting operators. The closed subpaths of this path define the area that can be painted. Marks falling inside this area will be applied to the page; those falling outside it will not. (Precisely what is considered to be inside a path is discussed under "Filling", above.)
- The initial clipping path includes the entire page. Both clipping path methods (Clip and EoClip) may appear after the last path construction operator and before the path-painting operator that terminates a path object. Although the clipping path operator appears before the painting operator, it does not alter the clipping path at the point where it appears. Rather, it modifies the effect of the succeeding painting operator. After the path has been painted, the clipping path in the graphics state is set to the intersection of the current clipping path and the newly constructed path.

procedure Closepath;

Close the current subpath by appending a straight line segment from the current point to the starting point of the subpath

- This operator terminates the current subpath; appending another segment to the current path will begin a new subpath, even if the new segment begins at the endpoint reached by the h operation
- If the current subpath is already closed or the current path is empty, it does nothing

procedure ClosepathEofillStroke;

Close, fill, and then stroke the path, using the even-odd rule to determine the region to fill

- This operator has the same effect as the sequence Closepath; EofillStroke;

procedure ClosepathFillStroke;

Close, fill, and then stroke the path, using the nonzero winding number rule to determine the region to fill

- This operator has the same effect as the sequence ClosePath; FillStroke;

procedure ClosePathStroke;

Close and stroke the path

- This operator has the same effect as the sequence ClosePath; Stroke;

procedure ConcatToCTM(a, b, c, d, e, f: Single; Decimals: Cardinal=6);

Modify the CTM by concatenating the specified matrix

- The current transformation matrix (CTM) maps positions from user coordinates to device coordinates
- This matrix is modified by each application of the ConcatToCTM method
- CTM Initial value is a matrix that transforms default user coordinates to device coordinates
- since floating-point precision does make sense for a transformation matrix, we added a custom decimal number parameter here

procedure CurveToC(x1, y1, x2, y2, x3, y3: Single);

Append a cubic Bezier curve to the current path

- The curve extends from the current point to the point (x3, y3), using (x1, y1) and (x2, y2) as the Bezier control points
- The new current point is (x3, y3)

procedure CurveToV(x2, y2, x3, y3: Single);

Append a cubic Bezier curve to the current path

- The curve extends from the current point to the point (x3, y3), using the current point and (x2, y2) as the Bezier control points
- The new current point is (x3, y3)

procedure CurveToY(x1, y1, x3, y3: Single);

Append a cubic Bezier curve to the current path

- The curve extends from the current point to the point (x3, y3), using (x1, y1) and (x3, y3) as the Bezier control points
- The new current point is (x3, y3)

procedure DrawXObject(X, Y, AWidth, AHeight: Single; **const** AXObjectName: PDFString);

Draw the specified object (typically an image) with stretching

procedure DrawXObjectEx(X, Y, AWidth, AHeight: Single; ClipX, ClipY, ClipWidth, ClipHeight: Single; **const** AXObjectName: PDFString);

Draw the specified object (typically an image) with stretching and clipping

procedure Ellipse(x, y, width, height: Single);

Draw an ellipse

- use Bezier curves internally to draw the ellipse

procedure EndMarkedContent;

Ends optional content (layer)

procedure EndText;

End a text object, discarding the text matrix

procedure EoClip;

Even-Odd winding clipping path set

- Modify the current clipping path by intersecting it with the current path, using the even-odd rule to determine which regions lie inside the clipping path

procedure EoFill;

Fill the path, using the even-odd rule to determine the region to fill

procedure EofillStroke;

Fill and then stroke the path, using the even-odd rule to determine the region to fill

- This operator produces the same result as FillStroke, except that the path is filled as if with Eofill instead of Fill

procedure ExecuteXObject(**const** xObject: PDFString);

Paint the specified XObject

procedure Fill;

Fill the path, using the nonzero winding number rule to determine the region to fill

procedure FillStroke;

Fill and then stroke the path, using the nonzero winding number rule to determine the region to fill

- This produces the same result as constructing two identical path objects, painting the first with Fill and the second with Stroke. Note, however, that the filling and stroking portions of the operation consult different values of several graphics state parameters, such as the color

procedure GRestore;

Restores the entire graphics state to its former value by popping it from the stack

procedure GSave;

Pushes a copy of the entire graphics state onto the stack

procedure LineTo(x, y: Single);

Append a straight line segment from the current point to the point (x, y).

- The new current point is (x, y)

procedure MoveTextPoint(tx, ty: Single);

Move to the start of the next line, offset from the start of the current line by (tx, ty)

- tx and ty are numbers expressed in unscaled text space units

procedure MoveTo(x, y: Single);

Change the current coordinates position

- Begin a new subpath by moving the current point to coordinates (x, y), omitting any connecting line segment. If the previous path construction operator in the current path was also MoveTo(), the new MoveTo() overrides it; no vestige of the previous MoveTo() call remains in the path.

procedure MoveToNextLine;

Move to the start of the next line

procedure MultilineTextRect(ARect: TPdfRect; **const** Text: PDFString; WordWrap: boolean);

Show the text in the specified rectangle and alignment

- text can be multiline, separated by CR + LF (i.e. #13#10)
- text can optionally word wrap
- note: this method only works with embedded fonts by now, not true type fonts (because it uses text width measuring)

procedure NewPath;

End the path object without filling or stroking it

- This operator is a "path-painting no-op", used primarily for the side effect of changing the clipping path

procedure Rectangle(x, y, width, height: Single);

Append a rectangle to the current path as a complete subpath, with lower-left corner (x, y) and dimensions width and height in user space

```
procedure RenderMetaFile(MF: TMetaFile; ScaleX: Single=1.0; ScaleY: Single=0.0;  
XOff: single=0.0; YOff: single=0.0; TextPositioning: TPdfCanvasRenderMetaFileTextPositioning=tpSetTextJustification;  
KerningHScaleBottom: single=99.0; KerningHScaleTop: single=101.0; TextClipping: TPdfCanvasRenderMetaFileTextClipping=tcAlwaysClip);
```

Draw a metafile content into the PDF page

- not 100% of content is handled yet, but most common are (even metafiles embedded inside metafiles)
- UseSetTextJustification is to be set to true to ensure better rendering if the EMF content used SetTextJustification() API call to justify text
- KerningHScaleBottom/KerningHScaleTop are limits below which and over which Font Kerning is transformed into PDF Horizontal Scaling commands
- TextClipping can be set to fix some issues e.g. when using Wine

Used for DI-2.3.2 (page 2560).

```
procedure RoundRect(x1,y1,x2,y2,cx,cy: Single);
```

Draw a rounded rectangle

- use Bezier curves internally to draw the rounded rectangle

```
procedure SetCharSpace(charSpace: Single);
```

Set the character spacing

- CharSpace is a number expressed in unscaled text space units.
- Character spacing is used by the ShowText and ShowTextNextLine methods
- Default value is 0

```
procedure SetCMYKFillColor(C, M, Y, K: integer);
```

Set the color space to a CMYK percent value

- this method set the color to use for nonstroking operations

```
procedure SetCMYKStrokeColor(C, M, Y, K: integer);
```

Set the color space to a CMYK value

- this method set the color to use for stroking operations

```
procedure SetDash(const aarray: array of integer; phase: integer=0);
```

Set the line dash pattern in the graphics state

- The line dash pattern controls the pattern of dashes and gaps used to stroke paths. It is specified by a dash array and a dash phase. The dash array's elements are numbers that specify the lengths of alternating dashes and gaps; the dash phase specifies the distance into the dash pattern at which to start the dash. The elements of both the dash array and the dash phase are expressed in user space units. Before beginning to stroke a path, the dash array is cycled through, adding up the lengths of dashes and gaps. When the accumulated length equals the value specified by the dash phase, stroking of the path begins, using the dash array cyclically from that point onward.

```
procedure SetFlat(flatness: Byte);
```

Set the flatness tolerance in the graphics state

- see Section 6.5.1, "Flatness Tolerance" of the PDF 1.3 reference: The flatness tolerance controls the maximum permitted distance in device pixels between the mathematically correct path and an approximation constructed from straight line segments
- Flatness is a number in the range 0 to 100; a value of 0 specifies the output device's default flatness tolerance

procedure SetFontAndSize(const fontshortcut: PDFString; size: Single);

Set the font, Tf, to font and the font size, Tfs, to size.

- font is the name of a font resource in the Font subdictionary of the current resource dictionary (e.g. 'F0')
- size is a number representing a scale factor
- There is no default value for either font or size; they must be specified using this method before any text is shown

procedure SetHorizontalScaling(hScaling: Single);

Set the horizontal scaling to (scale/100)

- hScaling is a number specifying the percentage of the normal width
- Default value is 100 (e.g. normal width)

procedure SetLeading(leading: Single);

Set the text leading, Tl, to the specified leading value

- leading which is a number expressed in unscaled text space units; it specifies the vertical distance between the baselines of adjacent lines of text
- Text leading is used only by the MoveToNextLine and ShowTextNextLine methods
- you can force the next line to be just below the current one by calling:
SetLeading(Attributes.FontSize);
- Default value is 0

procedure SetLineCap(linecap: TLineCapStyle);

Set the line cap style in the graphics state

- The line cap style specifies the shape to be used at the ends of open subpaths (and dashes, if any) when they are stroked

procedure SetLineJoin(linejoin: TLineJoinStyle);

Set the line join style in the graphics state

- The line join style specifies the shape to be used at the corners of paths that are stroked

procedure SetLineWidth(linewidth: Single);

Set the line width in the graphics state

- The line width parameter specifies the thickness of the line used to stroke a path. It is a nonnegative number expressed in user space units; stroking a path entails painting all points whose perpendicular distance from the path in user space is less than or equal to half the line width. The effect produced in device space depends on the current transformation matrix (CTM) in effect at the time the path is stroked. If the CTM specifies scaling by different factors in the x and y dimensions, the thickness of stroked lines in device space will vary according to their orientation. The actual line width achieved can differ from the requested width by as much as 2 device pixels, depending on the positions of lines with respect to the pixel grid.

procedure SetMiterLimit(miterlimit: Single);

Set the miter limit in the graphics state

- When two line segments meet at a sharp angle and mitered joins have been specified as the line join style, it is possible for the miter to extend far beyond the thickness of the line stroking the path. The miter limit imposes a maximum on the ratio of the miter length to the line width. When the limit is exceeded, the join is converted from a miter to a bevel

procedure SetPage(APage: TPdfPage); **virtual**;

Assign the canvas to the specified page

procedure SetPDFFont(AFont: TPdfFont; ASize: Single);

Set the current font for the PDF Canvas

procedure SetRGBFillColor(Value: TPdfColor);

Set the color space to a Device-dependent RGB value

- this method set the color to use for nonstroking operations

procedure SetRGBStrokeColor(Value: TPdfColor);

Set the color space to a Device-dependent RGB value

- this method set the color to use for stroking operations

procedure SetTextMatrix(a, b, c, d, x, y: Single);

Set the Text Matrix to a,b,c,d and the text line Matrix x,y

procedure SetTextRenderingMode(mode: TTextRenderingMode);

Set the text rendering mode

- the text rendering mode determines whether text is stroked, filled, or used as a clipping path

procedure SetTextRise(rise: word);

Set the text rise, Trise, to the specified value

- rise is a number expressed in unscaled text space units, which specifies the distance, in unscaled text space units, to move the baseline up or down from its default location. Positive values of text rise move the baseline up. Adjustments to the baseline are useful for drawing superscripts or subscripts. The default location of the baseline can be restored by setting the text rise to 0.

- Default value is 0

procedure SetWordSpace(wordSpace: Single);

Set the word spacing

- WordSpace is a number expressed in unscaled text space units

- word spacing is used by the ShowText and ShowTextNextLine methods

- Default value is 0

procedure ShowGlyph(PW: PWord; Count: integer);

Show an Unicode Text string, encoded as Glyphs or the current font

- PW must follow the ETO_GLYPH_INDEX layout, i.e. refers to an array as returned from the GetCharacterPlacement: all glyph indexes are 16-bit values

procedure ShowText(const text: PDFString; NextLine: boolean=false); overload;

Show a text string

- text is expected to be Ansi-Encoded, in the current CharSet; if some Unicode or MBCS conversion is necessary, it will be notified to the corresponding

- if NextLine is TRUE, moves to the next line and show a text string; in this case, method as the same effect as MoveToNextLine; ShowText(s);

procedure ShowText(PW: PWideChar; NextLine: boolean=false); overload;

Show an Unicode Text string

- if NextLine is TRUE, moves to the next line and show a text string; in this case, method as the same effect as MoveToNextLine; ShowText(s);

procedure Stroke;

Stroke the path

procedure TextOut(X, Y: Single; **const** Text: PDFString);

Show some text at a specified page position

procedure TextOutW(X, Y: Single; PW: PWideChar);

Show some unicode text at a specified page position

procedure TextRect(ARect: TPdfRect; **const** Text: PDFString; Alignment: TPdfAlignment; Clipping: boolean);

Show the text in the specified rectangle and alignment
- optional clipping can be applied

property Contents: TPdfStream **read** FContents;

Retrieve the current Canvas content stream, i.e. where the PDF commands are to be written to

property Doc: TPdfDocument **read** GetDoc;

Retrieve the associated PDF document instance which created this Canvas

property Page: TPdfPage **read** GetPage;

Retrieve the current Canvas Page

property RightToLeftText: Boolean **read** fRightToLeftText **write** fRightToLeftText;

If Uniscribe-related methods must handle the text from right to left

TPdfDictionaryWrapper = **class**(TPersistent)

Common ancestor to all dictionary wrapper classes

property Data: TPdfDictionary **read** FData **write** SetData;

The associated dictionary, containing all data

property HasData: boolean **read** GetHasData;

Return TRUE if has any data stored within

TPdfInfo = **class**(TPdfDictionaryWrapper)

A dictionary wrapper class for the PDF document information fields
- all values use the generic VCL string type, and will be encoded as Unicode if necessary

property Author: string **read** GetAuthor **write** SetAuthor;

The PDF document Author

property CreationDate: TDateTime **read** GetCreationDate **write** SetCreationDate;

The PDF document Creation Date

property Creator: string **read** GetCreator **write** SetCreator;

The Software or Library name which created this PDF document

property Keywords: string **read** GetKeywords **write** SetKeywords;

The PDF document associated key words

property ModDate: TDateTime **read** GetModDate **write** SetModDate;

The PDF document modification date

property Subject: string **read** GetSubject **write** SetSubject;

The PDF document subject

property Title: string read GetTitle write SetTitle;

The PDF document title

TPdfCatalog = class(TPdfDictionaryWrapper)

A dictionary wrapper class for the PDF document catalog fields

- It contains references to other objects defining the document's contents, outline, article threads (PDF 1.1), named destinations, and other attributes. In addition, it contains information about how the document should be displayed on the screen, such as whether its outline and thumbnail page images should be displayed automatically and whether some location other than the first page should be shown when the document is opened

property NonFullScreenPageMode: TPdfPageMode read GetNonFullScreenPageMode write SetNonFullScreenPageMode;

Page mode determines how the document should appear when opened

property OpenAction: TPdfDestination read FOpenAction write FOpenAction;

A Destination to be displayed when the document is opened

property PageLayout: TPdfPageLayout read GetPageLayout write SetPageLayout;

The page layout to be used when the document is opened

property PageMode: TPdfPageMode read GetPageMode write SetPageMode;

Page mode determines how the document should appear when opened

property Pages: TPdfDictionary read GetPages write SetPages;

The page tree node that is the root of the document's page tree

- Required, must be an indirect reference
- you can set a value to it in order to add some nested pages

property ViewerPreference: TPdfViewerPreferences read GetViewerPreference write SetViewerPreference;

A viewer preferences dictionary specifying the way the document is to be displayed on the screen
- If this entry is absent, viewer applications should use their own current user preference settings

TPdfFont = class(TPdfDictionaryWrapper)

A generic PDF font object

constructor Create(AXref: TPdfXref; const AName: PDFString);

Create the PDF font object instance

function GetAnsiCharWidth(const AText: PDFString; APos: integer): integer; **virtual**;

Retrieve the width of a specified character

- implementation of this method is either WinAnsi (by TPdfFontWinAnsi), either compatible with MBCS strings (TPdfFontCIDFontType2)
- return 0 by default (descendant must handle the Ansi charset)

procedure AddUsedWinAnsiChar(aChar: AnsiChar);

Mark some WinAnsi char as used

property Name: PDFString read FName;

The internal PDF font name (e.g. 'Helvetica-Bold')

- postscript font names are inside the unit: these postscript names could not match the "official" True Type font name, stored as UTF-8 in FTrueTypeFonts

property ShortCut: PDFString read FShortCut;

The internal PDF shortcut (e.g. 'F3')

property Unicode: boolean read fUnicode;

Is set to TRUE if the font is dedicated to Unicode Chars

TPdfFontWinAnsi = class(TPdfFont)

A generic PDF font object, handling at least WinAnsi encoding

- TPdfFontTrueType descendent will handle also Unicode chars, for all WideChar which are outside the WinAnsi selection

destructor Destroy; **override**;

Release the used memory

function GetAnsiCharWidth(const AText: PDFString; APos: integer): integer;
override;

Retrieve the width of a specified character

- implementation of this method expect WinAnsi encoding
- return the value contained in fWinAnsiWidth[] by default

TPdfFontType1 = class(TPdfFontWinAnsi)

An embedded WinAnsi-Encoded standard Type 1 font

- handle Helvetica, Courier and Times font by now

constructor Create(AXref: TPdfXref; const AName: PDFString; WidthArray: PSmallIntArray); **reintroduce**;

Create a standard font instance, with a given name and char widths

- if WidthArray is nil, it will create a fixed-width font of 600 units
- WidthArray[0]=Ascent, WidthArray[1]=Descent, WidthArray[2..]=Width(#32..)

TPdfFontCIDFontType2 = class(TPdfFont)

An embedded Composite CIDFontType2

- i.e. a CIDFont whose glyph descriptions are based on TrueType font technology
- typically handle Japan or Chinese standard fonts
- used with MBCS encoding, not WinAnsi

TPdfTTF = class(TObject)

Handle Unicode glyph description for a True Type Font

- cf <http://www.microsoft.com/typography/OTSPEC/otff.htm#otttables>
- handle Microsoft cmap format 4 encoding (i.e. most used true type fonts on Windows)

endCode: PWordArray;

End characterCode for each cmap format 4 segment

fmt4: ^TCmapFmt4;

Character to glyph mapping (cmap) table, in format 4

glyphIndexArray: PWordArray;

Glyph index array (arbitrary length)

head: ^TCmapHEAD;

These are pointers to the useful data of the True Type Font: Font header

hhea: ^TCmapHHEA;

Horizontal header

idDelta: PSmallIntArray;

Delta for all character codes in each cmap format 4 segment

idRangeOffset: PWordArray;

Offsets into glyphIndexArray or 0

startCode: PWordArray;

Start character code for each cmap format 4 segment

constructor Create(aUnicodeTTF: TPdfFontTrueType); **reintroduce;**

Create Unicode glyph description for a supplied True Type Font

- the HDC of its corresponding document must have selected the font first
- this constructor will fill fUsedWide[] and fUsedWideChar of aUnicodeTTF with every available unicode value, and its corresponding glyph and width

TPdfFontTrueType = class(TPdfFontWinAnsi)

Handle TrueType Font

- handle both WinAnsi text and Unicode characters in two separate TPdfFontTrueType instances (since PDF need two separate fonts with diverse encoding)

constructor Create(ADoc: TPdfDocument; AFontIndex: integer; AStyle: TPdfFontStyles;
const ALogFont: TLogFontW; AWinAnsiFont: TPdfFontTrueType); **reintroduce;**

Create the TrueType font object instance

destructor Destroy; **override;**

Release the associated memory and handles

function FindOrAddUsedWideChar(aWideChar: WideChar): integer;

Mark some UTF-16 codepoint as used

- return the index in fUsedWideChar[] and fUsedWide[]
- this index is the one just added, or the existing one if the value was found to be already in the fUserWideChar[] array

function GetWideCharWidth(aWideChar: WideChar): Integer;

Retrieve the width of an UTF-16 codepoint

- WinAnsi characters are taken from fWinAnsiWidth[], unicode chars from fUsedWide[].Width

property FixedWidth: boolean **read** fFixedWidth;

Is set to TRUE if the font has a fixed width

property Style: TPdfFontStyles **read** fStyle;

The associated Font Styles

property UnicodeFont: TPdfFontTrueType **read** fUnicodeFont;

Points to the corresponding Unicode font

- returns NIL if the Unicode font has not yet been created by the CreateUnicodeFont method
- may return SELF if the font is itself the Unicode version

property WideCharUsed: Boolean **read** GetWideCharUsed;

Is set to TRUE if the PDF used any true type encoding

property WinAnsiFont: TPdfFontTrueType **read** fWinAnsiFont;

Points to the corresponding WinAnsi font

- always return a value, whatever it is self

TPdfDestination = class(TObject)

A destination defines a particular view of a document, consisting of the following:

- The page of the document to be displayed
- The location of the display window on that page
- The zoom factor to use when displaying the page

constructor Create(APdfDoc: TPdfDocument);

Create the PDF destination object

- the current document page is associated with this destination

destructor Destroy; **override**;

Release the object

function GetValue: TPdfArray;

Retrieve the array containing the location of the display window

- the properties values which are not used are ignored

property Bottom: Integer **index 3** **read** GetElement **write** SetElement;

Retrieve the bottom coordinate of the location of the display window

property DestinationType: TPdfDestinationType **read** FType **write** FType;

Destination Type determines default user space coordinate system of Explicit destinations

property Doc: TPdfDocument **read** FDoc;

The associated PDF document which created this Destination object

property Left: Integer **index 0** **read** GetElement **write** SetElement;

Retrieve the left coordinate of the location of the display window

property Page: TPdfPage **read** FPage;

The associated Page

property PageHeight: Integer **read** GetPageHeight;

The page height of the current page

- return the corresponding MediaBox value

property PageWidth: Integer **read** GetPageWidth;

The page width of the current page
- return the corresponding MediaBox value

property Reference: TObject **read** FReference **write** FReference;

An object associated to this destination, to be used for convenience

property Right: Integer **index 2** **read** GetElement **write** SetElement;

Retrieve the right tcoordinate of the location of the display window

property Top: Integer **index 1** **read** GetElement **write** SetElement;

Retrieve the top coordinate of the location of the display window

property Zoom: Single **read** FZoom **write** SetZoom;

The associated Zoom factor
- by default, the Zoom factor is 1

TPdfOutlineEntry = **class**(TPdfDictionaryWrapper)

An Outline entry in the PDF document

constructor Create(AParent: TPdfOutlineEntry; TopPosition: integer=-1);
reintroduce;

Create the Outline entry instance
- if TopPosition is set, a corresponding destination is created on the current PDF Canvas page, at this Y position

destructor Destroy; **override**;

Release the associated memory and reference object

function AddChild(TopPosition: integer=-1): TPdfOutlineEntry;

Create a new entry in the outline tree
- this is the main method to create a new entry

property Dest: TPdfDestination **read** FDest **write** FDest;

The associated destination

property Doc: TPdfDocument **read** FDoc;

The associated PDF document which created this Destination object

property First: TPdfOutlineEntry **read** FFirst;

The first outline entry of this entry list

property Last: TPdfOutlineEntry **read** FLast;

The last outline entry of this entry list

property Level: integer **read** FLevel **write** FLevel;

An internal property (not exported to PDF content)

property Next: TPdfOutlineEntry **read** FNext;

The next outline entry of this entry

property Opened: boolean **read** FOpened **write** FOpened;

If the outline must be opened

property Parent: TPdfOutlineEntry read FParent;

The parent outline entry of this entry

property Prev: TPdfOutlineEntry read FPrev;

The previous outline entry of this entry

property Reference: TObject read FReference write FReference;

An object associated to this destination, to be used for convenience

property Title: string read FTitle write FTitle;

The associated title

- is a generic VCL string, so is Unicode ready

TPdfOutlineRoot = **class**(TPdfOutlineEntry)

Root entry for all Outlines of the PDF document

- this is a "fake" entry which must be used as parent for all true TPdfOutlineEntry instances, but must not be used as a true outline entry

constructor Create(ADoc: TPdfDocument); **reintroduce**;

Create the Root entry for all Outlines of the PDF document

procedure Save; **override**;

Update internal parameters (like outline entries count) before saving

TPdfPageGDI = **class**(TPdfPage)

A PDF page, with its corresponding Meta File and Canvas

destructor Destroy; **override**;

Release associated memory

TPdfDocumentGDI = **class**(TPdfDocument)

Class handling PDF document creation using GDI commands

- this class allows using a VCL standard Canvas class

- handles also PDF creation directly from TMetaFile content

constructor Create(AUseOutlines: Boolean=false; ACodePage: integer=0; APDFA1: boolean=false ; AEncryption: TPdfEncryption=nil);

Create the PDF document instance, with a VCL Canvas property

- see TPdfDocument.Create constructor for the arguments expectations

function AddPage: TPdfPage; **override**;

Add a Page to the current PDF document

procedure SaveToStream(AStream: TStream; ForceModDate: TDateTime=0); **override**;

Save the PDF file content into a specified Stream

- this overridden method draw first the all VCLCanvas content into the PDF

procedure SaveToStreamDirectPageFlush(FlushCurrentPageNow: boolean=false);
override;

Save the current page content to the PDF file

- this overridden method flush the content from the VCLCanvas into the PDF
- it will reduce the used memory as much as possible, by-passing page content compression
- typical use may be:

```
with TPdfDocumentGDI.Create do
  try
    Stream := TFileStream.Create(FileName, fmCreate);
    try
      SaveToStreamDirectBegin(Stream);
      for i := 1 to 9 do
        begin
          AddPage;
          with VCLCanvas do
            begin
              Font.Name := 'Times new roman';
              Font.Size := 150;
              Font.Style := [fsBold, fsItalic];
              Font.Color := clNavy;
              TextOut(100, 100, 'Page ' + IntToStr(i));
            end;
          SaveToStreamDirectPageFlush; // direct writing
        end;
      SaveToStreamDirectEnd;
    finally
      Stream.Free;
    end;
  finally
    Free;
  end;
```

property KerningHScaleBottom: Single **read** fKerningHScaleBottom **write** fKerningHScaleBottom;

- The % limit below which Font Kerning is transformed into PDF Horizontal Scaling commands (when text positioning is tpKerningFromAveragePosition)*
- set to 99.0 by default

property KerningHScaleTop: Single **read** fKerningHScaleTop **write** fKerningHScaleTop;

- The % limit over which Font Kerning is transformed into PDF Horizontal Scaling commands (when text positioning is tpKerningFromAveragePosition)*
- set to 101.0 by default

property UseMetaFileTextClipping: TPdfCanvasRenderMetaFileTextClipping **read** fUseMetaFileTextClipping **write** fUseMetaFileTextClipping;

- Defines how TMetaFile text clipping should be applied*
- tcNeverClip has been reported to work better e.g. when app is running on Wine

property UseMetaFileTextPositioning: TPdfCanvasRenderMetaFileTextPositioning **read** fUseMetaFileTextPositioning **write** fUseMetaFileTextPositioning;

- Defines how TMetaFile text positioning is rendered*
- default is tpSetTextJustification
 - tpSetTextJustification if content used SetTextJustification() API calls
 - tpExactTextCharacterPositining for exact font kerning, but resulting in bigger pdf size
 - tpKerningFromAveragePosition will compute average pdf Horizontal Scaling in association with KerningHScaleBottom/KerningHScaleTop properties
 - replace deprecated property UseSetTextJustification

property VCLCanvas: TCanvas **read** GetVCLCanvas;

The VCL Canvas of the current page

property VCLCanvasSize: TSize **read** GetVCLCanvasSize;

The VCL Canvas size of the current page

- useful to calculate coordinates for the current page
- filled with (0,0) before first call to VCLCanvas property

TPdfImage = class(TPdfXObject)

Generic image object

- is either bitmap encoded or jpeg encoded

constructor Create(aDoc: TPdfDocument; aImage: TGraphic; DontAddToFXref: boolean);
reintroduce;

Create the image from a supplied VCL TGraphic instance

- handle TBitmap and SynGdiPlus picture types, i.e. TJpegImage (stored as jpeg), and TGifImage/TPngImage (stored as bitmap)
- use TPdfForm to handle TMetafile in vectorial format
- an optional DontAddToFXref is available, if you don't want to add this object to the main XRef list of the PDF file

constructor CreateJpegDirect(aDoc: TPdfDocument; aJpegFile: TMemoryStream; DontAddToFXref: boolean=true); **reintroduce;** overload;

Create an image from a supplied JPEG content

- an optional DontAddToFXref is available, if you don't want to add this object to the main XRef list of the PDF file

constructor CreateJpegDirect(aDoc: TPdfDocument; **const** aJpegFileName: TFileName; DontAddToFXref: boolean=true); **reintroduce;** overload;

Create an image from a supplied JPEG file name

- will raise an EOpenError exception if the file doesn't exist
- an optional DontAddToFXref is available, if you don't want to add this object to the main XRef list of the PDF file

property PixelHeight: Integer **read** fPixelHeight;

Height of the image, in pixels units

property PixelWidth: Integer **read** fPixelWidth;

Width of the image, in pixels units

TPdfForm = class(TPdfXObject)

Handle any form XObject

- A form XObject (see Section 4.9, of PDF reference 1.3) is a self-contained description of an arbitrary sequence of graphics objects, defined as a PDF content stream

constructor Create(aDoc: TPdfDocumentGDI; aMetaFile: TMetafile); **reintroduce;**

Create a form XObject from a supplied TMetaFile

TPdfFormWithCanvas = class(TPdfXObject)

A form XObject with a Canvas for drawing

- once created, you can create this XObject, then draw it anywhere on any page - see sample

constructor Create(aDoc: TPdfDocument; W, H: Integer); **reintroduce;**

Create a form XObject with TPdfCanvas

destructor Destroy; **override;**

Release used memory

procedure CloseCanvas;

Close the internal canvas

property Canvas: TPdfCanvas **read** FCanvas;

Access to the private canvas associated with the PDF form XObject

TPdfObjectStream = class(TPdfXObject)

Used to handle compressed object stream (in PDF 1.5 format)

constructor Create(aDoc: TPdfDocument); **reintroduce;**

Create the instance, i.e. its associated stream

destructor Destroy; **override;**

Release internal memory structures

function AddObject(Value: TPdfObject): integer;

Add an object to this compressed object stream

- returns the object index in this object stream

property ObjectCount: integer **read** fObjectCount;

The number of compressed objects within this object stream

TScriptState = packed record

An Uniscribe script state

- uBidiLevel: Unicode Bidi algorithm embedding level (0..16)

- fFlags: Script state flags

TScriptAnalysis = packed record

An Uniscribe script analysis

- eScript: Shaping engine

- fFlags: Script analysis flags

- s: Script state

TScriptItem = packed record

A Uniscribe script item, after analysis of a unicode text

a: TScriptAnalysis;

Corresponding Uniscribe script analysis

iCharPos: Integer;

Logical offset to first character in this item

TScriptProperties = packed record

Contains information about Uniscribe special processing for each script

fFlags: TScriptProperties_set;

Set of possible Uniscribe processing properties for a given language

langid: Word;

Primary and sublanguage associated with script

TScriptVisAttr = packed record

Contains the visual (glyph) attributes that identify clusters and justification points, as generated by ScriptShape

- uJustification: Justification class
- fFlags: Uniscribe visual (glyph) attributes
- fShapeReserved: Reserved for use by shaping engines

Types implemented in the *SynPdf* unit

PDFString = AnsiString;

The PDF library use internally AnsiString text encoding

- the corresponding charset is the current system charset, or the one supplied as a parameter to TPdfDocument.Create

**TCmapSubTableArray = packed array[byte] of packed record platformID: word;
platformSpecificID: word; offset: Cardinal; end;**

Points to every 'cmap' encoding subtables

TGradientDirection = (gdHorizontal, gdVertical);

PDF gradient direction

TLineCapStyle = (lcButt_End, lcRound_End, lcProjectingSquareEnd);

Line cap style specifies the shape to be used at the ends of open subpaths when they are stroked

TLineJoinStyle = (ljMiterJoin, ljRoundJoin, ljBevelJoin);

The line join style specifies the shape to be used at the corners of paths that are stroked

TPdfALevel = (pdfaNone, pdfa1A, pdfa1B, pdfa2A, pdfa2B, pdfa3A, pdfa3B);

The PDF/A level

TPdfAlignment = (paLeftJustify, paRightJustify, paCenter);

PDF text paragraph alignment

TPdfAnnotationBorder = (abSolid, abDashed, abBeveled, abInset, abUnderline);

The border style of an annotation

TPdfAnnotationSubType = (asTextNotes, asLink);

The annotation types determines the valid annotation subtype of TPdfDoc

TPdfBuffer32 = array[0..31] of byte;

Internal 32 bytes buffer, used during encryption process

```
TPdfCanvasArcType = ( acArc, acArcTo, acArcAngle, acPie, acChoord );
```

Is used to define the TMetaFile kind of arc to be drawn

```
TPdfCanvasRenderMetaFileTextClipping = ( tcClipReference, tcClipExplicit, tcAlwaysClip, tcNeverClip );
```

Is used to define how TMetaFile text is clipped

- by default, text will be clipped with the specified TEMRText.ptlReference
- you could set tcClipExplicit to clip following the specified rclBounds
- or tcAlwaysClip to use the current clipping region (if any)
- finally, tcNeverClip would disable whole text clipping process, which has been reported to be preferred e.g. on Wine

```
TPdfCanvasRenderMetaFileTextPositioning = ( tpKerningFromAveragePosition, tpSetTextJustification, tpExactTextCharacterPositining );
```

Is used to define how TMetaFile text positioning is rendered

- tpSetTextJustification will handle efficiently the fact that TMetaFileCanvas used SetTextJustification() API calls to justify text: it will converted to SetWordSpace() pdf rendering
- tpExactTextCharacterPositining will use the individual glyph positioning information as specified within the TMetaFile content: resulting pdf size will be bigger, but font kerning will be rendered as expected
- tpKerningFromAveragePosition will use global font kerning via SetHorizontalScaling() pdf rendering

```
TPdfColor = -$7FFFFFFF-1..$7FFFFFFF;
```

The available PDF color range

```
TPdfColorRGB = cardinal;
```

The PDF color, as expressed in RGB terms

- maps COLORREF / TColorRef as used e.g. under windows

```
TPdfCompressionMethod = ( cmNone, cmFlateDecode );
```

Define if streams must be compressed

```
TPdfDate = PDFString;
```

A PDF date, encoded as 'D:20100414113241'

```
TPdfDestinationType = ( dtXYZ, dtFit, dtFitH, dtFitV, dtFitR, dtFitB, dtFitBH, dtFitBV );
```

Destination Type determines default user space coordinate system of Explicit destinations

```
TPdfEncryptionLevel = ( elNone, elRC4_40, elRC4_128 );
```

The available encryption levels

- in current version only RC4 40-bit and RC4 128-bit are available, which correspond respectively to PDF 1.3 and PDF 1.4 formats
- for RC4 40-bit and RC4 128-bit, associated password are restricted to a maximum length of 32 characters and could contain only characters from the Latin-1 encoding (i.e. no accent)

```
TPdfEncryptionPermission = ( epPrinting, epGeneralEditing, epContentCopy, epAuthoringComment, epFillingForms, epContentExtraction, epDocumentAssembly, epPrintingHighResolution );
```

PDF can encode various restrictions on document operations which can be granted or denied individually (some settings depend on others, though):

- Printing: If printing is not allowed, the print button in Acrobat will be disabled. Acrobat supports a distinction between high-resolution and low-resolution printing. Low-resolution printing generates a bitmapped image of the page which is suitable only for personal use, but prevents high-quality

reproduction and re-distilling. Note that bitmap printing not only results in low output quality, but will also considerably slow down the printing process.

- General Editing: If this is disabled, any document modification is prohibited. Content extraction and printing are allowed.

- Content Copying and Extraction: If this is disabled, selecting document contents and copying it to the clipboard for repurposing the contents is prohibited. The accessibility interface also is disabled. If you need to search such documents with Acrobat you must select the Certified Plugins Only preference in Acrobat.

- Authoring Comments and Form Fields: If this is disabled, adding, modifying, or deleting comments and form fields is prohibited. Form field filling is allowed.

- Form Field Fill-in or Signing: If this is enabled, users can sign and fill in forms, but not create form fields.

- Document Assembly: If this is disabled, inserting, deleting or rotating pages, or creating bookmarks and thumbnails is prohibited.

```
TPdfEncryptionPermissions = set of TPdfEncryptionPermission;
```

Set of restrictions on PDF document operations

```
TPdfFileFormat = ( pdf13, pdf14, pdf15, pdf16 );
```

The internal pdf file format

```
TPdfFontStandard = ( pfsTimes, pfsHelvetica, pfsCourier );
```

The recognized families of the Standard 14 Fonts

```
TPdfFontStyle = ( pfsBold, pfsItalic, pfsUnderline, pfsStrikeOut );
```

Potential font styles

```
TPdfFontStyles = set of TPdfFontStyle;
```

Set of font styles

```
TPdfGDIComment = ( pgcOutline, pgcBookmark, pgcLink, pgcLinkNoBorder, pgcJpegDirect );
```

Defines the data stored inside a EMR_GDICOMMENT message

- pgcOutline can be used to add an outline at the current position (i.e. the last Y parameter of a Move): the text is the associated title, UTF-8 encoded and the outline tree is created from the number of leading spaces in the title

- pgcBookmark will create a destination at the current position (i.e. the last Y parameter of a Move), with some text supplied as bookmark name

- pgcLink/pgcLinkNoBorder will create a asLink annotation, expecting the data to be filled with TRect inclusive-inclusive bounding rectangle coordinates, followed by the corresponding bookmark name

- use the GDIComment*() functions to append the corresponding EMR_GDICOMMENT message to a metafile content

```
TPdfObjectType = ( otDirectObject, otIndirectObject, otVirtualObject );
```

Allowed types for PDF objects (i.e. TPdfObject)

```
TPdfPageLayout = ( plSinglePage, plOneColumn, plTwoColumnLeft, plTwoColumnRight );
```

The page layout to be used when the document is opened

```
TPdfPageMode = ( pmUseNone, pmUseOutlines, pmUseThumbs, pmFullScreen );
```

Page mode determines how the document should appear when opened

```
TPDFPaperSize = ( psA4, psA5, psA3, psA2, psA1, psA0, psLetter, psLegal, psUserDefined );
```

Available known paper size (psA4 is the default on TPdfDocument creation)

```
TPdfViewerPreference = ( vpHideToolbar, vpHideMenubar, vpHideWindowUI, vpFitWindow, vpCenterWindow, vpEnforcePrintScaling );
```

Viewer preferences specifying how the reader User Interface must start
- vpEnforcePrintScaling will set the file version to be PDF 1.6

```
TPdfViewerPreferences = set of TPdfViewerPreference;
```

Set of Viewer preferences

```
TScriptPropertiesArray = array[byte] of TScriptProperties;
```

An array of Uniscribe processing information

```
TScriptAnalysis_enum = ( s0, s1, s2, s3, s4, s5, s6, s7, s8, s9, fRTL, fLayoutRTL, fLinkBefore, fLinkAfter, fLogicalOrder, fNoGlyphIndex );
```

Uniscribe script analysis flag elements

- s0,s1,s2,s3,s4,s5,s6,s7,s8,s9: map TScriptAnalysis.eScript
- fRTL: Rendering direction
- fLayoutRTL: Set for GCP classes ARABIC/HEBREW and LOCALNUMBER
- fLinkBefore: Implies there was a ZWJ before this item
- fLinkAfter: Implies there is a ZWJ following this item.
- fLogicalOrder: Set by client as input to ScriptShape/Place
- fNoGlyphIndex: Generated by ScriptShape/Place - this item does not use glyph indices

```
TScriptAnalysis_set = set of TScriptAnalysis_enum;
```

A set of Uniscribe script analysis flags

```
TScriptProperties_enum = ( fNumeric, fComplex, fNeedsWordBreaking, fNeedsCaretInfo, bCharSet0, bCharSet1, bCharSet2, bCharSet3, bCharSet4, bCharSet5, bCharSet6, bCharSet7, fControl, fPrivateUseArea, fNeedsCharacterJustify, fInvalidGlyph, fInvalidLogAttr, fCDM, fAmbiguousCharSet, fClusterSizeVaries, fRejectInvalid );
```

All possible Uniscribe processing properties of a given language

- fNumeric: if a script contains only digits
- fComplex: Script requires special shaping or layout
- fNeedsWordBreaking: Requires ScriptBreak for word breaking information
- fNeedsCaretInfo: Requires caret restriction to cluster boundaries
- bCharSet0 .. bCharSet7: Charset to use when creating font
- fControl: Contains only control characters
- fPrivateUseArea: This item is from the Unicode range U+E000 through U+F8FF
- fNeedsCharacterJustify: Requires inter-character justification
- fInvalidGlyph: Invalid combinations generate glyph wglInvalid in the glyph buffer
- fInvalidLogAttr: Invalid combinations are marked by fInvalid in the logical attributes
- fCDM: Contains Combining Diacritical Marks
- fAmbiguousCharSet: Script does not correspond 1// :1 with a charset
- fClusterSizeVaries: Measured cluster width depends on adjacent clusters
- fRejectInvalid: Invalid combinations should be rejected

```
TScriptProperties_set = set of TScriptProperties_enum;
```

Set of possible Uniscribe processing properties of a given language

```
TScriptState_enum = ( r0, r1, r2, r3, r4, fOverrideDirection, fInhibitSymSwap, fCharShape, fDigitSubstitute, fInhibitLigate, fDisplayZWG, fArabicNumContext, fGcpClusters );
```

UniScribe script state flag elements

- r0,r1,r2,r3,r4: map TScriptState.uBidiLevel
- fOverrideDirection: Set when in LRO/RLO embedding

- fInhibitSymSwap: Set by U+206A (ISS), cleared by U+206B (ASS)
- fCharShape: Set by U+206D (AAFS), cleared by U+206C (IAFS)
- fDigitSubstitute: Set by U+206E (NADS), cleared by U+206F (NODS)
- fInhibitLigate: Equiv !GCP_Ligate, no Unicode control chars yet
- fDisplayZWG: Equiv GCP_DisplayZWG, no Unicode control characters yet
- fArabicNumContext: For EN->AN Unicode rule
- fGcpClusters: For Generating Backward Compatible GCP Clusters (legacy Apps)

```
TScriptState_set = set of TScriptState_enum;
```

A set of UniScribe script state flags

```
TScriptVisAttr_enum = ( a0, a1, a2, a3, fClusterStart, fDiacritic, fZeroWidth, fReserved );
```

Uniscribe visual (glyph) attributes

- a0 .. a3: map the Justification class number
- fClusterStart: First glyph of representation of cluster
- fDiacritic: Diacritic
- fZeroWidth: Blank, ZWJ, ZWNJ etc, with no width
- fReserved: General reserved bit

```
TScriptVisAttr_set = set of TScriptVisAttr_enum;
```

Set of Uniscribe visual (glyph) attributes

```
TTextRenderingMode = ( trFill, trStroke, trFillThenStroke, trInvisible, trFillClipping, trStrokeClipping, trFillStrokeClipping, trClipping );
```

The text rendering mode determines whether text is stroked, filled, or used as a clipping path

```
TUsedWide = array of packed record case byte of 0: ( Width: word; Glyph: word; ); 1: ( Int: integer; ); end;
```

This dynamic array stores details about used unicode characters

- every used unicode character has its own width and glyph index in the true type font content

```
TXObjectID = integer;
```

Numerical ID for every XObject

Constants implemented in the SynPdf unit

```
CRLF = #10;
```

The Carriage Return and Line Feed values used in the PDF file generation

- expect #13 and #10 under Windows, but #10 (e.g. only Line Feed) is enough for the PDF standard, and will create somewhat smaller PDF files

```
LF = #10;
```

The Line Feed value

```
MSWINDOWS_DEFAULT_FONTS: RawUTF8 = 'Arial'#13#10'Courier New'#13#10'Georgia'#13#10+'Impact'#13#10'Lucida Console'#13#10'Roman'#13#10'Symbol'#13#10+'Tahoma'#13#10'Times New Roman'#13#10'Trebuchet'#13#10+'Verdana'#13#10'WingDings';
```

List of common fonts available by default since Windows 2000

- to not embed these fonts in the PDF document, and save some KB, just use the EmbeddedTTFIgnore property of TPdfDocument/TPdfDocumentGDI:

```
PdfDocument.EmbeddedTTFIgnore.Text := MSWINDOWS_DEFAULT_FONTS;
```

- note that this is useful only if the EmbeddedTTF property was set to TRUE

PDF_FREE_ENTRY = 'f';

Used for an unused (free) xref entry, e.g. the root entry

PDF_IN_USE_ENTRY = 'n';

Used for an used xref entry

PDF_MAX_GENERATION_NUM = 65535;

Used e.g. for the root xref entry

PDF_PERMISSION_ALL: TPdfEncryptionPermissions = [Low(TPdfEncryptionPermission)..high(TPdfEncryptionPermission)];

Allow all actions for a pdf encrypted file

- to be used as parameter for TPdfEncryption.New() class method

PDF_PERMISSION_NOCOPY: TPdfEncryptionPermissions = [epPrinting, epAuthoringComment, epPrintingHighResolution, epFillingForms];

Disable content extraction or copy for a pdf encrypted file

- to be used as parameter for TPdfEncryption.New() class method

PDF_PERMISSION_NOCOPYNORPRINT: TPdfEncryptionPermissions = [];

Disable printing and content extraction or copy for a pdf encrypted file

- to be used as parameter for TPdfEncryption.New() class method

PDF_PERMISSION_NOMODIF: TPdfEncryptionPermissions = [epPrinting, epContentCopy, epPrintingHighResolution, epFillingForms, epContentExtraction, epDocumentAssembly];

Disable modification and annotation of a pdf encrypted file

- to be used as parameter for TPdfEncryption.New() class method

PDF_PERMISSION_NOPRINT: TPdfEncryptionPermissions = [epGeneralEditing, epContentCopy, epAuthoringComment, epContentExtraction, epDocumentAssembly];

Disable printing for a pdf encrypted file

- to be used as parameter for TPdfEncryption.New() class method

USP_E_SCRIPT_NOT_IN_FONT = HRESULT((SEVERITY_ERROR shl 31) or (FACILITY_ITF shl 16)) or \$200;

Error returned by Uniscribe when the current selected font does not contain sufficient glyphs or shaping tables

Functions or procedures implemented in the SynPdf unit

Functions or procedures	Description	Page
CurrentPrinterPaperSize	Retrieve the paper size used by the current selected printer	1524
CurrentPrinterRes	Retrieve the current printer resolution	1524
GDICommentBookmark	Append a EMR_GDICOMMENT message for handling PDF bookmarks	1524
GDICommentJpegDirect	Append a EMR_GDICOMMENT message for adding jpeg direct	1524
GDICommentLink	Append a EMR_GDICOMMENT message for creating a Link into a specified bookmark	1524
GDICommentOutline	Append a EMR_GDICOMMENT message for handling PDF outline	1525

Functions or procedures	Description	Page
L2R	Reverse char orders for every hebrew and arabic words	1525
PdfBox	Wrapper to create a temporary PDF box	1525
PdfCoord	Convert some milli meters dimension to internal PDF twips value	1525
PdfRect	Wrapper to create a temporary PDF coordinates rectangle	1525
PdfRect	Wrapper to create a temporary PDF coordinates rectangle	1525
RawUTF8ToPDFString	Convert a specified UTF-8 content into a PDFString value	1525
ScriptApplyDigitSubstitution	Uniscribe function to apply the specified digit substitution settings to the specified script control and script state structures	1525
ScriptGetProperties	Uniscribe function to retrieve information about the current scripts	1525
ScriptItemize	Uniscribe function to break a Unicode string into individually shapeable items	1526
ScriptLayout	Uniscribe function to convert an array of run embedding levels to a map of visual-to-logical position and/or logical-to-visual position	1526
ScriptShape	Uniscribe function to generate glyphs and visual attributes for an Unicode run	1526
UInt32ToPDFString	Convert an unsigned integer into a PDFString text	1526
_DateTimeToPdfDate	Convert a date, into PDF string format, i.e. as 'D:20100414113241Z'	1526
_HasMultiByteString	This function returns TRUE if the supplied text contain any MBCS character	1527
_PdfDateToDateTime	Decode PDF date, encoded as 'D:20100414113241'	1527

function CurrentPrinterPaperSize: TPDFPaperSize;

Retrieve the paper size used by the current selected printer

function CurrentPrinterRes: TPoint;

Retrieve the current printer resolution

procedure GDICommentBookmark(MetaHandle: HDC; **const** aBookmarkName: RawUTF8);

Append a EMR_GDICOMMENT message for handling PDF bookmarks

- will create a PDF destination at the current position (i.e. the last Y parameter of a Move), with some text supplied as bookmark name

procedure GDICommentJpegDirect(MetaHandle: HDC; **const** aFileName: RawUTF8; **const** aRect: TRect);

Append a EMR_GDICOMMENT message for adding jpeg direct

procedure GDICommentLink(MetaHandle: HDC; **const** aBookmarkName: RawUTF8; **const** aRect: TRect; NoBorder: boolean);

Append a EMR_GDICOMMENT message for creating a Link into a specified bookmark

procedure GDICommentOutline(MetaHandle: HDC; **const** aTitle: RawUTF8; aLevel: Integer);

Append a EMR_GDICOMMENT message for handling PDF outline

- used to add an outline at the current position (i.e. the last Y parameter of a Move): the text is the associated title, UTF-8 encoded and the outline tree is created from the specified numerical level (0=root)

procedure L2R(W: PWideChar; L: integer);

Reverse char orders for every hebrew and arabic words

- just reverse all the UTF-16 codepoints in the supplied buffer

function PdfBox(Left, Top, Width, Height: Single): TPdfBox;

Wrapper to create a temporary PDF box

function PdfCoord(MM: single): integer;

Convert some milli meters dimension to internal PDF twips value

function PdfRect(Left, Top, Right, Bottom: Single): TPdfRect; overload;

Wrapper to create a temporary PDF coordinates rectangle

function PdfRect(**const** Box: TPdfBox): TPdfRect; overload;

Wrapper to create a temporary PDF coordinates rectangle

function RawUTF8ToPDFString(**const** Value: RawUTF8): PDFString;

Convert a specified UTF-8 content into a PDFString value

function ScriptApplyDigitSubstitution(**const** psds: Pointer; **const** psControl: pointer;
const psState: pointer): HRESULT; **stdcall**; **external** Usp10;

Uniscribe function to apply the specified digit substitution settings to the specified script control and script state structures

function ScriptGetProperties(**out** ppSp: PScriptPropertiesArray; **out** piNumScripts:
Integer): HRESULT; **stdcall**; **external** Usp10;

Uniscribe function to retrieve information about the current scripts

- ppSp: Pointer to an array of pointers to SCRIPT_PROPERTIES structures indexed by script.

