- thread-safe call of all SQLite3 queries (SQLITE_THREADSafe 0 in sqlite.c)
- can cache last results for SELECT statements, if property UseCache is true: this can speed up most read queries, for web server or client UI e.g.

Used for DI-2.2.1 (page 2558).

```
constructor Create(const aFileName: TFileName; const aPassword: RawUTF8='';  
aOpenV2Flags: integer=0; aDefaultCacheSize: integer=10000; aDefaultPageSize:  
integer=4096); reintroduce;
```

Open a SQLite3 database file

- open an existing database file or create a new one if no file exists
- if specified, the password will be used to cypher this file on disk (the main SQLite3 database file is encrypted, not the wal file during run); the password may be a JSON-serialized TSynSignerParams object, or will use AES-OFB-128 after SHAKE_128 with rounds=1000 and a fixed salt on plain password text; note that our custom encryption is not compatible with the official SQLite Encryption Extension module
- you can specify some optional flags for sqlite3.open_v2() as SQLITE_OPEN_READONLY or SQLITE_OPEN_READWRITE instead of supplied default value (which corresponds to the sqlite3.open() behavior)
- by default, 10000 pages are used to cache data in memory (using around 40 MB of RAM), but you may specify another value for performance tuning
- SYSTEMNOCASE collation is added (our custom fast UTF-8 case insensitive UTF8ILComp() function, which is used also in the SQLite3UI unit for coherency and efficiency)
- ISO8601 collation is added (TDateTime stored as ISO-8601 encoded TEXT)
- WIN32CASE and WIN32NOCASE collations are added (use slow but accurate Win32 CompareW)
- some additional SQL functions are registered: MOD, SOUNDEX/SOUNDEXFR/SOUNDEXES, RANK, CONCAT, TIMELOG, TIMELOGUNIX, JSONGET/JSONHAS/JSONSET and TDynArray-Blob Byte/Word/Integer/Cardinal/Int64/Currency/RawUTF8DynArrayContains
- initialize a internal mutex to ensure that all access to the database is atomic
- raise an ESQLite3Exception on any error

```
destructor Destroy; override;
```

Close a database and free its memory and context

- if TransactionBegin was called but not committed, a RollBack is performed

```
function Backup(const BackupFileName: TFileName): boolean;
```

Backup of the opened Database into an external file name

- warning: this method won't use the SQLite Online Backup API
- database is closed, VACCUUMed, copied, then reopened: it's very fast for small databases, but is blocking and should be an issue
- if you use some virtual tables, they won't be restored after backup: this method would probably fail e.g. in the context of mORMot.pas

```
function BackupBackground(const BackupFileName: TFileName; StepPageNumber,  
StepSleepMS: Integer; OnProgress: TSQLDatabaseBackupEvent; SynLzCompress:  
boolean=false; const aPassword: RawUTF8=''): boolean;
```

Backup of the opened Database into an external file name

- this method will use the SQLite Online Backup API and a dedicated background thread for the process
- this will be asynchronous, and would block the main database process only when copying the StepPageNumber number of pages for each step, waiting StepSleepMS milliseconds before performing the next step: as a result, the copy operation can be done incrementally, by blocks of StepPageNumber pages, in which case the source database does not need to be locked for the duration of the copy, only for the brief periods of time when it is actually being read from: this allows other database users to continue uninterrupted (at least during StepSleepMS milliseconds) while a backup is running
- if StepPageNumber is -1, the whole DB will be copied in a single step, therefore in blocking mode, e.g. with BackupBackgroundWaitUntilFinished
- if SynLzCompress is TRUE, the backup file would be compressed using FileSynLZ() function - you may use BackupUnSynLZ() class method to uncompress the .dbsynlz file into a proper SQLite3 file
- the supplied OnProgress event handler will be called at each step, in the context of the background thread
- the background thread will be released when the process is finished
- if only one connection to the database does exist (e.g. if you use only one TSQLDatabase instance on the same database file), any modification to the source database during the background process will be included in the backup - so this method will work perfectly e.g. for mORMot.pas
- if specified, a password will be used to cypher BackupFileName on disk (it will work only with SynSQLite3Static) - you can uncypher the resulting encrypted database file later via ChangeSQLEncryptTablePassWord()
- returns TRUE if backup started as expected, or FALSE in case of error (e.g. if there is already another backup started, if the source or destination databases are locked or invalid, or if the sqlite3.dll is too old and does not support the Online Backup API)
- you can also use this method to save an SQLite3 ':memory:' database, perhaps in conjunction with the BackupBackgroundWaitUntilFinished method

```
function BackupBackgroundToDB(BackupDB: TSQLDatabase; StepPageNumber, StepSleepMS:  
Integer; OnProgress: TSQLDatabaseBackupEvent): boolean;
```