- piNumScripts: Pointer to the number of scripts. The valid range for this value is 0 through piNumScripts-1.

```
function ScriptItemize( const pwcInChars: PWideChar; cInChars: Integer; cMaxItems: Integer; const psControl: pointer; const psState: pointer; pItems: PScriptItem; var pcItems: Integer): HRESULT; stdcall; external Usp10;
```

Uniscribe function to break a Unicode string into individually shapeable items

- pwcInChars: Pointer to a Unicode string to itemize.
- cInChars: Number of characters in pwcInChars to itemize.
- cMaxItems: Maximum number of SCRIPT_ITEM structures defining items to process.
- psControl: Optional. Pointer to a SCRIPT_CONTROL structure indicating the type of itemization to perform. Alternatively, the application can set this parameter to NULL if no SCRIPT_CONTROL properties are needed.
- psState: Optional. Pointer to a SCRIPT_STATE structure indicating the initial bidirectional algorithm state. Alternatively, the application can set this parameter to NULL if the script state is not needed.
- pItems: Pointer to a buffer in which the function retrieves SCRIPT_ITEM structures representing the items that have been processed. The buffer should be cMaxItems*sizeof(SCRIPT_ITEM) + 1 bytes in length. It is invalid to call this function with a buffer to hold less than two SCRIPT_ITEM structures. The function always adds a terminal item to the item analysis array so that the length of the item with zero-based index "i" is always available as:
 pItems[i+1].iCharPos - pItems[i].iCharPos;
- pcItems: Pointer to the number of SCRIPT_ITEM structures processed

```
function ScriptLayout(cRuns: Integer; const pbLevel: PByte; piVisualToLogical: PInteger; piLogicalToVisual: PInteger): HRESULT; stdcall; external Usp10;
```

Uniscribe function to convert an array of run embedding levels to a map of visual-to-logical position and/or logical-to-visual position

- cRuns: Number of runs to process
- pbLevel: Array of run embedding levels
- piVisualToLogical: List of run indices in visual order
- piLogicalToVisual: List of visual run positions

```
function ScriptShape(hdc: HDC; var psc: pointer; const pwcChars: PWideChar; cChars: Integer; cMaxGlyphs: Integer; psa: PScriptAnalysis; pwOutGlyphs: PWord; pwLogClust: PWord; psva: PScriptVisAttr; var pcGlyphs: Integer): HRESULT; stdcall; external Usp10;
```

Uniscribe function to generate glyphs and visual attributes for an Unicode run

- hdc: Optional (see under caching)
- psc: Uniscribe font metric cache handle
- pwcChars: Logical unicode run
- cChars: Length of unicode run
- cMaxGlyphs: Max glyphs to generate
- psa: Result of ScriptItemize (may have fNoGlyphIndex set)
- pwOutGlyphs: Output glyph buffer
- pwLogClust: Logical clusters
- psva: Visual glyph attributes
- pcGlyphs: Count of glyphs generated

```
function UInt32ToPDFString(Value: Cardinal): PDFString;
```

Convert an unsigned integer into a PDFString text

```
function _DateTimeToPdfDate(ADate: TDateTime): TPdfDate;
```

Convert a date, into PDF string format, i.e. as 'D:20100414113241Z'

```
function _HasMultiByteString(Value: PAnsiChar): boolean;
```

This function returns TRUE if the supplied text contain any MBCS character

- typical call must check first if MBCS is currently enabled

```
if SysLocale.FarEast and _HasMultiByteString(pointer(Text)) then ...
```

```
function _PdfDateToDateTime(const AText: TPdfDate): TDateTime;
```

Decode PDF date, encoded as 'D:20100414113241'

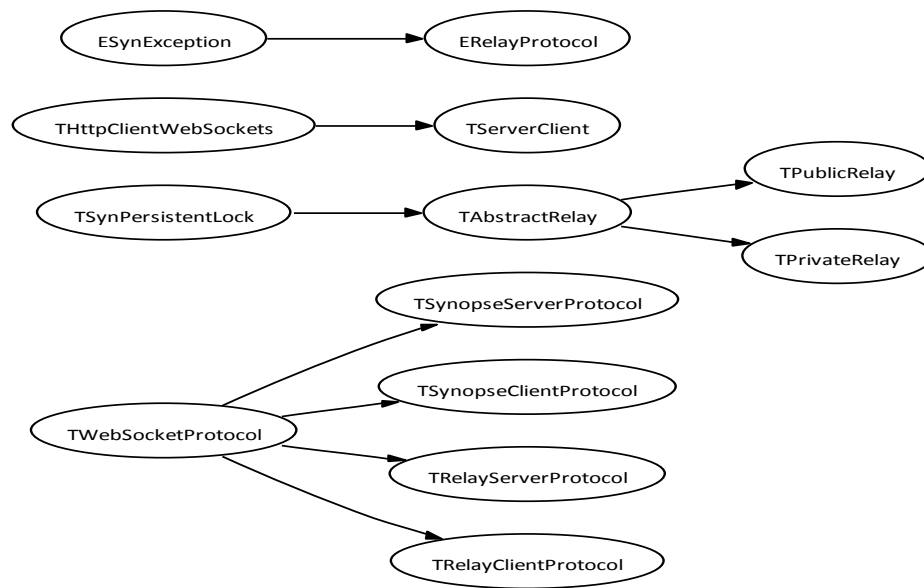

27.30. SynProtoRelay.pas unit

Purpose: Implements asynchronous safe WebSockets tunnelling

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the *SynProtoRelay* unit

Unit Name	Description	Page
<i>SynBidirSock</i>	Implements bidirectional client and server protocol, e.g. WebSockets - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	681
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynCrtSock</i>	Classes implementing TCP/UDP/HTTP client and server protocol - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1086
<i>SynCrypto</i>	Fast cryptographic routines (hashing and cypher) - implements AES,XOR,ADLER32,MD5,RC4,SHA1,SHA256,SHA384,SHA512,SHA3 and JWT - optimized for speed (tuned assembler and SSE3/SSE4/AES-NI/PADLOCK support) - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1143
<i>SynLog</i>	Logging functions used by Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1368
<i>SynTable</i>	Filter/database/cache/buffer/security/search/multithread/OS features - as a complement to SynCommons, which tended to increase too much - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1728
<i>SynWinSock</i>	Low level access to network Sockets for the Win32 platform - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1851

SynProtoRelay class hierarchy

Objects implemented in the *SynProtoRelay* unit

Objects	Description	Page
TPrivateRelay	Implements a Private Relay client, located in a private network behind a restricted firewall	1531
TPublicRelay	Implements a Public Relay server, e.g. located on a small Linux/BSD box	1531
TRelayClientProtocol	Private Relay to Public Relay connection, decapsulating connection ID	1530
TRelayFrame	Internal binary serialized content for frames tunnelling	1529
TRelayFrameRestPayload	TRelayFrame.payload for opcode = focRestPayload = focReservedF	1529
TRelayServerProtocol	Public Relay to Private Relay connection, encapsulating connection ID	1530
TServerClient	Implements a relayed link to the local ORM/SOA server instance	1531
TSynapseClientProtocol	Private Relay to local Server connection	1530
TSynapseServerProtocol	Regular mORMot client to Public Relay connection using synapsejson/synapsebin/synapsebinary protocols	1530

TRelayFrameRestPayload = packed record

TRelayFrame.payload for opcode = focRestPayload = focReservedF

TRelayFrame = packed record

Internal binary serialized content for frames tunnelling

TSynapseServerProtocol = class(TWebSocketProtocol)

Regular mORMot client to Public Relay connection using synapsejson/synapsebin/synapsebinary protocols

- any incoming frame will be encapsulated with the connection ID, then relayed to the Private Relay node using TRelayServerProtocol

constructor Create(aOwner: TPublicRelay); **reintroduce;**

Initialize the protocol to be processed on a given TPublicRelay

function Clone(const aClientURI: RawUTF8): TWebSocketProtocol; **override;**

Used server-side for any new connection

TRelayServerProtocol = class(TWebSocketProtocol)

Public Relay to Private Relay connection, encapsulating connection ID

- see also TRelayClientProtocol as the reversed process

- any incoming frame will be decapsulate the associated connection ID, then relayed to the proper client node using TSynapseServerProtocol

constructor Create(aOwner: TPublicRelay; const aServerKey: RawUTF8); **reintroduce;**

Initialize the protocol to be processed on a given TPublicRelay

function Clone(const aClientURI: RawUTF8): TWebSocketProtocol; **override;**

Used server-side for any new connection

TRelayClientProtocol = class(TWebSocketProtocol)

Private Relay to Public Relay connection, decapsulating connection ID

- see also TRelayServerProtocol as the reversed process

constructor Create(aOwner: TPrivateRelay; const aRelayKey: RawUTF8); **reintroduce;**

Initialize the protocol to be processed on a given TPrivateRelay

function Clone(const aClientURI: RawUTF8): TWebSocketProtocol; **override;**

Used server-side for any new connection

TSynapseClientProtocol = class(TWebSocketProtocol)

Private Relay to local Server connection

- forward raw frames from TSynapseServerProtocol

constructor Create(aOwner: TPrivateRelay; const aProtocolName: RawUTF8); **reintroduce;**

Initialize the protocol to be processed on a given TPrivateRelay

- the protocol is relayed from TRelayClientProtocol.ProcessIncomingFrame

function Clone(const aClientURI: RawUTF8): TWebSocketProtocol; **override;**

Used server-side for any new connection

TPublicRelay = class(TAbstractRelay)

Implements a Public Relay server, e.g. located on a small Linux/BSD box

constructor Create(aLog: TSynLogClass; **const** aClientsPort, aServerPort: SockString; **const** aServerKey: RawUTF8; aServerJWT: TJWTAbstract; aClientsThreadPoolCount: integer=2; aClientsKeepAliveTimeOut: integer=30000); **reintroduce**;

Initialize the Public Relay

- WebSockets clients will connect to aClientsPort as usual
- all communication will be encapsulated and relayed to aServerPort, using the optional aServerKey for TWebSocketProtocol.SetEncryptKey(), and aServerJWT to authenticate the incoming connection (owned by this instance)

destructor Destroy; **override**;

Finalize the Public Relay server

property Clients: TWebSocketServer **read** fClients;

Raw access to the ORM/SOA clients server instance

property Server: TWebSocketServer **read** fServer;

Raw access to the Private Relay server instance

property ServerJWT: TJWTAbstract **read** fServerJWT;

Access to the JWT authentication for TPrivateRelay communication

TServerClient = class(THttpClientWebSockets)

Implements a relayed link to the local ORM/SOA server instance

- add some internal fields for TPrivateRelay.fServers[]

TPrivateRelay = class(TAbstractRelay)

Implements a Private Relay client, located in a private network behind a restricted firewall

constructor Create(aLog: TSynLogClass; **const** aRelayHost, aRelayPort, aRelayKey, aRelayBearer, aServerHost, aServerPort, aServerRemoteIPHeader: RawUTF8); **reintroduce**;

Initialize the Private Relay

- communication will be encapsulated and relayed to aServerHost/aServerPort via a new TServerClient connection, using aServerWebSocketsURI, aServerWebSocketsEncryptionKey, aServerWebSocketsAJAX and aServerWebSocketsCompression parameters as any regular client in the local network - from the server point of view, those clients will appear like local clients unless ServerRemoteIPHeader is set according to the TSQLHttpServerDefinition.ServerRemoteIPHeader value (e.g. as 'X-Real-IP') and the remote client IP will be used instead
- Connected/TryConnect should be called on a regular basis to connect to the Public Relay using aRelayHost/aRelayPort/aRelayKey/aRelayBearer

destructor Destroy; **override**;

Finalize the Private Relay server

function Connected: boolean;

Check if the Public Relay did connect to this Private Relay instance

function Encrypted: boolean;

True if this Private Relay uses encryption with the Public Relay

function TryConnect: boolean;

*(re)connect to aRelayHost/aRelayPort Public Relay via a single link
- will first disconnect is needed*

procedure Disconnect;

Disconnect from aRelayHost/aRelayPort Public Relay

property Connections: integer **read** fServersCount;

How many client connections are actually relayed via this instance

property RelayConnected: boolean **read** Connected;

True if the Private Relay is connected to the Public Relay

property RelayEncrypted: boolean **read** Encrypted;

True if the Private Relay to the Public Relay link is encrypted

property RelayHost: RawUTF8 **read** fRelayHost;

Public Relay host address

property RelayPort: RawUTF8 **read** fRelayPort;

Public Relay host port

property ServerHost: RawUTF8 **read** fServerHost;

Local processing server host address

property ServerPort: RawUTF8 **read** fServerPort;

Local processing server host port

Constants implemented in the *SynProtoRelay* unit

focRestPayload = focReservedF;

If TRelayFrame.payload is in fact a TRelayFrameRestPayload

RELAYFRAME_VER = \$aa00;

As set to TRelayFrame

27.31. SynProtoRTSPHTTP.pas unit

Purpose: Implements asynchronous RTSP stream tunnelling over HTTP

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the *SynProtoRTSPHTTP* unit

Unit Name	Description	Page
<i>SynBidirSock</i>	Implements bidirectional client and server protocol, e.g. WebSockets - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	681
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynCrtSock</i>	Classes implementing TCP/UDP/HTTP client and server protocol - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1086
<i>SynLog</i>	Logging functions used by Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1368
<i>SynTests</i>	Unit test functions used by Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1840
<i>SynWinSock</i>	Low level access to network Sockets for the Win32 platform - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1851

SynProtoRTSPHTTP class hierarchy

Objects implemented in the *SynProtoRTSPHTTP* unit

Objects	Description	Page
TPostConnection	Holds a HTTP POST connection for RTSP proxy	1534
TRtspConnection	Holds a RTSP connection for HTTP GET proxy	1534
TRTSPOverHTTPServer	Implements RTSP over HTTP asynchronous proxy	1534

TPostConnection = class(TAsynchConnection)

Holds a HTTP POST connection for RTSP proxy
- as used by the TRTSPOverHTTPServer class

TRtspConnection = class(TAsynchConnection)

Holds a RTSP connection for HTTP GET proxy
- as used by the TRTSPOverHTTPServer class

TRTSPOverHTTPServer = class(TAsynchServer)

Implements RTSP over HTTP asynchronous proxy
- the HTTP transport is built from two separate HTTP GET and POST requests initiated by the client; the server then binds the connections to form a virtual full-duplex connection - see <https://goo.gl/CX6VA3> for reference material about this horrible, but widely accepted, Apple hack

constructor Create(**const** aRtspServer, aRtspPort, aHttpPort: SockString; aLog: TSynLogClass; aOnStart, aOnStop: TNotifyThreadEvent; aOptions: TAsynchConnectionsOptions = []); **reintroduce**;

Initialize the proxy HTTP server forwarding specified RTSP server:port

destructor Destroy; **override**;

Shutdown and finalize the server

function HttpToRtsp(**const** HttpURI: RawUTF8): RawUTF8;

Convert a http://... proxy URI into a rtsp://... URI

function RtspToHttp(**const** RtspURI: RawUTF8): RawUTF8;

Convert a rtsp://... URI into a http://... proxy URI

- will reuse the rtsp public server name, but change protocol to http:// and set the port to RtspPort

procedure RegressionTests(test: TSynTestCase; clientcount, steps: integer);

Perform some basic regression and benchmark testing on a running server

property HttpPort: SockString **read** GetHttpPort;

The bound HTTP port

property RtspPort: SockString **read** fRtspPort;

The associated RTSP server port

property RtspServer: SockString **read** fRtspServer;

The associated RTSP server address

27.32. SynSelfTests.pas unit

Purpose: Automated tests for common units of the Synopse mORMot Framework

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

The *SynSelfTests* unit is quoted in the following items

SWRS #	Description	Page
DI-2.2.2	The framework libraries, including all its <i>SQLite3</i> related features, shall be tested using Unitary testing	2559

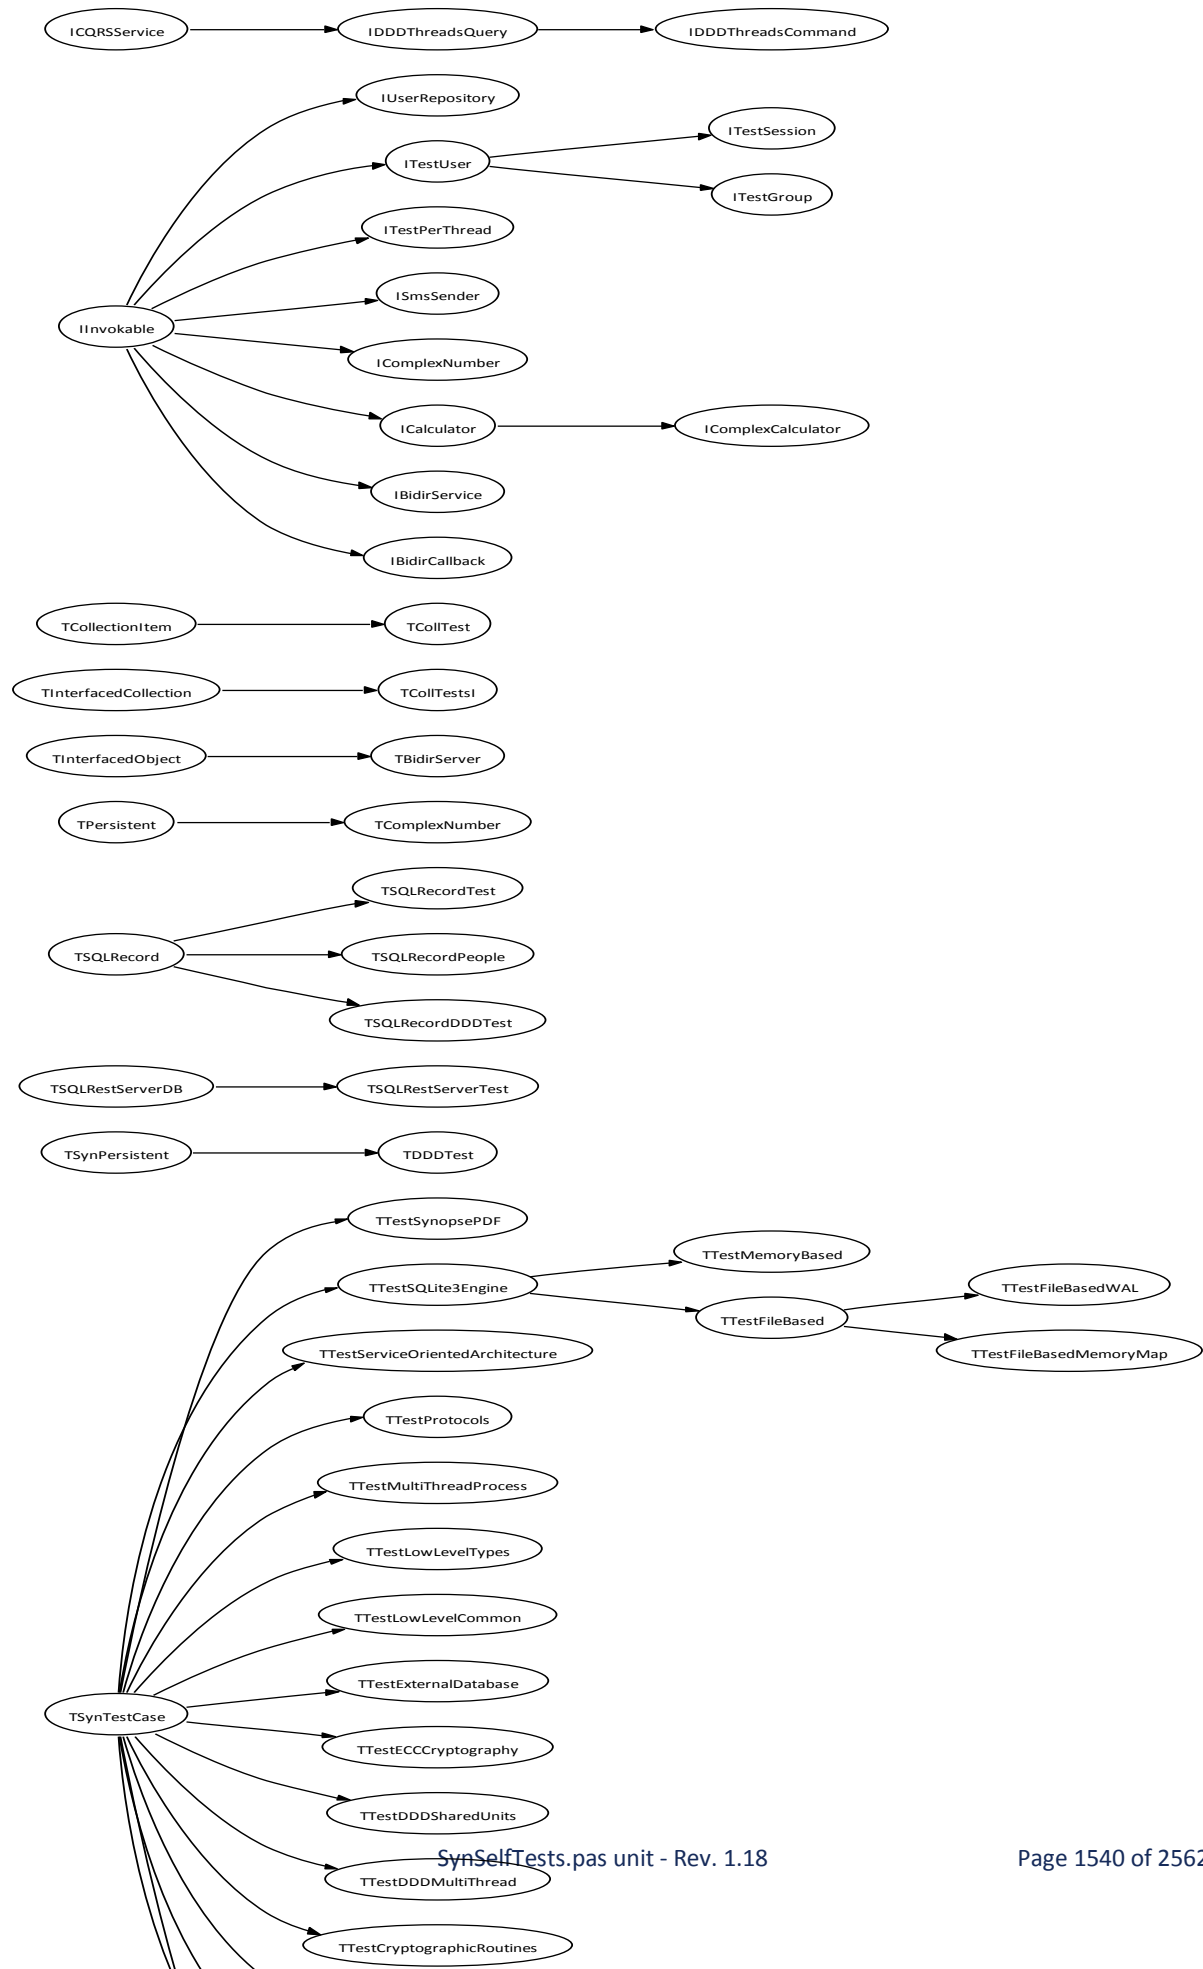

Units used in the *SynSelfTests* unit

Unit Name	Description	Page
<i>dddDomAuthInterfaces</i>	Shared DDD Domains: Authentication objects and interfaces - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	2447
<i>dddDomCountry</i>	Shared DDD Domains: TCountry object definition - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	2449
<i>dddDomUserInterfaces</i>	Shared DDD Domains: User interfaces definition - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	2455
<i>dddDomUserTypes</i>	Shared DDD Domains: User objects definition - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	2457
<i>dddInfraAuthRest</i>	Shared DDD Infrastructure: Authentication implementation - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	2473
<i>dddInfraEmail</i>	Shared DDD Infrastructure: implement an email validation service - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	2477
<i>dddInfraEmailer</i>	Shared DDD Infrastructure: generic emailing service - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	2481
<i>dddInfraRepoUser</i>	Shared DDD Infrastructure: User CQRS Repository via ORM - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	2485
<i>mORMot</i>	Common ORM and SOA classes for mORMot - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1907
<i>mORMotDB</i>	Virtual Tables for external DB access for mORMot - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	2286

Unit Name	Description	Page
<i>mORMotDDD</i>	Domain-Driven-Design toolbox for mORMot - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	2295
<i>mORMotHttpClient</i>	HTTP/1.1 RESTful JSON Client classes for mORMot - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	2316
<i>mORMotHttpServer</i>	HTTP/1.1 RESTFUL JSON Server classes for mORMot - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	2323
<i>mORMotMongoDB</i>	Direct optimized MongoDB access for mORMot's ORM - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	2344
<i>mORMotMVC</i>	Implements MVC patterns over mORMot's ORM/SOA and SynMustache - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	2349
<i>mORMotService</i>	Daemon managment classes for mORMot, including low-level Win NT Service - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	2380
<i>mORMotSQLite3</i>	SQLite3 embedded Database engine used as the mORMot SQL kernel - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	2392
<i>PasZip</i>	ZIP/LZ77 Deflate/Inflate Compression in pure pascal - this unit is a part of the freeware Synapse framework, licensed in the LGPL v3; version 1.18	675
<i>SynBidirSock</i>	Implements bidirectional client and server protocol, e.g. WebSockets - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	681
<i>SynCommons</i>	Common functions used by most Synapse projects - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynCrtSock</i>	Classes implementing TCP/UDP/HTTP client and server protocol - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1086
<i>SynCrypto</i>	Fast cryptographic routines (hashing and cypher) - implements AES,XOR,ADLER32,MD5,RC4,SHA1,SHA256,SHA384,SHA512,SHA3 and JWT - optimized for speed (tuned assembler and SSE3/SSE4/AES-NI/PADLOCK support) - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1143

Unit Name	Description	Page
<i>SynDB</i>	Abstract database direct access classes - this unit is a part of the freeware Synapse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1208
<i>SynDBODBC</i>	ODBC 3.x library direct access classes to be used with our SynDB architecture - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1278
<i>SynDBRemote</i>	Remote access to any RDBMS via HTTP using our SynDB architecture - this unit is a part of the freeware Synapse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1297
<i>SynDBSQLite3</i>	SQLite3 direct access classes to be used with our SynDB architecture - this unit is a part of the freeware Synapse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1302
<i>SynEcc</i>	Certificate-based public-key cryptography using ECC-secp256r1 - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1318
<i>SynGdiPlus</i>	GDI+ library API access - adds GIF, TIF, PNG and JPG pictures read/write support as standard TGraphic - make available most useful GDI+ drawing methods - allows Antialiased rendering of any EMF file using GDI+ - this unit is a part of the freeware Synapse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1355
<i>SynLizard</i>	Lizard (LZ5) compression routines (statically linked for FPC) - licensed under a MPL/GPL/LGPL tri-license; original Lizard is BSD 2-Clause	1364
<i>SynLog</i>	Logging functions used by Synapse projects - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1368
<i>SynLZ</i>	SynLZ Compression routines - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1399
<i>SynLZO</i>	Fast LZO Compression routines - licensed under a MPL/GPL/LGPL tri-license; version 1.13	1401
<i>SynMongoDB</i>	MongoDB document-oriented database direct access classes - this unit is a part of the freeware Synapse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1402
<i>SynMustache</i>	Logic-less mustache template rendering - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1456
<i>SynOleDB</i>	Fast OleDB direct access classes - this unit is a part of the freeware Synapse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1464

Unit Name	Description	Page
<i>SynPdf</i>	PDF file generation - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1479
<i>SynProtoRelay</i>	Implements asynchronous safe WebSockets tunnelling - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1528
<i>SynProtoRTSPHTTP</i>	Implements asynchronous RTSP stream tunnelling over HTTP - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1533
<i>SynSQLite3</i>	SQLite3 Database engine direct access - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1653
<i>SynSQLite3Static</i>	SQLite3 3.38.2 Database engine - statically linked for Windows/Linux - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1718
<i>SynTable</i>	Filter/database/cache/buffer/security/search/multithread/OS features - as a complement to SynCommons, which tended to increase too much - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1728
<i>SynTests</i>	Unit test functions used by Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1840
<i>SynZip</i>	Low-level access to ZLib compression (1.2.5 engine version) - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1853
<i>TestSQL3FPCInterfaces</i>	SOA interface methods definition to circumvent FPC missing RTTI - generated at 2016-06-14 13:49:41	2446

SynSelfTests class hierarchy

Objects implemented in the *SynSelfTests* unit

Objects	Description	Page
IBidirCallback	SOA callback definition as expected by TTestBidirectionalRemoteConnection	1554
IBidirService	SOA service definition as expected by TTestBidirectionalRemoteConnection	1554
ICalculator	A test interface, used by TTestServiceOrientedArchitecture	1556
IComplexCalculator	A test interface, used by TTestServiceOrientedArchitecture	1557
IComplexNumber	A test interface, used by TTestServiceOrientedArchitecture	1558
IDDDThreadsCommand	CQRS Command Interface for TTest	1555
IDDDThreadsQuery	CQRS Query Interface fo TTest	1555
ISmsSender	A test interface, used by TTestServiceOrientedArchitecture	1558
ITestGroup	A test interface, used by TTestServiceOrientedArchitecture	1558
ITestPerThread	A test interface, used by TTestServiceOrientedArchitecture	1558
ITestSession	A test interface, used by TTestServiceOrientedArchitecture	1558
ITestUser	A test interface, used by TTestServiceOrientedArchitecture	1558
IUserRepository	A test interface, used by TTestServiceOrientedArchitecture	1558
TComplexNumber	A test class, used by TTestServiceOrientedArchitecture	1556
TConsultaNav	A record used by IComplexCalculator.EchoRecord	1556
TCustomerData	A record used by IComplexCalculator.GetCustomer	1556
TDDDDTest	This is our simple Test data class. Will be mapped to TSQLRecordDDDDTest.	1555
TSQLRecordDDDDTest	The corresponding TSQLRecord for TDDDDTest.	1555
TSQLRecordPeople	Under Linux, port<1024 needs root user a record mapping used in the test classes of the framework	1542
TSQLRestServerTest	This class defined two published methods of type TSQLRestServerCallBack in order to test the Server-Side ModelRoot/TableName/ID/MethodName RESTful model	1551
TTestBasicClasses	This test case will test some generic classes defined and implemented in the mORMot.pas unit	1546
TTestBidirectionalRemoteConnection	A test case for all bidirectional remote access, e.g. WebSockets	1554

Objects	Description	Page
TTestClientServerAccess	This test case will test most functions, classes and types defined and implemented in the mORMotSQLite3 unit, i.e. the SQLite3 engine itself, used as a HTTP/1.1 server and client	1550
TTestCompression	This test case will test most functions, classes and types defined and implemented in the SynZip unit	1546
TTestCryptographicRoutines	This test case will test most functions, classes and types defined and implemented in the SynCrypto unit	1546
TTestDDDMultiThread	A test case for aggressive multi-threaded DDD ORM test	1556
TTestDDDDSharedUnits	A test case for all shared DDD types and services	1555
TTestECCCryptography	This test case will test ECDH and ECDSA cryptography as implemented in the SynECC unit	1547
TTestExternalDatabase	A test case which will test most external DB functions of the mORMotDB unit	1552
TTestFileBased	This test case will test most functions, classes and types defined and implemented in the mORMotSQLite3 unit, i.e. the SQLite3 engine itself, with a file-based approach	1549
TTestFileBasedMemoryMap	This test case will test most functions, classes and types defined and implemented in the mORMotSQLite3 unit, i.e. the SQLite3 engine itself, with a file-based approach	1550
TTestFileBasedWAL	This test case will test most functions, classes and types defined and implemented in the mORMotSQLite3 unit, i.e. the SQLite3 engine itself, with a file-based approach	1550
TTestLowLevelCommon	This test case will test most functions, classes and types defined and implemented in the SynCommons unit	1542
TTestLowLevelTypes	This test case will test most low-level functions, classes and types defined and implemented in the mORMot.pas unit	1545
TTestMemoryBased	This test case will test most functions, classes and types defined and implemented in the mORMotSQLite3 unit, i.e. the SQLite3 engine itself, with a memory-based approach	1549
TTestMultiThreadProcess	A test case for multi-threading abilities of the framework	1553
TTestProtocols	This test case will validate several low-level protocols	1548
TTestServiceOrientedArchitecture	A test case which will test the interface-based SOA implementation of the mORMot framework	1559
TTestSQLite3Engine	A parent test case which will test most functions, classes and types defined and implemented in the mORMotSQLite3 unit, i.e. the SQLite3 engine itself	1548
TTestSynapsePDF	This test case will test most functions, classes and types defined and implemented in the SynPDF unit	1548

Objects	Description	Page
TUser	A test value object, used by IUserRepository/ISmsSender interfaces	1558

TSQLRecordPeople = class(TSQLRecord)

Under Linux, port<1024 needs root user a record mapping used in the test classes of the framework

- this class can be used for debugging purposes, with the database created by TTestFileBased in mORMotSQLite3.pas
- this class will use 'People' as a table name

function DataAsHex(aClient: TSQLRestClientURI): RawUTF8;

Method used to test the Client-Side ModelRoot/TableName/ID/MethodName RESTful request, i.e. ModelRoot/People/ID/DataAsHex in this case

- this method calls the supplied TSQLRestClient to retrieve its results, with the ID taken from the current TSQLRecordPeople instance ID field
- parameters and result types depends on the purpose of the function
- TSQLRestServerTest.DataAsHex published method implements the result calculation on the Server-Side

class function Sum(aClient: TSQLRestClientURI; a, b: double; Method2: boolean): double;

Method used to test the Client-Side ModelRoot/MethodName RESTful request, i.e. ModelRoot/Sum in this case

- this method calls the supplied TSQLRestClient to retrieve its results
- parameters and result types depends on the purpose of the function
- TSQLRestServerTest.Sum published method implements the result calculation on the Server-Side
- this method doesn't expect any ID to be supplied, therefore will be called as class function - normally, it should be implement in a TSQLRestClient descendant, and not as a TSQLRecord, since it doesn't depend on TSQLRecordPeople at all
- you could also call the same service from the ModelRoot/People/ID/Sum URL, but it won't make any difference)

TTestLowLevelCommon = class(TSynTestCase)

This test case will test most functions, classes and types defined and implemented in the SynCommons unit

Used for DI-2.2.2 (page 2559).

procedure BaudotCode;

Test ASCII Baudot encoding

procedure Bits;

The low-level bit management functions

procedure BloomFilters;

Test TSynBloomFilter class

procedure Curr64;

The new fast Currency to/from string conversion

procedure CustomRTL;

Validate our optimized MoveFast/FillCharFast functions

procedure FastStringCompare;

Test StrlComp() and AnsilComp() functions

procedure IniFiles;

The fast .ini file content direct access

procedure Integers;

Test low-level integer/Int64 functions

procedure Iso8601DateAndTime;

The ISO-8601 date and time encoding
- test especially the conversion to/from text

procedure MimeTypes;

Test mime types recognition

procedure NumericalConversions;

Low level fast Integer or Floating-Point to/from string conversion
- especially the RawUTF8 or PUTF8Char relative versions

procedure QuickSelect;

Validates the median computation using the "Quick Select" algorithm

procedure Soundex;

The Soundex search feature (i.e. TSynSoundex and all related functions)

procedure SystemCopyRecord;

The faster CopyRecord function, enhancing the system.pas unit

procedure TimeZones;

Test the TSynTimeZone class and its cross-platform local time process

procedure UrlDecoding;

Test UrlEncode() and UrlDecode() functions
- this method use some ISO-8601 encoded dates and times for the testing

procedure UrlEncoding;

Test UrlEncode() and UrlDecode() functions

procedure _CamelCase;

The camel-case / camel-uncase features, used for i18n from Delphi RTII

procedure _crc32c;

Test crc32c in both software and hardware (SSE4.2) implementations

procedure _DeltaCompress;

Test DeltaCompress/DeltaExtract functions

procedure _GUID;

Test our internal fast TGUID process functions

procedure _IdemPropName;

Test IdemPropName() and IdemPropNameU() functions

procedure _IsMatch;

Test IsMatch() function

procedure _ParseCommandArguments;

Test ParseCommandArguments() function

procedure _Random32;

Test RDRAND Intel x86/x64 opcode if available, or fast gsl_rng_taus2

procedure _TDynArray;

Test the TDynArray object and methods

procedure _TDynArrayHashed;

*Test the TDynArrayHashed object and methods (dictionary features)
- this test will create an array of 200,000 items to test speed*

procedure _TEExprParserMatch;

Test TExprParserMatch class

procedure _TObjArray;

*Test T*ObjArray types and the ObjArray*() wrappers*

procedure _TObjectDynArrayWrapper;

Test TObjectDynArrayWrapper class

procedure _TObjectListHashed;

Test TObjectListHashed class

procedure _TObjectListSorted;

Test TObjectListSorted class

procedure _TRawUTF8Interning;

Test TRawUTF8Interning process

procedure _TRawUTF8List;

Test the TRawUTF8List class

procedure _TSynCache;

Test the TSynCache class

procedure _TSynDictionary;

Test the TSynDictionary class

procedure _TSynFilter;

Low-level TSynFilter classes

procedure _TSynLogFile;

Low-level TSynLogFile class

procedure _TSynNameValue;

Test TSynNameValue class

procedure _TSynQueue;

Validate the TSynQueue class

procedure _TSynTable;

Test TSynTable class and TSynTableVariantType new variant type

procedure _TSynUniqueIdentifier;

Client side genuine 64 bit identifiers generation

procedure _TSynValidate;

Low-level TSynValidate classes

procedure _UTF8;

Test UTF-8 and Win-Ansi conversion (from or to, through RawUnicode)

TTestLowLevelTypes = class(TSynTestCase)

This test case will test most low-level functions, classes and types defined and implemented in the mORMot.pas unit

Used for DI-2.2.2 (page 2559).

procedure EncodeDecodeJSON;

Some low-level JSON encoding/decoding

procedure JSONBenchmark;

Some performance numbers about JSON parsing and generating

procedure MustacheRenderer;

Test the Mustache template rendering unit

procedure RTTI;

Some low-level RTTI access

- especially the field type retrieval from published properties

procedure UrlEncoding;

Some low-level Url encoding from parameters

procedure Variants;

Some low-level variant process

procedure WikiMarkdownToHtml;

HTML generation from Wiki Or Markdown syntax

procedure _BSON;

BSON process (using TDocVariant)

procedure _TDecimal128;

Low-level TDecimal128 decimal value process (as used in BSON)

procedure _TDocVariant;

Variant-based JSON/BSON document process

procedure _TSynMonitorUsage;

Test advanced statistics monitoring

procedure _TSynTableStatement;

Test SELECT statement parsing

TTestBasicClasses = **class**(TSynTestCase)

*This test case will test some generic classes defined and implemented in the mORMot.pas unit
Used for DI-2.2.2 (page 2559).*

procedure _TSQLModel;

Test the TSQLModel class

procedure _TSQLRecord;

Test the TSQLRecord class

- especially SQL auto generation, or JSON export/import

procedure _TSQLRecordSigned;

Test the digital signature of records

procedure _TSQLRestServerFullMemory;

Test a full in-memory server over Windows Messages

*- Under Linux, URIDll will be used instead due to lack of message loop
- without any SQLite3 engine linked*

TTestCompression = **class**(TSynTestCase)

This test case will test most functions, classes and types defined and implemented in the SynZip unit

procedure GZIPFormat;

.gzip archive handling

procedure InMemoryCompression;

Direct deflate/inflate functions

procedure ZIPFormat;

.zip archive handling

procedure _SynLZ;

SynLZ internal format

procedure _SynLZO;

SynLZO internal format

procedure _TAlgoCompress;

TAlgoCompress classes

TTestCryptographicRoutines = **class**(TSynTestCase)

This test case will test most functions, classes and types defined and implemented in the SynCrypto unit

procedure Benchmark;

Compute some performance numbers, mostly against regression

procedure _Adler32;

Adler32 hashing functions

procedure _AES256;

AES encryption/decryption functions

procedure _AES_GCM;

AES-GCM encryption/decryption with authentication

procedure _Base64;

Base-64 encoding/decoding functions

procedure _CompressShaAes;

CompressShaAes() using SHA-256 / AES-256-CTR algorithm over SynLZ

procedure _CryptDataForCurrentUser;

CryptDataForCurrentUser() function

procedure _CryptDataForCurrentUserAPI;

CryptDataForCurrentUserAPI() function

procedure _JWT;

JWT classes

procedure _MD5;

MD5 hashing functions

procedure _RC4;

RC4 encryption function

procedure _SHA1;

SHA-1 hashing functions

procedure _SHA256;

SHA-256 hashing functions

procedure _SHA3;

SHA-3 / Keccak hashing functions

procedure _SHA512;

SHA-512 hashing functions

procedure _TAESPNRG;

AES-based pseudorandom number generator

TTestECCCryptography = class(TSynTestCase)

This test case will test ECDH and ECDSA cryptography as implemented in the SynECC unit

procedure CertificatesAndSignatures;

ECDSA certificates chains and digital signatures

procedure ECCCommandLineTool;

Run most commands of the ECC tool

procedure ECDHEStreamProtocol;

ECDHE stream protocol

procedure ReferenceVectors;

Avoid regression among platforms and compilers

procedure _ecc_make_key;

ECC private/public keys generation

procedure _ecdh_shared_secret;

ECDH key derivation

procedure _ecdsa_sign;

ECDSA signature computation

procedure _ecdsa_verify;

ECDSA signature verification

TTestProtocols = class(TSynTestCase)

This test case will validate several low-level protocols

procedure RTSPOverHTTP;

RTSP over HTTP, as implemented in SynProtoRTSPHTTP unit

TTestSynapsePDF = class(TSynTestCase)

This test case will test most functions, classes and types defined and implemented in the SynPDF unit

procedure _TPdfDocument;

Create a PDF document, using the PDF Canvas property
- test font handling, especially standard font substitution

procedure _TPdfDocumentGDI;

Create a PDF document, using a EMF content
- validates the EMF/TMetaFile enumeration, and its conversion into the PDF content, including PDF-1.5 and page orientation
- this method will produce a .pdf file in the executable directory, if you want to check out the result (it's simply a curve drawing, with data from NIST)

TTestSQLite3Engine = class(TSynTestCase)

A parent test case which will test most functions, classes and types defined and implemented in the mORMotSQLite3 unit, i.e. the SQLite3 engine itself
- it should not be called directly, but through TTestFileBased, TTestMemoryBased and TTestMemoryBased children

Used for DI-2.2.2 (page 2559).

procedure DatabaseDirectAccess;

Test direct access to the SQLite3 engine
- i.e. via TSQLDataBase and TSQLRequest classes

procedure VirtualTableDirectAccess;

Test direct access to the Virtual Table features of SQLite3

procedure _TRecordVersion;

Test Master/Slave replication using TRecordVersion field

procedure _TSQLRestClientDB;

Test the TSQLRestClientDB, i.e. a local Client/Server driven usage of the framework

- validates TSQLModel, TSQLRestServer and TSQLRestStorage by checking the coherency of the data between client and server instances, after update from both sides
- use all RESTful commands (GET/UPDATE/POST/DELETE...)
- test the 'many to many' features (i.e. TSQLRecordMany) and dynamic arrays published properties handling
- test dynamic tables

procedure _TSQLTableJSON;

Test the TSQLTableJSON table

- the JSON content generated must match the original data
- a VACCUM is performed, for testing some low-level SQLite3 engine implementation
- the SortField feature is also tested

TTestFileBased = class(TTestSQLite3Engine)

This test case will test most functions, classes and types defined and implemented in the mORMotSQLite3 unit, i.e. the SQLite3 engine itself, with a file-based approach

Used for DI-2.2.2 (page 2559).

TTestMemoryBased = class(TTestSQLite3Engine)

This test case will test most functions, classes and types defined and implemented in the mORMotSQLite3 unit, i.e. the SQLite3 engine itself, with a memory-based approach

- this class will also test the TSQLRestStorage class, and its 100% Delphi simple database engine

Used for DI-2.2.2 (page 2559).

procedure ShardRead;

Validate TSQLRestStorageShardDB reading among all sharded databases

procedure ShardReadAfterPurge;

Validate TSQLRestStorageShardDB reading after deletion of several shards

procedure ShardWrite;

Validate TSQLRestStorageShardDB add operation, with or without batch

procedure _MaxShardCount;

Validate TSQLRestStorageShardDB.MaxShardCount implementation

procedure _RTree;

Validate RTree virtual tables

procedure _TSQLTableWritable;

Test the TSQLTableWritable table

TTestFileBasedWAL = class(TTestFileBased)

This test case will test most functions, classes and types defined and implemented in the mORMotSQLite3 unit, i.e. the SQLite3 engine itself, with a file-based approach

- purpose of this class is to test Write-Ahead Logging for the database

Used for DI-2.2.2 (page 2559).

TTestFileBasedMemoryMap = class(TTestFileBased)

This test case will test most functions, classes and types defined and implemented in the mORMotSQLite3 unit, i.e. the SQLite3 engine itself, with a file-based approach

- purpose of this class is to test Memory-Mapped I/O for the database

TTestClientServerAccess = class(TSynTestCase)

This test case will test most functions, classes and types defined and implemented in the mORMotSQLite3 unit, i.e. the SQLite3 engine itself, used as a HTTP/1.1 server and client

- test a HTTP/1.1 server and client on the port 888 of the local machine

- require the 'test.db3' SQLite3 database file, as created by TTestFileBased

Used for DI-2.2.2 (page 2559).

class function RegisterAddUrl(OnlyDelete: boolean): string;

This could be called as administrator for THttpApiServer to work

procedure DirectInProcessAccess;

Validate the client implementation, using direct access to the server

- it connects directly the client to the server, therefore use the same process and memory during the run: it's the fastest possible way of communicating

- it then runs 1000 remote SQL queries, and check the JSON data retrieved

- the time elapsed for this step is computed, and displayed on the report

procedure HTTPClientCustomEncryptionAes;

Validates TSQLRest.SetCustomEncryption process with only AES

procedure HTTPClientCustomEncryptionAesSha;

Validates TSQLRest.SetCustomEncryption process with AES+SHA

procedure HTTPClientCustomEncryptionSha;

Validates TSQLRest.SetCustomEncryption process with only SHA

procedure HTTPClientEncrypted;

Validate the HTTP/1.1 client multi-query implementation with one connection for the all queries and our proprietary SHA-256 / AES-256-CTR encryption encoding

- it runs 1000 remote SQL queries, and check the JSON data retrieved

- the time elapsed for this step is computed, and displayed on the report

procedure HTTPClientKeepAlive;

Validate the HTTP/1.1 client multi-query implementation with one connection for the all queries

- this method keep alive the HTTP connection, so is somewhat faster

- it runs 1000 remote SQL queries, and check the JSON data retrieved

- the time elapsed for this step is computed, and displayed on the report

procedure HTTPClientMultiConnect;

Validate the HTTP/1.1 client multi-query implementation with one connection initialized per query

- this method don't keep alive the HTTP connection, so is somewhat slower: a new HTTP connection is created for every query
- it runs 1000 remote SQL queries, and check the JSON data retrieved
- the time elapsed for this step is computed, and displayed on the report

procedure HTTPSeveralDBServers;

Validate HTTP/1.1 client-server with multiple TSQLRestServer instances

procedure LocalWindowMessages;

Validate the Windows Windows Messages based client implementation

- it first launch the Server to handle Windows Messages
- it then runs 1000 remote SQL queries, and check the JSON data retrieved
- the time elapsed for this step is computed, and displayed on the report

procedure NamedPipeAccess;

Validate the Named-Pipe client implementation

- it first launch the Server as Named-Pipe
- it then runs 1000 remote SQL queries, and check the JSON data retrieved
- the time elapsed for this step is computed, and displayed on the report

procedure _TSQLHttpClient;

Validate the HTTP/1.1 client implementation

- by using a request of all records data

procedure _TSQLHttpServer;

Initialize a TSQLHttpServer instance

- uses the 'test.db3' SQLite3 database file generated by TTestSQLite3Engine
- creates and validates a HTTP/1.1 server on the port 888 of the local machine, using the THttpApiServer (using kernel mode http.sys) class if available

TSQLRestServerTest = class(TSQLRestServerDB)

This class defined two published methods of type TSQLRestServerCallBack in order to test the Server-Side ModelRoot/TableName/ID/MethodName RESTful model

procedure DataAsHex(Ctxt: TSQLRestServerURIContext);

Test ModelRoot/People/ID/DataAsHex

- this method is called by TSQLRestServer.URI when a ModelRoot/People/ID/DataAsHex GET request is provided
- Parameters values are not used here: this service only need aRecord.ID
- SentData is set with incoming data from a PUT method
- if called from ModelRoot/People/ID/DataAsHex with GET or PUT methods, TSQLRestServer.URI will create a TSQLRecord instance and set its ID (but won't retrieve its other field values automatically)
- if called from ModelRoot/People/DataAsHex with GET or PUT methods, TSQLRestServer.URI will leave aRecord.ID=0 before launching it
- if called from ModelRoot/DataAsHex with GET or PUT methods, TSQLRestServer.URI will leave aRecord=nil before launching it
- implementation must return the HTTP error code (e.g. 200 as success)
- Table is overloaded as TSQLRecordPeople here, and still match the TSQLRestServerCallback prototype: but you have to check the class at runtime: it can be called by another similar but invalid URL, like ModelRoot/OtherTableName/ID/DataAsHex

procedure Sum(Ctxt: TSQLRestServerURIContext);

Method used to test the Server-Side ModelRoot/Sum or ModelRoot/People/Sum Requests with JSON process

- implementation of this method returns the sum of two floating-points, named A and B, as in the public TSQLRecordPeople.Sum() method, which implements the Client-Side of this service
- Table nor ID are never used here

procedure Sum2(Ctxt: TSQLRestServerURIContext);

Method used to test the Server-Side ModelRoot/Sum or ModelRoot/People/Sum Requests with variant process

TTestExternalDatabase = class(TSynTestCase)

A test case which will test most external DB functions of the mORMotDB unit

- the external DB will be in fact a SynDBSQLite3 instance, expecting a test.db3 SQLite3 file available in the current directory, populated with some TSQLRecordPeople rows
- note that SQL statement caching at SQLite3 engine level makes those test 2 times faster: nice proof of performance improvement

procedure AutoAdaptSQL;

Check the SQL auto-adaptation features

procedure CryptDatabase;

Check the per-db encryption

- the testpass.db3-wal file is not encrypted, but the main testpass.db3 file will

procedure DBPropertiesPersistence;

Test TSQLDBConnectionProperties persistent as JSON

procedure ExternalRecords;

Initialize needed RESTful client (and server) instances

- i.e. a RESTful direct access to an external DB

procedure ExternalViaREST;

Test external DB implementation via faster REST calls

- will mostly call directly the TSQLRestStorageExternal instance, bypassing the Virtual Table mechanism of SQLite3

procedure ExternalViaRESTWithChangeTracking;

Test external DB implementation via faster REST calls and change tracking

- a TSQLRecordHistory table will be used to store record history

procedure ExternalViaVirtualTable;

Test external DB implementation via slower Virtual Table calls

- using the Virtual Table mechanism of SQLite3 is more than 2 times slower than direct REST access

procedure JETDatabase;

Test external DB using the JET engine

procedure _SynDBRemote;

Test SynDB connection remote access via HTTP

procedure _TQuery;

Test TQuery emulation class

procedure CleanUp; **override;**

Release used instances (e.g. server) and memory

TTestMultiThreadProcess = class(TSynTestCase)

A test case for multi-threading abilities of the framework

- will test all direct or remote access protocols with a growing number of concurrent clients (1,2,5,10,30,50 concurrent threads), to ensure stability, scalability and safety of the framework

constructor Create(Owner: TSynTests; **const** Ident: **string** = ''); **override;**

Create the test case instance

procedure BackgroundThread;

Test via TSQLRestClientDB instances with AcquireWriteMode=amBackgroundThread

procedure CreateThreadPool;

Initialize fDatabase and create MaxThreads threads for clients

procedure Locked;

Test via TSQLRestClientDB instances with AcquireWriteMode=amLocked

procedure MainThread;

Test via TSQLRestClientDB instances with AcquireWriteMode=amMainThread

procedure SocketAPI;

Test via TSQLHttpClientWinSock instances over OS's socket API server

- this test won't work within the Delphi IDE debugger

procedure Unlocked;

Test via TSQLRestClientDB instances with AcquireWriteMode=amUnlocked

procedure Websockets;

/ test via TSQLHttpClientWebsockets instances

procedure WindowsAPI;

Test via TSQLHttpClientWinHTTP instances over http.sys (HTTP API) server

procedure _TSQLRestClientDB;

Test via TSQLRestClientDB instances

procedure _TSQLRestClientURIMessage;

Test via TSQLRestClientURIMessage instances

procedure _TSQLRestClientURINamedPipe;

Test via TSQLRestClientURINamedPipe instances

procedure _TSQLRestServerDB;

Direct test of its RESTful methods

procedure CleanUp; **override**;

Release used instances (e.g. server) and memory

property ClientOnlyServerIP: RawByteString **read** fClientOnlyServerIP **write** fClientOnlyServerIP;

If not "", forces the test not to initiate any server and connect to the specified server IP address

property ClientPerThread: Integer **read** fClientPerThread **write** fClientPerThread;

How many TSQLRest instance is initialized per thread

- is 1 by default

property MaxThreads: integer **read** fMaxThreads **write** fMaxThreads;

The maximum number of threads used for this test

- is 50 by default

property MinThreads: integer **read** fMinThreads **write** fMinThreads;

The minimum number of threads used for this test

- is 1 by default

property OperationCount: integer **read** fOperationCount **write** fOperationCount;

How many Add() + Retrieve() operations are performed during each test

- is 200 by default, i.e. 200 Add() plus 200 Retrieve() globally

IBidirCallback = **interface**(IInvokable)

SOA callback definition as expected by TTestBidirectionalRemoteConnection

IBidirService = **interface**(IInvokable)

SOA service definition as expected by TTestBidirectionalRemoteConnection

TTestBidirectionalRemoteConnection = **class**(TSynTestCase)

A test case for all bidirectional remote access, e.g. WebSockets

procedure RelayConnectionRecreate;

Verify ability to reconnect from Private Relay to Public Relay

procedure RelayShutdown;

Finalize SynProtoRelay tunnelling

procedure RelaySOACallbackViaBinaryWebsockets;

Test SynProtoRelay tunnelling over binary WebSockets

procedure RelaySOACallbackViaJSONWebsockets;

Test SynProtoRelay tunnelling over JSON WebSockets

procedure RelayStart;

Initialize SynProtoRelay tunnelling

procedure RunHttpServer;

Launch the WebSockets-ready HTTP server

procedure SOACallbackOnServerSide;

Test the callback mechanism via interface-based services on server side

procedure SOACallbackViaBinaryWebsockets;

Test callbacks via interface-based services over binary WebSockets

procedure SOACallbackViaJSONWebsockets;

Test callbacks via interface-based services over JSON WebSockets

procedure WebsocketsBinaryProtocol;

Low-level test of our 'synopsebinary' WebSockets binary protocol

procedure WebsocketsJSONProtocol;

Low-level test of our 'synopsejson' WebSockets JSON protocol

procedure _TRecordVersion;

Test Master/Slave replication using TRecordVersion field over WebSockets

TDDDDTest = **class**(TSynPersistent)

This is our simple Test data class. Will be mapped to TSQLRecordDDDDTest.

TSQLRecordDDDDTest = **class**(TSQLRecord)

The corresponding TSQLRecord for TDDDDTest.

IDDDThreadsQuery = **interface**(ICQRSservice)

CQRS Query Interface fo TTest

IDDDThreadsCommand = **interface**(IDDDThreadsQuery)

CQRS Command Interface for TTest

TTestDDDDSharedUnits = **class**(TSynTestCase)

A test case for all shared DDD types and services

procedure AuthenticationModel;

Test the Authentication modelization types, and implementation

procedure EmailValidationProcess;

Test the Email validation process

```
procedure UserCQRSRepository;  
  Test the CQRS Repository for TUser persistence
```

```
procedure UserModel;  
  Test the User modelization types, including e.g. Address
```

```
TTestDDDMultiThread = class(TSynTestCase)  
  A test case for aggressive multi-threaded DDD ORM test
```

```
procedure DeleteOldDatabase;  
  Delete any old Test database on start
```

```
procedure MultiThreadedClientsTest;  
  Test concurrent access with multiple clients
```

```
procedure SingleClientTest;  
  Test straight-forward access using 1 thread and 1 client
```

```
procedure StartServer;  
  Start the whole DDD Server (http and rest)
```

```
TComplexNumber = class(TPersistent)  
  A test class, used by TTestServiceOrientedArchitecture  
  - to test TPersistent objects used as parameters for remote service calls
```

```
constructor Create(aReal, aImaginary: double); reintroduce;  
  Create an instance to store a complex number
```

```
property Imaginary: Double read fImaginary write fImaginary;  
  The imaginary part of this complex number
```

```
property Real: Double read fReal write fReal;  
  The real part of this complex number
```

```
TConsultaNav = packed record  
  A record used by IComplexCalculator.EchoRecord
```

```
TCustomerData = packed record  
  A record used by IComplexCalculator.GetCustomer
```

```
ICalculator = interface(IInvokable)  
  A test interface, used by TTestServiceOrientedArchitecture  
  - to test basic and high-level remote service calls
```

```
function Add(n1,n2: integer): integer;  
  Add two signed 32 bit integers
```

```
function ComplexCall(const Ints: TIntegerDynArray; const Strs1: TRawUTF8DynArray;
var Str2: TWideStringDynArray; const Rec1: TVirtualTableModuleProperties; var Rec2:
TSQLRestCacheEntryValue; Float1: double; var Float2: double):
TSQLRestCacheEntryValue;
```

Test integer, strings and wide strings dynamic arrays, together with records

```
function DirectCall(const Data: TSQLRawBlob): integer;
```

Validates ArgsInputsOctetStream raw binary upload

```
function Multiply(n1,n2: Int64): Int64;
```

Multiply two signed 64 bit integers

```
function RepeatJsonArray(const item: RawUTF8; count: integer): RawJSON;
```

Validates huge RawJSON/RawUTF8

```
function SpecialCall(Txt: RawUTF8; var Int: integer; var Card: cardinal; field:
TSynTableFieldTypes; fields: TSynTableFieldTypes; var options:
TSynTableFieldOptions): TSynTableFieldTypes;
```

Do some work with strings, sets and enumerates parameters, testing also var (in/out) parameters and set as a function result

```
function StackFloatMultiply(n1,n2,n3,n4,n5,n6,n7,n8,n9,n10: double): Int64;
```

Test float stack access

```
function StackIntMultiply(n1,n2,n3,n4,n5,n6,n7,n8,n9,n10: integer): Int64;
```

Test unaligned stack access

```
function Subtract(n1,n2: double): double;
```

Subtract two floating-point values

```
function ToTextFunc(Value: double): string;
```

Convert a floating-point value into text

```
procedure Swap(var n1,n2: double);
```

Swap two by-reference floating-point values

- would validate pointer use instead of XMM1/XMM2 registers under Win64

```
procedure ToText(Value: Currency; var Result: RawUTF8);
```

Convert a currency value into text

```
IComplexCalculator = interface(ICalculator)
```

A test interface, used by TTestServiceOrientedArchitecture

- to test remote service calls with objects as parameters (its published properties will be serialized as standard JSON objects)

- since it inherits from ICalculator interface, it will also test the proper interface inheritance handling (i.e. it will test that ICalculator methods are also available)

```
function GetCurrentThreadID: PtrUInt;
```

Returns the thread ID running the method on server side

```
function GetCustomer(CustomerId: Integer; out CustomerData: TCustomerData):
Boolean;
```

Validate record transmission

function IsNull(n: TComplexNumber): boolean;

Purpose of this method is to check for boolean handling

function TestBlob(n: TComplexNumber): TServiceCustomAnswer;

This will test the BLOB kind of remote answer

function TestVariants(const Text: RawUTF8; V1: Variant; var V2: variant): variant;

Test variant kind of parameters

procedure Collections(Item: TCollTest; var List: TCollTestsI; out Copy: TCollTestsI);

Test in/out collections

procedure FillPeople(var People: TSQLRecordPeople);

/ validate TSQLRecord transmission

procedure Subtract(n1,n2: TComplexNumber; out Result: TComplexNumber);

Purpose of this method is to subtract two complex numbers

- using class instances as parameters

IComplexNumber = interface(IInvokable)

A test interface, used by TTestServiceOrientedArchitecture

- to test sicClientDriven implementation pattern: data will remain on the server until the IComplexNumber instance is out of scope

ITestUser = interface(IInvokable)

A test interface, used by TTestServiceOrientedArchitecture

- to test sicPerUser implementation pattern

ITestGroup = interface(ITestUser)

A test interface, used by TTestServiceOrientedArchitecture

- to test sicPerGroup implementation pattern

ITestSession = interface(ITestUser)

A test interface, used by TTestServiceOrientedArchitecture

- to test sicPerSession implementation pattern

ITestPerThread = interface(IInvokable)

A test interface, used by TTestServiceOrientedArchitecture

- to test threading implementation pattern

TUser = record

A test value object, used by IUserRepository/ISmsSender interfaces

- to test stubbing/mocking implementation pattern

IUserRepository = interface(IInvokable)

A test interface, used by TTestServiceOrientedArchitecture

- to test stubbing/mocking implementation pattern

ISmsSender = interface(IInvokable)

A test interface, used by TTestServiceOrientedArchitecture

- to test stubbing/mocking implementation pattern

TTestServiceOrientedArchitecture = class(TSynTestCase)

A test case which will test the interface-based SOA implementation of the mORMot framework

procedure ClientSideJSONRPC;

Test the client-side implementation in JSON-RPC mode

procedure ClientSideREST;

Test the client-side implementation in RESTful mode

procedure ClientSideRESTAsJSONObject;

Test the client-side in RESTful mode with values transmitted as JSON objects

procedure ClientSideRESTBackgroundThread;

*Test the client-side implementation of opt*InPerInterfaceThread option*

procedure ClientSideRESTBasicAuthentication;

Test the client-side implementation using TSQLRestServerAuthenticationHttpBasic

procedure ClientSideRESTCustomRecordLayout;

Test the custom record JSON serialization

procedure ClientSideRESTLocked;

Test the client-side implementation of optExecLockedPerInterface

procedure ClientSideRESTMainThread;

*Test the client-side implementation of opt*InMainThread option*

procedure ClientSideRESTServiceLogToDB;

Test the client-side in RESTful mode with all calls logged in a table

procedure ClientSideRESTSessionsStats;

Test the client-side in RESTful mode with full session statistics

procedure ClientSideRESTSignWithCrc32c;

Test the client-side implementation with crc32c URI signature

procedure ClientSideRESTSignWithMd5;

Test the client-side implementation with MD5 URI signature

procedure ClientSideRESTSignWithSha256;

Test the client-side implementation with SHA256 URI signature

procedure ClientSideRESTSignWithSha512;

Test the client-side implementation with SHA512 URI signature

procedure ClientSideRESTSignWithXxhash;

Test the client-side implementation with xxHash32 URI signature

procedure ClientSideRESTWeakAuthentication;

Test the client-side implementation using TSQLRestServerAuthenticationNone

procedure DirectCall;

Test direct call to the class instance

procedure MocksAndStubs;

Test interface stubbing / mocking

procedure Security;

Test the security features

procedure ServerSide;

Test the server-side implementation

procedure ServiceInitialization;

Initialize the SOA implementation

procedure TestOverHTTP;

Test RESTful mode using HTTP client/server communication

procedure WeakInterfaces;

Test the SetWeak/SetWeakZero weak interface functions

Constants implemented in the *SynSelfTests* unit

Objects	Description	Page
ESMException	Generic parent class of all SpiderMonkey-related Exception types	1562
TSMEngine	Implements a ThreadSafe JavaScript engine	1571
TSMEngineManager	Main access point to the SpiderMonkey per-thread scripting engines	1574
TSMEngineMethodEvent	Used to store one registered method event	1570
TSMObject	Just a wrapper around JavaScript Object API type, to be used with other values wrappers	1566
TSMValue	Just a wrapper around jsval API type, to be used with our object wrappers	1562
TSMVariant	A custom variant type used to store a SpiderMonkey object in Delphi code	1575
TSMVariantData	Memory structure used for TSMVariant storage of any JavaScript object as Delphi variant	1576

ESMException = class(ESynException)

Generic parent class of all SpiderMonkey-related Exception types

TSMValue = object(TObject)

Just a wrapper around jsval API type, to be used with our object wrappers

- SpiderMonkey jsval type can be directly casted to this type via TSMValue(jsval)
- note that some methods expect an execution context to be supplied as parameter, as soon as it contains a non primitive type (double/integer)

function SetJSON(cx: PJSContext; **const** aJSON: RawUTF8): boolean;

Set the value from UTF-8 encoded JSON

- returns TRUE if aJSON was valid, FALSE in case of an error

function ToBoolean: boolean;

Read the value as boolean

function ToDateTime(cx: PJSContext): TDateTime;

Return the value as a date/time

- in SpiderMonkey non-simple type instances do exist in a given JSContext, so we need to know the execution context (using a property is not an option)

function ToDouble: double;

Read the value as floating point

function ToInt64: int64;

Read the value as one 64 bit integer

- note that SpiderMonkey is not able to store all Int64 values directly

function ToInteger: integer;

Read the value as one 32 bit integer

function ToJSON(cx: PJSContext): RawUTF8;

Return the value as UTF-8 encoded JSON

function ToNativeFunction(cx: PJSContext): PJSFunction;

Attempts to convert the value into a native function pointer

function ToNativeFunctionName(cx: PJSContext): RawUTF8;

Attempts to convert the value into a native function name

function ToSynUnicode(cx: PJSContext): SynUnicode; overload;

Return the value as an Unicode String

- in SpiderMonkey non-simple type instances do exist in a given JSContext, so we need to know the execution context (using a property is not an option)

function ToUTF8(cx: PJSContext): RawUTF8;

Return the value as an UTF-8 String

- in SpiderMonkey non-simple type instances do exist in a given JSContext, so we need to know the execution context (using a property is not an option)

function ToVariant(cx: PJSContext): Variant; overload;

Return the value as variant (not implemented yet)

- will return any JavaScript string value directly as a RawUTF8

- will return any JavaScript object value as a TDocVariant document

- in SpiderMonkey non-simple type instances do exist in a given JSContext, so we need to know the execution context (using a property is not an option)

function ToWideString(cx: PJSContext): WideString;

Return the value as an Unicode WideString

- in SpiderMonkey non-simple type instances do exist in a given JSContext, so we need to know the execution context (using a property is not an option)

function TransformToSynUnicode(cx: PJSContext): SynUnicode;

Transform a JSValue to its UTF-16 string representation

- JavaScript equivalent is
variable.toString()

function TransformToUTF8(cx: PJSContext): RawUTF8;

Transform a JSValue to its UTF-8 string representation

- JavaScript equivalent is
variable.toString()

function ValType(cx: PJSContext): JSType;

Type of the value

- you should better use this before calling other To*() methods

procedure AddJSON(cx: PJSContext; W: TTextWriter);

Add the value as UTF-8 encoded JSON

procedure SetAnsiChar(cx: PJSContext; Text: PAnsiChar; TextLen, CodePage: integer);

Set the value as an Ansi encoded buffer (may be UTF-8 or any code page)

- if CodePage is 0, will use the CurrentAnsiCodePage value
- in SpiderMonkey non-simple type instances do exist in a given JSContext, so we need to know the execution context (using a property is not an option)
- warning - JSString string is a subject for GC so you must root it or set as property of some object or use SetNativeString() method to pass the value by reference

procedure SetBoolean(const Value: boolean);

Set the value as boolean

procedure SetDateTime(cx: PJSContext; const Value: TDateTime);

Set the value as a date/time

- in SpiderMonkey non-simple type instances do exist in a given JSContext, so we need to know the execution context (using a property is not an option)

procedure SetDouble(const Value: double);

Set the value as floating point

procedure SetInt64(const Value: int64);

Set the value as one 64 bit integer

- this is a somewhat dirty hack, since SpiderMonkey don't support int64: but it is possible to transform int64 to double for ant value < (1 shl 51)
- sometimes we need int64 to be passed do SpiderMonkey (e.g. for an ID)

procedure SetInteger(const Value: integer);

Set the value as one 32 bit integer

procedure SetNativeString(cx: PJSContext; const aStr: SynUnicode);

Set the value as Unicode String by reference

- this is the fastest way to add a string to SpiderMonkey: String is in fact not copied to the SpiderMonkey engine, just passed by reference
- Only SynUnicode string support by now (SpiderMonkey is internally UTF-16 based)
- WARNING - as a consequence, aStr must be UNCHANGED until SpiderMonkey engine points to it (SpiderMonkey will also consider its strings as immutable, so will never change its content during execution) - for instance, never pass a function result as aStr, nor use a local SynUnicode variable unless you trigger the Garbage Collection before the end of the local method

procedure SetNull;

Set the value as NULL

procedure SetSynUnicode(cx: PJSContext; const aStr: SynUnicode);

Set the value as an Unicode String

- in SpiderMonkey non-simple type instances do exist in a given JSContext, so we need to know the execution context (using a property is not an option)
- warning - JSString string is a subject for GC so you must root it or set as property of some object or use SetNativeString() method to pass the value by reference

procedure SetTVarRec(cx: PJSCContext; **const** V: TVarRec);

Set the value as TVarRec (i.e. an "array of const" open parameter)

- here any AnsiString parameter is expected to be a RawUTF8 before Delphi 2009, or its correct code page will be retrieved since Delphi 2009
- in SpiderMonkey non-simple type instances do exist in a given JSContext, so we need to know the execution context (using a property is not an option)

procedure SetUTF8(cx: PJSCContext; **const** aStr: RawUTF8);

Set the value as an UTF-8 String

- in SpiderMonkey non-simple type instances do exist in a given JSContext, so we need to know the execution context (using a property is not an option)
- warning - JSString string is a subject for GC so you must root it or set as property of some object or use SetNativeString() method to pass the value by reference

procedure SetVariant(cx: PJSCContext; **const** Value: Variant);

Set the value as variant (not implemented yet)

- will set any custom variant type (e.g. TDocVariant) as a JavaScript object value computed from the JSON serialization of the variant
- in SpiderMonkey non-simple type instances do exist in a given JSContext, so we need to know the execution context (using a property is not an option)

procedure SetVoid;

Set the value as VOID

procedure SetWideChar(cx: PJSCContext; Text: PWideChar; TextLen: integer);

Set the value as an UTF-16 encoded buffer

- in SpiderMonkey non-simple type instances do exist in a given JSContext, so we need to know the execution context (using a property is not an option)
- warning - JSString string is a subject for GC so you must root it or set as property of some object or use SetNativeString() method to pass the value by reference

procedure SetWideString(cx: PJSCContext; **const** aStr: WideString);

Set the value as an Unicode WideString

- in SpiderMonkey non-simple type instances do exist in a given JSContext, so we need to know the execution context (using a property is not an option)
- warning - JSString string is a subject for GC so you must root it or set as property of some object or use SetNativeString() method to pass the value by reference

procedure ToSynUnicode(cx: PJSCContext; **var** result: SynUnicode); overload;

Return the value as an Unicode String

- in SpiderMonkey non-simple type instances do exist in a given JSContext, so we need to know the execution context (using a property is not an option)

procedure ToVariant(cx: PJSCContext; **var** result: Variant); overload;

Return the value as variant (not implemented yet)

- will return any JavaScript string value directly as a RawUTF8
- will return any JavaScript object value as a TDocVariant document
- in SpiderMonkey non-simple type instances do exist in a given JSContext, so we need to know the execution context (using a property is not an option)

property AsBoolean: boolean **read** ToBoolean **write** SetBoolean;

Access to the value as boolean

```
property AsDouble: double read ToDouble write SetDouble;
```

Access to the value as floating point

```
property AsInt64: int64 read ToInt64 write SetInt64;
```

Access to the value as one 64 bit integer

```
property AsInteger: integer read ToInteger write SetInteger;
```

Access to the value as integer

```
property AsJSVal: jsval read FValue write FValue;
```

Direct access to the internal jsval instance

```
TSMObject = object(TObject)
```

Just a wrapper around JavaScript Object API type, to be used with other values wrappers

- SpiderMonkey object type can NOT be directly casted to this type via TSMObject(jsobject) - use JSObject wrapper instead - since we expects an execution context to be specified
- to create instance of this structure, use TSMEngine.NewObject() or MakeObject() overloaded methods

```
function AsSMValue: TSMValue;
```

Returns the associated jsobject instance as a jsvalue

```
function DefineNativeMethod(const methodName: SynUnicode; func: JSNative; nargs:  
uintN; attrs: TJSPPropertyAttrs): PJSTFunction; overload;
```

Add JSNative compatible function into JS object

- here the method name is specified as SynUnicode
- func if reference to function with JSNative signature
- nargs is function argument count
- actually this method creates a JSFunction and assing its value to obj[methodName]
- to add a global function, define it into the "global" object - i.e. call TSMEngine.GlobalObject.DefineNativeMethod()
- this method will allow to set custom properties attributes of this engine

```
function DefineNativeMethod(const methodName: SynUnicode; func: JSNative; nargs:  
uintN): PJSTFunction; overload;
```

Add JSNative compatible function into JS object

- here the method name is specified as SynUnicode
- func if reference to function with JSNative signature
- nargs is function argument count
- actually this method creates a JSFunction and assing its value to obj[methodName]
- to add a global function, define it into the "global" object - i.e. call TSMEngine.GlobalObject.DefineNativeMethod()
- this method will use the default properties attributes of this engine

```
function DefineNativeMethod(const methodName: AnsiString; func: JSNative; nargs:
uintN; attrs: TJSPPropertyAttrs): PJSTFunction; overload;
```

Add JSNative compatible function into JS object

- here the method name is specified as AnsiString
- func if reference to function with JSNative signature
- nargs is function argument count
- this method will allow to set custom properties attributes of this engine

```
function DefineNativeMethod(const methodName: AnsiString; func: JSNative; nargs:
uintN): PJSTFunction; overload;
```

Add JSNative compatible function into JS object

- here the method name is specified as AnsiString
- func if reference to function with JSNative signature
- nargs is function argument count
- this method will use the default properties attributes of this engine

```
function Engine: TSMEngine;
```

Returns the associated script engine instance

```
function GetPrivateData(expectedClass: PJSTClass): pointer;
```

Retrieve the private data associated with an object, if that object is an instance of a specified class

- wrapper to JS_GetInstancePrivate()

```
function GetPropValue(const propName: SynUnicode): TSMValue;
```

Get object property value (call getter for native)

- JavaScript equivalent of
obj[name]
- returns JSVAL_VOID if object does not have such property

```
function GetPropVariant(const propName: SynUnicode): variant;
```

Get object property value (call getter for native)

- you can also use the property Properties[]
- JavaScript equivalent of
obj[name]
- returns null if object does not have such property

```
function HasOwnProperty(const propName: SynUnicode): Boolean;
```

Determine whether a property is physically present on a object

- JavaScript equivalent of
Object.hasOwnProperty(propName)

```
function HasProperty(const propName: SynUnicode): Boolean;
```

Check object property does exist (including prototype chain lookup)

```
function IsArray: boolean;
```

Return TRUE if the object is an array

```
function ItemsCount: cardinal;
```

Return the number of elements in this array

function Parent: TSMObject;

Get the parent object of a given object

function Prototype: TSMObject;

Get the prototype of a given object

function Run(const methodName: AnsiString; const argv: array of variant): variant;

Executes a JavaScript object method using a Delphi array of variants

- returns the function result as a variant

- JavaScript equivalent of

`rval := obj.methodName(argv[0], ...);`

procedure Clear;

Set properties obj and cx to nil

procedure DefineProperty(const name: SynUnicode; const value: TSMValue); overload;

Define an object property with a value, specified as jsvalue

- this is not a direct JavaScript equivalent of

`obj[name] = val`

since any setter will be called

- to set a property in a global object, call either

`SMEngine.Global.property := ...` // via late-binding

`SMEngine.GlobalObject.DefineProperty()` // direct via TSMObject

equivalent in JavaScript to:

`var name = value`

outside a JavaScript function context (i.e. in global scope)

- if property already exists, it will just replace its value with the supplied value

- this method will use the default properties attributes of this engine

procedure DefineProperty(const name: SynUnicode; const value: variant); overload;

Define an object property with a value, specified as variant

- you can also use the property Properties[]

- this is not a direct JavaScript equivalent of

`obj[name] = val`

since any setter will be called

- to set a property in a global object, call either

`SMEngine.Global.property := ...` // via late-binding

`SMEngine.GlobalObject.DefineProperty()` // direct via TSMObject

equivalent in JavaScript to:

`var name = value`

outside a JavaScript function context (i.e. in global scope)

- if property already exists, it will just replace its value with the supplied value

- this method will use the default properties attributes of this engine

procedure DefineProperty(const name: SynUnicode; const value: variant; attrs: TJSPPropertyAttrs); overload;

Define an object property with a value, specified as variant

- you can also use the property Properties[]
- this is not a direct JavaScript equivalent of
`obj[name] = val`

since any setter will be called

- to set a property in a global object, call either

```
SMEngine.Global.property := ...           // via Late-binding
SMEngine.GlobalObject.DefineProperty()    // direct via TSMObject
```

equivalent in JavaScript to:

```
var name = value
```

outside a JavaScript function context (i.e. in global scope)

- if property already exists, it will just replace its value with the supplied value
- this method will allow to set custom properties attributes of this engine

procedure DefineProperty(const name: SynUnicode; const value: TSMValue; attrs: TJSPPropertyAttrs); overload;

Define an object property with a value, specified as jsvalue

- this is not a direct JavaScript equivalent of
`obj[name] = val`

since any setter will be called

- to set a property in a global object, call either

```
SMEngine.Global.property := ...           // via Late-binding
SMEngine.GlobalObject.DefineProperty()    // direct via TSMObject
```

equivalent in JavaScript to:

```
var name = value
```

outside a JavaScript function context (i.e. in global scope)

- if property already exists, it will just replace its value with the supplied value
- this method will allow to set custom properties attributes of this engine

procedure DeleteItem(aIndex: integer);

Delete an item of this object as array

procedure Evaluate(const script: SynUnicode; const scriptName: RawUTF8; lineNo: Cardinal; out result: TSMValue);

Evaluate JavaScript script in the current object scope

- if exception raised in script - raise Delphi ESMException
- on success, returns the last executed expression statement processed in the script in low-level result output variable

- JavaScript Equivalent of

```
with(obj) eval(script)
```

- be careful about execution scope - see JS_ExecuteScript() description

- usually you need to evaluate script only in global object scope, so you should better always call TSMEngine.Evaluate()

procedure Root;

Protect the object from Garbage Collection

- if this object is not set as property value of any other object or passed as parameter to function, you must protect it

procedure RunMethod(**const** methodName: AnsiString; **const** argv: SMValArray; **out** rval: TSMValue); overload;

Executes a JavaScript object method using low-level SMVal arguments

- returns the function result as a TSMValue
- JavaScript equivalent of
 rval := obj.methodName(argv[0],);

procedure RunMethod(**const** methodName: AnsiString; **const** argv: array of **const**; **out** rval: TSMValue); overload;

Executes a JavaScript object method using a Delphi array of const

- returns the function result as a TSMValue
- JavaScript equivalent of
 rval := obj.methodName(argv[0],);
- here any AnsiString parameter is expected to be a RawUTF8 before Delphi 2009, or its correct code page will be retrieved since Delphi 2009

procedure UnRoot;

Unprotect a previously "rooted" object

- WARNING!! Object MUST be protected by a previous Root method call, otherwise you get an access violation

property cx: PJContext **read** fCx;

Returns the associated execution context

property DefaultPropertyAttrs: TJSPPropertyAttrs **read** FDefaultPropertyAttrs **write** SetDefaultPropertyAttrs;

Access to the default attributes when accessing any properties

property Items[aIndex: integer]: **variant** **read** GetItem **write** SetItem;

Access to an item of this object as array

property obj: PJXObject **read** fObj;

Returns the associated jsobject instance

property PrivateData: pointer **read** GetPrivate **write** SetPrivate;

Access the private data field of an object

- wrapper to JS_GetPrivate()/JS_SetPrivate()
- only works if the object's JSClass has the JSCLASS_HAS_PRIVATE flag: it is safer to use GetPrivateData() method and providing the JSClass

property Properties[**const** propName: SynUnicode]: **variant** **read** GetPropVariant **write** SetPropVariant;

Read/write access to the object properties as variant

TSMEngineMethodEvent = **record**

Used to store one registered method event

TSMEngine = class(TObject)

Implements a ThreadSafe JavaScript engine

- use TSMEngineManager.ThreadSafeEngine to retrieve the Engine instance corresponding to the current thread, in multithread application
- contains JSRuntime + JSContext (to be ready for new SpiderMonkey version where context and runtime is the same)
- contains also one "global" JavaScript object. From script it is accessible via "global." (in browser, this is the "window." object)
- set SpiderMonkey error reporter and store last SpiderMonkey error in LastError property

constructor Create(aManager: TSMEngineManager); **virtual**;

Create one threadsafe JavaScript Engine instance

- initialize internal JSRuntime, JSContext, and global objects and standard JavaScript classes
- do not create Engine directly via this constructor, but instead call TSMEngineManager.ThreadSafeEngine

destructor Destroy; **override**;

Finalize the JavaScript engine instance

function Evaluate(const script: SynUnicode; const scriptName: RawUTF8='script'; lineNo: Cardinal=1): **variant**;

Evaluate a JavaScript script in the global scope

- a wrapper to GlobalObject.Evaluate(...)
- if exception raised in script - raise Delphi ESMException
- on success returns last executed expression statement processed in the script as a variant
- JavaScript equivalent to
eval(script)

function NewSMVariant: **variant**;

Create new ordinary JavaScript object, stored as TSMVariant custom type

- JavaScript equivalent of
{}
- new object is subject to Garbage Collection, so should be assigned as value for a property to create new object type property, as in JavaScript:
var obj = {}

function RegisterMethod(obj: PJSObject; const MethodName: SynUnicode; const Event: TSMEngineMethodEventJSON; ArgumentsCount: integer): PJSFunction; **overload**;

Register a native Delphi JSON-based method for a given object

- the supplied function name is case-sensitive
- the supplied callback will be executed directly by the JavaScript engine, supplying all parameters as JSON array, and returning the function result either as a JSON value or a JSON object
- raise an ESMException if the function could not be registered

function RegisterMethod(obj: PJXObject; **const** MethodName: SynUnicode; **const** Event: TSMEngineMethodEventVariant; ArgumentsCount: integer): PJJFunction; overload;

Register a native Delphi variant-based method for a given object

- the supplied function name is case-sensitive
- the supplied callback will be executed directly by the JavaScript engine, supplying all parameters as variant (including TDocVariant for any complex object), and returning the function result as variant
- raise an ESMException if the function could not be registered

procedure CheckJSError(res: JSBool); **virtual**;

Check if last call to JSAPI compile/eval function was successful

- raise ESMException if any error occurred
- put error description to SynSMLog

procedure ClearLastError;

Clear last JavaScript error

- called before every evaluate() function call

procedure GarbageCollect;

Trigger Garbage Collection

- all unrooted things (JSString, JSObject, VSVal) will be released

procedure InitClass(clasp: PJJClass; ps: PJJPropertySpec; **var** newObj: TSMObject);

Create new JavaScript object from its class and property specifications

procedure MakeObject(**const** value: TSMValue; **out** obj: TSMObject); overload;

Converts a JavaScript value into a JavaScript object

procedure MakeObject(**const** value: jsval; **out** obj: TSMObject); overload;

Converts a JavaScript low-level value into a JavaScript object

procedure MakeObject(jsobj: PJJObject; **out** obj: TSMObject); overload;

Converts a JavaScript low-level object into a JavaScript object

procedure MaybeGarbageCollect;

Offer the JavaScript engine an opportunity to perform garbage collection if needed

- Tries to determine whether garbage collection in would free up enough memory to be worth the amount of time it would take. If so, it performs some garbage collection
- Frequent calls are safe and will not cause the application to spend a lot of time doing redundant garbage collection work

procedure NewObject(**const** prototype: TSMObject; **out** newObj: TSMObject); overload;

Create new JavaScript object with prototype

- JavaScript equivalent of
`{}.__proto__ := prototype;`

procedure NewObject(out newobj: TSMObject); overload;

Create new ordinary JavaScript object

- JavaScript equivalent of

```
{}
```

- new object is subject to Garbage Collection, so must be rooted or assigned as value for a property to create new object type property, as in JavaScript:

```
var obj = {}
```

procedure NewObjectWithClass(clasp: PJSClass; const prototype: TSMObject; const parent: TSMObject; var newobj: TSMObject); overload;

Create new JavaScript object from its prototype

procedure NewObjectWithClass(clasp: PJSClass; var newobj: TSMObject); overload;

Create new JavaScript object from its class

procedure NewSMVariantRooted(out newobj: variant);

Create new ordinary JavaScript object, stored as TSMVariant custom type, and rooted to avoid garbage collection

- JavaScript equivalent of

```
{}
```

- new object is subject to Garbage Collection, so is rooted and should be explicitly unrooted, e.g. via:

```
obj: variant;
```

```
...
```

```
FManager.ThreadSafeEngine.NewSMVariantRooted(obj);
```

```
try
```

```
... work with obj
```

```
finally
```

```
obj._UnRoot; // pseudo-method
```

```
end;
```

procedure UnRegisterMethod(JSFunction: PJSCFunction);

Unregister a native Delphi method for a given object

- raise an ESMException if the function was not previously registered

- you should not call it usually, but it is available in case

property comp: PJSCompartment read fcomp;

Access to the associated execution compartment

property cx: PJSCContext read fCx;

Access to the associated execution context

property DefaultPropertyAttrs: TJSPPropertyAttrs read FDefaultPropertyAttrs write SetDefaultPropertyAttrs;

Access to the default attributes when accessing any properties

property EngineContentVersion: Cardinal read FEngineContentVersion;

Internal version number of engine scripts

- used in TSMEngine.ThreadSafeEngine to determine if context is up to date, in order to trigger on-the-fly reload of scripts without the need if restarting the application

- caller must change this parameter value e.g. in case of changes in the scripts folder in an HTTP server

property ErrorExist: boolean **read** FErrorExist;

TRUE if an error was triggered during JavaScript execution

property Global: variant **read** FGlobal;

Access to the associated global object as a TSMVariant custom variant

- allows direct property and method executions in Delphi code, via late-binding, for instance:

```
engine.Global.MyVariable := 1.0594631;  
engine.Global.MyFunction(1, 'text');
```

property GlobalObj: PJSObject **read** FGlobalObject.fobj;

Access to the associated global object as low-level PJSObject

property GlobalObject: TSMObject **read** FGlobalObject;

Access to the associated global object as a TSMObject wrapper

- you can use it to register a method

property LastErrorFileName: RawUTF8 **read** FLastErrorFileName;

Last error file name triggered during JavaScript execution

property LastErrorLine: integer **read** FLastErrorLine;

Last error source code line number triggered during JavaScript execution

property LastErrorMsg: RawUTF8 **read** FLastErrorMsg;

Last error message triggered during JavaScript execution

property rt: PJSRuntime **read** frt;

Access to the associated execution runtime

property TimeOutAborted: boolean **read** FTimeOutAborted;

Notifies a WatchDog timeout

property TimeOutValue: Double **read** fTimeoutInterval **write** SetTimeoutValue;

Define a WatchDog timeout interval

- is set to -1 by default, i.e. meaning no execution timeout

TSMEngineManager = class(TObject)

Main access point to the SpiderMonkey per-thread scripting engines

- allow thread-safe access to an internal per-thread TSMEngine instance list

- contains runtime-level properties shared between thread-safe engines

- you can create several TSMEngineManager instances, if you need several separate scripting instances

- set OnNewEngine callback to initialize each TSMEngine, when a new thread is accessed, and tune per-engine memory allocation via MaxPerEngineMemory and MaxRecursionDepth

- get the current per-thread TSMEngine instance via ThreadSafeEngine method

constructor Create; **virtual**;

Initialize the SpiderMonkey scripting engine

destructor Destroy; **override**;

Finalize the SpiderMonkey scripting engine

function ThreadSafeEngine: TSMEngine;

Get or create one Engine associated with current running thread
 - in single thread application will return the MainEngine

procedure ReleaseCurrentThreadEngine;

Method to be called when a thread is about to be finished
 - you can call this method just before a thread is finished to ensure that the associated scripting Engine will be released
 - could be used e.g. in a try...finally block inside a TThread.Execute overridden method

property ContentVersion: Cardinal **read** FContentVersion **write** FContentVersion;

Internal version of the script files
 - used in TSMEngine.ThreadSafeEngine to determine if context is up to date, in order to trigger on-the-fly reload of scripts without the need if restarting the application

property Lock: TRTLCriticalSection **read** FEngineCS;

Lock/mutex used for thread-safe access to the TSMEngine list

property MaxPerEngineMemory: Cardinal **read** FMaxPerEngineMemory **write** SetMaxPerEngineMemory **default** 8*1024*1024;

Max amount of memory (in bytes) for a single SpiderMonkey instance
 - this parameter will be set only at Engine start, i.e. it must be set BEFORE any call to ThreadSafeEngine
 - default is 8 MB

property MaxRecursionDepth: Cardinal **read** FMaxRecursionDepth **write** FMaxRecursionDepth **default** 32;

Maximum expected recursion depth for JavaScript functions
 - to avoid out of memory situation in functions like
`function f(){ f() };`
 - default is 32, but you can specify some higher value

property OnNewEngine: TEngineEvent **read** FOnNewEngine **write** FOnNewEngine;

Event triggered every time a new Engine is created
 - here your code can change the initial state of the Engine

TSMVariant = class(TSynInvokeableVariantType)

A custom variant type used to store a SpiderMonkey object in Delphi code
 - via the magic of late binding, it will allow access of any JavaScript object property, or execute any of its methods
 - primitive types (i.e. null, string, or numbers) will be stored as simple variant instances, but JavaScript objects (i.e. objects, prototypes or functions) can be stored as an instance of this TSMVariant custom type
 - you can use the _Root and _UnRoot pseudo-methods, which will protect the object instance to avoid unexpected Garbage Collection

function DoFunction(**var** Dest: TVarData; **const** V: TVarData; **const** Name: **string**; **const** Arguments: TVarDataArray): Boolean; **override**;

Low-level callback to execute any JavaScript object method
 - add the _(Index: integer): variant method to retrieve an item if the object is an array

```
procedure Cast(var Dest: TVarData; const Source: TVarData); override;
```

Handle type conversion

- any TSMVariant will be converted to '<<JavaScript TSMVariant>>' text

```
procedure CastTo(var Dest: TVarData; const Source: TVarData; const AVarType: TVarType); override;
```

Handle type conversion

- any TSMVariant will be converted to '<<JavaScript TSMVariant>>' text

```
class procedure New(const aObject: TSMObject; out aValue: variant); overload;
```

Initialize a variant instance to store a JavaScript object

```
class procedure New(cx: PJSContext; obj: PJSObject; out aValue: variant); overload;
```

Initialize a variant instance to store a JavaScript object

```
class procedure New(engine: TSMEngine; out aValue: variant); overload;
```

Initialize a variant instance to store a new JavaScript object

```
procedure ToJSON(W: TTextWriter; const Value: variant; Escape: TTextWriterKind); override;
```

This implementation will let SpiderMonkey write directly the JSON content

```
TSMVariantData = object(TObject)
```

Memory structure used for TSMVariant storage of any JavaScript object as Delphi variant

- primitive types (i.e. null, string, or numbers) will be stored as simple variant instances, but JavaScript objects (i.e. objects, prototypes or functions) can be stored as an instance of this TSMVariant custom type

- this variant stores its execution context, so is pretty convenient to work with in plain Delphi code, also thanks to late-binding feature

```
procedure GetGlobal(out global: variant);
```

Retrieve the global object of this execution context

- you can use this from a native function, e.g.:

```
function TMyClass.MyFunction(const This: variant; const Args: array of variant): variant;
var global: variant;
begin
  TSMVariantData(This).GetGlobal(global);
  global.anotherFunction(Args[0],Args[1],'test');
  // same as:
  global := TSMVariantData(This).SMObject.Engine.Global;
  global.anotherFunction(Args[0],Args[1],'test');
  // but you may also write directly:
  with TSMVariantData(This).SMObject.Engine do
    Global.anotherFunction(Args[0],Args[1],'test');
  result := AnyTextFileToSynUnicode(Args[0]);
end;
```

```
procedure Init(aCx: PJSContext; aObj: PJSObject); overload;
```

Initialize a TSMVariant structure to store a specified JavaScript object

```
procedure Init(const aObject: TSMObject); overload;
```

Initialize a TSMVariant structure to store a specified JavaScript object

```
procedure InitNew(engine: TSMEngine);
  Initialize a TSMVariant structure to store a new JavaScript object

property cx: PJSTContext read VObject.fcx;
  Returns the associated execution context

property obj: PJSTObject read VObject.fobj;
  Returns the associated jsobject instance

property SMOobject: TSMObject read VObject;
  Returns the associated TSMObject instance

property VarType: word read VType;
  Return the custom variant type identifier, i.e. SMVariantType.VarType
```

Types implemented in the SynSM unit

```
PSMObject = ^TSMObject;
  Pointer to our wrapper around JavaScript Object

PSMValue = ^TSMValue;
  A pointer to a jsval wrapper

PSMValues = ^TSMValues;
  A pointer to a jsval wrappers array

PSMVariantData = ^TSMVariantData;
  Pointer to a TSMVariant storage

SMValArray = array of TSMValue;
  A dynamic array of jsval wrappers

TEngineEvent = procedure(const Engine: TSMEngine) of object;
  Prototype of SpideMonkey notification callback method

TSMEngineMethodEventDynArray = array of TSMEngineMethodEvent;
  Used to store the registered method events

TSMEngineMethodEventJSON = function(const This: TSMObject; const Args: RawUTF8):
RawUTF8 of object;
  / JSON-based callback signature used for TSMEngine.RegisterMethod()
  - any Delphi exception raised during this execution will be converted into a JavaScript exception by TSMEngine
  - similar to TServiceMethod.InternalExecute() as defined in mORMot.pas (for instance, this callback will be used to execute native Delphi interface-based methods from JavaScript code in mORMotSM.pas unit)
  - "this" JavaScript calling object is transmitted as low-level TSMObject
  - will expect as input a JSON array of parameters from Args, e.g.
    '[1,2,3]'
  - if the method only expect one result, shall return one JSON value, e.g.
    '6'
  - if the method expect more than one result (i.e. several var/out parameters in addition to the main function result), it shall return a JSON object, with parameter names for all var/out/result values, e.g.
    '{"first":1,"second":2,"result":3}'
```

- this allows the function result to be consumed by the JavaScript as a regular JS value or object
- corresponds to meJSON kind of callback method

```
TSMEngineMethodEventKind = ( meVariant, meJSON );
```

Kinds of callback methods available for TSMEngine.RegisterMethod()

```
TSMEngineMethodEventVariant = function(const This: variant; const Args: array of variant): variant of object;
```

/ variant-based callback signature used for TSMEngine.RegisterMethod()

- any Delphi exception raised during this execution will be converted into a JavaScript exception by TSMEngine
- "this" JavaScript calling object is transmitted as a TSMVariant custom variant: you can use late-binding over it to access its methods or properties, or transtype it using TSMVariantData(Instance) and access its low-level API content
- input arguments (and function result) are simple variant values, or TDocVariant custom variant instance for any object as complex document
- corresponds to meVariant kind of callback method

```
TSMValues = array[0..(MaxInt div sizeof(TSMValue))-1] of TSMValue;
```

A jsval wrappers array

Constants implemented in the SynSM unit

```
STACK_CHUNK_SIZE: cardinal = 8192;
```

Default stack growing size, in bytes

Functions or procedures implemented in the SynSM unit

Functions or procedures	Description	Page
JSError	To be used to catch Delphi exceptions inside JSNative function implementation	1578
VariantToJSVal	Convert a variant to a Java Script value	1578

```
procedure JSError(cx: PJSContext; aException: Exception; const aContext: RawByteString='');
```

To be used to catch Delphi exceptions inside JSNative function implementation

- usage example:

```
try
  doSomething()
  Result := JS_TRUE;
except
  on E: Exception do begin
    JS_SET_RVAL(cx, vp, JSVAL_VOID);
    JSError(cx, E);
    Result := JS_FALSE;
  end;
```

```
function VariantToJSVal(cx: PJSContext; const Value: Variant): jsval;
```

Convert a variant to a Java Script value

Variables implemented in the *SynSM* unit

SMVariantType: TSynInvokeableVariantType = **nil**;

The internal custom variant type used to register TSMVariant

SynSMLog: TSynLogClass=TSynLog;

Define the TSynLog class used for logging for all our SynSM related units

- you may override it with TSQLLog, if available from mORMot.pas
- since not all exceptions are handled specifically by this unit, you may better use a common TSynLog class for the whole application or module

27.34. SynSMAPI.pas unit

Purpose: SpiderMonkey *.h header port to Delphi

- this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the *SynSMAPI* unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synapse projects - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718

SynSMAPI class hierarchy

Objects implemented in the *SynSMAPI* unit

Objects	Description	Page
FrameDescription	Defines a frame of a stack trace	1586
FrameDescriptionEx	Defines an extended frame of a stack trace	1586
JSCompartment	JavaScript execution compartment	1582
JSConstDoubleSpec	JS object constant definition	1585
JSContext	JavaScript execution context	1581
JSErrorFormatString	Used by JSErrorCallback() callback	1585
JSErrorReport	Internal structure used to report JavaScript errors	1584
JSFunctionSpec	Defines a single function for an object	1585
JSNativeWrapper	Wrappers to replace JSNatives for JSFunctionSpecs	1585
JSObject	JSObject is the type of JavaScript objects in the JSAPI	1584
JSPropertyDesc	Points to a JavaScript object property description PJSPPropertyDesc = ^JSPropertyDesc; defines a JavaScript object property description	1586

Objects	Description	Page
JSPropertyDescArray	Stores JavaScript object properties description	1586
JSPropertyOpWrapper	Wrappers to replace PropertyOp for JSPropertySpecs	1585
JSPropertySpec	Defines custom JSProperty	1585
JSRuntime	JavaScript execution runtime	1582
JSStrictPropertyOpWrapper	Wrappers to replace StrictPropertyOp for JSPropertySpecs	1585
JSString	JavaScript string instance	1583
jsval_layout	Low-level definition of the jsval internals	1585
jsval_payload	Low-level definition of the jsval internals	1585
StackDescription	Defines a stack trace	1586
StackDescriptionEx	Defines to an extended stack trace	1586

JSContext = object(TObject)

JavaScript execution context

- this object does not store anything, but just provide some helper methods to access a PPJSContext value via JS_ *Context*(..) API functions

function InitStandardClasses(global: PJXObject): boolean;

Wrapper to JS_InitStandardClasses(@self,global)

function NewJSString(const Value: RawUTF8): PJSSString; overload;

Create a new JavaScript string instance from a given UTF-8 text

function NewJSString(const Value: SynUnicode): PJSSString; overload;

Create a new JavaScript string instance from a given UTF-16 text

function NewJSString(TextWide: PWideChar; TextLen: integer): PJSSString; overload;

Create a new JavaScript string instance from a given UTF-16 text buffer

function NewJSString(TextAnsi: PAnsiChar; TextLen, CodePage: integer): PJSSString; overload;

Create a new JavaScript string instance from a given Ansi text buffer

- will use the specified Ansi code page for the conversion

- if CodePage is 0, will use the CurrentAnsiCodePage value

function Runtime: PJSRuntime;

Wrapper to JS_GetRuntime(@self)

function VersionToString: RawUTF8;

Wrapper to JS_GetVersion() and string conversion

procedure Destroy;

Wrapper to JS_DestroyContext(@self)

property Options: TJOptions **read** GetOptions **write** SetOptions;

Wrapper to JS_GetOptions()/JS_SetOptions()

- due to a XE3 bug, you should use the GetOptions/SetOptions methods instead of this property, under this compiler revision

property PrivateData: Pointer **read** GetPrivate **write** SetPrivate;

Wrapper to JS_GetContextPrivate()/JS_SetContextPrivate()

property Version: JSVersion **read** GetVersion;

Wrapper to JS_GetVersion()/JS_SetVersion()

JSRuntime = object(TObject)

JavaScript execution runtime

- this object does not store anything, but just provide some helper methods to access a PJSRuntime value via JS_ *Runtime*(..) API functions

procedure Destroy;

Wrapper to JS_DestroyRuntime(@self)

procedure Lock;

Wrapper to JS_LockRuntime(@self)

procedure Unlock;

Wrapper to JS_UnLockRuntime(@self)

property PrivateData: Pointer **read** GetPrivate **write** SetPrivate;

Wrapper to JS_GetRuntimePrivate()/JS_SetRuntimePrivate()

JSCompartment = object(TObject)

JavaScript execution compartment

- this object does not store anything, but just provide some helper methods to access a PJSRuntime value via JS_ *Runtime*(..) API functions

function EnterCompartment(cx: PJContext; target: PJObject): PJCompartment;

Initialize and enter a JavaScript execution compartment

procedure Destroy;

Leave a JavaScript execution compartment

JSString = object(TObject)

JavaScript string instance

- this object does not store anything, but just provide some helper methods to access a PJSString value via JS_ *String*(..) API functions
- use function JSContext.NewJSString() to create a new instance for a given execution context
- to understand string in SpiderMonkey good point is comments in vm\String.h in short this is C structure:

```
struct Data
{
    size_t          lengthAndFlags;      /* JSString */
    union {
        const jschar *chars;           /* JSLinearString */
        JSString *left;                 /* JSRope */
    } u1;
    union {
        jschar inlineStorage[NUM_INLINE_CHARS]; /* JS(Inline|Short)String */
        struct {
            union {
                JSLinearString *base;      /* JSDependentString */
                JSString *right;          /* JSRope */
                size_t capacity;          /* JSFlatString (extensible) */
                size_t externalType;      /* JSExternalString */
            } u2;
            union {
                JSString *parent;          /* JSRope (temporary) */
                void *externalClosure;    /* JSExternalString */
                size_t reserved;          /* may use for bug 615290 */
            } u3;
        } s;
    };
} d;
```

but in API there is no need to use this structure, only pointer to it, and high-level access to the SpiderMonkey API via this JSString wrapper

function ToJSVal: jsval;

Get a jsval corresponding to this string

function ToString(cx: PJSContext): string;

Get the Delphi string text corresponding to this string, for a given runtime execution context

function ToSynUnicode(cx: PJSContext): SynUnicode;

Get the UTF-16 text corresponding to this string, for a given runtime execution context

function ToUTF8(cx: PJSContext): RawUTF8; overload;

Get the UTF-8 text corresponding to this string, for a given runtime execution context

function ToWideString(cx: PJSContext): WideString;

Get the UTF-16 text corresponding to this string, for a given runtime execution context

procedure ToJSONString(cx: PJSContext; W: TTextWriter);

Get the text encoded as a UTF-8 JSON string

procedure ToUTF8(cx: PJSContext; var result: RawUTF8); overload;

Get the UTF-8 text corresponding to this string, for a given runtime execution context
- slightly faster overloaded method (avoid string assignment)

procedure ToUTF8(cx: PJSContext; W: TTextWriter); overload;

Add UTF-8 text corresponding to this string to writer, without escaping

procedure ToVariant(cx: PJSContext; var Value: Variant);

Get the UTF-16 text corresponding to this string as a variant, for a given runtime execution context

- will store a SynUnicode value into the variant instance

JSObject = **object**(TObject)

JSObject is the type of JavaScript objects in the JSAPI

- this object does not store anything, but just provide some helper methods to access a PJSObject value via low-level API functions

function ToJSValue: jsval;

Get a jsval corresponding to this object

JSErrorReport = **record**

Internal structure used to report JavaScript errors

column: uintN;

Zero-based column index in line

errorNumber: uintN;

The error number, e.g. see js.msg

exnType: int16;

One of the JSExnType constants

filename: PCChar;

Source file name, URL, etc., or null

flags: uintN;

Error/warning, etc.

linebuf: PCChar;

Offending source line without final #13

lineno: uintN;

Source line number

messageArgs: PPjschar;

Arguments for the error message

originPrincipals: PJSPrincipals;

See 'originPrincipals' comment above

tokenptr: PCChar;

Pointer to error token in linebuf

uclinebuf: Pjschar;

Unicode (original) line buffer

ucmessage: Pjschar;

The (default) error message

uctokenptr: Pjschar;

Unicode (original) token pointer

JSErrorFormatString = record

Used by JSErrorCallback() callback

argCount: uint16;

The number of arguments to expand in the formatted error message

exnType: int16;

One of the JSExnType constants above

format: PCChar;

The error format string (UTF-8 if js_CStringsAreUTF8)

JSConstDoubleSpec = record

JS object constant definition

JSStrictPropertyOpWrapper = record

Wrappers to replace StrictPropertyOp for JSPropertySpecs

- This will allow us to pass one JSJitInfo per function with the property spec, without additional field overhead.

JSPropertyOpWrapper = record

Wrappers to replace PropertyOp for JSPropertySpecs

- This will allow us to pass one JSJitInfo per function with the property spec, without additional field overhead.

JSPropertySpec = record

Defines custom JSProperty

- This will allow us to pass one JSJitInfo per function with the property spec, without additional field overhead.

JSNativeWrapper = record

Wrappers to replace JSNatives for JSFunctionSpecs

- This will allow us to pass one JSJitInfo per function with the property spec, without additional field overhead.