Background backup to another opened database instance

- in respect to BackupBackground method, it will use an existing database the actual process
- by design, SynLZCompress or aPassword parameters are unavailable

```
class function BackupSynLZ(const SourceDB, DestSynLZ: TFileName; EraseSourceDB:  
boolean): boolean;
```

Compress a SQLite3 file into a proprietary but efficient .dbsynlz layout

- same format than BackupUnSynLZ() class method or if SynLZCompress parameter is TRUE for BackupBackground() method
- the SourceDB file should not be active (e.g. be a backup file), i.e. not currently opened by the SQLite3 engine, otherwise behavior is unknown
- returns TRUE on success, FALSE on failure

class function BackupUnSynLZ(**const** SourceSynLZ, DestDB: TFileName): boolean;

Uncompress a .dbsynlz backup file as previously compressed with BackupSynLZ() or if SynLZCompress parameter is TRUE for BackupBackground() method

- any DestDB file name would be overwritten
- returns TRUE on success, FALSE on failure

function Blob(**const** DBName, TableName, ColumnName: RawUTF8; RowID: Int64; ReadWrite: boolean=false): TSQLBlobStream;

Open a BLOB incrementally for read[/write] access

- find a BLOB located in row RowID, column ColumnName, table TableName in database DBName; in other words, the same BLOB that would be selected by:
 SELECT ColumnName FROM DBName.TableName WHERE rowid = RowID;
- use after a TSQLRequest.BindZero() to reserve Blob memory
- if RowID=0, then the last inserted RowID is used (beware that this value won't be thread-safe, if another thread run another INSERT)
- will raise an ESQLite3Exception on any error

function DBClose: integer;

Close the opened database

- TSQLDatabase.Destroy already closes the database: this method is to be used only on particular cases, e.g. to close temporary a DB file and allow making a backup on its content
- returns the SQLITE_* status code, as retrieved from sqlite3.close(fDB) so that it should be SQLITE_OK on success

function DBOpen: integer; **virtual**;

(re)open the database from file fFileName

- TSQLDatabase.Create already opens the database: this method is to be used only on particular cases, e.g. to close temporary a DB file and allow making a backup on its content
- returns the SQLITE_* status code, as retrieved from sqlite3.open() so that it should be SQLITE_OK on success

function EnableCustomTokenizer: integer;

For SQLite >= 3.11 - enable registration of a custom tokenizer

- see details at <http://sqlite.org/fts3.html#f3tknznz>

function Execute(**const** aSQL: RawUTF8; **var** Values: TRawUTF8DynArray): integer; overload;

Execute one SQL statement returning TEXT from the aSQL UTF-8 encoded string

- Execute the first statement in aSQL
- this statement must get (at least) one field/column result of TEXT
- return result as a dynamic array of RawUTF8 in ID
- return count of row in integer function result (may be < length(ID))
- raise an ESQLite3Exception on any error

function Execute(**const** aSQL: RawUTF8; **var** ID: TInt64DynArray): integer; overload;

Execute one SQL statement which return integers from the aSQL UTF-8 encoded string

- Execute the first statement in aSQL
- this statement must get a one field/column result of INTEGER
- return result as a dynamic array of RawUTF8, as TEXT result
- return count of row in integer function result (may be < length(ID))
- raise an ESQLite3Exception on any error

function ExecuteJSON(const aSQL: RawUTF8; Expand: boolean=false; aResultCount: PPtrInt=nil): RawUTF8;

Execute one SQL statement returning its results in JSON format
 - the BLOB data is encoded as ""\uFFFF0base64encodedbinary""

function ExecuteNoException(const aSQL: RawUTF8): boolean;