JSFunctionSpec = record

Defines a single function for an object

jsval_payload = record

Low-level definition of the jsval internals

- do not use directly

jsval_layout = record

Low-level definition of the jsval internals

- do not use directly

FrameDescription = record

Defines a frame of a stack trace

StackDescription = record

Defines a stack trace

FrameDescriptionEx = record

Defines an extended frame of a stack trace

StackDescriptionEx = record

Defines to an extended stack trace

JSPROPERTYDESC = record

Points to a JavaScript object property description PJSPROPERTYDESC = ^JSPROPERTYDESC; defines a JavaScript object property description

alias: jsval;

Contains the alias ID if dfAlias is included in description flags

flags: JSPROPERTYDESCFLAGS;

The property behavior

id: jsval;

The ID of this property

spare_notused: uint8;

This item is never used

value: jsval;

The JavaScript value of this property

JSPROPERTYDESCARRAY = record

Stores JavaScript object properties description

Types implemented in the SynSMAPI unit

int16 = Smallint;

16 bit signed integer type for C APIs

int32 = Integer;

32 bit signed integer type for C APIs

int8 = ShortInt;

8 bit signed integer type for C APIs

JSAccessMode = (JSACC_PROTO, JSACC_WATCH, JSACC_READ, JSACC_WRITE, JSACC_LIMIT);

Js_CheckAccess mode enumeration

JSArrayBufferViewType = (jsabTYPE_INT8, jsabTYPE_UINT8, jsabTYPE_INT16, jsabTYPE_UINT16, jsabTYPE_INT32, jsabTYPE_UINT32, jsabTYPE_FLOAT32, jsabTYPE_FLOAT64, jsabTYPE_UINT8_CLAMPED, jsabTYPE_DATAVIEW, jsabTYPE_MAX);

The available types of elements in a typed array or data view

- obj must have passed a JS_IsArrayBufferView/JS_Is*Array test, or somehow be known that it would pass such a test: it is an ArrayBufferView or a wrapper of an ArrayBufferView, and the unwrapping

will succeed.

- jsabTYPE_UINT8_CLAMPED is a special type that is a uint8_t, but assignments are clamped to [0,255]: treat the raw data type as a uint8_t.
- jsabTYPE_DATAVIEW is the type returned for a DataView. Note that there is no single element type in this case

JSBool = JSIntn;

Boolean type for variables and parameter types for SMAPI

- Use JS_FALSE and JS_TRUE constants for clarity of target type in assignments

jsbytecode = uint8;

Used to store a JavaScript bytecode item

jschar = Word;

Jschar is the type of JavaScript "characters", the 16 bits elements that make up JavaScript strings (maybe not truly valid UTF-16)

- It is a 16-bit unsigned integer type
- As required by the ECMAScript standard, ECMA 262-3 §4.3.16, JavaScript strings are arbitrary sequences of 16-bit values
- A string may contain unmatched surrogates, which are not valid UTF-16
- It may also contain zeroes (0)
- so we did not define it as WideChar, but as abstract Word element

JSCheckAccessOp = function(cx: PJSContext; var obj: PJSObject; var id: jsid; mode: JSAccessMode; vp: Pjsval): JSBool; cdecl;

*JSClass.checkAccess type: check whether obj[id] may be accessed per mode, returning false on error/exception, true on success with obj[id]'s last-got value in *vp, and its attributes in *attrsp. As for JSPropertyOp above, id is either a string or an int jsval.*

JSClassInternal = procedure; cdecl;

Returns the external-string finalizer index for this string, or -1 if it is an "internal" (native to JS engine) string. TODO - in current compiled version there is no this functions. seems like a BUG!!!!!! JS_GetExternalStringGCType function JS_IsExternalString(rt: PJSRuntime; str: PJSString): intN; cdecl; external SpiderMonkeyLib; For detailed comments on the function pointer types, see jsputd.h

JSContextCallback = function(cx: PJSContext; contextOp: uintN): JSBool; cdecl;

Callback prototype for a given runtime context

- the possible values for contextOp when the runtime calls the callback are defined by JSContextOp

JSContextOp = (JSCONTEXT_NEW, JSCONTEXT_DESTROY);

Flag used for JSContextCallback() argument

- JSCONTEXT_NEW: JS_NewContext successfully created a new JSContext instance. The callback can initialize the instance as required. If the callback returns false, the instance will be destroyed and JS_NewContext returns null. In this case the callback is not called again.
- JSCONTEXT_DESTROY: One of JS_DestroyContext* methods is called. The callback may perform its own cleanup and must always return true.
- Any other value: For future compatibility the callback must do nothing and return true in this case.

JSConvertOp = function(cx: PJSContext; var obj: PJSObject; typ: JSType; vp: pjsval): JSBool; cdecl;

Convert obj to the given type, returning true with the resulting value in vp on success, and returning false on error or exception.

JSDebugErrorHook = function(cx: PJSContext; message: PCChar; report: PJSErrorReport;

```
closure: pointer): JSBool; cdecl;
```

Callback type to be called when an error is triggered during script debugging

```
JSDebuggerHandler = function(cx: PJSContext; script: PJSScript; pc: pjsbytecode; rval: pjsval; closure: pointer): JSTrapStatus; cdecl;
```

Callback type to be called when a script is debugging

```
JSDeletePropertyOp = function(cx: PJSContext; var obj: PJSObject; var id: jsid; succeeded: PJSCBool):JSBool; cdecl;
```

JSClass method prototype to delete a property named by id in obj

- note the jsid id type -- id may be a string (Unicode property identifier) or an int (element index)
- the *succeeded out parameter, on success, is the JSVAL_TRUE. *succeeded is JSVAL_FALSE if obj[id] can't be deleted (because it's permanent)

```
JSDestroyScriptHook = procedure(fop: PJSCFreeOp; script: PJSScript; callerdata: Pointer); cdecl;
```

Callback type to be called when a JavaScript debugging hook is released

```
jsdouble = Double;
```

Jdouble is the internal type of numbers, i.e. floating-point values

- jsdouble is obsolete since JavaScript 1.8.7+ - instead we must use C double so let's do it for future now
- in all cases see JSFloat64 - NSPR's floating point type is always 64 bits.

```
JSEnumerateOp = function(cx: PJSContext; var obj: PJSObject): JSBool; cdecl;
```

The old-style JSClass.enumerate op should define all lazy properties not yet reflected in obj.

```
JSErrorCallback = function(userRef: Pointer; const locale: PCChar; const errorNumber: uintN): PJSErrorFormatString; cdecl;
```

Callback prototype for returning an execution error

```
JSErrorReporter = procedure(cx: PJSContext; _message: PCChar; report: PJSErrorReport); cdecl;
```

Callback prototype for reporting error for a given runtime context

```
JSEXnType = ( JSEXN_NONE, JSEXN_ERR, JSEXN_INTERNALERR, JSEXN_EVALERR, JSEXN_RANGEERR, JSEXN_REFERENCEERR, JSEXN_SYNTAXERR, JSEXN_TYPEERR, JSEXN_URIERR, JSEXN_LIMIT );
```

Possible exception types

- These types are part of a JSErrorFormatString structure
- They define which error to throw in case of a runtime error
- JSEXN_NONE marks an unthrowable error

```
JSFinalizeOp = procedure(cx: PJSContext; obj: PJSObject); cdecl;
```

Finalize obj, which the garbage collector has determined to be unreachable from other live objects or from GC roots. Obviously, finalizers must never store a reference to obj.

```
JSFloat64 = Double;
```

Internal type of numbers, i.e. floating-point values for SMAPI

- NSPR's floating point type is always 64 bits.

```
JSGCCallback = function(cx: PJSContext; status: JSGCStatus): JSBool; cdecl;
```

Callback prototype for a given runtime context garbage collection

```
JSGCStatus = ( JSGC_BEGIN, JSGC_END );
```

Flag used for callback for a given runtime context garbage collection

```
JSHasInstanceOp = function(cx: PJSCContext; obj: PJSObject; const v: Pjsval; var bp: JSBool): JSBool; cdecl;
```

Callback used to check whether v is an instance of obj or not

- Return false on error or exception, true on success with JS_TRUE in bp if v is an instance of obj, JS_FALSE in bp otherwise.

```
jsid = size_t;
```

Jsid is a generic identifier for any JavaScript object property of method

- a jsid is an identifier for a property or method of an object which is either a 31-bit signed integer, internal string or object. If XML is enabled, there is an additional singleton jsid value; see JS_DEFAULT_XML_NAMESPACE_ID below. Finally, there is an additional jsid value, JSID_VOID, which does not occur in JS scripts but may be used to indicate the absence of a valid jsid.

```
JSInt16 = SmallInt;
```

16 bit signed integer type for SMAPI

```
JSInt32 = Integer;
```

32 bit signed integer type for SMAPI

```
JSInt64 = Int64;
```

64 bit signed integer type for SMAPI

```
JSInt8 = ShortInt;
```

8 bit signed integer type for SMAPI

```
JSInterruptHook = function(cx: PJSCContext; script: PJSScript; pc: pjsbytecode; rval: pjsval; closure: pointer): JSTrapStatus; cdecl;
```

Callback type to be called when script debugging is interrupted

```
JSIntn = PtrInt;
```

Type appropriate for most signed integer variables for SMAPI

- They are guaranteed to be at least 16 bits, though various architectures may define them to be wider (e.g., 32 or even 64 bits). These types are never valid for fields of a structure.

```
JSIterateOp = ( JSENUMERATE_INIT, JSENUMERATE_INIT_ALL, JSENUMERATE_NEXT, JSENUMERATE_DESTROY );
```

This enum type is used to control the behavior of a JSObject property iterator function that has type JSNewEnumerate.

- JSENUMERATE_INIT A new, opaque iterator state should be allocated and stored in *statep. (You can use PRIVATE_TO_JSVAL() to tag the pointer to be stored). The number of properties that will be enumerated should be returned as an integer jsval in *idp, if idp is non-null, and provided the number of enumerable properties is known. If idp is non-null and the number of enumerable properties can't be computed in advance, *idp should be set to JSVAL_ZERO.

- JSENUMERATE_INIT_ALL Used identically to JSENUMERATE_INIT, but exposes all properties of the object regardless of enumerability.

- JSENUMERATE_NEXT A previously allocated opaque iterator state is passed in via statep. Return the next jsid in the iteration using *idp. The opaque iterator state pointed at by statep is destroyed and *statep is set to JSVAL_NULL if there are no properties left to enumerate.

- JSENUMERATE_DESTROY Destroy the opaque iterator state previously allocated in *statep by a call to this function when enum_op was JSENUMERATE_INIT or JSENUMERATE_INIT_ALL.

```
JSNative = function(cx: PJSCContext; argc: uintN; vp: Pjsval): JSBool; cdecl;
```

Here we miss trace and debug-only function definition callback typedef for native functions called by the JS VM

- cx is the execution context
- argc is the number of supplied arguments
- vp[0] is the callee - see JS_CALLEE()
- vp[1] is the object instance - see JS_THIS()
- vp[2]..vp[argc+1] are the supplied arguments - see JS_ARGV_PTR()

```
JSNewEnumerateOp = function(cx: PJSContext; var obj: PJSObject; enum_op: JSIterateOp;
statep: pjsval; idp: pjsid): JSBool; cdecl;
```

Function prototype used for callbacks that enumerate the properties of a JSObject

- The behavior depends on the value of enum_op
- The return value is used to indicate success, with a value of JS_FALSE indicating failure.

```
JSNewResolveOp = function(cx: PJSContext; var obj: PJSObject; var id: jsid; flags: uintN;
var objp: PPJSObject): JSBool; cdecl;
```

Function prototype used to resolve a lazy property named by id in obj by defining it directly in obj

- Like JSResolveOp, but flags provide contextual information as follows:

JSRESOLVE_QUALIFIED	a qualified property id: obj.id or obj[id], not id
JSRESOLVE_ASSIGNING	obj[id] is on the left-hand side of an assignment
JSRESOLVE_DETECTING	'if (o.p)...' or similar detection opcode sequence
JSRESOLVE_DECLARING	var , const , or function prolog declaration opcode
JSRESOLVE_CLASSNAME	class name used when constructing

- The *objp out parameter, on success, should be null to indicate that id was not resolved; and non-null, referring to obj or one of its prototypes, if id was resolved.
- This hook instead of JSResolveOp is called via the JSClass.resolve member if JSCLASS_NEW_RESOLVE is set in JSClass.flags.
- Setting JSCLASS_NEW_RESOLVE and JSCLASS_NEW_RESOLVE_GETS_START further extends this hook by passing in the starting object on the prototype chain via *objp. Thus a resolve hook implementation may define the property id being resolved in the object in which the id was first sought, rather than in a prototype object whose class led to the resolve hook being called.
- When using JSCLASS_NEW_RESOLVE_GETS_START, the resolve hook must therefore null *objp to signify "not resolved". With only JSCLASS_NEW_RESOLVE and no JSCLASS_NEW_RESOLVE_GETS_START, the hook can assume *objp is null on entry. This is not good practice, but enough existing hook implementations count on it that we can't break compatibility by passing the starting object in *objp without a new JSClass flag.

```
JSNewScriptHook = procedure(cx: PJSContext; filename: PCChar; lineno: uintn;
script: PJSScript; fun: PJSCFunction; callerdata: pointer); cdecl;
```

Callback type to be called when debugging a JavaScript context

```
JSONWriteCallback = function(const buf: Pjschar; len: uint32; data: pointer): JSBool;
cdecl;
```

Used by JS_Stringify() method to incrementally write the JSON content

```
JSOperationCallback = function(cx: PJSContext): JSBool; cdecl;
```

Generic operation callback prototype for a given runtime context

```
JSPackedBool = JSUint8;
```

Packed boolean type for variables and parameter types for SMAPI

- use JSPackedBool within structs where bitfields are not desirable but minimum and consistent overhead matters.

```
JSPropertyDescFlag = ( dfEnumerate, dfReadOnly, dfPermanent, dfAlias, dfException,
dfError );
```

Define object property behavior

- JSPD_ENUMERATE means that the property is visible to for/in loop
- JSPD_READONLY means that the property assignment will trigger an error
- JSPD_PERMANENT means that the property cannot be deleted
- JSPD_ALIAS means that the property has an alias id
- JSPD_EXCEPTION means that an exception occurred fetching the property: in this case, value is an exception
- JSPD_ERROR means that the native getter returned JS_FALSE without throwing an exception

JSPPropertyDescFlags = set of JSPPropertyDescFlag;

Define object property behaviors

JSPPropertyOp = function(cx: PJSContext; var obj: PJSObject; var id: jsid; vp: pjsval): JSBool; cdecl;

JSClass (and js::ObjectOps where appropriate) function pointer typedefs JSClass method prototype to add, or get a property named by id in obj

- note the jsid id type -- id may be a string (Unicode property identifier) or an int (element index)
- the vp out parameter, on success, is the new property value after an add or get. After a successful delete, *vp is JSVAL_FALSE iff obj[id] can't be deleted (because it's permanent)

JSPtrdiff = ptrdiff_t;

Type for pointer arithmetic difference for SMAPI

- Variables of this type are suitable for storing a pointer or pointer subtraction

JSResolveOp = function(cx: PJSContext; var obj: PJSObject; var id: jsid): JSBool; cdecl;

Function prototype used to resolve a lazy property named by id in obj by defining it directly in obj

- Lazy properties are those reflected from some peer native property space (e.g., the DOM attributes for a given node reflected as obj) on demand.
- JS looks for a property in an object, and if not found, tries to resolve the given id. If resolve succeeds, the engine looks again in case resolve defined obj[id]. If no such property exists directly in obj, the process is repeated with obj's prototype, etc.
- NB: JSNewResolveOp provides a cheaper way to resolve lazy properties.

JSSize = size_t;

A type for representing the size of objects for SMAPI

JSStrictPropertyOp = function(cx: PJSContext; var obj: PJSObject; var id: jsid; strict: JSBool; vp: pjsval): JSBool; cdecl;

JSClass method prototype to set a property named by id in obj, treating the assignment as strict mode code if strict is true

- note the jsid id type -- id may be a string (Unicode property identifier) or an int (element index)
- the vp out parameter, on success, is the new property value after the set

JSStringFinalizeOp = procedure(cx: PJSContext; var obj: PJString); cdecl;

Callback used by JS_AddExternalStringFinalizer and JS_RemoveExternalStringFinalizer to extend and reduce the set of string types finalized by the GC.

JSThrowHook = function(cx: PJSContext; script: PJSScript; pc: pjsbytecode; rval: pjsval; closure: pointer): JSTrapStatus; cdecl;

Callback type to be called when script throws an exception

JSTraceOp = procedure(cx: PJSContext; argc: uintN; vp: Pjsval); cdecl;

Callback used for trace operation of a given class

- enumerate all traceable things reachable from obj's private data structure.
- For each such thing, a trace implementation must call one of the JS_Call*Tracer variants on the

thing.

- JSTrapOp implementation can assume that no other threads mutates object state. It must not change state of the object or corresponding native structures. The only exception for this rule is the case when the embedding needs a tight integration with GC. In that case the embedding can check if the traversal is a part of the marking phase through calling JS_IsGCMarkingTracer and apply a special code like emptying caches or marking its native structures.

```
JSTrapHandler = function(cx: PJSContext; script: PJSScript; pc: pjsbytecode; rval: pjsval; closure: jsval): JSTrapStatus; cdecl;
```

Callback type to be called when a script is debugging and trapped

```
JSTrapStatus = ( JSTRAP_ERROR, JSTRAP_CONTINUE, JSTRAP_RETURN, JSTRAP_THROW, JSTRAP_LIMIT );
```

JavaScript debugging trap status

```
JSType = ( JSTYPE_VOID, JSTYPE_OBJECT, JSTYPE_FUNCTION, JSTYPE_STRING, JSTYPE_NUMBER, JSTYPE_BOOLEAN, JSTYPE_NULL, JSTYPE_LIMIT );
```

Result of typeof operator enumeration

```
JSTypeOfOp = function(cx: PJSContext; var obj: PJSObject): JSType; cdecl;
```

Callback used to delegate typeof to an object so it can cloak a primitive or another object

```
JSUInt16 = Word;
```

16 bit unsigned integer type for SMAPI

```
JSUInt32 = Cardinal;
```

32 bit unsigned integer type for SMAPI

```
JSUInt64 = QWord;
```

64 bit unsigned integer type for SMAPI

```
JSUInt8 = Byte;
```

8 bit unsigned integer type for SMAPI

```
JSUIntn = PtrUInt;
```

Type appropriate for most unsigned integer variables for SMAPI

- They are guaranteed to be at least 16 bits, though various architectures may define them to be wider (e.g., 32 or even 64 bits). These types are never valid for fields of a structure.

```
JSUIntPtr = PtrUInt;
```

Ordinal type used for pointer arithmetic

- Variables of this type are suitable for storing a pointer or pointer subtraction

```
JSUptrdiff = JSUIntPtr ;
```

Ordinal type used for pointer arithmetic

- Variables of this type are suitable for storing a pointer or pointer subtraction

```
JSUseHelperThreads = ( JS_NO_HELPER_THREADS, JS_USE_HELPER_THREADS );
```

See http://developer.mozilla.org/en/docs/Category:JSAPI_Reference some aliases defined in SM:

```
define JS_NewRuntime      JS_Init
define JS_DestroyRuntime JS_Finish
define JS_LockRuntime     JS_Lock
define JS_UnlockRuntime   JS_Unlock
```

defines how function JS_NewRuntime() instantiate its threading model

```
JSUword = PtrUInt;
```

A JSWord is an unsigned integer that is the same size as a pointer

jsval = type QWord;

Map a generic JavaScript value internal representation

- a variable of type jsval can hold exactly the same values as a JavaScript var or property: string, number, object, boolean, null, or undefined (including Arrays, functions, and Errors are all objects)
- jsval is a variant type whose exact representation varies by architecture.
- you should never use this value internals, but pjsval and its TSMValue wrapper, as defined in SynSM.pas unit, for a given TSMEngine execution context - see https://developer.mozilla.org/en-US/docs/SpiderMonkey/JSAPI_Reference/JSval

JSVersion = Integer;

Used to store a JavaScript version

JSWord = PtrInt;

A JSWord is a signed integer that is the same size as a pointer

JSXDRObjectOp = function(xdr: PJSXDRState; var objp: PJSObject): JSBool; cdecl;

Encode or decode an object, given an XDR state record representing external data

PCChar = PAnsiChar;

Define SpiderMonkey dedicated text buffer type

- in SM 1.8.5 exist mode JS_CSringAreUTF8, so it is possible to use our RawUTF8 strings (in all cases internally in SM it will be converted to Unicode - so need to test if SynCommons conversion faster or not -
- but in SM 1.8.8 JS_CSringAreUTF8 removed, and all API may have to switch to jschar (= Word/WideChar) ?

PFrameDescription = ^FrameDescription;

Points to a frame description of a stack trace

PFrameDescriptionEx = ^FrameDescriptionEx;

Points to an extended frame description of a stack trace

PJSAtom = Pointer;

Stores a JavaScript Atom

PJSBool = ^JSBool;

Pointer to boolean type for variables and parameter types for SMAPI

pjsbytecode = ^jsbytecode;

Used to store a pointer to JavaScript bytecode items

Pjschar = ^jschar;

Pointer to a sequence of JavaScript "characters", i.e. some 16 bits elements that make up JavaScript strings (maybe not truly valid UTF-16)

- As required by the ECMAScript standard, ECMA 262-3 §4.3.16, JavaScript strings are arbitrary sequences of 16-bit values
- A string may contain unmatched surrogates, which are not valid UTF-16
- It may also contain zeroes (0)

PJSCompartment = ^JSCompartment;

Points to a JavaScript execution compartment

- allows convenient access of JSCompartment wrapper methods

PJSContext = ^JSContext;

Pointer to JavaScript execution context
- allows convenient access of JSContext wrapper methods

PJSErrorFormatString = ^JSErrorFormatString;

Pointer used by JSErrorCallback() callback

PJSErrorReport = ^JSErrorReport;

Map an internal structure used to report JavaScript errors

PJSFreeOp = Pointer;

Callback type to be called when an operation is freed

PJSFunction = **type** Pointer;

Abstract pointer to a JavaScript function

pjsid = ^jsid;

Pointer to a JavaScript object property of method identifier

PJSIdArray = ^JSIdArray;

*Actually, length jsid words */*

PjsidVector = ^TjsidVector;

Map an array to JavaScript object property of method identifiers

PJSJitInfo = pointer;

JS object property definition

PJSObject = ^JSObject;

Pointer to a JS Object instance

PJSPrincipals = Pointer;

Security protocol

PJSRuntime = ^JSRuntime;

Pointer to a JS Runtime instance

PJSScript = **type** Pointer;

Pointer to JSScript structure defined if jsscript.h
- we do not directly use of this structure, so we define just a pointer

PJSString = ^JSString;

Pointer to a JS String instance

PJSStringFinalizer = ^JSStringFinalizer;

** Finalizes external strings created by JS_NewExternalString.*

PJSTracer = Pointer;

A JavaScript tracer instance

PJSuintptr = ^JSuintptr;

Pointer on an ordinal type used for pointer arithmetic

pjsval = ^jsval;

Pointer to a jsval JavaScript value

PjsvalVector = ^TjsvalVector;

Map an array of jsval JavaScript values

PJSXDRState = **type** Pointer;

State value as expected by JSXDRObjectOp() prototype

PPjschar = ^Pjschar;

Pointer to a pointer of JavaScript "characters"

- is mostly used for arrays of JavaScript strings

PPJSContext = ^PJSContext;

Pointer to a pointer of JavaScript execution context

PPJSObject = ^PJSObject;

Pointer to a pointer of JavaScript object

PPJSString = ^PJSString;

Pointer to a pointer of JavaScript string

PRCondVar = Pointer;

A event resource as defined by NSPR

PRIntervalTime = PRUint32;

Interval time type as defined by NSPR

PRLock = Pointer;

A mutex/lock resource as defined by NSPR

PRStatus = (PR_FAILURE, PR_SUCCESS);

Status codes as defined by NSPR

PRThread = Pointer;

A thread resource as defined by NSPR

PRThreadPriority = (PR_PRIORITY_FIRST, PR_PRIORITY_LOW, PR_PRIORITY_NORMAL, PR_PRIORITY_HIGH, PR_PRIORITY_URGENT, PR_PRIORITY_LAST);

Thread priority as defined by NSPR

- PR_PRIORITY_LOW is the lowest possible priority

- PR_PRIORITY_NORMAL is the most common expected priority

- PR_PRIORITY_HIGH is the slightly more aggressive scheduling

- PR_PRIORITY_URGENT is there because it does little good to have one more priority value

PRThreadScope = (PR_LOCAL_THREAD, PR_GLOBAL_THREAD, PR_GLOBAL_BOUND_THREAD);

Thread scope as defined by NSPR

PRThreadState = (PR_JOINABLE_THREAD, PR_UNJOINABLE_THREAD);

Thread state as defined by NSPR

PRThreadType = (PR_USER_THREAD, PR_SYSTEM_THREAD);

Thread type as defined by NSPR

PRUint32 = uint32;

Unsigned 32 bit integer type as defined by NSPR

PStackDescription = ^StackDescription;

Points to a stack trace

PStackDescriptionEx = ^StackDescriptionEx;

Points to an extended stack trace

```
ptrdiff_t = PtrInt;
```

Type for pointer arithmetic difference

- Variables of this type are suitable for storing a pointer or pointer subtraction

```
puintN = ^uintn;
```

Pointer to a flag set variable

```
size_t = PtrUInt;
```

Variable type used to store a buffer size (in bytes) for SMAPI

```
TjsidVector = array[0..(MaxInt div sizeof(jsid))-2] of jsid;
```

Abstract array to JavaScript object property of method identifiers

- set to -2 instead of -1 to allow JSIdArray record compilation

```
TJSOption = ( jsoExtraWarning, jsoWError, jsoVarObjFix, jsoPrivateIsNSISupports,
jsoCompileNGo, jsoUnused5, jsoUnused6, jsoUnused7, jsoDontReportUncaught, jsoUnused9,
jsoUnused10, jsoUnused11, jsoNoScriptRVal, jsoUnrootedGlobal, jsoBaseLine, jsoPcCount,
jsoTypeInference, jsoStrictMode, jsoIon, jsoAsmJS );
```

Available options for JS Objects

```
TJSOptions = set of TJSOption;
```

Set of available options for JS Objects

```
TJSPropertyAttr = ( jspEnumerate, jspReadOnly, jspPermanent, jspUnused, jspGetter,
jspSetter, jspShared, jspIndex, jspShortID );
```

Available options for JS Objects Properties

```
TJSPropertyAttrs = set of TJSPropertyAttr;
```

Set of available options for JS Objects Properties

```
TjsvalVector = array[0..(MaxInt div sizeof(jsval))-1] of jsval;
```

An abstract array of jsval JavaScript values

```
uint16 = Word;
```

16 bit unsigned integer type for C APIs

```
uint32 = Cardinal;
```

32 bit unsigned integer type for C APIs

```
uint8 = Byte;
```

8 bit unsigned integer type for C APIs

```
uintn = PtrUInt;
```

Type appropriate for most flag set variables

- They are guaranteed to be at least 16 bits, though various architectures may define them to be wider (e.g., 32 or even 64 bits). These types are never valid for fields of a structure.

Constants implemented in the SynSMAPI unit

```
JSCCLASS_EMULATES_UNDEFINED = 1 shl 6;
```

JSClass instance objects of this class act like the value undefined, in some contexts

```
JSCCLASS_HAS_PRIVATE = 1 shl 0;
```

JSClass instance objects have private slot

```
JSCLASS_IMPLEMENTES_BARRIERS = 1 shl 5;
```

Correctly implements GC read and write barriers

```
JSCLASS_IS_DOMJSCLASS = 1 shl 4;
```

JSClass instance objects are DOM

```
JSCLASS_NEW_ENUMERATE = 1 shl 1;
```

JSClass instance has JSNewEnumerateOp hook

```
JSCLASS_NEW_RESOLVE = 1 shl 2;
```

JSClass instance has JSNewResolveOp hook

```
JSCLASS_PRIVATE_IS_NSISUPPORTS = 1 shl 3;
```

JSClass instance private is (nsISupports

```
JSCLASS_RESERVED_SLOTS_SHIFT = 8;
```

JSClass instance room for 8 flags below

```
JSCLASS_RESERVED_SLOTS_WIDTH = 8;
```

JSClass instance and 16 above this field

```
JSCLASS_USERBIT1 = 1 shl 7;
```

Reserved for embeddings.

```
JSFUN_GENERIC_NATIVE = $800;
```

** Specify a generic native prototype methods, i.e., methods of a class * prototype that are exposed as static methods taking an extra leading * argument: the generic [this] parameter. * * If you set this flag in a JSFunctionSpec struct's flags initializer, then * that struct must live at least as long as the native static method object * created due to this flag by JS_DefineFunctions or JS_InitClass. Typically * JSFunctionSpec structs are allocated in static arrays.*

```
JSID_TYPE_STRING = $0;
```

A jsid is an identifier for a property or method of an object which is either a 31-bit signed integer, interned string or object. If XML is enabled, there is an additional singleton jsid value; see JS_DEFAULT_XML_NAMESPACE_ID below. Finally, there is an additional jsid value, JSID_VOID, which does not occur in JS scripts but may be used to indicate the absence of a valid jsid.

A jsid is not implicitly convertible to or from a jsval; JS_ValueToId or JS_IdToValue must be used instead.

```
JSPROP_ENUMERATE = $01;
```

TODO make jsid macro conversion jsapi.h line 308-462

```
define JSVAL_LOCK(cx,v)      (JSVAL_IS_GCTHING(v)                \
```

```
? JS_LockGCThing(cx, JSVAL_TO_GCTHING(v))    \ : JS_TRUE)
```

```
define JSVAL_UNLOCK(cx,v)    (JSVAL_IS_GCTHING(v)                \
```

```
? JS_UnlockGCThing(cx, JSVAL_TO_GCTHING(v)) \ : JS_TRUE) Property attributes, set in JSPropertySpec and passed to API functions
```

```
JSProto_LIMIT = 38;
```

JSProto_LIMIT is length of #include "jsproto.tbl"

```
JSREPORT_ERROR = 0;
```

JSErrorReporter function (set by JS_SetErrorReporter; see jspubtd.h for the JSErrorReporter typedef). JSReport flag values. These may be freely composed. JSReport pseudo-flag for default case

JSREPORT_EXCEPTION = 2;

JSReport exception was thrown

JSREPORT_STRICT = 4;

JSReport error or warning due to strict option

JSREPORT_STRICT_MODE_ERROR = 8;

JSReport error or warning depending on strict mode

- This condition is an error in strict mode code, a warning if JS_HAS_STRICT_OPTION(cx), and otherwise should not be reported at all. We check the strictness of the context's top frame's script; where that isn't appropriate, the caller should do the right checks itself instead of using this flag.

JSREPORT_WARNING = 1;

JSReport reported via JS_ReportWarning

JSRESOLVE_ASSIGNING = \$02;

Used by JS_ResolveStub() callback: resolve on the left of assignment

JSRESOLVE_CLASSNAME = \$10;

Used by JS_ResolveStub() callback: class name used when constructing

JSRESOLVE_DECLARING = \$08;

Used by JS_ResolveStub() callback: var, const, or function prolog op

JSRESOLVE_DETECTING = \$04;

Used by JS_ResolveStub() callback: 'if (o.p)...' or '(o.p) ?....:....'

JSRESOLVE_QUALIFIED = \$01;

Used by JS_ResolveStub() callback: resolve a qualified property id

JSRESOLVE_WITH = \$20;

Used by JS_ResolveStub() callback: resolve inside a with statement

JSVERSION_1_0 = 100;

Run-time version enumeration corresponding to 1.0

JSVERSION_1_1 = 110;

Run-time version enumeration corresponding to 1.1

JSVERSION_1_2 = 120;

Run-time version enumeration corresponding to 1.2

JSVERSION_1_3 = 130;

Run-time version enumeration corresponding to 1.3

JSVERSION_1_4 = 140;

Run-time version enumeration corresponding to 1.4

JSVERSION_1_5 = 150;

Run-time version enumeration corresponding to 1.5

JSVERSION_1_6 = 160;

Run-time version enumeration corresponding to 1.6

JSVERSION_1_7 = 170;

Run-time version enumeration corresponding to 1.7

JSVERSION_1_8 = 180;

Run-time version enumeration corresponding to 1.8

JSVERSION_DEFAULT = 0;

Run-time version enumeration corresponding to default version

JSVERSION_ECMA_3 = 148;

Run-time version enumeration corresponding to ECMA standard 3, i.e. 1.4.8

JSVERSION_ECMA_5 = 185;

Run-time version enumeration corresponding to ECMA standard 5, i.e. 1.8.5

JSVERSION_LATEST = JSVERSION_ECMA_5;

*Run-time version enumeration corresponding to the latest available
- that is, ECMA standard 5, i.e. 1.8.5*

JSVERSION_UNKNOWN = -1;

Run-time version enumeration corresponding to an identified version

JS_DONT_PRETTY_PRINT: uintN = \$8000;

API extension: OR this into indent to avoid pretty-printing the decompiled source resulting from JS_DecompileFunction{Body}.

JS_FALSE = JSBool(0);

Boolean FALSE value for variables and parameter types for SMAPI

JS_TRUE = JSBool(1);

Boolean TRUE value for variables and parameter types for SMAPI

PRMJ_USEC_PER_SEC = 1000000;

Numbers of micro secs per second

PR_INTERVAL_NO_TIMEOUT = \$ffffffff;

*Stipulate that the process should wait forever as defined by NSPR
- i.e. will never time out
- defined in the PRIntervalTime namespace*

PR_INTERVAL_NO_WAIT = \$0;

*Stipulate that the process should wait no time as defined by NSPR
- i.e. will return immediately
- defined in the PRIntervalTime namespace*

Functions or procedures implemented in the SynSMAPI unit

Functions or procedures	Description	Page
DescribeStack	Retrieve the stack trace of a given execution context	1614
DescribeStackEx	Retrieve the extended stack trace of a given execution context	1614
FormatStackDump	Dump stack trace info with the specified format	1614
FreeStackDescription	Release the stack trace description of a given execution context	1614

Functions or procedures	Description	Page
FreeStackDescriptionEx	Release the extended stack trace description of a given execution context	1614
JSVAL_IS_INT	Check if jsval is a 32 bit integer	1614
JSVAL_IS_NULL		1614
JSVAL_IS_VOID	Check if jsval is VOID	1614
JSVAL_TO_INT	Convert a jsval into a 32 bit integer	1614
JS_AddObjectRoot	Add a JSObject variable to the garbage collector's root set	1614
JS_AddStringRoot	Add a JSString variable to the garbage collector's root set	1615
JS_AddValueRoot	The JS_Add*Root functions add a C/C++ variable to the garbage collector's root set, the set of variables used as starting points each time the collector checks to see what memory is reachable	1615
JS_AlreadyHasOwnElement	JS_AliasElement OBSOLETE	1615
JS_AlreadyHasOwnProperty	JS_AliasProperty is Obsolete since JSAPI 8 function JS_AliasProperty(cx: PJSContext; obj: JSObject; name: PAnsiChar; alias: PAnsiChar): JSBool; cdecl; external SpiderMonkeyLib ; Determine whether a property is already physically present on a JSObject	1615
JS_AlreadyHasOwnPropertyById	Determine whether a property is already physically present on a JSObject	1615
JS_AlreadyHasOwnUCProperty	Determine whether a property is already physically present on a JSObject	1616
JS_ARGV	Points to the first argument of a JSNative callback	1616
JS_AtomKey	Retrieve the local name into a JavaScript atom	1616
JS_BeginRequest	Indicates to the JS engine that the calling thread is entering a region of code that may call into the JSAPI but does not block	1616
JS_BufferIsCompilableUnit	Validate a JavaScript statement	1616
JS_CALLEE	Extern JS_PUBLIC_API(JSBool) JS_GetClassObject(JSContext *cx, JSObject *obj, JSProtoKey key, JSObject **objp);	1616
JS_CallFunction	JS_CallFunction calls a specified function, fun, on an object, obj	1616
JS_CallFunctionName	Call a method of an object by name.	1617
JS_CallFunctionValue	Calls a specified JS function	1617
JS_CheckAccess	Check whether a running script may access a given object property.	1617
JS_ClearInterrupt	Clear a callback to be called when script debugging is interrupted	1617
JS_ClearTrap	Clear a trap debugging handler callback for a given execution context	1617

Functions or procedures	Description	Page
JS_CloneFunctionObject	JS_CloneFunctionObject creates a new function object from funobj	1617
JS_CompareStrings	Compares two JS strings, str1 and str2	1617
JS_CompileFunction	JS_CompileFunction compiles a function from a text string, bytes, and optionally associates it with a JS object, obj	1618
JS_CompileScript	JS_CompileScript compiles a script source, for execution	1618
JS_CompileUCFunction	JS_CompileUCFunction() is the Unicode version of JS_CompileFunction() function	1618
JS_CompileUCScript	Unicode version to compiles a script	1618
JS_ComputeThis	Low-level API used by JS_THIS() macro	1618
JS_ContextIterator	Cycles through the JS contexts associated with a particular JSRuntime	1618
JS_ConvertStub	Default callback matching JSConvertOp prototype of JSClass	1619
JS_ConvertValue	Converts a series of JS values, passed in an argument array, to their corresponding JS types	1619
JS_DecompileFunction	Generates the complete source code of a function declaration from a compiled function	1620
JS_DecompileFunctionBody	Generate the source code representing the body of a function, minus the function keyword, name, parameters, and braces	1620
JS_DecompileScript	Decompile a JavaScript script	1620
JS_DecompileScriptObject	Decompiles a Script Object back into its JavaScript representation	1620
JS_DeepFreezeObject	Freeze obj, and all objects it refers to, recursively	1620
JS_DefineConstDoubles	JS_DefineConstDoubles creates one or more properties for a specified object, obj, where each property consists of a double value.	1620
JS_DefineElement	JS_DefineElement defines a numeric property for a specified object, obj	1620
JS_DefineFunction	Create a native function and assign it as a property to a specified JS object	1620
JS_DefineFunctionById	Create a native function and assign it as a property to a specified JS object	1620
JS_DefineFunctions	JS_DefineFunctions creates zero or more functions and makes them properties (methods) of a specified object, obj, as if by calling JS_DefineFunction repeatedly	1621
JS_DefineObject	Create an object that is a property of another object	1621
JS_DefineOwnProperty	JS_DefineOwnProperty implements the ECMAScript defined function Object.defineProperty	1621

Functions or procedures	Description	Page
JS_DefineProperties	JS_DefineProperties creates properties on a specified object, obj. Each property is defined as though by calling JS_DefinePropertyWithTinyId	1621
JS_DefineProperty	JS_DefineProperty is the fundamental operation on which several more convenient, higher-level functions are based, including JS_DefineFunction, JS_DefineFunctions, JS_DefineProperties, JS_DefineConstDoubles, JS_DefineObject, and JS_InitClass.	1621
JS_DefinePropertyById	JS_DefinePropertyById is the same as JS_DefineProperty but takes a jsid for the property name	1621
JS_DefineUCFunction	Unicode version to create a native function	1621
JS_DefineUCProperty	Define unicode property	1622
JS_DeleteElement	Removes a specified element or numeric property from an object	1622
JS_DeleteElement2	Removes a specified element or numeric property from an object	1622
JS_DeleteProperty	Removes a specified property from an object	1622
JS_DeleteProperty2	Removes a specified property from an object and return the property value	1622
JS_DeletePropertyById	Removes a specified property from an object	1622
JS_DeletePropertyById2	Removes a specified property from an object and return the property value	1622
JS_DeletePropertyStub	Default callback matching JSDeletePropertyOp prototype of JSClass	1622
JS_DestroyContext	Release a new JSContext	1622
JS_DestroyContextMaybeGC	Release a new JSContext with potential garbage collection	1622
JS_DestroyContextNoGC	Release a new JSContext without performing garbage collection	1622
JS_DestroyRuntime	Release the JavaScript runtime	1622
JS_DoubleIsInt32	Check if the given double is in fact a 31 bit signed integer	1622
JS_DropExceptionState	Drop a specified exception state	1622
JS_EndRequest	Indicates to the JS engine that the calling thread is leaving a region of code that may call into the JSAPI but does not block	1623
JS_EnterCompartment	Declare entering a safe compartment of the specified object	1623
JS_Enumerate	JS_ClearScope - OBSOLETE JS_Enumerate gets the ids of all own properties of the specified object, obj,	1623
JS_EnumerateResolvedStandardClasses	Enumerate any already-resolved standard class ids into ida, or into a new JSIdArray if ida is null	1623
JS_EnumerateStub	Default callback matching JSEnumerateOp prototype of JSClass	1623

Functions or procedures	Description	Page
JS_ErrorFromException	Retrieve an error report from an exception object	1623
JS_EvaluateScript	JS_EvaluateScript compiles and executes a script in the specified scope (obj)	1623
JS_evaluateUCInStackFrame	Compile and execute a script in stack frame with raw identifier (obj)	1624
JS_EvaluateUCScript	Unicode version of JS_EvaluateScript	1624
JS_ExecuteScript	Execute a compiled script.	1624
JS_FlushCaches	Flush the code cache for the current thread	1624
JS_FreezeObject	Freezes an object; see ES5's Object.freeze(obj) method	1624
JS_GC	Launch the GarbageCollection process of the given execution RunTime	1625
JS_GetArrayBufferByteLength	Return the available byte length of an array buffer	1625
JS_GetArrayBufferData	Return a pointer to an array buffer's data	1625
JS_GetArrayBufferViewBuffer	Return the ArrayBuffer underlying an ArrayBufferView	1625
JS_GetArrayBufferViewByteLength	More generic name for JS_GetTypedArrayByteLength to cover DataViews as well	1625
JS_GetArrayBufferViewData	Return a pointer to the start of the data referenced by any typed array	1625
JS_GetArrayBufferViewType	Get the type of elements in a typed array, or jsabTYPE_DATAVIEW if a DataView	1625
JS_GetArrayLength	Retrieve the length of an object array	1625
JS_GetClass	Retrieve the JSClass of a given object	1625
JS_GetContextPrivate	Read access to a JSContext field for application-specific data	1625
JS_GetDebugMode	Check if the JavaScript debugging mode is set for a given context	1625
JS_GetElement	Find a specified numeric property of an object and return its current value	1626
JS_GetFloat32ArrayData	Return a pointer to the start of the data referenced by a typed 32 bit float (single) array	1626
JS_GetFloat64ArrayData	Return a pointer to the start of the data referenced by a typed 64 bit float (double) array	1626
JS_GetFunctionArgumentCount	Retrieves how many arguments expect a function	1626
JS_GetFunctionArity	Return the arity (params count) for a specified function	1626
JS_GetFunctionFlags	Return JSFUN_* flags for a specified function	1626

Functions or procedures	Description	Page
JS_GetFunctionId	Return the function's identifier as a JSString, or null if fun is unnamed.	1626
JS_GetFunctionLocalNameArray	Retrieve the local name array information of a given function	1626
JS_GetFunctionObject	Retrieves the object for a specified function.	1626
JS_GetFunctionScript	Cast a JavaScript function into a script instance	1626
JS_GetInt16ArrayData	Return a pointer to the start of the data referenced by a typed 16 bit signed integer array	1627
JS_GetInt32ArrayData	Return a pointer to the start of the data referenced by a typed 32 bit signed integer array	1627
JS_GetInt8ArrayData	Return a pointer to the start of the data referenced by a typed 8 bit signed integer array	1627
JS_GetInternedStringChars	See JS_InternedString for details about what InternedString is.	1627
JS_GetObjectAsArrayBuffer	Unwrap an object as its raw binary memory buffer	1627
JS_GetObjectAsArrayBufferView	Unwrap an object as its raw binary memory buffer	1627
JS_GetObjectAsFloat32Array	Unwrap 32 bit float (single) typed array into direct memory buffer	1627
JS_GetObjectAsFloat64Array	Unwrap 64 bit float (double) typed array into direct memory buffer	1627
JS_GetObjectAsInt16Array	Unwrap 16 bit signed integer typed array into direct memory buffer	1627
JS_GetObjectAsInt32Array	Unwrap 32 bit signed integer typed array into direct memory buffer	1628
JS_GetObjectAsInt8Array	Unwrap 8 bit signed integer typed array into direct memory buffer	1628
JS_GetObjectAsUint16Array	Unwrap 16 bit unsigned integer typed array into direct memory buffer	1628
JS_GetObjectAsUint32Array	Unwrap 32 bit unsigned integer typed array into direct memory buffer	1628
JS_GetObjectAsUint8Array	Unwrap 8 bit unsigned integer typed array into direct memory buffer	1628
JS_GetObjectAsUint8ClampedArray	Unwrap 8 bit unsigned integer typed array into direct memory buffer	1628
JS_GetObjectId	Get a unique identifier for obj, good for the lifetime of obj (even if it is moved by a copying GC)	1628
JS_GetOperationCallback	Retrieve the callback function that is automatically called periodically while JavaScript code runs in the given execution context	1628

Functions or procedures	Description	Page
JS_GetPendingException	Get the current exception being thrown within a context	1628
JS_GetProperty	Finds a specified property by name and retrieves its value	1629
JS_GetPropertyAttributes	Determine the attributes (JSPROP_* flags) of a property on a given object	1629
JS_GetPropertyById	Finds a specified property by jsid and retrieves its value	1629
JS_GetPropertyByIdDefault	Finds a specified property by jsid and retrieves its value or a default value	1629
JS_GetPropertyDescArray	Retrieve the description of a given JavaScript object property	1629
JS_GetPropertyDescriptorById	Finds a specified property of an object and gets a detailed description of that property	1629
JS_GetReservedSlot	Read access an object's reserved slots	1629
JS_GetRuntime	Retrieves a pointer to the JSRuntime with which a specified JSContext, is associated	1629
JS_GetScriptBaselineNumber	Retrieve the base line number of a given script	1630
JS_GetScriptLineExtent	Retrieve the extent of a given script	1630
JS_GetStringCharsAndLength	Retrieve a pointer to the 16-bit values that make up a given string.	1630
JS_GetStringCharsZ	Is the same as JS_GetStringChars except that it always returns either a null-terminated string or NULL, indicating out-of-memory	1630
JS_GetStringLength	TODO - no description provided in MSDN extern JS_PUBLIC_API(JSBool) JS_StringEqualsAscii(JSContext *cx, JSString *str, const char *asciiBytes, JSBool *match);	1631
JS_GetTypedArrayByteLength	Return the byte length of a typed array	1631
JS_GetTypedArrayByteOffset	Return the byte offset from the start of an array buffer to the start of a typed array view	1631
JS_GetTypedArrayLength	Return the number of elements in a typed array	1632
JS_GetTypeName	Determines the JS data type name of a JS value	1632
JS_GetUCPropertyAttributes	Determine the attributes (JSPROP_* flags) of a property on a given object	1632
JS_GetUint16ArrayData	Return a pointer to the start of the data referenced by a typed 16 bit unsigned integer array	1632

Functions or procedures	Description	Page
JS_GetUint32ArrayData	Return a pointer to the start of the data referenced by a typed 32 bit unsigned integer array	1632
JS_GetUint8ArrayData	Return a pointer to the start of the data referenced by a typed 8 bit unsigned integer array	1632
JS_GetUint8ClampedArrayData	Return a pointer to the start of the data referenced by a typed 8 bit unsigned integer array	1632
JS_GetVersion	Retrieve the JavaScript version number used within a specified executable script context	1632
JS_HasElement	Check if an object array has an element at the supplied index	1632
JS_HasProperty	JS_HasProperty searches an object, obj, and its prototype chain, for a property with the specified name	1633
JS_HasPropertyById	JS_HasProperty searches an object, obj, and its prototype chain, for a property with the specified jsid	1633
JS_HasUCProperty	Same as JS_HasProperty but unicode	1633
JS_InitClass	Make a JSClass accessible to JavaScript code by creating its prototype, constructor, properties, and functions.	1633
JS_InitStandardClasses		1633
JS_InternJSString	Get an interned string from a given null-terminated C string	1633
JS_InternString	Get an interned string from a given text buffer — that is, a JSString that is protected from GC and automatically shared with other code that needs a JSString with the same value	1633
JS_InternUCStringN	Unicode version of JS_InternString (faster)	1634
JS_IsAboutToBeFinalized	JS_IsAboutToBeFinalized() checks if the given object is going to be finalized at the end of the current GC	1634
JS_IsArrayBufferObject	Check whether obj supports the JS_GetArrayBuffer* APIs	1634
JS_IsArrayBufferViewObject	Check whether obj supports JS_GetArrayBufferView* APIs	1634
JS_IsArrayObject	Check if the supplied object is an array	1634
JS_IsConstructing	JS_IsConstructing must be called from within a native given the native's original cx and vp arguments	1634
JS_IsExceptionPending	Determine whether an exception is pending in the JS engine.	1634
JS_IsExtensible	Queries the [[Extensible]] property of the object.	1634
JS_IsFloat32Array	Test for specific 32 bit float (single) typed array types (ArrayBufferView subtypes)	1635

Functions or procedures	Description	Page
JS_IsFloat64Array	Test for specific 64 bit float (double) typed array types (ArrayBufferView subtypes)	1635
JS_IsInRequest	OBSOLETE procedure JS_YieldRequest(cx: PJSContext); cdecl; external SpiderMonkeyLib; OBSOLETE type OBSOLETE jsrefcount = JSInt32; OBSOLETE function JS_SuspendRequest(cx: PJSContext): jsrefcount; cdecl; external SpiderMonkeyLib; OBSOLETE procedure JS_ResumeRequest(cx: PJSContext; saveDepth: jsrefcount); cdecl; external SpiderMonkeyLib; checked is is within a code region protected by JS_BeginRequest()	1635
JS_IsInt16Array	Test for specific 16 bit signed integer typed array types (ArrayBufferView subtypes)	1635
JS_IsInt32Array	Test for specific 32 bit signed integer typed array types (ArrayBufferView subtypes)	1635
JS_IsInt8Array	Test for specific 8 bit signed integer typed array types (ArrayBufferView subtypes)	1635
JS_IsRunning	Determines if a script or function is currently executing in a specified JSContext, cx	1635
JS_IsTypedArrayObject	Check whether obj supports JS_GetTypedArray* APIs	1635
JS_IsUint16Array	Test for specific 16 bit unsigned integer typed array types (ArrayBufferView subtypes)	1635
JS_IsUint32Array	Test for specific 32 bit unsigned integer typed array types (ArrayBufferView subtypes)	1635
JS_IsUint8Array	Test for specific 8 bit unsigned integer typed array types (ArrayBufferView subtypes)	1635
JS_IsUint8ClampedArray	Test for specific 8 bit unsigned integer typed array types (ArrayBufferView subtypes)	1635
JS_LeaveCompartment	Declare leaving the safe compartment of the specified object	1635
JS_LineNumberToPC	Retrieve the byte code item position corresponding to a script line number	1635
JS_LocalNameToAtom	Convert a local name into a JavaScript atom	1636
JS_LookupElement	Determine if a specified numeric property exists	1636
JS_LookupProperty	Determine if a specified property exists, according to its name	1636
JS_LookupPropertyById	Determine if a specified property exists, according to its jsid	1636
JS_LookupUCProperty	Determine if a specified property exists	1636
JS_MaybeGC	Check if it would be worth it to launch the GarbageCollection process of the given execution RunTime, in the given context	1636

Functions or procedures	Description	Page
JS_New	As of SpiderMonkey 1.8.8, JS_ConstructObject and JS_ConstructObjectWithArguments have been removed from the JSAPI. The preferred alternative is to save a copy of the constructor function for the class, then to call it using JS_New. function JS_ConstructObject(cx: PJSContext; clasp: PJSClass; proto: PJSObject; parent: PJSObject): PJSObject; cdecl; external SpiderMonkeyLib; function JS_ConstructObjectWithArguments(cx: PJSContext; clasp: PJSClass; proto: PJSObject; parent: PJSObject; argc: uintN; argv: pjsval): PJSObject; cdecl; external SpiderMonkeyLib; Create an object as though by using the new keyword and a JavaScript function	1636
JS_NewArrayBuffer	Create a new ArrayBuffer with the given byte length.	1636
JS_NewArrayObject	JS_NewArrayObject creates a new array object with the specified length.	1637
JS_NewContext	Create a new JSContext	1637
JS_NewDateObject	Create a new JavaScript date object	1637
JS_NewDateObjectMsec	Create a new JavaScript date object from the Unix millisecond elapsed since EPOCH	1637
JS_NewExternalString	Creates a new JSString whose characters are stored in external memory, i.e., memory allocated by the application, not the JavaScript engine	1637
JS_NewFloat32Array	Create a new signed 32 bit float (single) typed array with nelements elements	1637
JS_NewFloat32ArrayFromArray	Create a new 32 bit float (single) typed array and copy in values from a given object	1637
JS_NewFloat32ArrayWithBuffer	Create a new 32 bit float (single) typed array using the given ArrayBuffer for storage	1638
JS_NewFloat64Array	Create a new signed 64 bit float (double) typed array with nelements elements	1638
JS_NewFloat64ArrayFromArray	Create a new 64 bit float (double) typed array and copy in values from a given object	1638
JS_NewFloat64ArrayWithBuffer	Create a new 64 bit float (double) typed array using the given ArrayBuffer for storage	1638
JS_NewFunction	JS_NewFunction creates a new JavaScript function implemented in Delphi	1638
JS_NewFunctionById	Create the function with the name given by the id	1638
JS_NewGlobalObject	JS_NewGlobalObject creates a new global object based on the specified class	1638
JS_NewInt16Array	Create a new signed 16 bit integer typed array with nelements elements	1639

Functions or procedures	Description	Page
JS_NewInt16ArrayFromArray	Create a new 16 bit signed integer typed array and copy in values from a given object	1639
JS_NewInt16ArrayWithBuffer	Create a new 16 bit signed integer typed array using the given ArrayBuffer for storage	1639
JS_NewInt32Array	Create a new signed 32 bit integer typed array with nelements elements	1639
JS_NewInt32ArrayFromArray	Create a new 32 bit signed integer typed array and copy in values from a given object	1639
JS_NewInt32ArrayWithBuffer	Create a new 32 bit signed integer typed array using the given ArrayBuffer for storage	1639
JS_NewInt8Array	Create a new signed 8 bit integer typed array with nelements elements	1639
JS_NewInt8ArrayFromArray	Create a new 8 bit signed integer typed array and copy in values from a given object	1639
JS_NewInt8ArrayWithBuffer	Create a new 8 bit signed integer typed array using the given ArrayBuffer for storage	1639
JS_NewObject	JS_NewObject creates a new object based on a specified class, prototype, and parent object	1640
JS_NewObjectWithGivenProto	Unlike JS_NewObject, JS_NewObjectWithGivenProto does not compute a default proto if proto's actual parameter value is null	1640
JS_NewPropertyIterator	Create an object to iterate over enumerable properties of obj, in arbitrary	1640
JS_NewRuntime	Initialize the JavaScript runtime	1640
JS_NewStringCopyN		1640
JS_NewStringCopyZ	Create a new JavaScript string based on a null-terminated C string	1640
JS_NewUCString	Creates and returns a new string, using the memory starting at buf and ending at buf + length as the character storage.	1641
JS_NewUCStringCopyN	Unicode version of JS_NewStringCopyN	1641
JS_NewUCStringCopyZ	Unicode version of JS_NewStringCopyZ	1641
JS_NewUint16Array	Create a new unsigned 16 bit integer typed array with nelements elements	1641
JS_NewUint16ArrayFromArray	Create a new 16 bit unsigned integer typed array and copy in values from a given object	1641
JS_NewUint16ArrayWithBuffer	Create a new 16 bit unsigned integer typed array using the given ArrayBuffer for storage	1641
JS_NewUint32Array	Create a new unsigned 32 bit integer typed array with nelements elements	1641

Functions or procedures	Description	Page
JS_NewUInt32ArrayFromArray	Create a new 32 bit unsigned integer typed array and copy in values from a given object	1641
JS_NewUInt32ArrayWithBuffer	Create a new 32 bit unsigned integer typed array using the given ArrayBuffer for storage	1642
JS_NewUInt8Array	Create a new unsigned 8 bit integer (byte) typed array with nelements elements	1642
JS_NewUInt8ArrayFromArray	Create a new 8 bit unsigned integer typed array and copy in values from a given object	1642
JS_NewUInt8ArrayWithBuffer	Create a new 8 bit unsigned integer typed array using the given ArrayBuffer for storage	1642
JS_NewUInt8ClampedArray	Create a new 8 bit integer typed array with nelements elements	1642
JS_NewUInt8ClampedArrayFromArray	Create a new 8 bit unsigned integer typed array and copy in values from a given object	1642
JS_NewUInt8ClampedArrayWithBuffer	Create a new 8 bit unsigned integer typed array using the given ArrayBuffer for storage	1642
JS_NextProperty	Return true on success with *idp containing the id of the next enumerable	1642
JS_NumberValue	JS_NewNumberValue Obsolete since JavaScript mozjs17 use JS_NumberValue instead https://developer.mozilla.org/en-US/docs/SpiderMonkey/JSAPI_Reference/JS_NewNumberValue	1642
JS_ObjectIsCallable	Check is the supplied object is callable	1643
JS_ObjectIsDate	Infallible predicate to test whether obj is a JavaScript date object	1643
JS_ObjectIsFunction	Test whether a given object is a Function	1643
JS_ParseJSON	Parse a string using the JSON syntax described in ECMAScript 5 and return the corresponding value into vp	1643
JS_PCToLineNumber	Retrieve the script line number from a byte code item position	1643
JS_PropertyStub	Default callback matching JSPropertyOp prototype of JSClass	1643
JS_PutPropertyDescArray	Define the description of a given JavaScript object property	1643
JS_ReleaseFunctionLocalNameArray	Release the local name array information of a given function	1643
JS_RemoveObjectRoot	Remove a JSObject variable from the garbage collector's root set	1643
JS_RemoveStringRoot	Remove a JSString variable from the garbage collector's root set	1643
JS_RemoveValueRoot	Remove a jsval variable from the garbage collector's root set	1643

Functions or procedures	Description	Page
JS_ReportAllocationOverflow	Call JS_ReportAllocationOverflow if an operation fails because it tries to use more memory (or more of some other resource) than the application is designed to handle	1644
JS_ReportError	JS_ReportError is the simplest JSAPI function for reporting errors	1644
JS_ReportErrorNumber	Report an error with an application-defined error code.	1644
JS_ReportErrorNumberUC	Report an error with an application-defined error code.	1644
JS_ReportOutOfMemory	Reports a memory allocation error	1644
JS_ReportWarning	Similar to JS_ReportError(), but report a warning instead of an error (JSREPORT_IS_WARNING(report.flags))	1645
JS_ResolveStandardClass	Resolve id, which must contain either a string or an int, to a standard class name in obj if possible, defining the class's constructor and/or prototype and storing true in resolved	1645
JS_ResolveStub	Default callback matching JSResolveOp prototype of JSClass	1645
JS_RestoreExceptionState	Restore a specified exception state	1645
JS_RVAL	Get the return value of a JSNative callback	1645
JS_SameValue	Determines if two jsvals are the same, as determined by the SameValue algorithm in ECMAScript 262, 5th edition	1645
JS_SaveExceptionState	Save the current exception state. This takes a snapshot of cx's current exception state without making any change to that state.	1645
JS_SetArrayLength	JS_SetArrayLength sets the length property of an object obj	1646
JS_SetContextCallback	Specifies a callback function that is automatically called whenever a JSContext is created or destroyed	1646
JS_SetContextPrivate	Write access to a JSContext field for application-specific data	1646
JS_SetDebugErrorHook	Set a callback to be called when an error is triggered during script debugging	1646
JS_SetDebuggerHandler	Set a debugging handler callback for a given hook and runtime	1646
JS_SetDebugMode	Enables the JavaScript debugging mode for a given context	1646
JS_SetDestroyScriptHookProc	Set the callback to be called when a JavaScript debugging hook is released	1646
JS_SetElement	Assign a value to a numeric property of an object	1646
JS_SetErrorReporter	Specify the error reporting mechanism for an application.	1647
JS_SetGCCallback	Defines a Garbage Collection call-back function	1647
JS_SetInterrupt	Set a callback to be called when script debugging is interrupted	1647

Functions or procedures	Description	Page
JS_SetNativeStackQuota	Set the size of the native stack that should not be exceeded	1647
JS_SetNewScriptHookProc	Set a JavaScript debugging hook callback	1647
JS_SetOperationCallback	These functions allow setting an operation callback that will be called from the thread the context is associated with some time after any thread triggered the callback using JS_TriggerOperationCallback(cx).	1648
JS_SetPendingException	Set the current exception being thrown within a context	1648
JS_SetProperty	The following functions behave like JS_GetProperty and JS_GetPropertyById except when operating on E4X XML objects extern JS_PUBLIC_API(JSBool) JS_GetMethodById(JSContext *cx, JSObject *obj, jsid id, JSObject **objp, jsval *vp); extern JS_PUBLIC_API(JSBool) JS_GetMethod(JSContext *cx, JSObject *obj, const char *name, JSObject **objp, jsval *vp); JS_SetProperty assigns the value vp to the property name of the object obj	1648
JS_SetPropertyAttributes	Set the attributes of a property on a given object	1649
JS_SetPropertyById	JS_SetProperty assigns the value vp to the property jsid of the object obj	1649
JS_SetReservedSlot	Write access an object's reserved slots	1649
JS_SetRuntimeDebugMode	Enables the JavaScript debugging mode for a given runtime	1649
JS_SetSingleStepMode	Set single step mode. In this mode script interrupts on each line	1649
JS_SetThrowHook	Set a callback to be called when script throws an exception	1649
JS_SetTrap	Set a trap debugging handler callback for a given execution context	1649
JS_SetUCPropertyAttributes	Set the attributes of a property on a given object.	1649
JS_SET_RVAL	Set the return value of a JSNative callback	1649
JS_ShutDown	Free all resources used by the JS engine, not associated with specific runtimes	1649
JS_StrictlyEqual	Determine whether two JavaScript values are equal in the sense of the === operator	1649
JS_StrictPropertyStub	Default callback matching JSStrictPropertyOp prototype of JSClass	1649
JS_Stringify	Converts a value to JSON, optionally replacing values if a replacer function is specified, or optionally including only the specified properties if a replacer array is specified	1649
JS_StringToVersion	Configure a JSContext to use a specific version of the JavaScript language	1650

Functions or procedures	Description	Page
JS_THIS	Return the this object of a JSNative callback	1650
JS_THIS_OBJECT	Return the this object of a JSNative callback	1650
JS_ThrowReportedError	Given a reported error's message and JSErrorReport struct pointer, throw the corresponding exception on cx	1650
JS_ThrowStopIteration	Throws a StopIteration exception on cx	1650
JS_TriggerOperationCallback	Triggers a callback set using JS_SetOperationCallback	1650
JS_TypeOfValue	Determines the JS data type of a JS value	1650
JS_ValueToBoolean	Convert a JavaScript value to a boolean	1650
JS_ValueToECMAInt32	Convert a JavaScript value to an integer type as specified by the ECMAScript standard	1650
JS_ValueToECMAUint32	Convert a JavaScript value to an integer type as specified by the ECMAScript standard	1650
JS_ValueToFunction	Convert a jsval to a JSFunction	1650
JS_ValueToInt32	JS_ValueToInt32 is obsolete	1650
JS_ValueToNumber	Convert any JavaScript value to a floating-point number of type jsdouble.	1650
JS_ValueToObject	JS_ValueToObject converts a specified JavaScript value, v, to an object	1651
JS_ValueToSource	Convert any JavaScript value to its source representation	1651
JS_ValueToString	JS_ValueToString converts a specified JavaScript value, v, to a string.	1651
JS_ValueToUint16	Convert a JavaScript value to a 16 bit integer	1651
JS_VersionToString	JS_SetVersion is not supported now Use CompartmentOptions in JS_NewGlobalObject retrieve the JavaScript version text used within a specified executable script context	1652
PR_CreateThread	Initializes a NSPR thread	1652
PR_DestroyCondVar	Free a previously allocated NSPR event	1652
PR_DestroyLock	Free a previously allocated NSPR lock	1652
PR_JoinThread	Join a NSPR thread	1652
PR_Lock	Enter a previously allocated NSPR mutex/lock	1652
PR_NewCondVar	Allocates a new NSPR event	1652
PR_NewLock	Allocates a new NSPR mutex/lock	1652
PR_NotifyAllCondVar	Notify all previously allocated NSPR event	1652

Functions or procedures	Description	Page
PR_NotifyCondVar	Notify a previously allocated NSPR event	1652
PR_SetCurrentThreadName	Change the current NSPR thread name	1652
PR_TicksPerSecond	Returns the number of ticks per seconds as expected by NSPR	1652
PR_Unlock	Leave a previously allocated NSPR mutex/lock	1652
PR_WaitCondVar	Wait until a previously allocated NSPR event is notified	1652

function DescribeStack(cx: PJSCContext; maxFrames: uintn): PStackDescription; **cdecl; external** SpiderMonkeyLib;

Retrieve the stack trace of a given execution context

function DescribeStackEx(cx: PJSCContext; maxFrames: uintn): PStackDescriptionEx; **cdecl; external** SpiderMonkeyLib;

Retrieve the extended stack trace of a given execution context

function FormatStackDump(cx: PJSCContext; buf: PCChar; showArgs, showLocals, showThisProps: JSBool): PCChar; **cdecl; external** SpiderMonkeyLib;

Dump stack trace info with the specified format

procedure FreeStackDescription(cx: PJSCContext; desc: PStackDescription); **cdecl; external** SpiderMonkeyLib;

Release the stack trace description of a given execution context

procedure FreeStackDescriptionEx(cx: PJSCContext; desc: PStackDescriptionEx); **cdecl; external** SpiderMonkeyLib;

Release the extended stack trace description of a given execution context

function JSVAL_IS_INT(const v: jsval): Boolean;

Check if jsval is a 32 bit integer

function JSVAL_IS_NULL(const v: jsval): Boolean;

```
define IMPL_TO_JSVAL(v) (v)
define JSID_BITS(id) ((id).asBits)
check if a jsval is NULL
```

function JSVAL_IS_VOID(const v: jsval): Boolean;

Check if jsval is VOID

function JSVAL_TO_INT(const v: jsval): jsint;

Convert a jsval into a 32 bit integer

- there is no check that jsval is really a 32 bit integer: caller shall ensure this is the case (by using

function JS_AddObjectRoot(cx: PJSCContext; rp: PPJSObject): JSBool; **cdecl; external** SpiderMonkeyLib;

Add a JSObject variable to the garbage collector's root set

- similar to JS_AddValueRoot(), but with a JSObject value

function JS_AddStringRoot(cx: PJSContext; rp: PPJSString): JSBool; cdecl; external SpiderMonkeyLib;

Add a JSString variable to the garbage collector's root set
 - similar to JS_AddValueRoot(), but with a JSString value

function JS_AddValueRoot(cx: PJSContext; vp: Pjsval): JSBool; cdecl; external SpiderMonkeyLib;

*The JS_Add*Root functions add a C/C++ variable to the garbage collector's root set, the set of variables used as starting points each time the collector checks to see what memory is reachable*
 - The garbage collector aggressively collects and recycles memory that it deems unreachable, so roots are often necessary to protect data from being prematurely collected.
 - vp/spp/opp/rp is the address of a C/C++ variable (or field, or array element) of type JSString *, JSObject *, or jsval. This variable must already be initialized. (For example, it must not be an uninitialized local variable. That could cause sporadic crashes during garbage collection, which can be hard to debug.) The variable must remain in memory until the balancing call to JS_RemoveRoot. Note that this means that if the root is meant to live past the end of a function, the address of a local (stack-based) variable may not be used for rp. If JS_Add*Root succeeds, then as long as this variable points to a JavaScript value or pointer to GC-thing, that value/GC-thing is protected from garbage collection. If the variable points to an object, then any memory reachable from its properties is automatically protected from garbage collection, too.
 - JS_AddGCThingRoot allows the caller to have a single root that may hold either strings or objects. A jsval is not a GC-thing (it has tag bits and may be a different size altogether) and thus the address of a jsval variable must not be passed to JS_AddGCThingRoot.
 - Do not pass a pointer to a JS string or object to any of these functions—rp must point to a variable, the location of the pointer itself, and not an object or string.

function JS_AlreadyHasOwnElement(cx: PJSContext; obj: PJSObject; index: jsint; var foundp: JSBool): JSBool; cdecl; external SpiderMonkeyLib;

JS_AliasElement OBSOLETE

function JS_AlreadyHasOwnProperty(cx: PJSContext; obj: PJSObject; const name: PCChar; var found: JSBool): JSBool; cdecl; external SpiderMonkeyLib;

JS_AliasProperty is Obsolete since JSAPI 8 function JS_AliasProperty(cx: PJSContext; obj: PJSObject; name: PAnsiChar; alias: PAnsiChar): JSBool; cdecl; external SpiderMonkeyLib ; Determine whether a property is already physically present on a JSObject

- For native objects—objects whose properties are stored in the default data structure provided by SpiderMonkey, these functions simply check that data structure to see if the specified field is present. They do not search anywhere else for the property. This means that:
 - The prototype chain of obj is not searched.
 - The object's JSClass.resolve hook is not called, so lazily defined properties are not found. (This is the only API that can directly detect that a lazily resolved property has not yet been resolved.)
 - Shared, permanent, delegated properties are not found. (Such properties are an implementation detail of SpiderMonkey. They are meant to be a transparent optimization; this is the only API that breaks the abstraction)

function JS_AlreadyHasOwnPropertyById(cx: PJSContext; obj: PJSObject; id: jsid; var found: JSBool): JSBool; cdecl; external SpiderMonkeyLib;

Determine whether a property is already physically present on a JSObject
 - this function will locate the property not by name, but by its jsid

```
function JS_AlreadyHasOwnUCProperty(cx: PJSContext; obj: PJSObject; const name:
Pjschar; namelen: size_t; var foundp: JSBool): JSBool; cdecl; external
SpiderMonkeyLib;
```

Determine whether a property is already physically present on a JSObject

- For native objects—objects whose properties are stored in the default data structure provided by SpiderMonkey, these functions simply check that data structure to see if the specified field is present. They do not search anywhere else for the property. This means that: The prototype chain of obj is not searched. The object's JSClass.resolve hook is not called, so lazily defined properties are not found. (This is the only API that can directly detect that a lazily resolved property has not yet been resolved.) Shared, permanent, delegated properties are not found.
- (Such properties are an implementation detail of SpiderMonkey. They are meant to be a transparent optimization; this is the only API that breaks the abstraction)

```
function JS_ARGV(cx: PJSContext; vp: Pjsval): PjsvalVector;
```

Points to the first argument of a JSNative callback

```
function JS_AtomKey(atom: PJSAtom): PJSSString; cdecl; external SpiderMonkeyLib;
```

Retrieve the local name into a JavaScript atom

```
procedure JS_BeginRequest(cx: PJSContext); cdecl; external SpiderMonkeyLib;
```

Indicates to the JS engine that the calling thread is entering a region of code that may call into the JSAPI but does not block

```
function JS_BufferIsCompilableUnit(cx: PJSContext; obj: PJSObject; bytes: PCChar;
length: size_t): JSBool; cdecl; external SpiderMonkeyLib;
```

Validate a JavaScript statement

- Given a buffer, return JS_FALSE if the buffer might become a valid javascript statement with the addition of more lines
- Otherwise return JS_TRUE. The intent is to support interactive compilation - accumulate
- lines in a buffer until JS_BufferIsCompilableUnit is true, then pass it to the compiler.

```
function JS_CALLEE(cx: PJSContext; vp: Pjsval): jsvval;
```

*Extern JS_PUBLIC_API(JSBool) JS_GetClassObject(JSContext *cx, JSObject *obj, JSProtoKey key, JSObject **objp);*

*extern JS_PUBLIC_API(JSObject *) JS_GetScopeChain(JSContext *cx);*

*extern JS_PUBLIC_API(JSObject *) JS_GetGlobalForObject(JSContext *cx, JSObject *obj);*

*extern JS_PUBLIC_API(JSObject *) JS_GetGlobalForScopeChain(JSContext *cx); here is #ifdef JS_HAS_CTYPES - currently not shure we can use it. return the callee function of a JSNative callback*

```
function JS_CallFunction(cx: PJSContext; this: PJSObject; fun: PJSFunction; argc:
uintN; argv: pjsval; var rval: jsvval): JSBool; cdecl; external SpiderMonkeyLib;
```

JS_CallFunction calls a specified function, fun, on an object, obj

- In terms of function execution, the object is treated as this
- Warning: Calling JS_CallFunction is safe only if the fun argument could be passed to JS_GetFunctionObject safely: that is, it is a function implemented by a JSNative or JSFastNative or the result of a call to JS_CompileFunction, JS_CompileUCFunction, JS_CompileFunctionForPrincipals, or JS_CompileUCFunctionForPrincipals.
- Passing any other JSFunction pointer can lead to a crash or worse

function JS_CallFunctionName(cx: PJSContext; this: PJSObject; **const** name: PCChar; argc: uintN; argv: Pjsval; **var** rval: jsval): JSBool; **cdecl**; **external** SpiderMonkeyLib;

Call a method of an object by name.

- JS_CallFunctionName executes a function-valued property, name, belonging to a specified JS object, obj

function JS_CallFunctionValue(cx: PJSContext; this: PJSObject; fval: jsval; argc: uintN; argv: Pjsval; **var** rval: jsval): JSBool; **cdecl**; **external** SpiderMonkeyLib;

Calls a specified JS function

- fval is function value

function JS_CheckAccess(cx: PJSContext; obj: PJSObject; id: jsid; mode: JSAccessMode; **var** vp: jsval; **var** attrsp: uintN): JSBool; **cdecl**; **external** SpiderMonkeyLib;

Check whether a running script may access a given object property.

- The access check proceeds as follows.

- If obj has custom JSObjectOps, the access check is delegated to the JSObjectOps.checkAccess callback.

- Otherwise, if obj's class has a non-null JSClass.checkAccess callback, then it is called to perform the check.

- Otherwise, if a runtime-wide check-object-access callback has been installed by calling JS_SetCheckObjectAccessCallback, then that is called to perform the check.

- Otherwise, access is granted.

- On success, JS_CheckAccess returns JS_TRUE, *vp is set to the current value stored value, of the specified property, and *attrsp is set to the property's attributes.

- On error or exception, including if access is denied, JS_CheckAccess returns JS_FALSE, and the values left in *vp and *attrsp are undefined

function JS_ClearInterrupt(rt: PJSRuntime; hook: PJSInterruptHook; closurep: PPointer): JSBool; **cdecl**; **external** SpiderMonkeyLib;

Clear a callback to be called when script debugging is interrupted

procedure JS_ClearTrap(cx: PJSContext; script: PJSScript; pc: pjsbytecode; handler: JSTrapHandler; closure: jsval); **cdecl**; **external** SpiderMonkeyLib;

Clear a trap debugging handler callback for a given execution context

function JS_CloneFunctionObject(cx: PJSContext; funobj: PJSObject; parent: PJSObject): PJSObject; **cdecl**; **external** SpiderMonkeyLib;

JS_CloneFunctionObject creates a new function object from funobj

- The new object has the same code and argument list as funobj, but uses parent as its enclosing scope.

- This can be helpful if funobj is an extant function that you wish to use as if it were enclosed by a newly-created global object

function JS_CompareStrings(cx: PJSContext; str1, str2: PJSStr; **var** res: int32): JSBool; **cdecl**; **external** SpiderMonkeyLib;

Compares two JS strings, str1 and str2

- If the strings are identical in content and length, JS_CompareStrings stores 0 in *result.

- If str1 is less than str2, *result is less than 0. (If str1 is greater than str2, *result is greater than 0.

- On success the function returns JS_TRUE.

- On error, it returns JS_FALSE and the value in result is unchanged.

- This function imposes a total order on all JavaScript strings, the same order imposed by the JavaScript string comparison operators (<, <=, >, >=), as described in ECMA 262-3 § 11.8.5.

```
function JS_CompileFunction(cx: PJSContext; obj: PJSObject; name: PCChar; nargs:
uintN; argnames: PCStringVector; bytes: PCChar; length: size_t; filename: PCChar;
lineno: uintN): PJSFunction; cdecl; external SpiderMonkeyLib;
```

JS_CompileFunction compiles a function from a text string, bytes, and optionally associates it with a JS object, obj

- name is the name to assign to the newly created function.
- nargs is the number of arguments the function takes, and argnames is a pointer to the first element of an array of names to assign each argument.
- The number of argument names should match the number of arguments specified in nargs.
- body is a string containing the source code of the function.
- length is the length of the source code in characters.
- filename is the name of the file (or URL) containing the function. This information is used in error messages if an error occurs during compilation.
- Similarly, lineno is used to report the line number where an error occurred during compilation.
- If both obj and name are non-null, the new function becomes a method of obj (a new property is defined on obj with the given name and the new Function object as its value).

```
function JS_CompileScript(cx: PJSContext; obj: PJSObject; bytes: PCChar; length:
size_t; filename: PCChar; lineno: uintN): PJSScript; cdecl; external SpiderMonkeyLib;
```

JS_CompileScript compiles a script source, for execution

- The script is associated with a JS object.
- source is the string containing the text of the script.
- length indicates the size of the text version of the script in characters.
- filename is the name of the file (or URL) containing the script.
- This information is included in error messages if an error occurs during compilation.
- Similarly, lineno is used to report the line number of the script or file where an error occurred during compilation.
- If the script is not part of a larger document, lineno should be 1 (as the first line of a file is universally considered to be line 1, not line 0).
- On success, JS_CompileScript and JS_CompileUCScript return an object representing the newly compiled script.
- Otherwise, they report an error and return NULL.
- To compile a script from an external file source rather than passing the actual script as an argument, use JS_CompileFile instead of JS_CompileScript

```
function JS_CompileUCFunction(cx: PJSContext; obj: PJSObject; name: PCChar; nargs:
uintN; argnames: PCStringVector; chars: Pjschar; length: size_t; filename: PCChar;
lineno: uintN): PJSFunction; cdecl; external SpiderMonkeyLib;
```

JS_CompileUCFunction() is the Unicode version of JS_CompileFunction() function

```
function JS_CompileUCScript(cx: PJSContext; obj: PJSObject; chars: Pjschar; length:
size_t; filename: PCChar; lineno: uintN): PJSScript; cdecl; external SpiderMonkeyLib;
```

Unicode version to compiles a script

```
function JS_ComputeThis(cx: PJSContext; vp: Pjsval): jsval; cdecl; external
SpiderMonkeyLib;
```

Low-level API used by JS_THIS() macro

```
function JS_ContextIterator(rt: JSRuntime; iterp: PPJSContext): PJSContext; cdecl;
external SpiderMonkeyLib;
```

Cycles through the JS contexts associated with a particular JSRuntime

```
function JS_ConvertStub(cx: PJSContext; var obj: PJSObject; _type: JSType; vp:
pjsval): JSBool; cdecl; external SpiderMonkeyLib;
```

Default callback matching JSConvertOp prototype of JSClass

```
function JS_ConvertValue(cx: PJSContext; v: jsval; _type: JSType; var vp: jsval):
JSBool; cdecl; external SpiderMonkeyLib;
```

Converts a series of JS values, passed in an argument array, to their corresponding JS types

- Format is a string of the following characters (spaces are insignificant), specifying the tabulated type conversions:

b	JSBool	Boolean
c	uint16/jschar	ECMA uint16, Unicode char
i	int32	ECMA int32
u	uint32	ECMA uint32
j	int32	Rounded int32 (coordinate)
d	jsdouble	IEEE double
I	jsdouble	Integral IEEE double
S	JSString *	Unicode string, accessed by a JSString pointer
W	jschar *	Unicode character vector, 0-terminated (W for wide)
o	JSObject *	Object reference
f	JSFunction *	Function private
v	jsval	Argument value (no conversion)
*	N/A	Skip this argument (no vararg)
/	N/A	End of required arguments

The variable argument list after format must consist of &b, &c, &s, e.g., where those variables have the types given above. For the pointer types char *, JSString *, and JSObject *, the pointed-at memory returned belongs to the JS runtime, not to the calling native code. The runtime promises to keep this memory valid so long as argv refers to allocated stack space (so long as the native function is active).

- Fewer arguments than format specifies may be passed only if there is a / in format after the last required argument specifier and argc is at least the number of required arguments. More arguments than format specifies may be passed without error; it is up to the caller to deal with trailing unconverted arguments. NOTE: we did not include this function yet, since it uses C varargs function JS_ConvertArguments(cx: PJSContext; argc: uintN; argv: pjsval; const format: PCChar): JSBool; varargs; cdecl; external SpiderMonkeyLib;

!!!!!!!!!!!!!!!!!!!!!!**TODO**!!!!!!!!!!!!!!!!!!!!!!

very important to provide similar but for Delphi!! **TODO** JS_Convert(Push)Arguments - provide conversation to(from) array of TVarRec? JS_ConvertValue converts a JavaScript value, v, to the specified type

- On success, the converted value is stored in *vp. Typically users of this function set vp to point to v, so that if conversion is successful, v now contains the converted value.
- JS_ConvertValue calls other, type-specific conversion routines based on the type argument
- Converting any value to JSTYPE_VOID always succeeds. The result is JSVAL_VOID.
- Converting to JSTYPE_OBJECT works exactly like JS_ValueToObject.
- Converting to JSTYPE_FUNCTION works like JS_ValueToFunction, but better: the result is a function object that has not been stripped of its lexical scope. It is safe to call the result (e.g. using JS_CallFunctionValue).
- Converting to JSTYPE_STRING works exactly like JS_ValueToString.
- Converting to JSTYPE_NUMBER works exactly like JS_ValueToNumber.
- Converting to JSTYPE_BOOLEAN works exactly like JS_ValueToBoolean.
- On success, JS_ConvertValue stores the converted value in *vp and returns JS_TRUE.
- On error or exception, it returns JS_FALSE, and the value left in *vp is undefined

```
function JS_DecompileFunction(cx: PJSContext; fun: PJSFunction; indent: uintN):
PJSSString; cdecl; external SpiderMonkeyLib;
```

Generates the complete source code of a function declaration from a compiled function

```
function JS_DecompileFunctionBody(cx: PJSContext; fun: PJSFunction; indent: uintN):
PJSSString; cdecl; external SpiderMonkeyLib;
```

Generate the source code representing the body of a function, minus the function keyword, name, parameters, and braces

```
function JS_DecompileScript(cx: PJSContext; script: PJSScript; name: PCChar; indent:
uintN ): PJSSString; cdecl; external SpiderMonkeyLib;
```

Decompile a JavaScript script

```
function JS_DecompileScriptObject(cx: PJSContext; scriptObj: PJSObject; name:
PCChar; indent: uintN): PJSSString; cdecl; external SpiderMonkeyLib;
```

Decompiles a Script Object back into its JavaScript representation

```
function JS_DeepFreezeObject(cx: PJSContext; obj: PJSObject): JSBool; cdecl; external
SpiderMonkeyLib;
```

Freeze obj, and all objects it refers to, recursively

- This will not recurse through non-extensible objects, on the assumption that those are already deep-frozen.

```
function JS_DefineConstDoubles(cx: PJSContext; obj: PJSObject; cds:
PJSConstDoubleSpec): JSBool; cdecl; external SpiderMonkeyLib;
```

JS_DefineConstDoubles creates one or more properties for a specified object, obj, where each property consists of a double value.

- Each property is automatically assigned attributes as specified in the flags field of the JSConstDoubleSpec structure pointed to by cds.

- If flags is set to 0, the attributes for the property are automatically set to JSPROP_PERMANENT | JSPROP_READONLY

```
function JS_DefineElement(cx: PJSContext; obj: PJSObject; index: jsint; value: jsval;
getter: JSPropertyOp; setter: JSPropertyOp; attrs: uintN): JSBool; cdecl; external
SpiderMonkeyLib;
```

JS_DefineElement defines a numeric property for a specified object, obj

- Starting in SpiderMonkey 1.8.5, jsval can store a full 32-bit integer, so index is any 32-bit integer

```
function JS_DefineFunction(cx: PJSContext; obj: PJSObject; name: PCChar; call:
JSNative; nargs: uintN; attrs: uintN): PJSFunction; cdecl; external SpiderMonkeyLib;
```

Create a native function and assign it as a property to a specified JS object

```
function JS_DefineFunctionById(cx: PJSContext; obj: PJSObject; id: jsid; call:
JSNative; nargs: uintN; attrs: uintN): PJSFunction; cdecl; external SpiderMonkeyLib;
```

Create a native function and assign it as a property to a specified JS object

function JS_DefineFunctions(cx: PJSContext; obj: PJSObject; fs: PJSFunctionSpec): JSBool; **cdecl; external** SpiderMonkeyLib;

JS_DefineFunctions creates zero or more functions and makes them properties (methods) of a specified object, obj, as if by calling JS_DefineFunction repeatedly

- fs is a pointer to the first element of an array of JSFunctionSpec records
- This array is usually defined as a static global, with each record initialized using JS_FS or JS_FN.
- Each array element defines a single function: its name, the native Delphi implementation, the number of JavaScript arguments the function expects, and any function flags and property attributes.
- The last element of the array must contain 0 values

function JS_DefineObject(cx: PJSContext; obj: PJSObject; name: PCChar; clasp: PJSClass; proto: PJSObject; attrs: uintN): PJSObject; **cdecl; external** SpiderMonkeyLib;

Create an object that is a property of another object

function JS_DefineOwnProperty(cx: PJSContext; obj: PJSObject; id: jsid; descriptor: jsval; bp: JSBool): JSBool; **cdecl; external** SpiderMonkeyLib;

JS_DefineOwnProperty implements the ECMAScript defined function Object.defineProperty

- So the same restrictions apply as for that function (e.g. it is not possible to change a non-configurable property).
- descriptor is supposed to be a property descriptor, this means you need to create an object with properties such as value, writable, get or set.
- See Object.defineProperty for a list of possible fields.
- A getter or setter defined with this functions will be observable from JS code.

function JS_DefineProperties(cx: PJSContext; obj: PJSObject; ps: PJSPPropertySpec): JSBool; **cdecl; external** SpiderMonkeyLib;

JS_DefineProperties creates properties on a specified object, obj. Each property is defined as though by calling JS_DefinePropertyWithTinyld

function JS_DefineProperty(cx: PJSContext; obj: PJSObject; **const** name: PCChar; value: jsval; getter: JSPropertyOp; setter: JSStrictPropertyOp; attrs: uintN): JSBool; **cdecl; external** SpiderMonkeyLib;

JS_DefineProperty is the fundamental operation on which several more convenient, higher-level functions are based, including JS_DefineFunction, JS_DefineFunctions, JS_DefineProperties, JS_DefineConstDoubles, JS_DefineObject, and JS_InitClass.

- It differs from JS_SetProperty in that: it does not behave like ordinary property assignment in the JavaScript language; it allows the application to specify additional details (getter, setter, and attrs) governing the new property's behavior; it never calls a setter; it can call the JSClass.addProperty callback when JS_SetProperty would not, because it can replace an existing property.
- The parameters specify the new property's name, initial stored value, getter, setter, and property attributes (attrs).

function JS_DefinePropertyById(cx: PJSContext; obj: PJSObject; id: jsid; value: jsval; getter: JSPropertyOp; setter: JSStrictPropertyOp; attrs: uintN): JSBool; **cdecl; external** SpiderMonkeyLib;

JS_DefinePropertyById is the same as JS_DefineProperty but takes a jsid for the property name

function JS_DefineUCFunction(cx: PJSContext; obj: PJSObject; name: Pjschar; namelen: size_t; call: JSNative; nargs: uintN; attrs: uintN): PJSFunction; **cdecl; external** SpiderMonkeyLib;

Unicode version to create a native function

```
function JS_DefineUCProperty(cx: PJSContext; obj: PJSObject; const name: Pjschar;
namelen: size_t; const value: jsval; getter: JSPropertyOp; setter:
JSStrictPropertyOp; attrs: uintN): JSBool; cdecl; external SpiderMonkeyLib;
```

Define unicode property
 - see JS_DefineProperty for details

```
function JS_DeleteElement(cx: PJSContext; obj: PJSObject; index: jsint): JSBool;
cdecl; external SpiderMonkeyLib;
```

Removes a specified element or numeric property from an object

```
function JS_DeleteElement2(cx: PJSContext; obj: PJSObject; index: jsint; var rval:
jsval): JSBool; cdecl; external SpiderMonkeyLib;
```

Removes a specified element or numeric property from an object
 - this function also returns the deleted element

```
function JS_DeleteProperty(cx: PJSContext; obj: PJSObject; const name: PCChar):
JSBool; cdecl; external SpiderMonkeyLib;
```

Removes a specified property from an object

```
function JS_DeleteProperty2(cx: PJSContext; obj: PJSObject; const name: PCChar; var
rval: jsval): JSBool; cdecl; external SpiderMonkeyLib;
```

Removes a specified property from an object and return the property value

```
function JS_DeletePropertyById(cx: PJSContext; obj: PJSObject; id: jsid): JSBool;
cdecl; external SpiderMonkeyLib;
```

Removes a specified property from an object

```
function JS_DeletePropertyById2(cx: PJSContext; obj: PJSObject; id: jsid; var rval:
jsval): JSBool; cdecl; external SpiderMonkeyLib;
```

Removes a specified property from an object and return the property value

```
function JS_DeletePropertyStub(cx: PJSContext; var obj: PJSObject; var id: jsid;
succeeded: PJSBool): JSBool; cdecl; external SpiderMonkeyLib;
```

Default callback matching JSDeletePropertyOp prototype of JSClass

```
procedure JS_DestroyContext(cx: PJSContext); cdecl; external SpiderMonkeyLib;
```

Release a new JSContext

```
procedure JS_DestroyContextMaybeGC(cx: PJSContext); cdecl; external SpiderMonkeyLib;
```

Release a new JSContext with potential garbage collection

- this function may or may not perform garbage collection: the engine makes an educated guess as to whether enough memory would be reclaimed to justify the work

```
procedure JS_DestroyContextNoGC(cx: PJSContext); cdecl; external SpiderMonkeyLib;
```

Release a new JSContext without performing garbage collection

```
procedure JS_DestroyRuntime(rt: PJSRuntime); cdecl; external SpiderMonkeyLib;
```

Release the JavaScript runtime

```
function JS_DoubleIsInt32(d: jsdouble; var i: jsint): JSBool; cdecl; external
SpiderMonkeyLib;
```

Check if the given double is in fact a 31 bit signed integer

```
procedure JS_DropExceptionState(cx: PJSContext; state: PJSExceptionState); cdecl;
external SpiderMonkeyLib;
```

Drop a specified exception state

procedure JS_EndRequest(cx: PJSContext); cdecl; external SpiderMonkeyLib;

Indicates to the JS engine that the calling thread is leaving a region of code that may call into the JSAPI but does not block

function JS_EnterCompartment(cx: PJSContext; target: PJSObject): PJSCompartment; cdecl; external SpiderMonkeyLib;

Declare entering a safe compartment of the specified object

- NB: This API is infallible; a NULL return value does not indicate error

function JS_Enumerate(cx: PJSContext; obj: PJSObject): PJSIdArray; cdecl; external SpiderMonkeyLib;

JS_ClearScope - OBSOLETE JS_Enumerate gets the ids of all own properties of the specified object, obj,

- that have the JSPROP_ENUMERATE attribute. This calls obj's JSClass.enumerate hook.

- On success, JS_Enumerate returns a pointer to the first element of an array of property IDs.

- The application must free this array using JS_DestroyIdArray. On error or exception, JS_Enumerate returns NULL.

- Warning: The property ids in the returned JSIdArray are subject to garbage collection.

- Therefore a program that loops over the property ids must either root them all, ensure that the properties are not deleted (in a multithreaded program this requires even greater care), or ensure that garbage collection does not occur

function JS_EnumerateResolvedStandardClasses(cx: PJSContext; obj: PJSObject; ida: PJSIdArray): PJSIdArray; cdecl; external SpiderMonkeyLib;

Enumerate any already-resolved standard class ids into ida, or into a new JSIdArray if ida is null

- Return the augmented array on success, null on failure with ida (if it was non-null on entry) destroyed

function JS_EnumerateStub(cx: PJSContext; var obj: PJSObject): JSBool; cdecl; external SpiderMonkeyLib;

Default callback matching JSEnumerateOp prototype of JSClass

function JS_ErrorFromException(cx: PJSContext; v: jsval): PJSErrorReport; cdecl; external SpiderMonkeyLib;

Retrieve an error report from an exception object

- If the given value is an exception object that originated from an error, the exception will contain an error report struct, and this API will return the address of that struct. Otherwise, it returns NULL.

- The lifetime of the error report struct that might be returned is the same as the lifetime of the exception object

function JS_EvaluateScript(cx: PJSContext; obj: PJSObject; bytes: PCChar; length: uintN; filename: PCChar; lineno: uintN; var rval: jsval): JSBool; cdecl; external SpiderMonkeyLib;

JS_EvaluateScript compiles and executes a script in the specified scope (obj)

- Warning: this function perform conversion from Ansi to unicode (internally SM is unicode), so for best performance convert your scripts from RawUTF8/Ansi to unicode using SynCommons Utf8DecodeToRawUnicode / WinAnsiConvert.AnsiToRawUnicode and use JS_EvaluateUCScript()

- For details about scope see JS_ExecuteScript

- We recomend to use JSOPTION_VAROBJFIX and some of quality tools like jslint/jshint - jshint is preferred, because it support ECMA5 (let strict and so on), jslint - only ECMA3

- to avoid declare variables in global use var x = 10 instead of x = 10

```
function JS_evaluateUCInStackFrame(cx: PJSContext; raw: JSuintptr; chars: Pjschar;
length: size_t; filename: PCChar; lineno: uintN; var rval: jsval): boolean; cdecl;
external SpiderMonkeyLib;
```

Compile and execute a script in stack frame with raw identifier (obj)

```
function JS_EvaluateUCScript(cx: PJSContext; obj: PJSObject; chars: pjschar; length:
uintN; filename: PCChar; lineno: uintN; var rval: jsval): JSBool; cdecl; external
SpiderMonkeyLib;
```

Unicode version of JS_EvaluateScript

- For details about scope see JS_ExecuteScript
- remember length is "the length of src, in characters" not in bytes for pjschar = PRawUnicode use length = (length(RawUnicode) shr 1)

```
function JS_ExecuteScript(cx: PJSContext; obj: PJSObject; scriptObj: PJSObject; var
rval: jsval): JSBool; cdecl; external SpiderMonkeyLib;
```

Execute a compiled script.

- On success, *rval receives the value from the last executed expression statement processed in the script
- NB: JS_ExecuteScript and the JS_Evaluate*Script* quadruplets use the obj parameter as the initial scope chain header, the 'this' keyword value, and the variables object (ECMA parlance for where 'var' and 'function' bind names) of the execution context for script.
- Using obj as the variables object is problematic if obj's parent (which is the scope chain link; see JS_SetParent and JS_NewObject) is not null: in this case, variables created by 'var x = 0', e.g., go in obj, but variables created by assignment to an unbound id, 'x = 0', go in the last object on the scope chain linked by parent.
- ECMA calls that last scoping object the "global object", but note that many embeddings have several such objects. ECMA requires that "global code" be executed with the variables object equal to this global object. But these JS API entry points provide freedom to execute code against a "sub-global", i.e., a parented or scoped object, in which case the variables object will differ from the last object on the scope chain, resulting in confusing and non-ECMA explicit vs. implicit variable creation.
- Caveat embedders: unless you already depend on this buggy variables object binding behavior, you should call JS_SetOptions(cx, JSOPTION_VAROBJFIX) or JS_SetOptions(cx, JS_GetOptions(cx) | JSOPTION_VAROBJFIX) -- the latter if someone may have set other options on cx already -- for each context in the application, if you pass parented objects as the obj parameter, or may ever pass such objects in the future.
- Why a runtime option? The alternative is to add six or so new API entry points with signatures matching the following six, and that doesn't seem worth the code bloat cost. Such new entry points would probably have less obvious names, too, so would not tend to be used. The JS_SetOption call, OTOH, can be more easily hacked into existing code that does not depend on the bug; such code can continue to use the familiar JS_EvaluateScript, etc., entry points.

```
procedure JS_FlushCaches(cx: PJSContext); cdecl; external SpiderMonkeyLib;
```

Flush the code cache for the current thread

- The operation might be delayed if the cache cannot be flushed currently because native code is currently executing.

```
function JS_FreezeObject(cx: PJSContext; obj: PJSObject): JSBool; cdecl; external
SpiderMonkeyLib;
```

Freezes an object; see ES5's Object.freeze(obj) method

procedure JS_GC(rt: PJSRuntime); cdecl; external SpiderMonkeyLib;

Launch the GarbageCollection process of the given execution RunTime

function JS_GetArrayBufferByteLength(obj: PJSObject): uint32; cdecl; external SpiderMonkeyLib;

Return the available byte length of an array buffer

- obj must have passed a JS_IsArrayBufferObject test, or somehow be known that it would pass such a test: it is an ArrayBuffer or a wrapper of an ArrayBuffer, and the unwrapping will succeed

function JS_GetArrayBufferData(obj: PJSObject): Puint8Vector; cdecl; external SpiderMonkeyLib;

Return a pointer to an array buffer's data

- The buffer is still owned by the array buffer object, and should not be modified on another thread. The returned pointer is stable across GCs
 - obj must have passed a JS_IsArrayBufferObject test, or somehow be known that it would pass such a test: it is an ArrayBuffer or a wrapper of an ArrayBuffer, and the unwrapping will succeed.

function JS_GetArrayBufferViewBuffer(obj: PJSObject): PJSObject; cdecl; external SpiderMonkeyLib;

Return the ArrayBuffer underlying an ArrayBufferView

- If the buffer has been neutered, this will still return the neutered buffer.
 - obj must be an object that would return true for JS_IsArrayBufferViewObject()

function JS_GetArrayBufferViewByteLength(obj: PJSObject): uint32; cdecl; external SpiderMonkeyLib;

More generic name for JS_GetTypedArrayByteLength to cover DataViews as well

function JS_GetArrayBufferViewData(obj: PJSObject): Pointer; cdecl; external SpiderMonkeyLib;

Return a pointer to the start of the data referenced by any typed array

- The data is still owned by the typed array, and should not be modified on another thread
 - obj must have passed a JS_Is*Array test, or somehow be known that it would pass such a test: it is a typed array or a wrapper of a typed array, and the unwrapping will succeed
 - Prefer the type-specific versions when possible

function JS_GetArrayBufferViewType(obj: PJSObject): JSArrayBufferViewType; cdecl; external SpiderMonkeyLib;

Get the type of elements in a typed array, or jsabTYPE_DATAVIEW if a DataView

function JS_GetArrayLength(cx: PJSContext; obj: PJSObject; var length: jsuint): JSBool; cdecl; external SpiderMonkeyLib;

Retrieve the length of an object array

function JS_GetClass(obj: PJSObject): PJSClass; cdecl; external SpiderMonkeyLib name 'JS_GetClass';

Retrieve the JSClass of a given object

- JS_GetClass() expects only one parameter in every case

function JS_GetContextPrivate(cx: PJSContext): Pointer; cdecl; external SpiderMonkeyLib;

Read access to a JSContext field for application-specific data

function JS_GetDebugMode(cx: PJSContext): JSBool; cdecl; external SpiderMonkeyLib;

Check if the JavaScript debugging mode is set for a given context

```
function JS_GetElement(cx: PJSContext; obj: PJSObject; index: jsint; var vp: jsval): JSBool; cdecl; external SpiderMonkeyLib;
```

Find a specified numeric property of an object and return its current value

```
function JS_GetFloat32ArrayData(obj: PJSObject): Pfloat32Vector; cdecl; external SpiderMonkeyLib;
```

Return a pointer to the start of the data referenced by a typed 32 bit float (single) array

- The data is still owned by the typed array, and should not be modified on another thread
- obj must have passed a JS_Is*Array test, or somehow be known that it would pass such a test: it is a typed array or a wrapper of a typed array, and the unwrapping will succeed

```
function JS_GetFloat64ArrayData(obj: PJSObject): Pfloat64Vector; cdecl; external SpiderMonkeyLib;
```

Return a pointer to the start of the data referenced by a typed 64 bit float (double) array

- The data is still owned by the typed array, and should not be modified on another thread
- obj must have passed a JS_Is*Array test, or somehow be known that it would pass such a test: it is a typed array or a wrapper of a typed array, and the unwrapping will succeed

```
function JS_GetFunctionArgumentCount(cx: PJSContext; fun: PJSFunction): uint; cdecl; external SpiderMonkeyLib;
```

Retrieves how many arguments expect a function

```
function JS_GetFunctionArity(fun: PJSFunction): uint16; cdecl; external SpiderMonkeyLib;
```

Return the arity (params count) for a specified function

```
function JS_GetFunctionFlags(fun: PJSFunction): uintN; cdecl; external SpiderMonkeyLib;
```

Return JSFUN_ flags for a specified function*

```
function JS_GetFunctionId(fun: PJSFunction): PJSSString; cdecl; external SpiderMonkeyLib;
```

Return the function's identifier as a JSString, or null if fun is unnamed.

- The returned string lives as long as fun, so you don't need to root a saved
- reference to it if fun is well-connected or rooted, and provided you bound
- the use of the saved reference by fun's lifetime.

```
function JS_GetFunctionLocalNameArray(cx: PJSContext; fun: PJSFunction; var markp: pointer): PJSuintptr; cdecl; external SpiderMonkeyLib;
```

Retrieve the local name array information of a given function

```
function JS_GetFunctionObject(fun: PJSFunction): PJSObject; cdecl; external SpiderMonkeyLib;
```

Retrieves the object for a specified function.

- fun should be a native function or JSAPI-compiled function! (result of a call to JS_CompileFunction, JS_CompileUCFunction)

```
function JS_GetFunctionScript(cx: PJSContext; fun: PJSFunction): PJSScript; cdecl; external SpiderMonkeyLib;
```

Cast a JavaScript function into a script instance

function JS_GetInt16ArrayData(obj: PJSObject): Pint16Vector; cdecl; external SpiderMonkeyLib;

Return a pointer to the start of the data referenced by a typed 16 bit signed integer array
- The data is still owned by the typed array, and should not be modified on another thread
- obj must have passed a JS_Is*Array test, or somehow be known that it would pass such a test: it is a typed array or a wrapper of a typed array, and the unwrapping will succeed

function JS_GetInt32ArrayData(obj: PJSObject): Pint32Vector; cdecl; external SpiderMonkeyLib;

Return a pointer to the start of the data referenced by a typed 32 bit signed integer array
- The data is still owned by the typed array, and should not be modified on another thread
- obj must have passed a JS_Is*Array test, or somehow be known that it would pass such a test: it is a typed array or a wrapper of a typed array, and the unwrapping will succeed

function JS_GetInt8ArrayData(obj: PJSObject): Pint8Vector; cdecl; external SpiderMonkeyLib;

Return a pointer to the start of the data referenced by a typed 8 bit signed integer array
- The data is still owned by the typed array, and should not be modified on another thread
- obj must have passed a JS_Is*Array test, or somehow be known that it would pass such a test: it is a typed array or a wrapper of a typed array, and the unwrapping will succeed

function JS_GetInternedStringChars(str: PJSString): Pjschar; cdecl; external SpiderMonkeyLib;

See JS_InternedString for details about what InternedString is.

function JS_GetObjectAsArrayBuffer(obj: PJSObject; var length: uint32; var Data: Puint8Vector): PJSObject; cdecl; external SpiderMonkeyLib;

Unwrap an object as its raw binary memory buffer
- Return nil without throwing any exception if the object cannot be viewed as the correct typed array, or the typed array object on success, filling both out parameters

function JS_GetObjectAsArrayBufferView(obj: PJSObject; var length: uint32; var Data: Puint8Vector): PJSObject; cdecl; external SpiderMonkeyLib;

Unwrap an object as its raw binary memory buffer
- Return nil without throwing any exception if the object cannot be viewed as the correct typed array, or the typed array object on success, filling both out parameters

function JS_GetObjectAsFloat32Array(obj: PJSObject; var length: uint32; var Data: Pfloat32Vector): PJSObject; cdecl; external SpiderMonkeyLib;

Unwrap 32 bit float (single) typed array into direct memory buffer
- Return nil without throwing any exception if the object cannot be viewed as the correct typed array, or the typed array object on success, filling both out parameters

function JS_GetObjectAsFloat64Array(obj: PJSObject; var length: uint32; var Data: Pfloat64Vector): PJSObject; cdecl; external SpiderMonkeyLib;

Unwrap 64 bit float (double) typed array into direct memory buffer
- Return nil without throwing any exception if the object cannot be viewed as the correct typed array, or the typed array object on success, filling both out parameters

function JS_GetObjectAsInt16Array(obj: PJSObject; var length: uint32; var Data: Pint16Vector): PJSObject; cdecl; external SpiderMonkeyLib;

Unwrap 16 bit signed integer typed array into direct memory buffer
- Return nil without throwing any exception if the object cannot be viewed as the correct typed array, or the typed array object on success, filling both out parameters

function JS_GetObjectAsInt32Array(obj: PJSObject; var length: uint32; var Data: Pint32Vector): PJSObject; cdecl; external SpiderMonkeyLib;

Unwrap 32 bit signed integer typed array into direct memory buffer

- Return nil without throwing any exception if the object cannot be viewed as the correct typed array, or the typed array object on success, filling both out parameters

function JS_GetObjectAsInt8Array(obj: PJSObject; var length: uint32; var Data: Pint8Vector): PJSObject; cdecl; external SpiderMonkeyLib;

Unwrap 8 bit signed integer typed array into direct memory buffer

- Return nil without throwing any exception if the object cannot be viewed as the correct typed array, or the typed array object on success, filling both out parameters

function JS_GetObjectAsUint16Array(obj: PJSObject; var length: uint32; var Data: Puint16Vector): PJSObject; cdecl; external SpiderMonkeyLib;

Unwrap 16 bit unsigned integer typed array into direct memory buffer

- Return nil without throwing any exception if the object cannot be viewed as the correct typed array, or the typed array object on success, filling both out parameters

function JS_GetObjectAsUint32Array(obj: PJSObject; var length: uint32; var Data: Puint32Vector): PJSObject; cdecl; external SpiderMonkeyLib;

Unwrap 32 bit unsigned integer typed array into direct memory buffer

- Return nil without throwing any exception if the object cannot be viewed as the correct typed array, or the typed array object on success, filling both out parameters

function JS_GetObjectAsUint8Array(obj: PJSObject; var length: uint32; var Data: Puint8Vector): PJSObject; cdecl; external SpiderMonkeyLib;

Unwrap 8 bit unsigned integer typed array into direct memory buffer

- Return nil without throwing any exception if the object cannot be viewed as the correct typed array, or the typed array object on success, filling both out parameters

function JS_GetObjectAsUint8ClampedArray(obj: PJSObject; var length: uint32; var Data: Puint8Vector): PJSObject; cdecl; external SpiderMonkeyLib;

Unwrap 8 bit unsigned integer typed array into direct memory buffer

- Return nil without throwing any exception if the object cannot be viewed as the correct typed array, or the typed array object on success, filling both out parameters

function JS_GetObjectId(cx: PJSContext; obj: PJSObject; idp: Pjsid): JSBool; cdecl; external SpiderMonkeyLib;

Get a unique identifier for obj, good for the lifetime of obj (even if it is moved by a copying GC)

- Return false on failure (likely out of memory), and true with idp containing the unique id on success

function JS_GetOperationCallback(cx: PJSContext): JSOperationCallback; cdecl; external SpiderMonkeyLib;

Retrieve the callback function that is automatically called periodically while JavaScript code runs in the given execution context

function JS_GetPendingException(cx: PJSContext; var vp: jsval): JSBool; cdecl; external SpiderMonkeyLib;

Get the current exception being thrown within a context

function JS_GetProperty(cx: PJSContext; obj: PJSObject; **const** name: PCChar; **var** vp: jsval): JSBool; **cdecl; external** SpiderMonkeyLib;

Finds a specified property by name and retrieves its value

- JS_GetProperty examines a specified JS object obj and its prototype chain for a property with the specified name
- It behaves like the JavaScript expression obj[name].

function JS_GetPropertyAttributes(cx: PJSContext; obj: PJSObject; **const** name: PCChar; **var** attrsp: uintN; **var** foundp: JSBool): JSBool; **cdecl; external** SpiderMonkeyLib;

Determine the attributes (JSPROP_ flags) of a property on a given object*

- If the object does not have a property by that name, *foundp will be JS_FALSE and the value of *attrsp is undefined.

function JS_GetPropertyById(cx: PJSContext; obj: PJSObject; id: jsid; **var** vp: jsval): JSBool; **cdecl; external** SpiderMonkeyLib;

Finds a specified property by jsid and retrieves its value

- JS_GetProperty examines a specified JS object obj and its prototype chain for a property with the specified jsid

function JS_GetPropertyByIdDefault(cx: PJSContext; obj: PJSObject; id: jsid; def: jsval; **var** vp: jsval): JSBool; **cdecl; external** SpiderMonkeyLib;

Finds a specified property by jsid and retrieves its value or a default value

function JS_GetPropertyDescArray(cx: PJSContext; obj: PJSObject; **var** pda: JSPropertyDescArray): JSBool; **cdecl; external** SpiderMonkeyLib;

Retrieve the description of a given JavaScript object property

function JS_GetPropertyDescriptorById(cx: PJSContext; obj: PJSObject; id: jsid; flags: uintN; objp: PPJSObject; desc: PJSPPropertyDescriptor): JSBool; **cdecl; external** SpiderMonkeyLib;

Finds a specified property of an object and gets a detailed description of that property

function JS_GetReservedSlot(cx: PJSContext; obj: PJSObject; **index**: uint32; vp: jsval): JSBool; **cdecl; external** SpiderMonkeyLib;

Read access an object's reserved slots

- If a JSClass has JSCCLASS_HAS_RESERVED_SLOTS(n) in its flags, with n > 0, or has a non-null JSCClass.reserveSlots callback, then objects of that class have n reserved slots in which the application may store data. These fields are not directly exposed to scripts.
- Reserved slots may contain any jsvalue, and the garbage collector will hold the value alive as long as the object itself is alive
- Reserved slots may also contain private values to store pointer values (whose lowest bit is 0) or uint32_t, when non-JavaScript values must be stored; the garbage collector ignores such values when it sees them.
- Note that private values must not be exposed directly to JavaScript. It's only legal to store and retrieve data from private values. They cannot be returned from functions, set as properties on objects, embedded in JavaScript arrays, and so on
- New objects' reserved slots are initialized to undefined.
- TODO - collision in MSDN no parameter vp: jsval but in jsapi.h is!

function JS_GetRuntime(cx: PJSContext): PJSRuntime; **cdecl; external** SpiderMonkeyLib;

Retrieves a pointer to the JSRuntime with which a specified JSContext, is associated

```
function JS_GetScriptBaseLineNumber(cx: PJSContext; script: PJSScript): uint; cdecl;  
external SpiderMonkeyLib;
```

Retrieve the base line number of a given script

```
function JS_GetScriptLineExtent(cx: PJSContext; script: PJSScript): uint; cdecl;  
external SpiderMonkeyLib;
```

Retrieve the extent of a given script

```
function JS_GetStringCharsAndLength(cx: PJSContext; str: PJSStr; var len: size_t):  
pjschar; cdecl; external SpiderMonkeyLib;
```

Retrieve a pointer to the 16-bit values that make up a given string.

- The array is not necessarily null-terminated. To get the length of the string, use JS_GetStringLength.
- The program must not modify the array. If it does, the behavior is undefined.
- The content of a JS string is not guaranteed to be valid UTF-16. It may contain surrogate code units that aren't properly paired. It may also contain zeroes.
- The array returned by this function remains valid as long as str is valid. (Eventually, str becomes unreachable, the garbage collector collects it, and the array is freed by the system.)

```
function JS_GetStringCharsZ(cx: PJSContext; str: PJSStr): pjschar; cdecl; external  
SpiderMonkeyLib;
```

Is the same as JS_GetStringChars except that it always returns either a null-terminated string or NULL, indicating out-of-memory

- help provided at

https://developer.mozilla.org/en-US/docs/SpiderMonkey/JSAPI_Reference/JS_GetStringChars

function JS_GetStringLength(str: PJSSString): size_t; cdecl; external SpiderMonkeyLib;

*TODO - no description provided in MSDN extern JS_PUBLIC_API(JSBool)
 JS_StringEqualsAscii(JSContext *cx, JSString *str, const char *asciiBytes, JSBool *match);*
*extern JS_PUBLIC_API(size_t) JS_PutEscapedString(JSContext *cx, char *buffer, size_t size,
 JSString *str, char quote);*
*extern JS_PUBLIC_API(JSBool) JS_FileEscapedString(FILE *fp, JSString *str, char quote); Extracting
 string characters and length.*

- While getting the length of a string is infallible, getting the chars can fail. As indicated by the lack of a JSContext parameter, there are two special cases where getting the chars is infallible:
- The first case is interned strings, i.e., strings from JS_InternString or JSID_TO_STRING(id), using JS_GetInternedStringChars//.
- The second case is "flat" strings that have been explicitly prepared in a fallible context by JS_FlattenString. To catch errors, a separate opaque JSFlatString type is returned by JS_FlattenString and expected by JS_GetFlatStringChars. Note, though, that this is purely a syntactic distinction: the input and output of JS_FlattenString are the same actual GC-thing so only one needs to be rooted. If a JSString is known to be flat, JS_ASSERT_STRING_IS_FLAT can be used to make a debug-checked cast. Example: // in a fallible context JSFlatString *fstr = JS_FlattenString(cx, str); if (!fstr) return JS_FALSE; JS_ASSERT(fstr == JS_ASSERT_STRING_IS_FLAT(str));
- // in an infallible context, for the same 'str' const jschar *chars = JS_GetFlatStringChars(fstr)
 JS_ASSERT(chars);

The CharsZ APIs guarantee that the returned array has a null character at chars[length]. This can require additional copying so clients should prefer APIs without CharsZ if possible. The infallible functions also return null-terminated arrays. (There is no additional cost or non-Z alternative for the infallible functions, so 'Z' is left out of the identifier.) Reports the length, in 16-bit code units, of the string str.

- This is the same as the length property of the string.
- This is the same as the length of the array returned by JS_GetStringChars, in jschars (not bytes).
- Because some Unicode characters are represented using two 16-bit code units, the result is not necessarily the same as the number of Unicode characters in the string.

function JS_GetTypedArrayByteLength(obj: PJSObject): uint32; cdecl; external SpiderMonkeyLib;

Return the byte length of a typed array
 - obj must have passed a JS_IsTypedArrayObject/JS_Is*Array test, or somehow be known that it would pass such a test: it is a typed array or a wrapper of a typed array, and the unwrapping will succeed

function JS_GetTypedArrayByteOffset(obj: PJSObject): uint32; cdecl; external SpiderMonkeyLib;

Return the byte offset from the start of an array buffer to the start of a typed array view
 - obj must have passed a JS_IsTypedArrayObject/JS_Is*Array test, or somehow be known that it would pass such a test: it is a typed array or a wrapper of a typed array, and the unwrapping will succeed.

```
function JS_GetTypedArrayLength(obj: PJSObject): uint32; cdecl; external SpiderMonkeyLib;
```

Return the number of elements in a typed array

- obj must have passed a JS_IsTypedArrayObject/JS_Is*Array test, or somehow be known that it would pass such a test: it is a typed array or a wrapper of a typed array, and the unwrapping will succeed.

```
function JS_GetTypeName(cx: PJSContext; _type: JSType): PCChar; cdecl; external SpiderMonkeyLib;
```

Determines the JS data type name of a JS value

```
function JS_GetUCPropertyAttributes(cx: PJSContext; obj: PJSObject; const name: Pjschar; namelen: size_t; var attrsp: uintN; var foundp: JSBool): JSBool; cdecl; external SpiderMonkeyLib;
```

Determine the attributes (JSPROP_ flags) of a property on a given object*

- If the object does not have a property by that name, *foundp will be

- JS_FALSE and the value of *attrsp is undefined.

```
function JS_GetUint16ArrayData(obj: PJSObject): Puint16Vector; cdecl; external SpiderMonkeyLib;
```

Return a pointer to the start of the data referenced by a typed 16 bit unsigned integer array

- The data is still owned by the typed array, and should not be modified on another thread

- obj must have passed a JS_Is*Array test, or somehow be known that it would pass such a test: it is a typed array or a wrapper of a typed array, and the unwrapping will succeed

```
function JS_GetUint32ArrayData(obj: PJSObject): Puint32Vector; cdecl; external SpiderMonkeyLib;
```

Return a pointer to the start of the data referenced by a typed 32 bit unsigned integer array

- The data is still owned by the typed array, and should not be modified on another thread

- obj must have passed a JS_Is*Array test, or somehow be known that it would pass such a test: it is a typed array or a wrapper of a typed array, and the unwrapping will succeed

```
function JS_GetUint8ArrayData(obj: PJSObject): Puint8Vector; cdecl; external SpiderMonkeyLib;
```

Return a pointer to the start of the data referenced by a typed 8 bit unsigned integer array

- The data is still owned by the typed array, and should not be modified on another thread

- obj must have passed a JS_Is*Array test, or somehow be known that it would pass such a test: it is a typed array or a wrapper of a typed array, and the unwrapping will succeed

```
function JS_GetUint8ClampedArrayData(obj: PJSObject): Puint8Vector; cdecl; external SpiderMonkeyLib;
```

Return a pointer to the start of the data referenced by a typed 8 bit unsigned integer array

- The data is still owned by the typed array, and should not be modified on another thread

- obj must have passed a JS_Is*Array test, or somehow be known that it would pass such a test: it is a typed array or a wrapper of a typed array, and the unwrapping will succeed

```
function JS_GetVersion(cx: PJSContext): JSVersion; cdecl; external SpiderMonkeyLib;
```

Retrieve the JavaScript version number used within a specified executable script context

```
function JS_HasElement(cx: PJSContext; obj: PJSObject; index: jsint; var foundp: JSBool): JSBool; cdecl; external SpiderMonkeyLib;
```

Check if an object array has an element at the supplied index

function JS_HasProperty(cx: PJSContext; obj: PJSObject; **const** name: PCChar; **var** found: JSBool): JSBool; **cdecl; external** SpiderMonkeyLib;

JS_HasProperty searches an object, obj, and its prototype chain, for a property with the specified name

- It behaves like the JavaScript expression name in obj

function JS_HasPropertyById(cx: PJSContext; obj: PJSObject; id: jsid; **var** found: JSBool): JSBool; **cdecl; external** SpiderMonkeyLib;

JS_HasProperty searches an object, obj, and its prototype chain, for a property with the specified jsid

function JS_HasUCProperty(cx: PJSContext; obj: PJSObject; **const** name: Pjschar; namelen: size_t; **var** found: JSBool): JSBool; **cdecl; external** SpiderMonkeyLib;

Same as JS_HasProperty but unicode

function JS_InitClass(cx: PJSContext; obj: PJSObject; parent_proto: PJSObject; clasp: PJSClass; _constructor: JSNative; nargs: uintN; ps: PJSPPropertySpec; fs: PJSPFunctionSpec; static_ps: PJSPPropertySpec; static_fs: PJSPFunctionSpec): PJSObject; **cdecl; external** SpiderMonkeyLib;

Make a JSClass accessible to JavaScript code by creating its prototype, constructor, properties, and functions.

- see https://developer.mozilla.org/en-US/docs/SpiderMonkey/JSAPI_Reference/JS_InitClass

function JS_InitStandardClasses(cx: PJSContext; obj: PJSObject): JSBool; **cdecl; external** SpiderMonkeyLib;

*Extern JS_PUBLIC_API(JSObject *) JS_GetGlobalObject(JSContext *cx);*

*extern JS_PUBLIC_API(void) JS_SetGlobalObject(JSContext *cx, JSObject *obj); initializes the built-in JavaScript global properties.*

- These include all the standard ECMAScript global properties defined in ECMA 262-3 §15: Array, Boolean, Date, decodeURI, decodeURIComponent, encodeURI, encodeURIComponent, Error, eval, EvalError, Function, Infinity, isNaN, isFinite, Math, NaN, Number, Object, parseInt, parseFloat, RangeError, ReferenceError, RegExp, String, SyntaxError, TypeError, undefined, and URIError
 - and set obj as a global object for cx!

function JS_InternJSString(cx: PJSContext; str: PJSString): PJSString; **cdecl; external** SpiderMonkeyLib;

Get an interned string from a given null-terminated C string

function JS_InternString(cx: PJSContext; s: PCChar): PJSString; **cdecl; external** SpiderMonkeyLib;

Get an interned string from a given text buffer — that is, a JSString that is protected from GC and automatically shared with other code that needs a JSString with the same value

- JS_InternUCString and JS_InternUCStringN are the Unicode versions of the function.
 - Each JSRuntime keeps a table of all existing interned strings. If an interned string already exists with the desired value, these functions return the existing string. Otherwise a new string is created and added to the table.
 - Strings created with these functions are protected from garbage collection for the lifetime of the JSRuntime
 - On success, these functions return a pointer to the interned string.
 - Otherwise they report an error and return NULL.

```
function JS_InternUCStringN(cx: PJSContext; const s: pjschar; len: size_t):  
PJSString; cdecl; external SpiderMonkeyLib;
```

Unicode version of JS_InternString (faster)

```
function JS_IsAboutToBeFinalized(obj: PPJSObject): JSBool; cdecl; external  
SpiderMonkeyLib;
```

JS_IsAboutToBeFinalized() checks if the given object is going to be finalized at the end of the current GC

- When called outside of the context of a GC, this function will return false
- Typically this function is used on weak references, where the reference should be nulled out or destroyed if the given object is about to be finalized
- The argument to JS_IsAboutToBeFinalized is an in-out param: when the function returns false, the object being referenced is still alive, but the garbage collector might have moved it. In this case, the reference passed to JS_IsAboutToBeFinalized will be updated to the object's new location
- Callers of this method are responsible for updating any state that is dependent on the object's address. For example, if the object's address is used as a key in a hashtable, then the object must be removed and re-inserted with the correct hash

```
function JS_IsArrayBufferObject(obj: PJSObject): JSBool; cdecl; external  
SpiderMonkeyLib;
```

Check whether obj supports the JS_GetArrayBuffer APIs*

- Note that this may return false if a security wrapper is encountered that denies the unwrapping
- If this test succeeds, then it is safe to call the various accessor JSAPI calls

```
function JS_IsArrayBufferViewObject(obj: PJSObject): JSBool; cdecl; external  
SpiderMonkeyLib;
```

Check whether obj supports JS_GetArrayBufferView APIs*

- Note that this may return false if a security wrapper is encountered that denies the unwrapping.
- if this test or one of the JS_Is*Array tests succeeds, then it is safe to call the dedicated ArrayBufferView accessor JSAPI calls

```
function JS_IsArrayObject(cx: PJSContext; obj: PJSObject): JSBool; cdecl; external  
SpiderMonkeyLib;
```

Check if the supplied object is an array

```
function JS_IsConstructing(cx: PJSContext; const vp: PjsvalVector): boolean;
```

JS_IsConstructing must be called from within a native given the native's original cx and vp arguments

- If JS_IsConstructing is true, JS_THIS must not be used; the constructor should construct and return a new object
- Otherwise, the native is called as an ordinary function and JS_THIS may be used

```
function JS_IsExceptionPending(cx: PJSContext): JSBool; cdecl; external  
SpiderMonkeyLib;
```

Determine whether an exception is pending in the JS engine.

- JS_IsExceptionPending returns JS_TRUE if an exception has been thrown in the context cx and the exception has not yet been caught or cleared. Otherwise, it returns JS_FALSE
- This can be used from JSNative functions which call JS code to determine if the called JS code threw an exception or not.

```
function JS_IsExtensible(obj: PJSObject): JSBool; cdecl; external SpiderMonkeyLib;  
Queries the [[Extensible]] property of the object.
```

function JS_IsFloat32Array(obj: PJSObject): JSBool; cdecl; external SpiderMonkeyLib;
Test for specific 32 bit float (single) typed array types (ArrayBufferView subtypes)

function JS_IsFloat64Array(obj: PJSObject): JSBool; cdecl; external SpiderMonkeyLib;
Test for specific 64 bit float (double) typed array types (ArrayBufferView subtypes)

function JS_IsInRequest(cx: PJSContext): JSBool; cdecl; external SpiderMonkeyLib;
OBSOLETE procedure JS_YieldRequest(cx: PJSContext); cdecl; external SpiderMonkeyLib; OBSOLETE type OBSOLETE jsrefcount = JSInt32; OBSOLETE function JS_SuspendRequest(cx: PJSContext): jsrefcount; cdecl; external SpiderMonkeyLib; OBSOLETE procedure JS_ResumeRequest(cx: PJSContext; saveDepth: jsrefcount); cdecl; external SpiderMonkeyLib; checked is is within a code region protected by JS_BeginRequest()

function JS_IsInt16Array(obj: PJSObject): JSBool; cdecl; external SpiderMonkeyLib;
Test for specific 16 bit signed integer typed array types (ArrayBufferView subtypes)

function JS_IsInt32Array(obj: PJSObject): JSBool; cdecl; external SpiderMonkeyLib;
Test for specific 32 bit signed integer typed array types (ArrayBufferView subtypes)

function JS_IsInt8Array(obj: PJSObject): JSBool; cdecl; external SpiderMonkeyLib;
Test for specific 8 bit signed integer typed array types (ArrayBufferView subtypes)

function JS_IsRunning(cx: PJSContext): JSBool; cdecl; external SpiderMonkeyLib;
Determines if a script or function is currently executing in a specified JSContext, cx
 - If a script is executing, JS_IsRunning returns JS_TRUE
 - Otherwise it returns JS_FALSE.

function JS_IsTypedArrayObject(obj: PJSObject): JSBool; cdecl; external SpiderMonkeyLib;
Check whether obj supports JS_GetTypedArray APIs*
 - Note that this may return false if a security wrapper is encountered that denies the unwrapping.
 - if this test or one of the JS_Is*Array tests succeeds, then it is safe to call the dedicated accessor JSAPI calls

function JS_IsUint16Array(obj: PJSObject): JSBool; cdecl; external SpiderMonkeyLib;
Test for specific 16 bit unsigned integer typed array types (ArrayBufferView subtypes)

function JS_IsUint32Array(obj: PJSObject): JSBool; cdecl; external SpiderMonkeyLib;
Test for specific 32 bit unsigned integer typed array types (ArrayBufferView subtypes)

function JS_IsUint8Array(obj: PJSObject): JSBool; cdecl; external SpiderMonkeyLib;
Test for specific 8 bit unsigned integer typed array types (ArrayBufferView subtypes)

function JS_IsUint8ClampedArray(obj: PJSObject): JSBool; cdecl; external SpiderMonkeyLib;
Test for specific 8 bit unsigned integer typed array types (ArrayBufferView subtypes)

procedure JS_LeaveCompartment(cx: PJSContext; oldCompartment: PJSCompartment); cdecl; external SpiderMonkeyLib;
Declare leaving the safe compartment of the specified object

function JS_LineNumberToPC(cx: PJSContext; script: PJSScript; lineno: uintn): pjsbytecode; cdecl; external SpiderMonkeyLib;
Retrieve the byte code item position corresponding to a script line number

function JS_LocalNameToAtom(w: JSuintptr): PJSAAtom; cdecl; external SpiderMonkeyLib;

Convert a local name into a JavaScript atom

function JS_LookupElement(cx: PJSContext; obj: PJSObject; index: jsint; var vp: jsval): JSBool; cdecl; external SpiderMonkeyLib;

Determine if a specified numeric property exists

- examines a specified JavaScript object, obj, for a numeric property numbered index
- On success, *vp receives the stored value of the property, if any.

function JS_LookupProperty(cx: PJSContext; obj: PJSObject; name: PCChar; var vp: jsval): JSBool; cdecl; external SpiderMonkeyLib;

Determine if a specified property exists, according to its name

- On success, *vp receives the stored value of the property, if any.

function JS_LookupPropertyById(cx: PJSContext; obj: PJSObject; id: jsid; var vp: jsval): JSBool; cdecl; external SpiderMonkeyLib;

Determine if a specified property exists, according to its jsid

function JS_LookupUCProperty(cx: PJSContext; obj: PJSObject; const name: Pjschar; namelen: size_t; var vp: jsval): JSBool; cdecl; external SpiderMonkeyLib;

Determine if a specified property exists

- On success, *vp receives the stored value of the property, if any.

procedure JS_MaybeGC(cx: PJSContext); cdecl; external SpiderMonkeyLib;

Check if it would be worth it to launch the GarbageCollection process of the given execution RunTime, in the given context

- this function is a no-op if there is nothing interesting to garbage

function JS_New(cx: PJSContext; ctor: PJSObject; argc: uintN; argv: Pjsval): PJSObject; cdecl; external SpiderMonkeyLib;

As of SpiderMonkey 1.8.8, JS_ConstructObject and JS_ConstructObjectWithArguments have been removed from the JSAPI. The preferred alternative is to save a copy of the constructor function for the class, then to call it using JS_New. function JS_ConstructObject(cx: PJSContext; clasp: PJSClass; proto: PJSObject; parent: PJSObject): PJSObject; cdecl; external SpiderMonkeyLib; function JS_ConstructObjectWithArguments(cx: PJSContext; clasp: PJSClass; proto: PJSObject; parent: PJSObject; argc: uintN; argv: pjsval): PJSObject; cdecl; external SpiderMonkeyLib; Create an object as though by using the new keyword and a JavaScript function

- for instance:

JS_New(cx, ctor, argc, argv)

is equivalent to the JavaScript expression

new ctor(argv[0], argv[1], ... argv[argc-1]).

If ctor is not an object that can be used as a constructor, a TypeError is raised.

function JS_NewArrayBuffer(cx: PJSContext; nbytes: uint32): PJSObject; cdecl; external SpiderMonkeyLib;

Create a new ArrayBuffer with the given byte length.

function JS_NewArrayObject(cx: PJSContext; length: jsint; vector: PjsvalVector): PJSObject; **cdecl; external** SpiderMonkeyLib;

JS_NewArrayObject creates a new array object with the specified length.

- If vector is non-null, then for each index i from 0 to length - 1,
- JS_NewArrayObject defines an enumerable array element with the value vector[i] on the new array (This means that if length is nonzero and vector is null, the result is like the JavaScript expression new Array(length): i.e. the new array has the specified length, but it doesn't have any elements)
- On success, JS_NewArrayObject returns the new array object.
- Otherwise it reports an error as though by calling JS_ReportOutOfMemory and returns NULL.
- IMPORTANT! It is often better to call JS_NewArrayObject(cx, 0, NULL), store the returned object in a GC root, and then populate its elements with JS_SetElement or JS_DefineElement: this avoids unrooted jsvals in vector from being subject to garbage collection until the new object has been populated

function JS_NewContext(rt: PJSRuntime; stackChunkSize: size_t): PJSContext; **cdecl; external** SpiderMonkeyLib;

Create a new JSContext

function JS_NewDateObject(cx: PJSContext; year, mon, mday, hour, min, sec: int32): PJSObject; **cdecl; external** SpiderMonkeyLib;

Create a new JavaScript date object

function JS_NewDateObjectMsec(cx: PJSContext; msec: jsdouble): PJSObject; **cdecl; external** SpiderMonkeyLib;

Create a new JavaScript date object from the Unix millisecond elapsed since EPOCH

function JS_NewExternalString(cx: PJSContext; chars: pjschar; length: size_t; **const** fin: PJSStringFinalizer): PJSString; **cdecl; external** SpiderMonkeyLib;

Creates a new JSString whose characters are stored in external memory, i.e., memory allocated by the application, not the JavaScript engine

- Since the program allocated the memory, it will need to free it; this happens in an external string finalizer indicated by the type parameter.
- chars is Pointer to the first element of an array of jschars. This array is used as the character buffer of the JSString to be created. The array must be populated with the desired character data before JS_NewExternalString is called, and the array must remain in memory, with its contents unchanged, for as long as the JavaScript engine needs to hold on to it. (Ultimately, the string will be garbage collected, and the JavaScript engine will call the string finalizer callback, allowing the application to free the array)
- The text buffer array does not need to be zero-terminated.

function JS_NewFloat32Array(cx: PJSContext; nelements: uint32): PJSObject; **cdecl; external** SpiderMonkeyLib;

Create a new signed 32 bit float (single) typed array with nelements elements

- will fill the newly created array with zeros

function JS_NewFloat32ArrayFromArray(cx: PJSContext; arr: PJSObject): PJSObject; **cdecl; external** SpiderMonkeyLib;

Create a new 32 bit float (single) typed array and copy in values from a given object

- The object is used as if it was an array; that is, the new array (if successfully created) will have length given by array.length, and its elements will be those specified by array[0], array[1], and so on, after conversion to the typed array element type.

function JS_NewFloat32ArrayWithBuffer(cx: PJSContext; arrayBuffer: PJSObject; byteOffset: uint32; length: int32): PJSObject; **cdecl; external** SpiderMonkeyLib;

Create a new 32 bit float (single) typed array using the given ArrayBuffer for storage

- The length value is optional; if -1 is passed, enough elements to use up the remainder of the byte array is used as the default value

function JS_NewFloat64Array(cx: PJSContext; nelements: uint32): PJSObject; **cdecl; external** SpiderMonkeyLib;

Create a new signed 64 bit float (double) typed array with nelements elements

- will fill the newly created array with zeros

function JS_NewFloat64ArrayFromArray(cx: PJSContext; arr: PJSObject): PJSObject; **cdecl; external** SpiderMonkeyLib;

Create a new 64 bit float (double) typed array and copy in values from a given object

- The object is used as if it was an array; that is, the new array (if successfully created) will have length given by array.length, and its elements will be those specified by array[0], array[1], and so on, after conversion to the typed array element type.

function JS_NewFloat64ArrayWithBuffer(cx: PJSContext; arrayBuffer: PJSObject; byteOffset: uint32; length: int32): PJSObject; **cdecl; external** SpiderMonkeyLib;

Create a new 64 bit float (double) typed array using the given ArrayBuffer for storage

- The length value is optional; if -1 is passed, enough elements to use up the remainder of the byte array is used as the default value

function JS_NewFunction(cx: PJSContext; call: JSNative; nargs: uintN; flags: uintN; parent: PJSObject; **const** name: PCChar): PJSFunction; **cdecl; external** SpiderMonkeyLib;

JS_NewFunction creates a new JavaScript function implemented in Delphi

- To create a new function implemented in JavaScript, use JS_CompileFunction

- call is a C/C++ function pointer that the new function wraps

- nargs is the number of arguments the function expects

- flags must be 0. parent may be used to specify the new function's parent; NULL is usually the right thing here.

- name is the name to assign to the function. If name is NULL, the new function has no name.

(JS_GetFunctionId, passed the new function, will return NULL)

- On success, JS_NewFunction returns a pointer to the newly created function

- Otherwise it reports an out-of-memory error and returns NULL

function JS_NewFunctionById(cx: PJSContext; call: JSNative; nargs: uintN; flags: uintN; parent: PJSObject; id: jsid): PJSFunction; **cdecl; external** SpiderMonkeyLib;

Create the function with the name given by the id

- JSID_IS_STRING(id) must be true.

function JS_NewGlobalObject(cx: PJSContext; clasp: PJSClass; principals: PJSPrincipals; options: PCompartmentOptions): PJSObject; **cdecl; external** SpiderMonkeyLib;

JS_NewGlobalObject creates a new global object based on the specified class

- The new object has no parent. It initially has no prototype either, since it is typically the first object created; call JS_InitStandardClasses to create all the standard objects, including Object.prototype, and set the global object's prototype

```
function JS_NewInt16Array(cx: PJSContext; nelements: uint32): PJSObject; cdecl;  
external SpiderMonkeyLib;
```

Create a new signed 16 bit integer typed array with nelements elements
- will fill the newly created array with zeros

```
function JS_NewInt16ArrayFromArray(cx: PJSContext; arr: PJSObject): PJSObject;  
cdecl; external SpiderMonkeyLib;
```

Create a new 16 bit signed integer typed array and copy in values from a given object
- The object is used as if it was an array; that is, the new array (if successfully created) will have length given by array.length, and its elements will be those specified by array[0], array[1], and so on, after conversion to the typed array element type.

```
function JS_NewInt16ArrayWithBuffer(cx: PJSContext; arrayBuffer: PJSObject;  
byteOffset: uint32; length: int32): PJSObject; cdecl; external SpiderMonkeyLib;
```

Create a new 16 bit signed integer typed array using the given ArrayBuffer for storage
- The length value is optional; if -1 is passed, enough elements to use up the remainder of the byte array is used as the default value

```
function JS_NewInt32Array(cx: PJSContext; nelements: uint32): PJSObject; cdecl;  
external SpiderMonkeyLib;
```

Create a new signed 32 bit integer typed array with nelements elements
- will fill the newly created array with zeros

```
function JS_NewInt32ArrayFromArray(cx: PJSContext; arr: PJSObject): PJSObject;  
cdecl; external SpiderMonkeyLib;
```

Create a new 32 bit signed integer typed array and copy in values from a given object
- The object is used as if it was an array; that is, the new array (if successfully created) will have length given by array.length, and its elements will be those specified by array[0], array[1], and so on, after conversion to the typed array element type.

```
function JS_NewInt32ArrayWithBuffer(cx: PJSContext; arrayBuffer: PJSObject;  
byteOffset: uint32; length: int32): PJSObject; cdecl; external SpiderMonkeyLib;
```

Create a new 32 bit signed integer typed array using the given ArrayBuffer for storage
- The length value is optional; if -1 is passed, enough elements to use up the remainder of the byte array is used as the default value

```
function JS_NewInt8Array(cx: PJSContext; nelements: uint32): PJSObject; cdecl;  
external SpiderMonkeyLib;
```

Create a new signed 8 bit integer typed array with nelements elements
- will fill the newly created array with zeros

```
function JS_NewInt8ArrayFromArray(cx: PJSContext; arr: PJSObject): PJSObject; cdecl;  
external SpiderMonkeyLib;
```

Create a new 8 bit signed integer typed array and copy in values from a given object
- The object is used as if it was an array; that is, the new array (if successfully created) will have length given by array.length, and its elements will be those specified by array[0], array[1], and so on, after conversion to the typed array element type.

```
function JS_NewInt8ArrayWithBuffer(cx: PJSContext; arrayBuffer: PJSObject;  
byteOffset: uint32; length: int32): PJSObject; cdecl; external SpiderMonkeyLib;
```

Create a new 8 bit signed integer typed array using the given ArrayBuffer for storage
- The length value is optional; if -1 is passed, enough elements to use up the remainder of the byte array is used as the default value

function JS_NewObject(cx: PJSContext; clasp: PJSClass; proto: PJSObject; parent: PJSObject): PJSObject; **cdecl; external** SpiderMonkeyLib;

JS_NewObject creates a new object based on a specified class, prototype, and parent object
 - cx is a pointer to a context associated with the runtime in which to establish the new object.
 - clasp is a pointer to an existing class to use for internal methods, such as finalize
 - proto is an optional pointer to the prototype object with which to associate the new object see https://developer.mozilla.org/en-US/docs/SpiderMonkey/JSAPI_Reference/JS_NewObject

function JS_NewObjectWithGivenProto(cx: PJSContext; clasp: PJSClass; proto: PJSObject; parent: PJSObject): PJSObject; **cdecl; external** SpiderMonkeyLib;

Unlike JS_NewObject, JS_NewObjectWithGivenProto does not compute a default proto if proto's actual parameter value is null

function JS_NewPropertyIterator(cx: PJSContext; obj: PJSObject): PJSObject; **cdecl; external** SpiderMonkeyLib;

Create an object to iterate over enumerable properties of obj, in arbitrary
 - property definition order. NB: This differs from longstanding for..in loop
 - order, which uses order of property definition in obj.

function JS_NewRuntime(maxbytes: uint32; useHelperThreads: JSUseHelperThreads): JSRuntime; **cdecl; external** SpiderMonkeyLib;

Initialize the JavaScript runtime
 - JS_NewRuntime initializes the JavaScript runtime environment. Call JS_NewRuntime before making any other API calls.
 - JS_NewRuntime allocates memory for the JSRuntime and initializes certain internal runtime structures. maxbytes specifies the number of allocated bytes after which garbage collection is run.

function JS_NewStringCopyN(cx: PJSContext; s: PCChar; n: size_t): PJSString; **cdecl; external** SpiderMonkeyLib;

Caller. So the caller must free bytes in the error case, if it has no use for them. In contrast, all the JS_New//StringCopy// functions do not take ownership of the character memory passed to them -- they copy it. JS_NewStringCopyN allocates space for a JavaScript string and its underlying storage, and copies n characters from a C character array, s, into the new JSString.
 - JS_NewUCStringCopyN is the Unicode version of the function. The two functions differ only in the type of the character array s; both functions create ordinary JavaScript strings, and all JavaScript strings are made up of 16-bit characters.
 - If the array s contains more than n characters, the new string contains a truncated version of the original string. The string may contain null characters (#0). They are copied into the new string like any other character.
 - You can use JS_NewStringCopyN to copy binary data or to copy only a certain portion of a C string into a JavaScript string.
 - On success, JS_NewStringCopyN and JS_NewUCStringCopyN return a pointer to the new JS string.
 - Otherwise they return NULL.

function JS_NewStringCopyZ(cx: PJSContext; s: PCChar): PJSString; **cdecl; external** SpiderMonkeyLib;

Create a new JavaScript string based on a null-terminated C string

```
function JS_NewUCString(cx: PJSContext; s: pjschar; len: size_t): PJSString; cdecl;  
external SpiderMonkeyLib;
```

Creates and returns a new string, using the memory starting at buf and ending at buf + length as the character storage.

- The character array, buf, MUST be allocated on the heap using JS_malloc.
- On success, the JavaScript engine adopts responsibility for memory management of this region.
- The application must not read, write, or free the buffer.
- This allows the JavaScript engine to avoid needless data copying.
- On success, JS_NewUCString return a pointer to the new string.
- On error or exception, they return NUL
- !!!!! DO NOT USE THIS FUNCTION WITH DELPHI strings!!!!!!!!!!

```
function JS_NewUCStringCopyN(cx: PJSContext; s: pjschar; n: size_t): PJSString;  
cdecl; external SpiderMonkeyLib;
```

Unicode version of JS_NewStringCopyN

- faster then JS_NewStringCopyN because no need to transform into unicode

```
function JS_NewUCStringCopyZ(cx: PJSContext; const s: pjschar): PJSString; cdecl;  
external SpiderMonkeyLib;
```

Unicode version of JS_NewStringCopyZ

```
function JS_NewUint16Array(cx: PJSContext; nelements: uint32): PJSObject; cdecl;  
external SpiderMonkeyLib;
```

Create a new unsigned 16 bit integer typed array with nelements elements

- will fill the newly created array with zeros

```
function JS_NewUint16ArrayFromArray(cx: PJSContext; arr: PJSObject): PJSObject;  
cdecl; external SpiderMonkeyLib;
```

Create a new 16 bit unsigned integer typed array and copy in values from a given object

- The object is used as if it was an array; that is, the new array (if successfully created) will have length given by array.length, and its elements will be those specified by array[0], array[1], and so on, after conversion to the typed array element type.

```
function JS_NewUint16ArrayWithBuffer(cx: PJSContext; arrayBuffer: PJSObject;  
byteOffset: uint32; length: int32): PJSObject; cdecl; external SpiderMonkeyLib;
```

Create a new 16 bit unsigned integer typed array using the given ArrayBuffer for storage

- The length value is optional; if -1 is passed, enough elements to use up the remainder of the byte array is used as the default value

```
function JS_NewUint32Array(cx: PJSContext; nelements: uint32): PJSObject; cdecl;  
external SpiderMonkeyLib;
```

Create a new unsigned 32 bit integer typed array with nelements elements

- will fill the newly created array with zeros

```
function JS_NewUint32ArrayFromArray(cx: PJSContext; arr: PJSObject): PJSObject;  
cdecl; external SpiderMonkeyLib;
```

Create a new 32 bit unsigned integer typed array and copy in values from a given object

- The object is used as if it was an array; that is, the new array (if successfully created) will have length given by array.length, and its elements will be those specified by array[0], array[1], and so on, after conversion to the typed array element type.

```
function JS_NewUint32ArrayWithBuffer(cx: PJSContext; arrayBuffer: PJSObject;  
byteOffset: uint32; length: int32): PJSObject; cdecl; external SpiderMonkeyLib;
```

Create a new 32 bit unsigned integer typed array using the given ArrayBuffer for storage

- The length value is optional; if -1 is passed, enough elements to use up the remainder of the byte array is used as the default value

```
function JS_NewUint8Array(cx: PJSContext; nelements: uint32): PJSObject; cdecl;  
external SpiderMonkeyLib;
```

Create a new unsigned 8 bit integer (byte) typed array with nelements elements

- will fill the newly created array with zeros

```
function JS_NewUint8ArrayFromArray(cx: PJSContext; arr: PJSObject): PJSObject;  
cdecl; external SpiderMonkeyLib;
```

Create a new 8 bit unsigned integer typed array and copy in values from a given object

- The object is used as if it was an array; that is, the new array (if successfully created) will have length given by array.length, and its elements will be those specified by array[0], array[1], and so on, after conversion to the typed array element type.

```
function JS_NewUint8ArrayWithBuffer(cx: PJSContext; arrayBuffer: PJSObject;  
byteOffset: uint32; length: int32): PJSObject; cdecl; external SpiderMonkeyLib;
```

Create a new 8 bit unsigned integer typed array using the given ArrayBuffer for storage

- The length value is optional; if -1 is passed, enough elements to use up the remainder of the byte array is used as the default value

```
function JS_NewUint8ClampedArray(cx: PJSContext; nelements: uint32): PJSObject;  
cdecl; external SpiderMonkeyLib;
```

Create a new 8 bit integer typed array with nelements elements

- will fill the newly created array with zeros

```
function JS_NewUint8ClampedArrayFromArray(cx: PJSContext; arr: PJSObject):  
PJSObject; cdecl; external SpiderMonkeyLib;
```

Create a new 8 bit unsigned integer typed array and copy in values from a given object

- The object is used as if it was an array; that is, the new array (if successfully created) will have length given by array.length, and its elements will be those specified by array[0], array[1], and so on, after conversion to the typed array element type.

```
function JS_NewUint8ClampedArrayWithBuffer(cx: PJSContext; arrayBuffer: PJSObject;  
byteOffset: uint32; length: int32): PJSObject; cdecl; external SpiderMonkeyLib;
```

Create a new 8 bit unsigned integer typed array using the given ArrayBuffer for storage

- The length value is optional; if -1 is passed, enough elements to use up the remainder of the byte array is used as the default value

```
function JS_NextProperty(cx: PJSContext; iterobj: PJSObject; var idp: jsid): JSBool;  
cdecl; external SpiderMonkeyLib;
```

*Return true on success with *idp containing the id of the next enumerable*

- property to visit using iterobj, or JSID_IS_VOID if there is no such property
- left to visit. Return false on error.

```
function JS_NumberValue(d: double): jsval; cdecl; external SpiderMonkeyLib name  
'JS_NumberValue_';
```

JS_NewNumberValue Obsolete since JavaScript mozjs17 use JS_NumberValue instead

https://developer.mozilla.org/en-US/docs/SpiderMonkey/JSAPI_Reference/JS_NewNumberValue

function JS_ObjectIsCallable(cx: PJSContext; obj: PJSObject): JSBool; cdecl; external SpiderMonkeyLib;

Check if the supplied object is callable

function JS_ObjectIsDate(cx: PJSContext; obj: PJSObject): JSBool; cdecl; external SpiderMonkeyLib;

Infallible predicate to test whether obj is a JavaScript date object

function JS_ObjectIsFunction(cx: PJSContext; obj: PJSObject): JSBool; cdecl; external SpiderMonkeyLib;

Test whether a given object is a Function

function JS_ParseJSON(cx: PJSContext; const chars: Pjschar; len: uint32; vp: Pjsval): JSBool; cdecl; external SpiderMonkeyLib;

Parse a string using the JSON syntax described in ECMAScript 5 and return the corresponding value into vp

function JS_PCToLineNumber(cx: PJSContext; script: PJSScript; pc: pjsbytecode): uintn; cdecl; external SpiderMonkeyLib;

Retrieve the script line number from a byte code item position

function JS_PropertyStub(cx: PJSContext; var obj: PJSObject; var id: jsid; vp: Pjsval): JSBool; cdecl; external SpiderMonkeyLib;

Default callback matching JSPropertyOp prototype of JSClass

procedure JS_PutPropertyDescArray(cx: PJSContext; var pda: JSPropertyDescArray); cdecl; external SpiderMonkeyLib;

Define the description of a given JavaScript object property

procedure JS_ReleaseFunctionLocalNameArray(cx: PJSContext; markp: pointer); cdecl; external SpiderMonkeyLib;

Release the local name array information of a given function

function JS_RemoveObjectRoot(cx: PJSContext; rp: PPJSObject): JSBool; cdecl; external SpiderMonkeyLib;

Remove a JSObject variable from the garbage collector's root set

function JS_RemoveStringRoot(cx: PJSContext; rp: PPJSString): JSBool; cdecl; external SpiderMonkeyLib;

Remove a JSString variable from the garbage collector's root set

function JS_RemoveValueRoot(cx: PJSContext; vp: Pjsval): JSBool; cdecl; external SpiderMonkeyLib;

Remove a jsval variable from the garbage collector's root set

procedure JS_ReportAllocationOverflow(cx: PJSContext); **cdecl**; **external** SpiderMonkeyLib;

Call JS_ReportAllocationOverflow if an operation fails because it tries to use more memory (or more of some other resource) than the application is designed to handle

- When a script tries to grow an array beyond 230-1 elements, for example, or concatenate strings such that the result is more than 229-1 characters long, the JavaScript engine reports an error as though by calling this function.
- The main difference between these two functions is that JS_ReportOutOfMemory does not cause a JavaScript exception to be thrown. The error therefore cannot be caught by try...catch statements in scripts. JS_ReportAllocationOverflow throws an InternalError which scripts can catch.

procedure JS_ReportError(cx: PJSContext; **const** format: PCChar); **cdecl**; varargs; **external** SpiderMonkeyLib;

JS_ReportError is the simplest JSAPI function for reporting errors

- First it builds an error message from the given sprintf-style format string and any additional arguments passed after it. The resulting error message is passed to the context's JSReporter callback, if any
- If the caller is in a JSAPI callback, JS_ReportError also creates a new JavaScript Error object and sets it to be the pending exception on cx
- The callback must then return JS_FALSE to cause the exception to be propagated to the calling script
- An example is shown in the JSAPI Phrasebook
- For internationalization, use JS_ReportErrorNumber instead
- To report an out-of-memory error, use JS_ReportOutOfMemory

procedure JS_ReportErrorNumber(cx: PJSContext; errorCallback: JSErrorCallback; userRef: pointer; **const** errorNubmer: uintN); **cdecl**; varargs; **external** SpiderMonkeyLib;

Report an error with an application-defined error code.

- varargs is Additional arguments for the error message.
- These arguments must be of type char*
- The number of additional arguments required depends on the error message, which is determined by the errorCallback

procedure JS_ReportErrorNumberUC(cx: PJSContext; errorCallback: JSErrorCallback; userRef: pointer; **const** errorNubmer: uintN); **cdecl**; varargs; **external** SpiderMonkeyLib;

Report an error with an application-defined error code.

- varargs is Additional arguments for the error message.
- These arguments must be of type jschar*
- The number of additional arguments required depends on the error message, which is determined by the errorCallback

procedure JS_ReportOutOfMemory(cx: PJSContext); **cdecl**; **external** SpiderMonkeyLib;

Reports a memory allocation error

- Call JS_ReportOutOfMemory to report that an operation failed because the system is out of memory
- When the JavaScript engine tries to allocate memory and allocation fails, it reports an error as though by calling this function

procedure JS_ReportWarning(cx: PJSContext; **const** format: PCChar); **cdecl**; **varargs**;
external SpiderMonkeyLib;

*Similar to JS_ReportError(), but report a warning instead of an error
 (JSREPORT_IS_WARNING(report.flags))*

- Return true if there was no error trying to issue the warning, and if the warning was not converted into an error due to the JSOPTION_WERROR option being set, false otherwise

function JS_ResolveStandardClass(cx: PJSContext; obj: PJSObject; id: jsid; **var** resolved: JSBool): JSBool; **cdecl**; **external** SpiderMonkeyLib;

Resolve id, which must contain either a string or an int, to a standard class name in obj if possible, defining the class's constructor and/or prototype and storing true in resolved

- If id does not name a standard class or a top-level property induced by initializing a standard class, store false in *resolved and just return true. Return false on error, as usual for JSBool result-typed API entry points.

- This API can be called directly from a global object class's resolve op, to define standard classes lazily. The class's enumerate op should call JS_EnumerateStandardClasses(cx, obj), to define eagerly during for..in loops any classes not yet resolved lazily.

function JS_ResolveStub(cx: PJSContext; **var** obj: PJSObject; **var** id: jsid): JSBool;
cdecl; **external** SpiderMonkeyLib;

Default callback matching JSResolveOp prototype of JSClass

procedure JS_RestoreExceptionState(cx: PJSContext; state: PJSEnvironmentState); **cdecl**;
external SpiderMonkeyLib;

Restore a specified exception state

function JS_RVAL(cx: PJSContext; vp: Pjsval): jsval;

Get the return value of a JSNative callback

function JS_SameValue(cx: PJSContext; v1, v2: jsval; equal: JSBool): JSBool; **cdecl**;
external SpiderMonkeyLib;

Determines if two jsvals are the same, as determined by the SameValue algorithm in ECMA Script 262, 5th edition

- SameValue slightly differs from strict equality (===) in that +0 and -0 are not the same and in that NaN is the same as NaN

function JS_SaveExceptionState(cx: PJSContext): PJSEnvironmentState; **cdecl**; **external** SpiderMonkeyLib;

Save the current exception state. This takes a snapshot of cx's current exception state without making any change to that state.

- The returned state pointer MUST be passed later to JS_RestoreExceptionState (to restore that saved state, overriding any more recent state) or else to JS_DropExceptionState (to free the state struct in case it is not correct or desirable to restore it). Both Restore and Drop free the state struct, so callers must stop using the pointer returned from Save after calling the Release or Drop API.

function JS_SetArrayLength(cx: PJSContext; obj: PJSObject; length: jsuint): JSBool;
cdecl; external SpiderMonkeyLib;

JS_SetArrayLength sets the length property of an object obj

- length indicates the number of elements
- JS_SetArrayLength(cx, obj, n) is exactly the same as setting the length property of obj to n using JS_SetProperty
- This is true even if obj is not an Array object
- You can call JS_SetArrayLength either to set the number of elements for an array object you created without specifying an initial number of elements, or to change the number of elements allocated for an array
- If you set a shorter array length on an existing array, the elements that no longer fit in the array are destroyed
- Setting the number of array elements does not initialize those elements
- To initialize an element call JS_DefineElement
- If you call JS_SetArrayLength on an existing array, and length is less than the highest index number for previously defined elements, all elements greater than or equal to length are automatically deleted
- On success, JS_SetArrayLength returns JS_TRUE. Otherwise it returns JS_FALSE.

function JS_SetContextCallback(rt: PJSRuntime; cxCallback: JSContextCallback):
JSContextCallback; **cdecl; external** SpiderMonkeyLib;

Specifies a callback function that is automatically called whenever a JSContext is created or destroyed

procedure JS_SetContextPrivate(cx: PJSContext; data: Pointer); **cdecl; external**
SpiderMonkeyLib;

Write access to a JSContext field for application-specific data

function JS_SetDebugErrorHook(rt: PJSRuntime; hook: JSDebugErrorHook; closure:
pointer): JSBool; **cdecl; external** SpiderMonkeyLib;

Set a callback to be called when an error is triggered during script debugging

function JS_SetDebuggerHandler(rt: PJSRuntime; hook: JSDebuggerHandler; closure:
pointer): JSBool; **cdecl; external** SpiderMonkeyLib;

Set a debugging handler callback for a given hook and runtime

function JS_SetDebugMode(cx: PJSContext; debug: JSBool): JSBool; **cdecl; external**
SpiderMonkeyLib;

Enables the JavaScript debugging mode for a given context

procedure JS_SetDestroyScriptHookProc(rt: PJSRuntime; hook: JSDestroyScriptHook;
callerdata: Pointer); **cdecl; external** SpiderMonkeyLib;

Set the callback to be called when a JavaScript debugging hook is released

function JS_SetElement(cx: PJSContext; obj: PJSObject; index: jsint; var vp: jsval):
JSBool; **cdecl; external** SpiderMonkeyLib;

Assign a value to a numeric property of an object

```
function JS_SetErrorReporter(cx: PJSContext; er: JSErrorReporter): JSErrorReporter;  
cdecl; external SpiderMonkeyLib;
```

Specify the error reporting mechanism for an application.

- JS_SetErrorReporter enables you to define and use your own error reporting mechanism in your applications.
- The reporter you define is automatically passed a JSErrorReport structure when an error occurs and has been parsed by JS_ReportError.
- JS_SetErrorReporter returns the previous error reporting function of the context, or NULL if no such function had been set.
- Typically, the error reporting mechanism you define should log the error where appropriate (such as to a log file), and display an error to the user of your application.
- The error you log and display can make use of the information passed about the error condition in the JSErrorReport structure.
- The error reporter callback must not reenter the JSAPI.
- Like all other SpiderMonkey callbacks, the error reporter callback must not throw any Delphi exception.

```
function JS_SetGCCallback(rt: PJSRuntime; cb: JSGCCallback): JSGCCallback; cdecl;  
external SpiderMonkeyLib;
```

Defines a Garbage Collection call-back function

```
function JS_SetInterrupt(rt: PJSRuntime; handler: JSInterruptHook; closure:  
pointer): JSBool; cdecl; external SpiderMonkeyLib;
```

Set a callback to be called when script debugging is interrupted

```
procedure JS_SetNativeStackQuota(tr: PJSRuntime; stackSize: size_t); cdecl; external  
SpiderMonkeyLib;
```

Set the size of the native stack that should not be exceeded

- to disable stack size checking, just pass 0 as value

```
procedure JS_SetNewScriptHookProc(rt: PJSRuntime; hook: JSNewScriptHook; callerdata:  
Pointer); cdecl; external SpiderMonkeyLib;
```

Set a JavaScript debugging hook callback

function JS_SetOperationCallback(cx: PJSContext; callback: JSOperationCallback): JSOperationCallback; **cdecl; external** SpiderMonkeyLib;

These functions allow setting an operation callback that will be called from the thread the context is associated with some time after any thread triggered the callback using JS_TriggerOperationCallback(cx).

In a threadsafe build the engine internally triggers operation callbacks under certain circumstances (i.e. GC and title transfer) to force the context to yield its current request, which the engine always automatically does immediately prior to calling the callback function. The embedding should thus not rely on callbacks being triggered through the external API only.

Important note: Additional callbacks can occur inside the callback handler if it re-enters the JS engine. The embedding must ensure that the callback is disconnected before attempting such re-entry. Set a callback function that is automatically called periodically while JavaScript code runs

- cx is a Pointer to a JSContext in which this callback was installed.
- The callback may use this context to call JSAPI functions, but it should first use JS_SetOperationCallback
- to set the context's operation callback to NULL. Otherwise the engine may call the operation callback again, reentering it.
- Provides request. In JS_THREADSAFE builds, the JavaScript engine calls this callback only from within an active request on cx.
- The callback does not need to call JS_BeginRequest()
- Some common uses for an operation callback are: To run garbage collection periodically, by calling JS_MaybeGC; To periodically take a break from script execution to update the UI (though note that Mozilla does not do this, by design); To enforce application limits on the amount of time a script may run. (In this case, the callback may terminate the script by returning JS_FALSE.)

procedure JS_SetPendingException(cx: PJSContext; v: jsval); **cdecl; external** SpiderMonkeyLib;

Set the current exception being thrown within a context

- JS_SetPendingException sets the current exception being thrown within a context. If an exception is already being thrown, it is replaced with the new one given.
- v is the new value to throw as an exception.
- A native function or hook using this to throw an exception must also return JS_FALSE to ensure the exception is thrown.
- Each JSContext's pending-exception field is a GC root. That is, garbage collection never collects a pending exception

function JS_SetProperty(cx: PJSContext; obj: PJSObject; **const** name: PCChar; **var** vp: jsval): JSBool; **cdecl; external** SpiderMonkeyLib;

*The following functions behave like JS_GetProperty and JS_GetPropertyById except when operating on E4X XML objects extern JS_PUBLIC_API(JSBool) JS_GetMethodById(JSContext *cx, JSObject *obj, jsid id, JSObject **objp, jsval *vp); extern JS_PUBLIC_API(JSBool) JS_GetMethod(JSContext *cx, JSObject *obj, **const** char *name, JSObject **objp, jsval *vp); JS_SetProperty assigns the value vp to the property name of the object obj*

- it behaves like the JavaScript expression obj[name] = v
- it will create the property if it does not exist, but for details see https://developer.mozilla.org/en-US/docs/SpiderMonkey/JSAPI_Reference/JS_SetProperty
- remark: in mozilla description "sealed" object they talking about is OBSOLETE!

```
function JS_SetPropertyAttributes(cx: PJSContext; obj: PJSObject; const name: PCChar;
attrs: uintN; var foundp: JSBool): JSBool; cdecl; external SpiderMonkeyLib;
```

Set the attributes of a property on a given object

- If the object does not have a property by that name, *foundp will be JS_FALSE and nothing will be altered.

```
function JS_SetPropertyById(cx: PJSContext; obj: PJSObject; id: jsid; vp: Pjsval):
JSBool; cdecl; external SpiderMonkeyLib;
```

JS_SetProperty assigns the value vp to the property jsid of the object obj

```
function JS_SetReservedSlot(cx: PJSContext; obj: PJSObject; index: uint32; v: jsval):
JSBool; cdecl; external SpiderMonkeyLib;
```

Write access an object's reserved slots

```
procedure JS_SetRuntimeDebugMode(rt: PJSRuntime; debug: JSBool); cdecl; external
SpiderMonkeyLib;
```

Enables the JavaScript debugging mode for a given runtime

```
function JS_SetSingleStepMode(cx: PJSContext; script: PJSScript; singleStep:
JSBool): JSBool; cdecl; external SpiderMonkeyLib;
```

Set single step mode. In this mode script interrupts on each line

```
function JS_SetThrowHook(rt: PJSRuntime; hook: JSThrowHook; closure: pointer):
JSBool; cdecl; external SpiderMonkeyLib;
```

Set a callback to be called when script throws an exception

```
function JS_SetTrap(cx: PJSContext; script: PJSScript; pc: pjsbytecode; handler:
JSTrapHandler; closure: jsval): JSBool; cdecl; external SpiderMonkeyLib;
```

Set a trap debugging handler callback for a given execution context

```
function JS_SetUCPropertyAttributes(cx: PJSContext; obj: PJSObject; const name:
Pjschar; namelen: size_t; attrs: uintN; var foundp: JSBool): JSBool; cdecl; external
SpiderMonkeyLib;
```

Set the attributes of a property on a given object.

- If the object does not have a property by that name, *foundp will be
 - JS_FALSE and nothing will be altered.

```
procedure JS_SET_RVAL(cx: PJSContext; vp: Pjsval; v: jsval);
```

Set the return value of a JSNative callback

```
procedure JS_ShutDown;
```

Free all resources used by the JS engine, not associated with specific runtimes

```
function JS_StrictlyEqual(cx: PJSContext; v1, v2: jsval; equal: PJSBool): JSBool;
cdecl; external SpiderMonkeyLib;
```

Determine whether two JavaScript values are equal in the sense of the === operator

```
function JS_StrictPropertyStub(cx: PJSContext; var obj: PJSObject; var id: jsid;
strict: JSBool; vp: pjsval): JSBool; cdecl; external SpiderMonkeyLib;
```

Default callback matching JSStrictPropertyOp prototype of JSClass

```
function JS_Stringify(cx: PJSContext; vp: Pjsval; replacer: PJSObject; space: jsval;
callback: JSONWriteCallback; data: pointer): JSBool; cdecl; external SpiderMonkeyLib;
```

Converts a value to JSON, optionally replacing values if a replacer function is specified, or optionally including only the specified properties if a replacer array is specified

function JS_StringToVersion(_string: PCChar): JSVersion; cdecl; external SpiderMonkeyLib;

Configure a JSContext to use a specific version of the JavaScript language

function JS_THIS(cx: PJSContext; vp: Pjsval): jsval;

Return the this object of a JSNative callback

function JS_THIS_OBJECT(cx: PJSContext; vp: Pjsval): PJSObject;

Return the this object of a JSNative callback

function JS_ThrowReportedError(cx: PJSContext; const msg: PCChar; reportp: PJSErrorReport): JSBool; cdecl; external SpiderMonkeyLib;

Given a reported error's message and JSErrorReport struct pointer, throw the corresponding exception on cx

function JS_ThrowStopIteration(cx: PJSContext): JSBool; cdecl; external SpiderMonkeyLib;

Throws a StopIteration exception on cx

procedure JS_TriggerOperationCallback(rt: PJSRuntime); cdecl; external SpiderMonkeyLib;

Triggers a callback set using JS_SetOperationCallback

function JS_TypeOfValue(cx: PJSContext; v: jsval): JSType; cdecl; external SpiderMonkeyLib;

Determines the JS data type of a JS value

function JS_ValueToBoolean(cx: PJSContext; v: jsval; var b: JSBool): JSBool; cdecl; external SpiderMonkeyLib;

Convert a JavaScript value to a boolean

function JS_ValueToECMAInt32(cx: PJSContext; v: jsval; var i: int32): JSBool; cdecl; external SpiderMonkeyLib;

Convert a JavaScript value to an integer type as specified by the ECMAScript standard

function JS_ValueToECMAUint32(cx: PJSContext; v: jsval; var ui: uint32): JSBool; cdecl; external SpiderMonkeyLib;

Convert a JavaScript value to an integer type as specified by the ECMAScript standard

function JS_ValueToFunction(cx: PJSContext; v: jsval): PJSFunction; cdecl; external SpiderMonkeyLib;

Convert a jsval to a JSFunction

- If v is a Function object, this returns the associated JSFunction.
- If v is null, undefined, a boolean, a number, or a string, a TypeError is reported and JS_ValueToFunction returns nil
- Otherwise, v is an object. The JavaScript engine attempts to convert it to a function, which can be pretty unsafe! You have been warned!

function JS_ValueToInt32(cx: PJSContext; v: jsval; var i: int32): JSBool; cdecl; external SpiderMonkeyLib;

JS_ValueToInt32 is obsolete

function JS_ValueToNumber(cx: PJSContext; v: jsval; var dp: jsdouble): JSBool; cdecl; external SpiderMonkeyLib;

Convert any JavaScript value to a floating-point number of type jsdouble.

```
function JS_ValueToObject(cx: PJSContext; v: jsval; var objp: PJSObject): JSBool; cdecl; external SpiderMonkeyLib;
```

JS_ValueToObject converts a specified JavaScript value, v, to an object

- On success, this function stores either NULL or a pointer to the resulting object in objp and returns JS_TRUE. Otherwise it returns JS_FALSE and the value left in objp is unspecified.
- If v is JSVAL_NULL or JSVAL_VOID, the result is NULL.
- If v is a boolean value, a number, or a string, the result is a new wrapper object of type Boolean, Number, or String.
- Otherwise v is an object, and the result depends on the object. If v is a native JavaScript Object, this calls the object's valueOf method, if any. In any case, the result is not guaranteed to be the same object as v. (Implementation note: the object's JSObjectOps.defaultValue method is called with hint=JSTYPE_OBJECT.)
- The resulting object is subject to garbage collection unless the variable objp is protected by a local root scope, an object property, or the JS_AddRoot function. Note that a local root scope is not sufficient to protect the resulting object in some cases involving the valueOf method!

```
function JS_ValueToSource(cx: PJSContext; v: jsval): PJSString; cdecl; external SpiderMonkeyLib;
```

Convert any JavaScript value to its source representation

```
function JS_ValueToString(cx: PJSContext; v: jsval): PJSString; cdecl; external SpiderMonkeyLib;
```

JS_ValueToString converts a specified JavaScript value, v, to a string.

- It implements the ToString operator specified in ECMA 262-3 §9.8
- The result is like the JavaScript expression ""+v.
- If v is already a string, conversion succeeds.
- If v is true, false, null, or undefined, conversion succeeds, and the result is the string "true", "false", "null", or "undefined", accordingly.
- If v is a number, conversion succeeds, and the result is a string representation of that number as specified in ECMA 262-3 §9.8.1. This might be "NaN", "Infinity", or "-Infinity". Otherwise the result is a decimal representation of the number, possibly using exponential notation.
- Otherwise v is an object. JS_ValueToString uses the steps below to convert it to a string. If at any point an error or exception occurs, or conversion succeeds, the rest of the steps are skipped. (This behavior is implemented by v's JSObjectOps.defaultValue method, so host objects can override it all.) If v.toString() is a function, it is called. If that method returns a primitive value, the value is converted to a string as described above and conversion succeeds. Otherwise, the resulting object's JSCClass.convert callback is called. For standard classes, this is JS_ConvertStub, which simply calls v.valueOf() if present. If the convert callback produces a primitive value, the value is converted to a string as described above and conversion succeeds. Otherwise conversion fails with a TypeError.
- On success, JS_ValueToString returns a pointer to a string. On error or exception, it returns NULL. This happens, for example, if v is an object and v.toString() throws an exception.
- The resulting JSString is subject to garbage collection. Protect it using a local root, an object property, or the JS_AddRoot function.

```
function JS_ValueToUint16(cx: PJSContext; v: jsval; var ui16: uint16): JSBool; cdecl; external SpiderMonkeyLib;
```

Convert a JavaScript value to a 16 bit integer

- ECMA ToUint16, e.g. for mapping a jsval to a Unicode point.

function JS_VersionToString(version: JSVersion): PCChar; **cdecl; external** SpiderMonkeyLib;

JS_SetVersion is not supported now Use CompartmentOptions in JS_NewGlobalObject retrieve the JavaScript version text used within a specified executable script context

function PR_CreateThread(type_: PRThreadType; start: pointer; arg: pointer; priority: PRThreadPriority; scope: PRThreadScope; state: PRThreadState; stackSize: PRUint32): PRThread; **cdecl; external** NSPRLib;

Initializes a NSPR thread

procedure PR_DestroyCondVar(cvar: PRCondVar); **cdecl; external** NSPRLib;

Free a previously allocated NSPR event

procedure PR_DestroyLock(lock: PRLock); **cdecl; external** NSPRLib;

Free a previously allocated NSPR lock

function PR_JoinThread(thred: PRThread): PRStatus; **cdecl; external** NSPRLib;

Join a NSPR thread

procedure PR_Lock(lock: PRLock); **cdecl; external** NSPRLib;

Enter a previously allocated NSPR mutex/lock

function PR_NewCondVar(lock: PRLock): PRCondVar; **cdecl; external** NSPRLib;

Allocates a new NSPR event

function PR_NewLock: PRLock; **cdecl; external** NSPRLib;

Allocates a new NSPR mutex/lock

function PR_NotifyAllCondVar(cvar: PRCondVar): PRStatus; **cdecl; external** NSPRLib;

Notify all previously allocated NSPR event

function PR_NotifyCondVar(cvar: PRCondVar): PRStatus; **cdecl; external** NSPRLib;

Notify a previously allocated NSPR event

function PR_SetCurrentThreadName(name: PAnsiChar): PRStatus; **cdecl; external** NSPRLib;

Change the current NSPR thread name

function PR_TicksPerSecond(): PRUint32; **cdecl; external** NSPRLib;

Returns the number of ticks per seconds as expected by NSPR

function PR_Unlock(lock: PRLock): PRStatus; **cdecl; external** NSPRLib;

Leave a previously allocated NSPR mutex/lock

function PR_WaitCondVar(cvar: PRCondVar; timeout: PRIntervalTime): PRStatus; **cdecl; external** NSPRLib;

Wait until a previously allocated NSPR event is notified

27.35. SynSQLite3.pas unit

Purpose: SQLite3 Database engine direct access

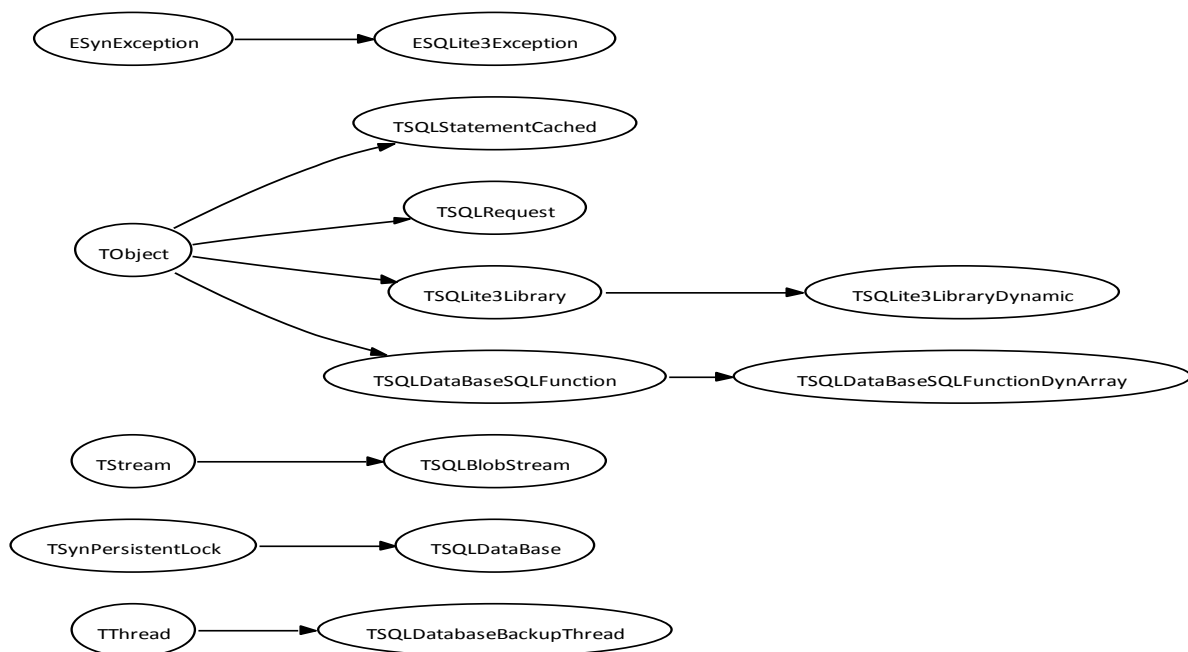

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

The *SynSQLite3* unit is quoted in the following items

SWRS #	Description	Page
DI-2.2.1	The <i>SQLite3</i> engine shall be embedded to the framework	2558

Units used in the *SynSQLite3* unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynLog</i>	Logging functions used by Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1368
<i>SynTable</i>	Filter/database/cache/buffer/security/search/multithread/OS features - as a complement to SynCommons, which tended to increase too much - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1728

SynSQLite3 class hierarchy

Objects implemented in the *SynSQLite3* unit

Objects	Description	Page
---------	-------------	------

Objects	Description	Page
ESQLite3Exception	Custom SQLite3 dedicated Exception type	1685
TFTSMATCHInfo	Map the matchinfo function returned BLOB value	1654
TSQlBLOBStream	Used to read or write a BLOB Incrementaly	1702
TSQlDataBase	Simple wrapper for direct SQLite3 database manipulation	1693
TSQlDatabaseBackupThread	Background thread used for TSQlDatabase.BackupBackground() process	1702
TSQlDataBaseSQLFunction	Those classes can be used to define custom SQL functions inside a TSQlDataBase	1692
TSQlDataBaseSQLFunctionDynArray	To be used to define custom SQL functions for dynamic arrays BLOB search	1692
TSQlite3IndexConstraint	Records WHERE clause constraints of the form "column OP expr"	1655
TSQlite3IndexConstraintUsage	Define what information is to be passed to xFilter() for a given WHERE clause constraint of the form "column OP expr"	1656
TSQlite3IndexInfo	Structure used as part of the virtual table interface to pass information into and receive the reply from the xBestIndex() method of a virtual table module	1656
TSQlite3IndexOrderBy	ORDER BY clause, one item per column	1655
TSQlite3Library	Wrapper around all SQLite3 library API calls	1666
TSQlite3LibraryDynamic	Allow access to an external SQLite3 library engine	1684
TSQlite3MemMethods	Defines the interface between SQLite and low-level memory allocation routines	1666
TSQlite3Module	Defines a module object used to implement a virtual table.	1659
TSQlite3VTab	Virtual Table Instance Object	1658
TSQlite3VTabCursor	Virtual Table Cursor Object	1658
TSQlRequest	Wrapper to a SQLite3 request	1685
TSQlStatementCache	Used to retrieve a prepared statement	1691
TSQlStatementCached	Handle a cache of prepared statements	1691

TFTSMATCHInfo = **packed record**

Map the matchinfo function returned BLOB value

- i.e. the default 'pcx' layout, for both FTS3 and FTS4

- see <http://www.sqlite.org/fts3.html#matchinfo>

- used for the FTS3/FTS4 ranking of results by TSQlRest.FTSMATCH method and the internal RANK() function as proposed in http://www.sqlite.org/fts3.html#appendix_a

TSQLite3IndexConstraint = record

Records WHERE clause constraints of the form "column OP expr"

- Where "column" is a column in the virtual table, OP is an operator like "=" or "<", and EXPR is an arbitrary expression

- So, for example, if the WHERE clause contained a term like this:

a = 5

Then one of the constraints would be on the "a" column with operator "=" and an expression of "5"

- For example, if the WHERE clause contained something like this:

x BETWEEN 10 AND 100 AND 999>y

The query optimizer might translate this into three separate constraints:

x >= 10

x <= 100

y < 999

iColumn: integer;

Column on left-hand side of constraint

- The first column of the virtual table is column 0

- The ROWID of the virtual table is column -1

- Hidden columns are counted when determining the column index.

iTermOffset: integer;

Used internally - xBestIndex() should ignore this field

op: byte;

Constraint operator

- OP is =, <, <=, >, or >= using one of the SQLITE_INDEX_CONSTRAINT_* values

usable: boolean;

True if this constraint is usable

- The aConstraint[] array contains information about all constraints that apply to the virtual table. But some of the constraints might not be usable because of the way tables are ordered in a join. The xBestIndex method must therefore only consider constraints that have a usable flag which is true, and just ignore constraints with usable set to false

TSQLite3IndexOrderBy = record

ORDER BY clause, one item per column

desc: boolean;

True for DESC. False for ASC.

iColumn: integer;

Column number

- The first column of the virtual table is column 0

- The ROWID of the virtual table is column -1

- Hidden columns are counted when determining the column index.

TSQLite3IndexConstraintUsage = record

Define what information is to be passed to xFilter() for a given WHERE clause constraint of the form "column OP expr"

argvIndex: Integer;

If argvIndex>0 then the right-hand side of the corresponding aConstraint[] is evaluated and becomes the argvIndex-th entry in argv

- Exactly one entry should be set to 1, another to 2, another to 3, and so forth up to as many or as few as the xBestIndex() method wants.
- The EXPR of the corresponding constraints will then be passed in as the argv[] parameters to xFilter()
- For example, if the aConstraint[3].argvIndex is set to 1, then when xFilter() is called, the argv[0] passed to xFilter will have the EXPR value of the aConstraint[3] constraint.

omit: bytebool;

If omit is true, then the constraint is assumed to be fully handled by the virtual table and is not checked again by SQLite

- By default, the SQLite core double checks all constraints on each row of the virtual table that it receives. If such a check is redundant, xBestFilter() method can suppress that double-check by setting this field

TSQLite3IndexInfo = record

Structure used as part of the virtual table interface to pass information into and receive the reply from the xBestIndex() method of a virtual table module

- Outputs fields will be passed as parameter to the xFilter() method, and will be initialized to zero by SQLite
- For instance, xBestIndex() method fills the idxNum and idxStr fields with information that communicates an indexing strategy to the xFilter method. The information in idxNum and idxStr is arbitrary as far as the SQLite core is concerned. The SQLite core just copies the information through to the xFilter() method. Any desired meaning can be assigned to idxNum and idxStr as long as xBestIndex() and xFilter() agree on what that meaning is. Use the SetInfo() method of this object in order to make a temporary copy of any needed data.

aConstraint: PSQLite3IndexConstraintArray;

Input: List of WHERE clause constraints of the form "column OP expr"

aConstraintUsage: PSQLite3IndexConstraintUsageArray;

Output: filled by xBestIndex() method with information about what parameters to pass to xFilter() method

- has the same number of items than the aConstraint[] array
- should set the aConstraintUsage[].argvIndex to have the corresponding argument in xFilter() argc/argv[] expression list

aOrderBy: PSQLite3IndexOrderByArray;

Input: List of ORDER BY clause, one per column

colUsed: UInt64;

Input: Mask of columns used by statement (since 3.10.0)

- indicates which fields of the virtual table are actually used by the statement being prepared. If the lowest bit of colUsed is set, that means that the first column is used. The second lowest bit corresponds to the second column. And so forth. If the most significant bit of colUsed is set, that means that one or more columns other than the first 63 columns are used.
- If column usage information is needed by the xFilter method, then the required bits must be encoded into either the idxNum or idxStr output fields

estimatedCost: Double;

Output: Estimated cost of using this index

- Should be set to the estimated number of disk access operations required to execute this query against the virtual table
- The SQLite core will often call xBestIndex() multiple times with different constraints, obtain multiple cost estimates, then choose the query plan that gives the lowest estimate

estimatedRows: Int64;

Output: Estimated number of rows returned (since 3.8.2)

- may be set to an estimate of the number of rows returned by the proposed query plan. If this value is not explicitly set, the default estimate of 25 rows is used

idxFlags: Integer;

Output: Mask of SQLITE_INDEX_SCAN_ flags (since 3.9.0)*

- may be set to SQLITE_INDEX_SCAN_UNIQUE to indicate that the virtual table will return only zero or one rows given the input constraints. Additional bits of the idxFlags field might be understood in later versions of SQLite

idxNum: integer;

Output: Number used to identify the index

idxStr: PAnsiChar;

Output: String, possibly obtained from sqlite3.malloc()

- may contain any variable-length data or class/record content, as necessary

nConstraint: integer;

Input: Number of entries in aConstraint array

needToFreeIdxStr: integer;

Output: Free idxStr using sqlite3.free() if true (=1)

nOrderBy: integer;

Input: Number of terms in the aOrderBy array

orderByConsumed: integer;

Output: True (=1) if output is already ordered

- i.e. if the virtual table will output rows in the order specified by the ORDER BY clause
- if False (=0), will indicate to the SQLite core that it will need to do a separate sorting pass over the data after it comes out of the virtual table

TSQLite3VTab = record

Virtual Table Instance Object

- Every virtual table module implementation uses a subclass of this object to describe a particular instance of the virtual table.
- Each subclass will be tailored to the specific needs of the module implementation. The purpose of this superclass is to define certain fields that are common to all module implementations. This structure therefore contains a pInstance field, which will be used to store a class instance handling the virtual table as a pure Delphi class: the TSQLVirtualTableModule class will use it internally

nRef: integer;

No longer used

pInstance: TObject;

This will be used to store a Delphi class instance handling the Virtual Table

pModule: PSQLite3Module;

The module for this virtual table

zErrMsg: PUTF8Char;

Error message from sqlite3.mprintf()

- Virtual tables methods can set an error message by assigning a string obtained from sqlite3.mprintf() to zErrMsg.
- The method should take care that any prior string is freed by a call to sqlite3.free() prior to assigning a new string to zErrMsg.
- After the error message is delivered up to the client application, the string will be automatically freed by sqlite3.free() and the zErrMsg field will be zeroed.

TSQLite3VTabCursor = record

Virtual Table Cursor Object

- Every virtual table module implementation uses a subclass of the following structure to describe cursors that point into the virtual table and are used to loop through the virtual table.
- Cursors are created using the xOpen method of the module and are destroyed by the xClose method. Cursors are used by the xFilter, xNext, xEof, xColumn, and xRowid methods of the module.
- Each module implementation will define the content of a cursor structure to suit its own needs.
- This superclass exists in order to define fields of the cursor that are common to all implementations. This structure therefore contains a pInstance field, which will be used to store a class instance handling the virtual table as a pure Delphi class: the TSQLVirtualTableModule class will use it internally

pInstance: TObject;

This will be used to store a Delphi class instance handling the cursor

pVtab: PSQLite3VTab;

Virtual table of this cursor

TSQLite3Module = record

Defines a module object used to implement a virtual table.

- Think of a module as a class from which one can construct multiple virtual tables having similar properties. For example, one might have a module that provides read-only access to comma-separated-value (CSV) files on disk. That one module can then be used to create several virtual tables where each virtual table refers to a different CSV file.
- The module structure contains methods that are invoked by SQLite to perform various actions on the virtual table such as creating new instances of a virtual table or destroying old ones, reading and writing data, searching for and deleting, updating, or inserting rows.

iVersion: integer;

Defines the particular edition of the module table structure

- Currently, handled iVersion is 2, but in future releases of SQLite the module structure definition might be extended with additional methods and in that case the iVersion value will be increased

xBegin: function(var pVTab: TSQLite3VTab): Integer; cdecl;

Begins a transaction on a virtual table

- This method is always followed by one call to either the xCommit or xRollback method.
- Virtual table transactions do not nest, so the xBegin method will not be invoked more than once on a single virtual table without an intervening call to either xCommit or xRollback. For nested transactions, use xSavepoint, xRelease and xRollBackTo methods.
- Multiple calls to other methods can and likely will occur in between the xBegin and the corresponding xCommit or xRollback.

xBestIndex: function(var pVTab: TSQLite3VTab; var pInfo: TSQLite3IndexInfo): Integer; cdecl;

Used to determine the best way to access the virtual table

- The pInfo parameter is used for input and output parameters
- The SQLite core calls the xBestIndex() method when it is compiling a query that involves a virtual table. In other words, SQLite calls this method when it is running sqlite3.prepare() or the equivalent.
- By calling this method, the SQLite core is saying to the virtual table that it needs to access some subset of the rows in the virtual table and it wants to know the most efficient way to do that access. The xBestIndex method replies with information that the SQLite core can then use to conduct an efficient search of the virtual table, via the xFilter() method.
- While compiling a single SQL query, the SQLite core might call xBestIndex multiple times with different settings in pInfo. The SQLite core will then select the combination that appears to give the best performance.
- The information in the pInfo structure is ephemeral and may be overwritten or deallocated as soon as the xBestIndex() method returns. If the xBestIndex() method needs to remember any part of the pInfo structure, it should make a copy. Care must be taken to store the copy in a place where it will be deallocated, such as in the idxStr field with needToFreeIdxStr set to 1.

xClose: function(pVtabCursor: PSQLite3VTabCursor): Integer; cdecl;

Closes a cursor previously opened by xOpen

- The SQLite core will always call xClose once for each cursor opened using xOpen.
- This method must release all resources allocated by the corresponding xOpen call.
- The routine will not be called again even if it returns an error. The SQLite core will not use the pVtabCursor again after it has been closed.

xColumn: function(var pVtabCursor: TSQLite3VTabCursor; sContext: TSQLite3FunctionContext; N: Integer): Integer; cdecl;

The SQLite core invokes this method in order to find the value for the N-th column of the current row

- N is zero-based so the first column is numbered 0.
- The xColumn method may return its result back to SQLite using one of the standard `sqlite3.result_*`() functions with the specified sContext
- If the xColumn method implementation calls none of the `sqlite3.result_*`() functions, then the value of the column defaults to an SQL NULL.
- The xColumn method must return `SQLITE_OK` on success.
- To raise an error, the xColumn method should use one of the `result_text()` methods to set the error message text, then return an appropriate error code.

xCommit: function(var pVTab: TSQLite3VTab): Integer; cdecl;

Causes a virtual table transaction to commit

xConnect: function(DB: TSQLite3DB; pAux: Pointer; argc: Integer; const argv: PUTF8CharArray; var ppVTab: PSQLite3VTab; var pzErr: PUTF8Char): Integer; cdecl;

XConnect is called to establish a new connection to an existing virtual table, whereas xCreate is called to create a new virtual table from scratch

- It has the same parameters and constructs a new PSQLite3VTab structure
- xCreate and xConnect methods are only different when the virtual table has some kind of backing store that must be initialized the first time the virtual table is created. The xCreate method creates and initializes the backing store. The xConnect method just connects to an existing backing store.

```
xCreate: function(DB: TSQLite3DB; pAux: Pointer; argc: Integer; const argv: PUTF8CharArray; var ppVTab: PSQLite3VTab; var pzErr: PUTF8Char): Integer; cdecl;
```

Called to create a new instance of a virtual table in response to a CREATE VIRTUAL TABLE statement

- The job of this method is to construct the new virtual table object (an PSQLite3VTab object) and return a pointer to it in ppVTab
- The DB parameter is a pointer to the SQLite database connection that is executing the CREATE VIRTUAL TABLE statement
- The pAux argument is the copy of the client data pointer that was the fourth argument to the sqlite3.create_module_v2() call that registered the virtual table module
- The argv parameter is an array of argc pointers to null terminated strings
- The first string, argv[0], is the name of the module being invoked. The module name is the name provided as the second argument to sqlite3.create_module() and as the argument to the USING clause of the CREATE VIRTUAL TABLE statement that is running.
- The second, argv[1], is the name of the database in which the new virtual table is being created. The database name is "main" for the primary database, or "temp" for TEMP database, or the name given at the end of the ATTACH statement for attached databases.
- The third element of the array, argv[2], is the name of the new virtual table, as specified following the TABLE keyword in the CREATE VIRTUAL TABLE statement
- If present, the fourth and subsequent strings in the argv[] array report the arguments to the module name in the CREATE VIRTUAL TABLE statement
- As part of the task of creating a new PSQLite3VTab structure, this method must invoke sqlite3.declare_vtab() to tell the SQLite core about the columns and datatypes in the virtual table

```
xDestroy: function(pVTab: PSQLite3VTab): Integer; cdecl;
```

Releases a connection to a virtual table, just like the xDisconnect method, and it also destroys the underlying table implementation.

- This method undoes the work of xCreate
- The xDisconnect method is called whenever a database connection that uses a virtual table is closed. The xDestroy method is only called when a DROP TABLE statement is executed against the virtual table.

```
xDisconnect: function(pVTab: PSQLite3VTab): Integer; cdecl;
```

Releases a connection to a virtual table

- Only the pVTab object is destroyed. The virtual table is not destroyed and any backing store associated with the virtual table persists. This method undoes the work of xConnect.

```
xEOF: function(var pVtabCursor: TSQLite3VtabCursor): Integer; cdecl;
```

Checks if cursor reached end of rows

- Must return false (zero) if the specified cursor currently points to a valid row of data, or true (non-zero) otherwise

```
xFilter: function(var pVtabCursor: TSQLite3VTabCursor; idxNum: Integer; const  
idxStr: PAnsiChar; argc: Integer; var argv: TSQLite3ValueArray): Integer; cdecl;
```

Begins a search of a virtual table

- The first argument is a cursor opened by xOpen.
- The next two arguments define a particular search index previously chosen by xBestIndex(). The specific meanings of idxNum and idxStr are unimportant as long as xFilter() and xBestIndex() agree on what that meaning is.
- The xBestIndex() function may have requested the values of certain expressions using the aConstraintUsage[].argvIndex values of its pInfo structure. Those values are passed to xFilter() using the argc and argv parameters.
- If the virtual table contains one or more rows that match the search criteria, then the cursor must be left point at the first row. Subsequent calls to xEOF must return false (zero). If there are no rows match, then the cursor must be left in a state that will cause the xEOF to return true (non-zero). The SQLite engine will use the xColumn and xRowid methods to access that row content. The xNext method will be used to advance to the next row.
- This method must return SQLITE_OK if successful, or an sqlite error code if an error occurs.

```
xFindFunction: function(var pVtab: TSQLite3VTab; nArg: Integer; const zName:  
PAnsiChar; var pxFunc: TSQLiteFunctionFunc; var ppArg: Pointer): Integer; cdecl;
```

Called during sqlite3.prepare() to give the virtual table implementation an opportunity to overload SQL functions

- When a function uses a column from a virtual table as its first argument, this method is called to see if the virtual table would like to overload the function. The first three parameters are inputs: the virtual table, the number of arguments to the function, and the name of the function. If no overloading is desired, this method returns 0. To overload the function, this method writes the new function implementation into pxFunc and writes user data into ppArg and returns 1.
- Note that infix functions (LIKE, GLOB, REGEXP, and MATCH) reverse the order of their arguments. So "like(A,B)" is equivalent to "B like A". For the form "B like A" the B term is considered the first argument to the function. But for "like(A,B)" the A term is considered the first argument.
- The function pointer returned by this routine must be valid for the lifetime of the pVtab object given in the first parameter.

```
xNext: function(var pVtabCursor: TSQLite3VTabCursor): Integer; cdecl;
```

Advances a virtual table cursor to the next row of a result set initiated by xFilter

- If the cursor is already pointing at the last row when this routine is called, then the cursor no longer points to valid data and a subsequent call to the xEOF method must return true (non-zero).
- If the cursor is successfully advanced to another row of content, then subsequent calls to xEOF must return false (zero).
- This method must return SQLITE_OK if successful, or an sqlite error code if an error occurs.

```
xOpen: function(var pVTab: TSQLite3VTab; var ppCursor: PSQLite3VTabCursor): Integer; cdecl;
```

Creates a new cursor used for accessing (read and/or writing) a virtual table

- A successful invocation of this method will allocate the memory for the TSQLite3VTabCursor (or a subclass), initialize the new object, and make ppCursor point to the new object. The successful call then returns SQLITE_OK.
- For every successful call to this method, the SQLite core will later invoke the xClose method to destroy the allocated cursor.
- The xOpen method need not initialize the pVtab field of the ppCursor structure. The SQLite core will take care of that chore automatically.
- A virtual table implementation must be able to support an arbitrary number of simultaneously open cursors.
- When initially opened, the cursor is in an undefined state. The SQLite core will invoke the xFilter method on the cursor prior to any attempt to position or read from the cursor.

```
xRelease: function(var pVTab: TSQLite3VTab; iSavepoint: integer): Integer; cdecl;
```

Merges a transaction into its parent transaction, so that the specified transaction and its parent become the same transaction

- Causes all savepoints back to and including the most recent savepoint with a matching identifier to be removed from the transaction stack
- Some people view RELEASE as the equivalent of COMMIT for a SAVEPOINT. This is an acceptable point of view as long as one remembers that the changes committed by an inner transaction might later be undone by a rollback in an outer transaction.
- iSavepoint parameter indicates the unique name of the SAVEPOINT

```
xRename: function(var pVTab: TSQLite3VTab; const zNew: PAnsiChar): Integer; cdecl;
```

Provides notification that the virtual table implementation that the virtual table will be given a new name

- If this method returns SQLITE_OK then SQLite renames the table.
- If this method returns an error code then the renaming is prevented.

```
xRollback: function(var pVTab: TSQLite3VTab): Integer; cdecl;
```

Causes a virtual table transaction to rollback

```
xRollbackTo: function(var pVTab: TSQLite3VTab; iSavepoint: integer): Integer; cdecl;
```

Reverts the state of the virtual table content back to what it was just after the corresponding SAVEPOINT

- iSavepoint parameter indicates the unique name of the SAVEPOINT

```
xRowid: function(var pVtabCursor: TSQLite3VTabCursor; var pRowid: Int64): Integer; cdecl;
```

Should fill pRowid with the rowid of row that the virtual table cursor pVtabCursor is currently pointing at

```
xSavepoint: function(var pVTab: TSQLite3VTab; iSavepoint: integer): Integer; cdecl;
```

Starts a new transaction with the virtual table

- SAVEPOINTS are a method of creating transactions, similar to BEGIN and COMMIT, except that the SAVEPOINT and RELEASE commands are named and may be nested. See http://www.sqlite.org/lang_savepoint.html
- iSavepoint parameter indicates the unique name of the SAVEPOINT

xSync: function(var pVTab: TSQLite3VTab): Integer; cdecl;

Signals the start of a two-phase commit on a virtual table

- This method is only invoked after call to the xBegin method and prior to an xCommit or xRollback.
- In order to implement two-phase commit, the xSync method on all virtual tables is invoked prior to invoking the xCommit method on any virtual table.
- If any of the xSync methods fail, the entire transaction is rolled back.

```
xUpdate: function(var pVTab: TSQLite3VTab; nArg: Integer; var ppArg:
TSQLite3ValueArray; var pRowid: Int64): Integer; cdecl;
```

Makes a change to a virtual table content (insert/delete/update)

- The nArg parameter specifies the number of entries in the ppArg[] array
- The value of nArg will be 1 for a pure delete operation or N+2 for an insert or replace or update where N is the number of columns in the table (including any hidden columns)
- The ppArg[0] parameter is the rowid of a row in the virtual table to be deleted. If ppArg[0] is an SQL NULL, then no deletion occurs
- The ppArg[1] parameter is the rowid of a new row to be inserted into the virtual table. If ppArg[1] is an SQL NULL, then the implementation must choose a rowid for the newly inserted row. Subsequent ppArg[] entries contain values of the columns of the virtual table, in the order that the columns were declared. The number of columns will match the table declaration that the xConnect or xCreate method made using the sqlite3.declare_vtab() call. All hidden columns are included.
- When doing an insert without a rowid (nArg>1, ppArg[1] is an SQL NULL), the implementation must set pRowid to the rowid of the newly inserted row; this will become the value returned by the sqlite3.last_insert_rowid() function. Setting this value in all the other cases is a harmless no-op; the SQLite engine ignores the pRowid return value if nArg=1 or ppArg[1] is not an SQL NULL.
- Each call to xUpdate() will fall into one of cases shown below. Note that references to ppArg[i] mean the SQL value held within the ppArg[i] object, not the ppArg[i] object itself:

```
nArg = 1
```

The single row with rowid equal to ppArg[0] is deleted. No insert occurs.

```
nArg > 1
ppArg[0] = NULL
```

A new row is inserted with a rowid ppArg[1] and column values in ppArg[2] and following. If ppArg[1] is an SQL NULL, the a new unique rowid is generated automatically.

```
nArg > 1
ppArg[0] <> NULL
ppArg[0] = ppArg[1]
```

The row with rowid ppArg[0] is updated with new values in ppArg[2] and following parameters.

```
nArg > 1
ppArg[0] <> NULL
ppArg[0] <> ppArg[1]
```

The row with rowid ppArg[0] is updated with rowid ppArg[1] and new values in ppArg[2] and following parameters. This will occur when an SQL statement updates a rowid, as in the statement:

```
UPDATE table SET rowid=rowid+1 WHERE ...;
```

- The xUpdate() method must return SQLITE_OK if and only if it is successful. If a failure occurs, the xUpdate() must return an appropriate error code. On a failure, the pVTab.zErrMsg element may optionally be replaced with a custom error message text.
- If the xUpdate() method violates some constraint of the virtual table (including, but not limited to, attempting to store a value of the wrong datatype, attempting to store a value that is too large or too small, or attempting to change a read-only value) then the xUpdate() must fail with an appropriate error code.
- There might be one or more TSQLite3VTabCursor objects open and in use on the virtual table instance and perhaps even on the row of the virtual table when the xUpdate() method is invoked. The implementation of xUpdate() must be prepared for attempts to delete or modify rows of the table out from other existing cursors. If the virtual table cannot accommodate such changes, the xUpdate() method must return an error code.

TSQLite3MemMethods = record

Defines the interface between SQLite and low-level memory allocation routines

- as used by `sqlite3.config(SQLITE_CONFIG_MALLOC,pMemMethods);`

pAppData: pointer;

Argument to `xInit()` and `xShutdown()`

xFree: **procedure**(ptr: pointer); **cdecl;**

Free a prior allocation

xInit: **function**(appData: pointer): integer; **cdecl;**

Initialize the memory allocator

xMalloc: **function**(size: integer): pointer; **cdecl;**

Memory allocation function

xRealloc: **function**(ptr: pointer; size: integer): pointer; **cdecl;**

Resize an allocation

xRoundup: **function**(size: integer): integer; **cdecl;**

Round up request size to allocation size

xShutdown: **procedure**(appData: pointer); **cdecl;**

Deinitialize the memory allocator

xSize: **function**(ptr: pointer): integer; **cdecl;**

Return the size of an allocation

TSQLite3Library = class(TObject)

Wrapper around all SQLite3 library API calls

- abstract class allowing direct binding of static `sqlite3.obj` (TSQLite3LibrayStatic) or with an external library (TSQLite3LibraryDynamic)

- a global `sqlite3: TSQLite3Library` will be defined in this unit, so you should call `sqlite3.open()` instead of `sqlite3_open()` for instance

- if your project refers to SynSQLite3Static unit, it will initialize a TSQLite3LibrayStatic instance

Used for DI-2.2.1 (page 2558).

aggregate_context: function(Context: TSQLite3FunctionContext; nBytes: integer): pointer; cdecl;

Implementations of aggregate SQL functions use this routine to allocate memory for storing their state.

- The first time the `sqlite3.aggregate_context(C,N)` routine is called for a particular aggregate function, SQLite allocates N of memory, zeroes out that memory, and returns a pointer to the new memory. On second and subsequent calls to `sqlite3.aggregate_context()` for the same aggregate function instance, the same buffer is returned. `sqlite3.aggregate_context()` is normally called once for each invocation of the `xStep` callback and then one last time when the `xFinal` callback is invoked. When no rows match an aggregate query, the `xStep()` callback of the aggregate function implementation is never called and `xFinal()` is called exactly once. In those cases, `sqlite3.aggregate_context()` might be called for the first time from within `xFinal()`.
- The `sqlite3.aggregate_context(C,N)` routine returns a nil pointer if N is less than or equal to zero or if a memory allocate error occurs.
- The amount of space allocated by `sqlite3.aggregate_context(C,N)` is determined by the N parameter on first successful call. Changing the value of N in subsequent call to `sqlite3.aggregate_context()` within the same aggregate function instance will not resize the memory allocation.
- SQLite automatically frees the memory allocated by `sqlite3.aggregate_context()` when the aggregate query concludes.

backup_finish: function(Backup: TSQLite3Backup): integer; cdecl;

Finalize a Backup process on a given database

- When `backup_step()` has returned `SQLITE_DONE`, or when the application wishes to abandon the backup operation, the application should destroy the `TSQLite3Backup` by passing it to `backup_finish()`.
- The `backup_finish()` interfaces releases all resources associated with the `TSQLite3Backup` object. If `backup_step()` has not yet returned `SQLITE_DONE`, then any active write-transaction on the destination database is rolled back.
- The `TSQLite3Backup` object is invalid and may not be used following a call to `backup_finish()`.
- The value returned by `backup_finish` is `SQLITE_OK` if no `backup_step()` errors occurred, regardless of whether or not `backup_step()` completed. If an out-of-memory condition or IO error occurred during any prior `backup_step()` call on the same `TSQLite3Backup` object, then `backup_finish()` returns the corresponding error code.
- A return of `SQLITE_BUSY` or `SQLITE_LOCKED` from `backup_step()` is not a permanent error and does not affect the return value of `backup_finish()`.

backup_init: function(DestDB: TSQLite3DB; DestDatabaseName: PUTF8Char; SourceDB: TSQLite3DB; SourceDatabaseName: PUTF8Char): TSQLite3Backup; cdecl;

Initialize a backup process of a given SQLite3 database instance

- The DestDB and DestDatabaseName arguments are the database connection associated with the destination database and the database name, respectively. The database name is "main" for the main database, "temp" for the temporary database, or the name specified after the AS keyword in an ATTACH statement for an attached database.
- The SourceDB and SourceDatabaseName arguments identify the database connection and database name of the source database, respectively.
- The source and destination database connections (parameters SourceDB and DestDB) must be different or else function will fail with an error.
- If an error occurs within backup_init(), then nil is returned and an error code and error message are stored in the destination database connection DestDB. The error code and message for the failed call to backup_init() can be retrieved using the errcode() or errmsg() functions.
- A successful call to backup_init() returns a pointer to an TSQLite3Backup object. The TSQLite3Backup object may be used with the backup_step() and backup_finish() functions to perform the specified backup operation.

backup_pagecount: function(Backup: TSQLite3Backup): integer; cdecl;

Returns the the total number of pages in the source database file for a given Backup process

- The values returned by this function is only updated by backup_step(). If the source database is modified during a backup operation, then the value is not updated to account for any extra pages that need to be updated or the size of the source database file changing.

backup_remaining: function(Backup: TSQLite3Backup): integer; cdecl;

Returns the number of pages still to be backed up for a given Backup

- The values returned by this function is only updated by backup_step(). If the source database is modified during a backup operation, then the value is not updated to account for any extra pages that need to be updated or the size of the source database file changing.

backup_step: function(Backup: TSQLite3Backup; nPages: integer): integer; cdecl;

Perform a backup step to transfer the data between the two databases

- backup_step() will copy up to nPages pages between the source and destination databases specified by TSQLite3Backup object Backup.
- If nPages is negative, all remaining source pages are copied.
- If backup_step() successfully copies nPages pages and there are still more pages to be copied, then the function returns SQLITE_OK.
- If backup_step() successfully finishes copying all pages from source to destination, then it returns SQLITE_DONE.
- If an error occurs while running backup_step(), an error code is returned.
- As well as SQLITE_OK and SQLITE_DONE, a call to backup_step() may return SQLITE_READONLY, SQLITE_NOMEM, SQLITE_BUSY, SQLITE_LOCKED, or an SQLITE_IOERR_XXX extended error code. The function might return SQLITE_READONLY if the destination database was opened read-only, or is using WAL journaling and the destination and source page sizes differ, or the destination database is an in-memory database and the destination and source page sizes differ. SQLITE_BUSY indicates that the file-system lock did not succeed: in this case the call to backup_step() can be retried later. If the source database connection is being used to write to the source database when backup_step() is called, then SQLITE_LOCKED is returned immediately. Again, in this case the call to backup_step() can be retried later on. If SQLITE_IOERR_XXX, SQLITE_NOMEM, or SQLITE_READONLY is returned, then there is no point in retrying the call to backup_step(). These errors are considered fatal. The application must accept that the backup operation has failed and pass the backup operation handle to the backup_finish() to release associated resources.
- The first call to sqlite3_backup_step() obtains an exclusive lock on the destination file. The exclusive lock is not released until either backup_finish() is called or the backup operation is complete and backup_step() returns SQLITE_DONE. Every call to backup_step() obtains a shared lock on the source database that lasts for the duration of the backup_step() call.
- Because the source database is not locked between calls to backup_step(), the source database may be modified mid-way through the backup process. If the source database is modified by an external process or via a database connection other than the one being used by the backup operation, then the backup will be automatically restarted by the next call to backup_step(). If the source database is modified by the using the same database connection as is used by the backup operation (which is the case in the SynSQLite3 and mORMotSQLite3 units), then the backup database is automatically updated at the same time, so you won't lose any data.

bind_blob: function(S: TSQLite3Statement; Param: integer; Buf: pointer; Buf_bytes: integer; DestroyPtr: TSQLDestroyPtr=SQLITE_TRANSIENT): integer; cdecl;

Note that the official SQLite3 documentation could lead into misunderstanding: Text_bytes must EXCLUDE the null terminator, otherwise a #0 is appended to all column values Bind a Blob Value to a parameter of a prepared statement

- return SQLITE_OK on success or an error code - see SQLITE_* and sqlite3.errmsg()
- S is a statement prepared by a previous call to sqlite3.prepare_v2()
- Param is the index of the SQL parameter to be set (leftmost=1)
- Buf must point to a memory buffer of Buf_bytes bytes
- Buf_bytes contains the number of bytes in Buf
- set DestroyPtr as SQLITE_STATIC (nil) for static binding
- set DestroyPtr to SQLITE_TRANSIENT (-1) for SQLite to make its own private copy of the data (this is the preferred way in our Framework)
- set DestroyPtr to @sqlite3InternalFree if Value must be released via Freemem()

bind_double: function(S: TSQLite3Statement; Param: integer; Value: double): integer; cdecl;

Bind a floating point Value to a parameter of a prepared statement

- return SQLITE_OK on success or an error code - see SQLITE_* and sqlite3.errmsg()
- S is a statement prepared by a previous call to sqlite3.prepare_v2()
- Param is the index of the SQL parameter to be set (leftmost=1)
- Value is the floating point number to bind

bind_int: function(S: TSQLite3Statement; Param: integer; Value: integer): integer; cdecl;

Bind a 32 bits Integer Value to a parameter of a prepared statement

- return SQLITE_OK on success or an error code - see SQLITE_* and sqlite3.errmsg()
- S is a statement prepared by a previous call to sqlite3.prepare_v2()
- Param is the index of the SQL parameter to be set (leftmost=1)
- Value is the 32 bits Integer to bind

bind_int64: function(S: TSQLite3Statement; Param: integer; Value: Int64): integer; cdecl;

Bind a 64 bits Integer Value to a parameter of a prepared statement

- return SQLITE_OK on success or an error code - see SQLITE_* and sqlite3.errmsg()
- S is a statement prepared by a previous call to sqlite3.prepare_v2()
- Param is the index of the SQL parameter to be set (leftmost=1)
- Value is the 64 bits Integer to bind

bind_null: function(S: TSQLite3Statement; Param: integer): integer; cdecl;

Bind a NULL Value to a parameter of a prepared statement

- return SQLITE_OK on success or an error code - see SQLITE_* and sqlite3.errmsg()
- S is a statement prepared by a previous call to sqlite3.prepare_v2()
- Param is the index of the SQL parameter to be set (leftmost=1)

bind_parameter_count: function(S: TSQLite3Statement): integer; cdecl;

Number Of SQL Parameters for a prepared statement

- returns the index of the largest (rightmost) parameter. For all forms except ?NNN, this will correspond to the number of unique parameters.
- If parameters of the ?NNN type are used, there may be gaps in the list.

bind_text: function(S: TSQLite3Statement; Param: integer; Text: PUTF8Char; Text_bytes: integer=-1; DestroyPtr: TSQLDestroyPtr=SQLITE_TRANSIENT): integer; cdecl;

Bind a Text Value to a parameter of a prepared statement

- return SQLITE_OK on success or an error code - see SQLITE_* and sqlite3.errmsg()
- S is a statement prepared by a previous call to sqlite3.prepare_v2()
- Param is the index of the SQL parameter to be set. The leftmost SQL parameter has an index of 1.
- Text must contains an UTF8-encoded null-terminated string query
- Text_bytes contains -1 (to stop at the null char) or the number of chars in the input string, excluding the null terminator
- set DestroyPtr as SQLITE_STATIC (nil) for static binding
- set DestroyPtr to SQLITE_TRANSIENT (-1) for SQLite to make its own private copy of the data (this is the preferred way in our Framework)
- set DestroyPtr to @sqlite3InternalFree if Value must be released via Freemem()

```
bind_zeroblob: function(S: TSQLite3Statement; Param: integer; Size: integer):  
integer; cdecl;
```

Bind a ZeroBlob buffer to a parameter

- uses a fixed amount of memory (just an integer to hold its size) while it is being processed. Zeroblobs are intended to serve as placeholders for BLOBs whose content is later written using incremental BLOB I/O routines.
- a negative value for the Size parameter results in a zero-length BLOB
- the leftmost SQL parameter has an index of 1, but ?NNN may override it

```
blob_bytes: function(Blob: TSQLite3Blob): Integer; cdecl;
```

Return The Size Of An Open BLOB

```
blob_close: function(Blob: TSQLite3Blob): Integer; cdecl;
```

Close A BLOB Handle

```
blob_open: function(DB: TSQLite3DB; DBName, TableName, ColumnName: PUTF8Char;  
RowID: Int64; Flags: Integer; var Blob: TSQLite3Blob): Integer; cdecl;
```

Open a BLOB For Incremental I/O

- returns a BLOB handle for row RowID, column ColumnName, table TableName in database DBName; in other words, the same BLOB that would be selected by:
SELECT ColumnName FROM DBName.TableName WHERE rowid = RowID;

```
blob_read: function(Blob: TSQLite3Blob; const Data; Count, Offset: Integer):  
Integer; cdecl;
```

Read Data From a BLOB Incrementally

```
blob_reopen: function(Blob: TSQLite3Blob; RowID: Int64): Integer; cdecl;
```

Move a BLOB Handle to a New Row

- will point to a different row of the same database table
- this is faster than closing the existing handle and opening a new one

```
blob_write: function(Blob: TSQLite3Blob; const Data; Count, Offset: Integer):  
Integer; cdecl;
```

Write Data To a BLOB Incrementally

```
busy_handler: function(DB: TSQLite3DB; CallbackPtr: TSQLBusyHandler; user:  
Pointer): integer; cdecl;
```

Register A Callback To Handle SQLITE_BUSY Errors

- This routine sets a callback function that might be invoked whenever an attempt is made to open a database table that another thread or process has locked.
- If the busy callback is nil, then SQLITE_BUSY or SQLITE_IOERR_BLOCKED is returned immediately upon encountering the lock. If the busy callback is not nil, then the callback might be invoked with two arguments.
- The default busy callback is nil.

busy_timeout: function(DB: TSQLite3DB; Milliseconds: integer): integer; cdecl;

Set A Busy Timeout

- This routine sets a busy handler that sleeps for a specified amount of time when a table is locked. The handler will sleep multiple times until at least "ms" milliseconds of sleeping have accumulated. After at least "ms" milliseconds of sleeping, the handler returns 0 which causes sqlite3.step() to return SQLITE_BUSY or SQLITE_IOERR_BLOCKED.
- Calling this routine with an argument less than or equal to zero turns off all busy handlers.
- There can only be a single busy handler for a particular database connection any given moment. If another busy handler was defined (using sqlite3.busy_handler()) prior to calling this routine, that other busy handler is cleared.

changes: function(DB: TSQLite3DB): Integer; cdecl;

Count The Number Of Rows Modified

- This function returns the number of database rows that were changed or inserted or deleted by the most recently completed SQL statement on the database connection specified by the first parameter. Only changes that are directly specified by the INSERT, UPDATE, or DELETE statement are counted. Auxiliary changes caused by triggers or foreign key actions are not counted. Use the sqlite3.total_changes() function to find the total number of changes including changes caused by triggers and foreign key actions.
- If a separate thread makes changes on the same database connection while sqlite3.changes() is running then the value returned is unpredictable and not meaningful.

clear_bindings: function(S: TSQLite3Statement): integer; cdecl;

Reset All Bindings On A Prepared Statement

close: function(DB: TSQLite3DB): integer; cdecl;

Destructor for the sqlite3 object, which handle is DB

- Applications should finalize all prepared statements and close all BLOB handles associated with the sqlite3 object prior to attempting to close the object (sqlite3.next_stmt() interface can be used for this task)
- if invoked while a transaction is open, the transaction is automatically rolled back
- SynSQLite3Static will use its own internal function for handling properly its own encryption format

column_blob: function(S: TSQLite3Statement; Col: integer): PAnsiChar; cdecl;

Converts the Col column in the current row of prepared statement S into a BLOB and then returns a pointer to the converted value

- NULL is converted into nil
- INTEGER or FLOAT are converted into ASCII rendering of the numerical value
- TEXT and BLOB are returned directly

column_bytes: function(S: TSQLite3Statement; Col: integer): integer; cdecl;

Number of bytes for a BLOB or UTF-8 string result

- S is the SQL statement, after sqlite3.step(S) returned SQLITE_ROW
- Col is the column number, indexed from 0 to sqlite3.column_count(S)-1
- an implicit conversion into UTF-8 text is made for a numeric value or UTF-16 column: you must call sqlite3.column_text() or sqlite3.column_blob() before calling sqlite3.column_bytes() to perform the conversion itself

column_count: function(S: TSQLite3Statement): integer; cdecl;

Get the number of columns in the result set for the statement

column_decltype: function(S: TSQLite3Statement; Col: integer): PAnsiChar; cdecl;

Returns a zero-terminated UTF-8 string containing the declared datatype of a result column

column_double: function(S: TSQLite3Statement; Col: integer): double; cdecl;

Converts the Col column in the current row prepared statement S into a floating point value and returns a copy of that value

- NULL is converted into 0.0
- INTEGER is converted into corresponding floating point value
- TEXT or BLOB is converted from all correct ASCII numbers with 0.0 as default

column_int: function(S: TSQLite3Statement; Col: integer): integer; cdecl;

Converts the Col column in the current row prepared statement S into a 32 bit integer value and returns a copy of that value

- NULL is converted into 0
- FLOAT is truncated into corresponding integer value
- TEXT or BLOB is converted from all correct ASCII numbers with 0 as default

column_int64: function(S: TSQLite3Statement; Col: integer): int64; cdecl;

Converts the Col column in the current row prepared statement S into a 64 bit integer value and returns a copy of that value

- NULL is converted into 0
- FLOAT is truncated into corresponding integer value
- TEXT or BLOB is converted from all correct ASCII numbers with 0 as default

column_name: function(S: TSQLite3Statement; Col: integer): PUTF8Char; cdecl;

Returns the name of a result column as a zero-terminated UTF-8 string

column_text: function(S: TSQLite3Statement; Col: integer): PUTF8Char; cdecl;

Converts the Col column in the current row prepared statement S into a zero-terminated UTF-8 string and returns a pointer to that string

- NULL is converted into nil
- INTEGER or FLOAT are converted into ASCII rendering of the numerical value
- TEXT is returned directly (with UTF-16 -> UTF-8 encoding if necessary)
- BLOB add a zero terminator if needed

column_text16: function(S: TSQLite3Statement; Col: integer): PWideChar; cdecl;

Converts the Col column in the current row prepared statement S into a zero-terminated UTF-16 string and returns a pointer to that string

- NULL is converted into nil
- INTEGER or FLOAT are converted into ASCII rendering of the numerical value
- TEXT is returned directly (with UTF-8 -> UTF-16 encoding if necessary)
- BLOB add a zero terminator if needed

column_type: function(S: TSQLite3Statement; Col: integer): integer; cdecl;

Datatype code for the initial data type of a result column

- returned value is one of SQLITE_INTEGER, SQLITE_FLOAT, SQLITE_TEXT, SQLITE_BLOB or SQLITE_NULL
- S is the SQL statement, after sqlite3.step(S) returned SQLITE_ROW
- Col is the column number, indexed from 0 to sqlite3.column_count(S)-1
- must be called before any sqlite3.column_*() statement, which may result in an implicit type conversion: in this case, value is undefined

column_value: function(S: TSQLite3Statement; Col: integer): TSQLite3Value; **cdecl**;

Get the value handle of the Col column in the current row of prepared statement S

- this handle represent a sqlite3.value object
- this handle can then be accessed with any sqlite3.value_*() function below

commit_hook: function(DB: TSQLite3DB; xCallback: TSQLCommitCallback; pArg: Pointer): Pointer; **cdecl**;

Register Commit Notification Callbacks

- The sqlite3.commit_hook() interface registers a callback function to be invoked whenever a transaction is committed.
- Any callback set by a previous call to sqlite3.commit_hook() for the same database connection is overridden.
- Registering a nil function disables the Commit callback.
- The sqlite3.commit_hook(DB,C,P) function returns the P argument from the previous call of the same function on the same database connection DB, or nil for the first call for each function on DB.

config: function(operation: integer): integer; **cdecl** varargs;

Used to make global configuration changes to current database

context_db_handle: function(Context: TSQLite3FunctionContext): TSQLite3DB; **cdecl**;

Returns a copy of the pointer to the database connection (the 1st parameter) of the sqlite3.create_function() routine that originally registered the application defined function

create_collation: function(DB: TSQLite3DB; CollationName: PUTF8Char; StringEncoding: integer; CollateParam: pointer; cmp: TSQLCollateFunc): integer; **cdecl**;

Define New Collating Sequences

- add new collation sequences to the database connection specified
- collation name is to be used in CREATE TABLE t1 (a COLLATE CollationName); or in SELECT * FROM t1 ORDER BY c COLLATE CollationName;
- StringEncoding is either SQLITE_UTF8 either SQLITE_UTF16
- TSQLDataBase.Create add WIN32CASE, WIN32NOCASE and ISO8601 collations

```
create_function: function(DB: TSQLite3DB; FunctionName: PUTF8Char; nArg, eTextRep: integer; pApp: pointer; xFunc, xStep: TSQLFunctionFunc; xFinal: TSQLFunctionFinal): Integer; cdecl;
```

Add SQL functions or aggregates or to redefine the behavior of existing SQL functions or aggregates

- The first parameter is the database connection to which the SQL function is to be added. If an application uses more than one database connection then application-defined SQL functions must be added to each database connection separately.
- The second parameter is the name of the SQL function to be created or redefined. The length of the name is limited to 255 bytes in a UTF-8 representation, exclusive of the zero-terminator. Note that the name length limit is in UTF-8 bytes, not characters nor UTF-16 bytes. Any attempt to create a function with a longer name will result in SQLITE_MISUSE being returned.
- The third parameter (nArg) is the number of arguments that the SQL function or aggregate takes. If this parameter is -1, then the SQL function or aggregate may take any number of arguments between 0 and the SQLITE_LIMIT_FUNCTION_ARG current limit. If the third parameter is less than -1 or greater than 127 then the behavior is undefined.
- The fourth parameter, eTextRep, specifies what text encoding this SQL function prefers for its parameters. Every SQL function implementation must be able to work with UTF-8, UTF-16le, or UTF-16be. But some implementations may be more efficient with one encoding than another. When multiple implementations of the same function are available, SQLite will pick the one that involves the least amount of data conversion. If there is only a single implementation which does not care what text encoding is used, then the fourth argument should be SQLITE_ANY.
- The fifth parameter, pApp, is an arbitrary pointer. The implementation of the function can gain access to this pointer using sqlite3.user_data().
- The seventh, eighth and ninth parameters, xFunc, xStep and xFinal, are pointers to C-language functions that implement the SQL function or aggregate. A scalar SQL function requires an implementation of the xFunc callback only; nil pointers must be passed as the xStep and xFinal parameters. An aggregate SQL function requires an implementation of xStep and xFinal and nil pointer must be passed for xFunc. To delete an existing SQL function or aggregate, pass nil pointers for all three function callbacks.
- It is permitted to register multiple implementations of the same functions with the same name but with either differing numbers of arguments or differing preferred text encodings. SQLite will use the implementation that most closely matches the way in which the SQL function is used.

```
create_function_v2: function(DB: TSQLite3DB; FunctionName: PUTF8Char; nArg, eTextRep: integer; pApp: pointer; xFunc, xStep: TSQLFunctionFunc; xFinal: TSQLFunctionFinal; xDestroy: TSQLDestroyPtr): Integer; cdecl;
```

Add SQL functions or aggregates or to redefine the behavior of existing SQL functions or aggregates, including destruction

- if the additional xDestroy parameter is not nil, then it is invoked when the function is deleted, either by being overloaded or when the database connection closes.
- When the destructure callback of the tenth parameter is invoked, it is passed a single argument which is a copy of the pointer which was the fifth parameter to sqlite3.create_function_v2().
- this function is not available in older revisions - e.g. 3.6.*

```
create_module_v2: function(DB: TSQLite3DB; const zName: PAnsiChar; var p:
TSQLite3Module; pClientData: Pointer; xDestroy: TSQLDestroyPtr): Integer; cdecl;
```

Used to register a new virtual table module name

- The module name is registered on the database connection specified by the first DB parameter.
- The name of the module is given by the second parameter.
- The third parameter is a pointer to the implementation of the virtual table module.
- The fourth parameter is an arbitrary client data pointer that is passed through into the xCreate and xConnect methods of the virtual table module when a new virtual table is being created or reinitialized.
- The fifth parameter can be used to specify a custom destructor for the pClientData buffer. SQLite will invoke the destructor function (if it is not nil) when SQLite no longer needs the pClientData pointer. The destructor will also be invoked if call to sqlite3.create_module_v2() fails.

```
create_window_function: function(DB: TSQLite3DB; FunctionName: PUTF8Char; nArg,
eTextRep: integer; pApp: pointer; xStep: TSQLFunctionFunc; xFinal, xValue:
TSQLFunctionFinal; xInverse: TSQLFunctionFunc; xDestroy: TSQLDestroyPtr): Integer;
cdecl;
```

Add SQL functions or aggregates or to redefine the behavior of existing SQL functions or aggregates, including extra callback functions needed by aggregate window functions

- see https://www.sqlite.org/windowfunctions.html#aggregate_window_functions
- sixth, seventh, eighth and ninth parameters (xStep, xFinal, xValue and xInverse) passed to this function are pointers to callbacks that implement the new aggregate window function. xStep and xFinal must both be non-nil. xValue and xInverse may either both be nil, in which case a regular aggregate function is created, or must both be non-nil, in which case the new function may be used as either an aggregate or aggregate window function
- this function is not available in older revisions, i.e. before 3.25.2

```
db_config: function(DestDB: TSQLite3DB; operation: integer): integer; cdecl
varargs;
```

Used to make global configuration changes to current database connection

```
declare_vtab: function(DB: TSQLite3DB; const zSQL: PAnsiChar): Integer; cdecl;
```

Declare the Schema of a virtual table

- The xCreate() and xConnect() methods of a virtual table module call this interface to declare the format (the names and datatypes of the columns) of the virtual tables they implement. The string can be deallocated and/or reused as soon as the sqlite3.declare_vtab() routine returns.
- If a column datatype contains the special keyword "HIDDEN" (in any combination of upper and lower case letters) then that keyword it is omitted from the column datatype name and the column is marked as a hidden column internally. A hidden column differs from a normal column in three respects: 1. Hidden columns are not listed in the dataset returned by "PRAGMA table_info", 2. Hidden columns are not included in the expansion of a "*" expression in the result set of a SELECT, and 3. Hidden columns are not included in the implicit column-list used by an INSERT statement that lacks an explicit column-list.

deserialize: function(DB: TSQLite3DB; Schema: PUTF8Char; Data: pointer; DBSize, BufSize: Int64; Flags: integer): pointer; cdecl;

Deserialize a database

- causes the database connection DB to disconnect from database Schema and then reopen Schema as an in-memory database based on the serialization contained in Data; the serialized database Data is DBSize bytes in size
- BufSize is the size of the buffer Data, which might be larger than DBSize

errmsg: function(DB: TSQLite3DB): PUTF8Char; cdecl;

Returns English-language text that describes an error, using UTF-8 encoding (which, with English text, is the same as Ansi).

- Memory to hold the error message string is managed internally. The application does not need to worry about freeing the result. However, the error string might be overwritten or deallocated by subsequent calls to other SQLite interface functions.

extended_errcode: function(DB: TSQLite3DB): integer; cdecl;

Returns the numeric result code or extended result code for the most recent failed sqlite3 API call associated with a database connection

finalize: function(S: TSQLite3Statement): integer; cdecl;

Delete a previously prepared statement

- return SQLITE_OK on success or an error code - see SQLITE_* and sqlite3.errmsg()
- this routine can be called at any point during the execution of the prepared statement. If the virtual machine has not completed execution when this routine is called, that is like encountering an error or an interrupt. Incomplete updates may be rolled back and transactions canceled, depending on the circumstances, and the error code returned will be SQLITE_ABORT

free_: procedure(p: Pointer); cdecl;

Releases memory previously returned by sqlite3.malloc() or sqlite3.realloc()

- should call native free() function, i.e. FreeMem() in this unit
- renamed free_ in order not to override TObject.Free method

initialize: function: integer; cdecl;

Initialize the SQLite3 database code

- automatically called by the initialization block of this unit
- so sqlite3.c is compiled with SQLITE_OMIT_AUTOINIT defined

key: function(DB: TSQLite3DB; key: pointer; keyLen: Integer): integer; cdecl;

Specify the encryption key on a newly opened database connection

- Assigned(key)=false if encryption is not available for this .dll
- SynSQLite3Static will use its own internal encryption format
- key/keylen may be a JSON-serialized TSynSignerParams object, or will use AES-OFB-128 after SHAKE_128 with rounds=1000 and a fixed salt on plain password text

last_insert_rowid: function(DB: TSQLite3DB): Int64; cdecl;

Returns the rowid of the most recent successful INSERT into the database

libversion: function: PUTF8Char; cdecl;

Return the version of the SQLite database engine, in ascii format

- currently returns '3.40.0', when used with our SynSQLite3Static unit
- if an external SQLite3 library is used, version may vary
- you may use the VersionText property (or Version for full details) instead

limit: function(DB: TSQLite3DB; id, newValue: integer): integer; cdecl;

Allows the size of various constructs to be limited on a connection by connection basis

- The first parameter is the database connection whose limit is to be set or queried
- The second parameter is one of the limit categories that define a class of constructs to be size limited - see TSQLLimitCategory enumerate
- The third parameter is the new limit for that construct. If the new limit is a negative number, the limit is unchanged.
- Regardless of whether or not the limit was changed, the sqlite3.limit() interface returns the prior value of the limit. Hence, to find the current value of a limit without changing it, simply invoke this interface with the third parameter set to -1.

malloc: function(n: Integer): Pointer; cdecl;

Returns a pointer to a block of memory at least N bytes in length

- should call native malloc() function, i.e. GetMem() in this unit

memory_highwater: function(resetFlag: Integer): Int64; cdecl;

Returns the maximum value of sqlite3.memory_used() since the high-water mark was last reset

memory_used: function: Int64; cdecl;

Returns the number of bytes of memory currently outstanding (malloced but not freed)

next_stmt: function(DB: TSQLite3DB; S: TSQLite3Statement): TSQLite3Statement; cdecl;

Find the next prepared statement

- this interface returns a handle to the next prepared statement after S, associated with the database connection DB.
- if S is 0 then this interface returns a pointer to the first prepared statement associated with the database connection DB.
- if no prepared statement satisfies the conditions of this routine, it returns 0

open: function(filename: PUTF8Char; var DB: TSQLite3DB): integer; cdecl;

Open a SQLite3 database filename, creating a DB handle

- filename must be UTF-8 encoded (filenames containing international characters must be converted to UTF-8 prior to passing them)
- allocate a sqlite3 object, and return its handle in DB
- return SQLITE_OK on success
- an error code (see SQLITE_* const) is returned otherwise - sqlite3.errmsg() can be used to obtain an English language description of the error
- Whatever or not an error occurs when it is opened, resources associated with the database connection handle should be released by passing it to sqlite3.close() when it is no longer required

```
open_v2: function(filename: PUTF8Char; var DB: TSQLite3DB; flags: integer; zVfszVfs: PUTF8Char): integer; cdecl;
```

Open a SQLite3 database filename, creating a DB handle

- sqlite3.open_v2() interface works like sqlite3.open() except that it accepts two additional parameters for additional control over the new database connection.
- flags parameter to sqlite3.open_v2() can take one of SQLITE_OPEN_READONLY, SQLITE_OPEN_READWRITE or (SQLITE_OPEN_READWRITE or SQLITE_OPEN_CREATE) values, optionally combined with the SQLITE_OPEN_NOMUTEX, SQLITE_OPEN_FULLMUTEX, SQLITE_OPEN_SHARED_CACHE, SQLITE_OPEN_PRIVATE_CACHE, and/or SQLITE_OPEN_URI flags
- If the flags parameter is not one of the combinations shown above optionally combined with other SQLITE_OPEN_* bits then the behavior is undefined.
- The fourth parameter is the name of the sqlite3_vfs object that defines the operating system interface that the new database connection should use. If the fourth parameter is a nil pointer then the default sqlite3_vfs object is used

```
prepare_v2: function(DB: TSQLite3DB; SQL: PUTF8Char; SQL_bytes: integer; var S: TSQLite3Statement; var SQLtail: PUTF8Char): integer; cdecl;
```

Compile a SQL query into byte-code

- SQL must contain a UTF8-encoded null-terminated string query
- SQL_bytes contains -1 (to stop at the null char) or the number of bytes in the input string, including the null terminator
- return SQLITE_OK on success or an error code - see SQLITE_* and sqlite3.errmsg()
- S will contain a handle of the resulting statement (an opaque sqlite3.stmt object) on success, or will be 0 on error - the calling procedure is responsible for deleting the compiled SQL statement using sqlite3.finalize() after it has finished with it
- in this "v2" interface, the prepared statement that is returned contains a copy of the original SQL text
- this routine only compiles the first statement in SQL, so SQLtail is left pointing to what remains uncompiled

```
realloc: function(pOld: Pointer; n: Integer): Pointer; cdecl;
```

Attempts to resize a prior memory allocation

- should call native realloc() function, i.e. ReallocMem() in this unit

```
rekey: function(DB: TSQLite3DB; key: pointer; keyLen: Integer): integer; cdecl;
```

Change the encryption key on a database connection that is already opened

- can also decrypt a previously encrypted database (so that it is accessible from any version of SQLite) by specifying a nil key
- Assigned(rekey)=false if encryption is not available, i.e. if NOSQLITE3STATIC is defined
- also see ChangeSQLEncryptTablePassWord() procedure

```
reset: function(S: TSQLite3Statement): integer; cdecl;
```

Reset a prepared statement object back to its initial state, ready to be re-Prepared

- if the most recent call to sqlite3.step(S) returned SQLITE_ROW or SQLITE_DONE, or if sqlite3.step(S) has never before been called with S, then sqlite3.reset(S) returns SQLITE_OK.
- return an appropriate error code if the most recent call to sqlite3.step(S) failed
- any SQL statement variables that had values bound to them using the sqlite3.bind_*() API retain their values. Use sqlite3.clear_bindings() to reset the bindings.

```
result_blob: procedure(Context: TSQLite3FunctionContext; Value: Pointer;  
Value_bytes: Integer=0; DestroyPtr: TSQLDestroyPtr=SQLITE_TRANSIENT); cdecl;
```

Sets the result from an application-defined function to be the BLOB

- content is pointed to by the Value and which is Value_bytes bytes long
- set DestroyPtr as SQLITE_STATIC (nil) for static binding
- set DestroyPtr to SQLITE_TRANSIENT (-1) for SQLite to make its own private copy of the data (this is the preferred way in our Framework)
- set DestroyPtr to @sqlite3InternalFree if Value must be released via Freemem() or to @sqlite3InternalFreeObject if Value must be released via a Free method

```
result_double: procedure(Context: TSQLite3FunctionContext; Value: double); cdecl;
```

Sets the result from an application-defined function to be a floating point value specified by its 2nd argument

```
result_error: procedure(Context: TSQLite3FunctionContext; Msg: PUTF8Char; MsgLen:  
integer=-1); cdecl;
```

Cause the implemented SQL function to throw an exception

- SQLite interprets the error message string from sqlite3.result_error() as UTF-8
- if MsgLen is negative, Msg must be #0 ended, or MsgLen must tell the number of characters in the Msg UTF-8 buffer

```
result_int64: procedure(Context: TSQLite3FunctionContext; Value: Int64); cdecl;
```

Sets the return value of the application-defined function to be the 64-bit signed integer value given in the 2nd argument

```
result_null: procedure(Context: TSQLite3FunctionContext); cdecl;
```

Sets the return value of the application-defined function to be NULL

```
result_text: procedure(Context: TSQLite3FunctionContext; Value: PUTF8Char;  
Value_bytes: Integer=-1; DestroyPtr: TSQLDestroyPtr=SQLITE_TRANSIENT); cdecl;
```

Sets the return value of the application-defined function to be a text string which is represented as UTF-8

- if Value_bytes is negative, then SQLite takes result text from the Value parameter through the first zero character
- if Value_bytes is non-negative, then as many bytes (NOT characters: this parameter must include the #0 terminator) of the text pointed to by the Value parameter are taken as the application-defined function result
- set DestroyPtr as SQLITE_STATIC (nil) for static binding
- set DestroyPtr to SQLITE_TRANSIENT (-1) for SQLite to make its own private copy of the data (this is the preferred way in our Framework)
- set DestroyPtr to @sqlite3InternalFree if Value must be released via Freemem() or to @sqlite3InternalFreeObject if Value must be released via a Free method

```
result_value: procedure(Context: TSQLite3FunctionContext; Value: TSQLite3Value);  
cdecl;
```

Sets the result of the application-defined function to be a copy the unprotected sqlite3.value object specified by the 2nd parameter

- The sqlite3.result_value() interface makes a copy of the sqlite3.value so that the sqlite3.value specified in the parameter may change or be deallocated after sqlite3.result_value() returns without harm

```
rollback_hook: function(DB: TSQLite3DB; xCallback: TSQLCommitCallback; pArg: Pointer): Pointer; cdecl;
```

Register Rollback Notification Callbacks

- The `sqlite3.rollback_hook()` interface registers a callback function to be invoked whenever a transaction is rolled back.
- Any callback set by a previous call to `sqlite3.rollback_hook()` for the same database connection is overridden.
- Registering a nil function disables the Rollback callback.
- The `sqlite3.rollback_hook(D,C,P)` function returns the P argument from the previous call of the same function on the same database connection D, or nil for the first call for each function on D.

```
serialize: function(DB: TSQLite3DB; Schema: PUTF8Char; Size: PInt64; Flags: integer): pointer; cdecl;
```

Serialize a database

- returns a pointer to memory that is a serialization of the Schema database on database connection DB
- if Size is not nil, then the size of the database in bytes is written into Size^
- for an ordinary on-disk database file, the serialization is just a copy of the disk file; for an in-memory database or a "TEMP" database, the serialization is the same sequence of bytes which would be written to disk if that database were backed up to disk
- caller is responsible for freeing the returned value (using `free_`) to avoid a memory leak

```
set_authorizer: function(DB: TSQLite3DB; xAuth: TSQLAuthorizerCallback; pUserData: Pointer): Integer; cdecl;
```

Registers an authorizer callback to a specified DB connection

- Only a single authorizer can be in place on a database connection at a time
- Each call to `sqlite3.set_authorizer` overrides the previous call
- Disable the authorizer by installing a nil callback
- The authorizer is disabled by default

```
shutdown: function: integer; cdecl;
```

Shutdown the SQLite3 database core

- automatically called by the finalization block of this unit

```
soft_heap_limit64: function(N: Int64): Int64; cdecl;
```

Sets and/or queries the soft limit on the amount of heap memory that may be allocated by SQLite

- SQLite strives to keep heap memory utilization below the soft heap limit by reducing the number of pages held in the page cache as heap memory usages approaches the limit. The soft heap limit is "soft" because even though SQLite strives to stay below the limit, it will exceed the limit rather than generate an SQLITE_NOMEM error. In other words, the soft heap limit is advisory only
- The return value from `soft_heap_limit64()` is the size of the soft heap limit prior to the call, or negative in the case of an error. If the argument N is negative then no change is made to the soft heap limit. Hence, the current size of the soft heap limit can be determined by invoking `soft_heap_limit64()` with a negative argument
- This function is useful when you have many SQLite databases open at the same time, as the cache-size setting is per-database (connection), while this limit is global for the process, so this allows to limit the total cache size

step: function(S: TSQLite3Statement): integer; cdecl;

Evaluate An SQL Statement, returning a result status:

- SQLITE_BUSY means that the database engine was unable to acquire the database locks it needs to do its job. If the statement is a COMMIT or occurs outside of an explicit transaction, then you can retry the statement. If the statement is not a COMMIT and occurs within a explicit transaction then you should rollback the transaction before continuing.
- SQLITE_DONE means that the statement has finished executing successfully. `sqlite3.step()` should not be called again on this virtual machine without first calling `sqlite3.reset()` to reset the virtual machine state back.
- SQLITE_ROW is returned each time a new row of data is ready for processing by the caller. The values may be accessed using the column access functions below. `sqlite3.step()` has to be called again to retrieve the next row of data.
- SQLITE_MISUSE means that the this routine was called inappropriately. Perhaps it was called on a prepared statement that has already been finalized or on one that had previously returned SQLITE_ERROR or SQLITE_DONE. Or it could be the case that the same database connection is being used by two or more threads at the same moment in time.
- SQLITE_SCHEMA means that the database schema changes, and the SQL statement has been recompiled and run again, but the schame changed in a way that makes the statement no longer valid, as a fatal error.
- another specific error code is returned on fatal error

stmt_readonly: function(S: TSQLite3Statement): integer; cdecl;

Returns true (non-zero) if and only if the prepared statement X makes no direct changes to the content of the database file

- Transaction control statements such as BEGIN, COMMIT, ROLLBACK, SAVEPOINT, and RELEASE cause `sqlite3.stmt_readonly()` to return true, since the statements themselves do not actually modify the database but rather they control the timing of when other statements modify the database. The ATTACH and DETACH statements also cause `sqlite3.stmt_readonly()` to return true since, while those statements change the configuration of a database connection, they do not make changes to the content of the database files on disk.

total_changes: function(DB: TSQLite3DB): Integer; cdecl;

Total Number Of Rows Modified

- This function returns the number of row changes caused by INSERT, UPDATE or DELETE statements since the database connection was opened. The count returned by `sqlite3.total_changes()` includes all changes from all trigger contexts and changes made by foreign key actions. However, the count does not include changes used to implement REPLACE constraints, do rollbacks or ABORT processing, or DROP TABLE processing. The count does not include rows of views that fire an INSTEAD OF trigger, though if the INSTEAD OF trigger makes changes of its own, those changes are counted. The `sqlite3.total_changes()` function counts the changes as soon as the statement that makes them is completed (when the statement handle is passed to `sqlite3.reset()` or `sqlite3.finalize()`).
- If a separate thread makes changes on the same database connection while `sqlite3.total_changes()` is running then the value returned is unpredictable and not meaningful.

```
trace_v2: function(DB: TSQLite3DB; Mask: TSQLTraceMask; Callback: TSQLTraceCallback; UserData: Pointer): Pointer; cdecl;
```

Register callback function that can be used for tracing the execution of SQL statements

- registers a trace callback function Callback against database connection DB, using property mask TSQLTraceMask and context pointer UserData
- if the Callback parameter is nil or if the TSQLTraceMask mask is zero, then tracing is disabled
- parameters of the Callback functions depend of the TSQLTraceMask involved

```
update_hook: function(DB: TSQLite3DB; xCallback: TSQLUpdateCallback; pArg: pointer): pointer; cdecl;
```

Register Data Change Notification Callbacks

- The sqlite3.update_hook() interface registers a callback function with the database connection identified by the first argument to be invoked whenever a row is updated, inserted or deleted.
- Any callback set by a previous call to this function for the same database connection is overridden.
- sqlite3.update_hook(D,C,P) function returns the P argument from the previous call on the same database connection D, or nil for the first call on database connection D.
- The update hook is not invoked when internal system tables are modified (i.e. sqlite_master and sqlite_sequence).
- In the current implementation, the update hook is not invoked when duplication rows are deleted because of an ON CONFLICT REPLACE clause. Nor is the update hook invoked when rows are deleted using the truncate optimization. The exceptions defined in this paragraph might change in a future release of SQLite.
- Note that you should also trace COMMIT and ROLLBACK commands (calling sqlite3.commit_hook() and sqlite3.rollback_hook() functions) if you want to ensure that the notified update was not canceled by a later Rollback.

```
user_data: function(Context: TSQLite3FunctionContext): pointer; cdecl;
```

Returns a copy of the pointer that was the pUserData parameter (the 5th parameter) of the sqlite3.create_function() routine that originally registered the application defined function

- This routine must be called from the same thread in which the application-defined function is running

```
value_blob: function(Value: TSQLite3Value): pointer; cdecl;
```

Converts a sqlite3.value object, specified by its handle, into a blob memory, and returns a copy of that value

```
value_bytes: function(Value: TSQLite3Value): integer; cdecl;
```

Number of bytes for a sqlite3.value object, specified by its handle

- used after a call to sqlite3.value_text() or sqlite3.value_blob() to determine buffer size (in bytes)

```
value_double: function(Value: TSQLite3Value): double; cdecl;
```

Converts a sqlite3.value object, specified by its handle, into a floating point value and returns a copy of that value

```
value_int64: function(Value: TSQLite3Value): Int64; cdecl;
```

Converts a sqlite3.value object, specified by its handle, into an integer value and returns a copy of that value

value_numeric_type: function(Value: TSQLite3Value): integer; cdecl;

Attempts to apply numeric affinity to the value

- This means that an attempt is made to convert the value to an integer or floating point. If such a conversion is possible without loss of information (in other words, if the value is a string that looks like a number) then the conversion is performed. Otherwise no conversion occurs. The datatype after conversion is returned.
- returned value is one of SQLITE_INTEGER, SQLITE_FLOAT, SQLITE_TEXT, SQLITE_BLOB or SQLITE_NULL

value_text: function(Value: TSQLite3Value): PUTF8Char; cdecl;

Converts a sqlite3.value object, specified by its handle, into an UTF-8 encoded string, and returns a copy of that value

value_type: function(Value: TSQLite3Value): integer; cdecl;

Datatype code for a sqlite3.value object, specified by its handle

- returned value is one of SQLITE_INTEGER, SQLITE_FLOAT, SQLITE_TEXT, SQLITE_BLOB or SQLITE_NULL
- must be called before any sqlite3.value_*() statement, which may result in an implicit type conversion: in this case, value is undefined

constructor Create; virtual;

Initialize the internal version numbers

procedure ForceToUseSharedMemoryManager; virtual;

Will change the SQLite3 configuration to use Delphi/FPC memory manager

- this will reduce memory fragmentation, and enhance speed, especially under multi-process activity
- this method should be called before sqlite3.initialize()

property Version: RawUTF8 read GetVersion;

Will return the class name and SQLite3 version number

- if self (e.g. global sqlite3) is nil, will return ""

property VersionNumber: cardinal read fVersionNumber;

Returns the current version number as a plain integer

- equals e.g. 3008003001 for '3.8.3.1'

property VersionText: RawUTF8 read fVersionText;

Returns the current version number as a text

- equals e.g. '3.8.3.1'
- use the Version property for the full information about this instance

TSQLite3LibraryDynamic = class(TSQLite3Library)

Allow access to an external SQLite3 library engine

- you can e.g. replace the main sqlite3 engine with any external library:
FreeAndNil(sqlite3); *// release any previous instance (e.g. static)*
sqlite3 := TSQLite3LibraryDynamic.Create;

Used for DI-2.2.1 (page 2558).

constructor Create(const LibraryName: TFileName=SQLITE_LIBRARY_DEFAULT_NAME);
reintroduce;

Initialize the specified external library
 - raise an ESQlite3Exception on error

destructor Destroy; **override;**

Unload the external library

ESQlite3Exception = **class**(ESynException)

Custom SQLite3 dedicated Exception type

DB: TSQlite3DB;

The DB which raised this exception

constructor Create(aDB: TSQlite3DB; aErrorCode: integer; **const** aSQL: RawUTF8);
reintroduce; **overload;**

Create the exception, getting the message from DB

property ErrorCode: integer **read** fErrorCode;

The corresponding error code, e.g. 21 (for SQLITE_MISUSE)

property SQLite3ErrorCode: TSQlite3ErrorCode **read** fSQLite3ErrorCode;

The corresponding error code, e.g. secMISUSE

TSQLRequest = **object**(TObject)

Wrapper to a SQLite3 request

- defined as a record, so that it may be allocated on the stack
- do not forget to call the Close method to release the request resources

Used for DI-2.2.1 (page 2558).

function Execute(aDB: TSQlite3DB; **const** aSQL: RawUTF8; **var** Values: TRawUTF8DynArray): integer; **overload;**

Execute a SQL statement which return TEXT from the aSQL UTF-8 encoded string

- Execute the first statement in aSQL
- this statement must get (at least) one field/column result of TEXT
- return result as a dynamic array of RawUTF8 in ID
- return count of row in integer function result (may be < length(ID))
- raise an ESQlite3Exception on any error

Used for DI-2.2.1 (page 2558).

function Execute(aDB: TSQlite3DB; **const** aSQL: RawUTF8; **var** ID: TInt64DynArray): integer; **overload;**

Execute a SQL statement which return integers from the aSQL UTF-8 encoded string

- Execute the first statement in aSQL
- this statement must get (at least) one field/column result of INTEGER
- return result as a dynamic array of Int64 in ID
- return count of row in integer function result (may be < length(ID))
- raise an ESQlite3Exception on any error

Used for DI-2.2.1 (page 2558).

function Execute(aDB: TSQLite3DB; **const** aSQL: RawUTF8; JSON: TStream; Expand: boolean=false): PtrInt; overload;

Execute one SQL statement which return the results in JSON format

- JSON format is more compact than XML and well supported
- Execute the first statement in aSQL
- if SQL is "", the statement should have been prepared, reset and bound if necessary
- raise an ESQlite3Exception on any error
- JSON data is added to TStream, with UTF-8 encoding
- if Expand is true, JSON data is an array of objects, for direct use with any Ajax or .NET client:
 [{ "col1":val11,"col2":"val12"}, {"col1":val21,... }]
- if Expand is false, JSON data is serialized (used in TSQLTableJSON)
 { "FieldCount":1,"Values":["col1","col2",val11,"val12",val21,..] }
- BLOB field value is saved as Base64, in the ""\uFFF0base64encodedbinary"" format and contains true BLOB data (no conversion into TEXT, as with TSQLTableDB) - so will work for sftBlob, sftBlobDynArray and sftBlobRecord
- returns the number of data rows added to JSON (excluding the headers)

Used for DI-2.2.1 (page 2558).

function ExecuteJSON(aDB: TSQLite3DB; **const** aSQL: RawUTF8; Expand: boolean=false; aResultCount: PPtrInt=nil): RawUTF8;

Execute one SQL statement which return the results in JSON format

- use internaly Execute() above with a TRawByteStringStream, and return a string
- BLOB field value is saved as Base64, e.g. ""\uFFF0base64encodedbinary""
- returns the number of data rows added to JSON (excluding the headers) in the integer variable mapped by aResultCount (if any)
- if any error occurs, the ESQlite3Exception is handled and "" is returned

function ExecuteNoException(aDB: TSQLite3DB; **const** aSQL: RawUTF8): boolean;

Execute one SQL statement in the aSQL UTF-8 encoded string

- Execute the first statement in aSQL: call Prepare() then Step once
- Close is always called internaly
- returns TRUE on success, and raise no ESQlite3Exception on error, but returns FALSE

function FieldA(Col: integer): WinAnsiString;

Return a field as Win-Ansi (i.e. code page 1252) encoded text value, first Col is 0

function FieldBlob(Col: integer): RawByteString;

Return a field as a blob value (RawByteString/TSQLRawBlob is an AnsiString), first Col is 0

function FieldBlobToStream(Col: integer): TStream;

Return a field as a TStream blob value, first Col is 0

- caller shall release the returned TStream instance

function FieldDeclaredType(Col: Integer): RawUTF8;

Return the type of this column, as declared at creation

- textual type used for CREATE TABLE of the corresponding column, as returned by sqlite3.column_decltype()

function FieldDeclaredTypeS(Col: Integer): string;

Return the generic VCL string type of this column, as declared at creation
- textual type used for CREATE TABLE of corresponding column, as returned by
sqlite3.column_decltype()
- note that prior to Delphi 2009, you may loose content during conversion

function FieldDouble(Col: integer): double;

Return a field floating point value, first Col is 0

function FieldIndex(const aColumnName: RawUTF8): integer;

The field index matching this name
- return -1 if not found

function FieldInt(Col: integer): Int64;

Return a field integer value, first Col is 0

function FieldName(Col: integer): RawUTF8;

3. Field attributes after a successful Step() (returned SQLITE_ROW) the field name of the current ROW

function FieldNull(Col: Integer): Boolean;

Return TRUE if the column value is NULL, first Col is 0

function FieldS(Col: integer): string;

Return a text value value as generic VCL string, first Col is 0
- note that prior to Delphi 2009, you may loose content during conversion

function FieldType(Col: Integer): integer;

Return the field type of this column
- retrieve the "SQLite3" column type as returned by sqlite3.column_type - i.e. SQLITE_NULL, SQLITE_INTEGER, SQLITE_FLOAT, SQLITE_TEXT, or SQLITE_BLOB

function FieldUTF8(Col: integer): RawUTF8;

Return a field UTF-8 encoded text value, first Col is 0

function FieldValue(Col: integer): TSQLite3Value;

Return the field as a sqlite3.value object handle, first Col is 0

function FieldW(Col: integer): RawUnicode;

Return a field RawUnicode encoded text value, first Col is 0

function Prepare(DB: TSQLite3DB; const SQL: RawUTF8; NoExcept: boolean=false): integer;

1. general request process Prepare a UTF-8 encoded SQL statement
- compile the SQL into byte-code
- parameters ? ?NNN :VV @VV \$VV can be bound with Bind*() functions below
- raise an ESQlite3Exception on any error, unless NoExcept is TRUE

function PrepareAnsi(DB: TSQLite3DB; const SQL: WinAnsiString): integer;

Prepare a WinAnsi SQL statement
- behave the same as Prepare()

function PrepareNext: integer;

Prepare the next SQL command initialized in previous Prepare()

- raise an ESQLite3Exception on any error

function Reset: integer;

Reset A Prepared Statement Object

- reset a prepared statement object back to its initial state, ready to be re-executed.
- any SQL statement variables that had values bound to them using the Bind*() function below retain their values. Use BindReset() to reset the bindings
- return SQLITE_OK on success, or the previous Step error code

function Step: integer;

Evaluate An SQL Statement, returning the sqlite3.step() result status:

- return SQLITE_ROW on success, with data ready to be retrieved via the Field*() methods
- return SQLITE_DONE if the SQL commands were executed
- raise an ESQLite3Exception on any error

procedure Bind(Param: Integer; Data: TCustomMemoryStream); overload;

Bind a Blob TCustomMemoryStream buffer to a parameter

- the leftmost SQL parameter has an index of 1, but ?NNN may override it
- raise an ESQLite3Exception on any error

procedure Bind(Param: Integer; Value: double); overload;

Bind a double value to a parameter

- the leftmost SQL parameter has an index of 1, but ?NNN may override it
- raise an ESQLite3Exception on any error

procedure Bind(Param: Integer; const Value: RawUTF8); overload;

Bind a UTF-8 encoded string to a parameter

- the leftmost SQL parameter has an index of 1, but ?NNN may override it
- raise an ESQLite3Exception on any error
- this function will use copy-on-write assignment of Value, with no memory allocation, then let sqlite3InternalFreeRawByteString release the variable

procedure Bind(Param: Integer; Data: pointer; Size: integer); overload;

Bind a Blob buffer to a parameter

- the leftmost SQL parameter has an index of 1, but ?NNN may override it
- raise an ESQLite3Exception on any error

procedure Bind(Param: Integer; Value: Int64); overload;

Bind an integer value to a parameter

- the leftmost SQL parameter has an index of 1, but ?NNN may override it
- raise an ESQLite3Exception on any error

procedure BindBlob(Param: Integer; const Data: RawByteString);

Bind a Blob buffer to a parameter

- the leftmost SQL parameter has an index of 1, but ?NNN may override it
- raise an ESQLite3Exception on any error
- this function will use copy-on-write assignment of Data, with no memory allocation, then let sqlite3InternalFreeRawByteString release the variable

procedure BindNull(Param: Integer);

Bind a NULL value to a parameter

- the leftmost SQL parameter has an index of 1, but ?NNN may override it
- raise an ESQlite3Exception on any error

procedure BindReset;

2. Bind parameters to a SQL query (for the last prepared statement) Reset All Bindings On A Prepared Statement

- Contrary to the intuition of many, Reset() does not reset the bindings on a prepared statement. Use this routine to reset all host parameter

procedure BindS(Param: Integer; **const** Value: **string**);

Bind a generic VCL string to a parameter

- with versions prior to Delphi 2009, you may loose some content here: Bind(Param: integer; Value: RawUTF8) is the preferred method
- the leftmost SQL parameter has an index of 1, but ?NNN may override it
- raise an ESQlite3Exception on any error

procedure BindZero(Param: Integer; Size: integer);

Bind a ZeroBlob buffer to a parameter

- uses a fixed amount of memory (just an integer to hold its size) while it is being processed. Zeroblobs are intended to serve as placeholders for BLOBs whose content is later written using incremental BLOB I/O routines (as with TSQLBlobStream created from TSQLDataBase.Blob() e.g.).
- a negative value for the Size parameter results in a zero-length BLOB
- the leftmost SQL parameter has an index of 1, but ?NNN may override it
- raise an ESQlite3Exception on any error

procedure Close;

Close the Request handle

- call it even if an ESQlite3Exception has been raised

procedure Execute(aDB: TSQLite3DB; **const** aSQL: RawUTF8); **overload**;

Execute one SQL statement in the aSQL UTF-8 encoded string

- Execute the first statement in aSQL: call Prepare() then Step once
- Close is always called internally
- raise an ESQlite3Exception on any error

Used for DI-2.2.1 (page 2558).

procedure Execute; **overload**;

Execute one SQL statement already prepared by a call to Prepare()

- the statement is closed
- raise an ESQlite3Exception on any error

Used for DI-2.2.1 (page 2558).

procedure Execute(aDB: TSQLite3DB; const aSQL: RawUTF8; out ID: Int64); overload;

Execute a SQL statement which return one integer from the aSQL UTF-8 encoded string

- Execute the first statement in aSQL
- this statement must get (at least) one field/column result of INTEGER
- return result as an unique Int64 in ID
- raise an ESQLite3Exception on any error }

Used for DI-2.2.1 (page 2558).

procedure Execute(aDB: TSQLite3DB; const aSQL: RawUTF8; out Value: RawUTF8); overload;

Execute a SQL statement which return one TEXT value from the aSQL UTF-8 encoded string

- Execute the first statement in aSQL
- this statement must get (at least) one field/column result of TEXT
- raise an ESQLite3Exception on any error

Used for DI-2.2.1 (page 2558).

procedure ExecuteAll; overload;

Execute all SQL statements already prepared by a call to Prepare()

- the statement is closed
- raise an ESQLite3Exception on any error

procedure ExecuteAll(aDB: TSQLite3DB; const aSQL: RawUTF8); overload;

Execute all SQL statements in the aSQL UTF-8 encoded string

- internally call Prepare() then Step then PrepareNext until end of aSQL
- Close is always called internally
- raise an ESQLite3Exception on any error

procedure ExecuteDebug(aDB: TSQLite3DB; const aSQL: RawUTF8; var OutFile: Text);

Execute all SQL statements in the aSQL UTF-8 encoded string, results will be written as ANSI text in OutFile

procedure FieldsToJSON(WR: TJSONWriter; DoNotFetchBlobs: boolean=false);

Append all columns values of the current Row to a JSON stream

- will use WR.Expand to guess the expected output format
- BLOB field value is saved as Base64, in the ""\uFFFF0base64encodedbinary" format and contains true BLOB data

property FieldCount: integer read fFieldCount;

The column/field count of the current ROW

- fields numerotation starts with 0

property IsReadOnly: Boolean read GetReadOnly;

Returns true if the current prepared statement makes no direct changes to the content of the database file

- Transaction control statements such as BEGIN, COMMIT, ROLLBACK, SAVEPOINT, and RELEASE cause this property to return true, since the statements themselves do not actually modify the database but rather they control the timing of when other statements modify the database. The ATTACH and DETACH statements also cause this property to return true since, while those statements change the configuration of a database connection, they do not make changes to the content of the database files on disk.

property ParamCount: integer **read** GetParamCount;

The bound parameters count

property Request: TSQLite3Statement **read** fRequest;

Read-only access to the Request (SQLite3 statement) handle

property RequestDB: TSQLite3DB **read** fDB;

Read-only access to the SQLite3 database handle

TSQLStatementCache = record

Used to retrieve a prepared statement

Statement: TSQLRequest;

Associated prepared statement, ready to be executed after binding

StatementSQL: RawUTF8;

Associated SQL statement

Timer: TSynMonitor;

Used to monitor execution time

TSQLStatementCached = object(TObject)

Handle a cache of prepared statements

- is defined either as an object either as a record, due to a bug in Delphi 2009/2010 compiler (at least): this structure is not initialized if defined as an object on the stack, but will be as a record :(

Cache: TSQLStatementCachedDynArray;

Prepared statements with parameters for faster SQLite3 execution

- works for SQL code with ? internal parameters

Caches: TDynArrayHashed;

Hashing wrapper associated to the Cache[] array

Count: integer;

Current number of items in the Cache[] array

DB: TSQLite3DB;

The associated SQLite3 database instance

- any direct access to this cache list should be protected via DB.Lock

function Prepare(**const** GenericSQL: RawUTF8; WasPrepared: PBoolean=**nil**;
 ExecutionTimer: PPPrecisionTimer=**nil**; ExecutionMonitor: PSynMonitor=**nil**):
 PSQLRequest;

Add or retrieve a generic SQL (with ? parameters) statement from cache

procedure Init(aDB: TSQLite3DB);

Initialize the cache

procedure ReleaseAllDBStatements;

Used internally to release all prepared statements from Cache[]

procedure SortCacheByTotalTime(**var** aIndex: TIntegerDynArray);

Could be used e.g. for statistics

- will use internally the function StatementCacheTotalTimeCompare()

TSQLDataBaseSQLFunction = class(TObject)

Those classes can be used to define custom SQL functions inside a TSQLDataBase

constructor Create(aFunction: TSQLFunctionFunc; aFunctionParametersCount: Integer;
const aFunctionName: RawUTF8=''); **reintroduce**;

Initialize the corresponding SQL function

- expects at least the low-level TSQLFunctionFunc implementation (in sqlite3.create_function() format) and the number of expected parameters
- if the function name is not specified, it will be retrieved from the type information (e.g. TReferenceDynArray will declare 'ReferenceDynArray')

property FunctionName: RawUTF8 **read** fSQLName;

The SQL function name, as called from the SQL statement

- the same function name may be registered several times with a diverse number of parameters (e.g. to implement optional parameters)

property FunctionParametersCount: integer **read** fFunctionParametersCount;

The number of parameters expected by the SQL function

property InternalFunction: TSQLFunctionFunc **read** fInternalFunction;

The internal function prototype

- ready to be assigned to sqlite3.create_function() xFunc parameter

TSQLDataBaseSQLFunctionDynArray = class(TSQLDataBaseSQLFunction)

To be used to define custom SQL functions for dynamic arrays BLOB search

constructor Create(aTypeInfo: pointer; aCompare: TDynArraySortCompare; **const**
aFunctionName: RawUTF8=''); **reintroduce**;

Initialize the corresponding SQL function

- if the function name is not specified, it will be retrieved from the type information (e.g. TReferenceDynArray will declare 'ReferenceDynArray')
- the SQL function will expect two parameters: the first is the BLOB field content, and the 2nd is the array element to search (set with TDynArray.ElemSave() or with BinToBase64WithMagic(aDynArray.ElemSave())) if called via a Client and a JSON prepared parameter)
- you should better use the already existing faster SQL functions Byte/Word/Integer/Cardinal/Int64/CurrencyDynArrayContains() if possible (this implementation will allocate each dynamic array into memory before comparison, and will be therefore slower than those optimized versions)

TSQLDataBase = class(TSynPersistentLock)

Simple wrapper for direct SQLite3 database manipulation

- embed the SQLite3 database calls into a common object