Execute one SQL statements in aSQL UTF-8 encoded string
 - can be prepared with TransactionBegin()
 - raise no Exception on error, but returns FALSE in such case

function ExecuteNoExceptionInt64(const aSQL: RawUTF8): Int64;

Seamless execution of a SQL statement which returns one integer
 - Execute the first statement in aSQL
 - this statement must get a one field/column result of INTEGER
 - returns 0 on any error

function ExecuteNoExceptionUTF8(const aSQL: RawUTF8): RawUTF8;

Seamless execution of a SQL statement which returns one UTF-8 encoded string
 - Execute the first statement in aSQL
 - this statement must get a one field/column result of TEXT
 - returns "" on any error

function HasTable(const Name: RawUTF8): boolean;

Check if the given table do exist

class function IsBackupSynLZFile(const SynLZFile: TFileName): boolean;

Returns TRUE if the supplied name is a SQLite3 .dbsynlz compressed file
 - i.e. on the format generated by the BackupUnSynLZ() class method or if SynLZCompress parameter is TRUE for BackupBackground() method

function LastChangeCount: integer;

Count the number of rows modified by the last SQL statement
 - this method returns the number of database rows that were changed or inserted or deleted by the most recently completed SQL statement on the database connection specified by the first parameter. Only changes that are directly specified by the INSERT, UPDATE, or DELETE statement are counted.
 - wrapper around the sqlite3.changes() low-level function

function LastInsertRowID: Int64;

Return the last Insert Rowid

function LockJSON(const aSQL: RawUTF8; aResultCount: PPtrInt): RawUTF8;

Enter the internal mutex: called before any DB access
 - provide the SQL statement about to be executed: handle proper caching
 - if this SQL statement has an already cached JSON response, return it and don't enter the internal mutex: no UnlockJSON() call is necessary
 - if this SQL statement is not a SELECT, cache is flushed and the next call to UnlockJSON() won't add any value to the cache since this statement is not a SELECT and doesn't have to be cached!
 - if aResultCount does map to an integer variable, it will be filled with the returned row count of data (excluding field names) in the result

function TotalChangeCount: integer;

Return the number of row changes caused by INSERT, UPDATE or DELETE statements since the database connection was opened

- wrapper around the sqlite3.total_changes() low-level function

procedure BackupBackgroundWaitUntilFinished(TimeoutSeconds: Integer=-1);

Wait until any previous BackupBackground() is finished

- warning: this method won't call the Windows message loop, so should not be called from main thread, unless the UI may become unresponsive: you should better rely on OnProgress() callback for any GUI application

- by default, it will wait for ever so that process is finished, but you can set a time out (in seconds) after which the process will be aborted

- could be used with BackupBackground() and StepPageNumber=-1 to perform a whole copy of a database in one shot:

```
if aDB.BackupBackground('backup.db3',-1,0,nil) then
  aDB.BackupBackgroundWaitUntilFinished;
```

procedure CacheFlush;

Flush the internal SQL-based JSON cache content

- to be called when the regular Lock/LockJSON methods are not called, e.g. with external tables as defined in SQLite3DB unit

- will also increment the global InternalState property value (if set)

procedure Commit;

End a transaction: write all Execute() statements to the disk

procedure Execute(const aSQL: RawUTF8; out ID: Int64; NoLog: boolean=false); overload;

Execute one SQL statement which returns one integer from the aSQL UTF-8 encoded string

- Execute the first statement in aSQL

- this statement must get a one field/column result of INTEGER

- raise an ESQLite3Exception on any error

procedure Execute(const aSQL: RawUTF8); overload;

Execute one SQL statements in aSQL UTF-8 encoded string

- can be prepared with TransactionBegin()

- raise an ESQLite3Exception on any error

procedure Execute(const aSQL: RawUTF8; out ID: RawUTF8; NoLog: boolean=false); overload;

Execute one SQL statement which returns one UTF-8 encoded string value

- Execute the first statement in aSQL

- this statement must get a one field/column result of TEXT

- raise an ESQLite3Exception on any error

procedure ExecuteAll(const aSQL: RawUTF8);

Execute all SQL statements in aSQL UTF-8 encoded string

- can be prepared with TransactionBegin()

- raise an ESQLite3Exception on any error

procedure GetFieldNames(var Names: TRawUTF8DynArray; const TableName: RawUTF8);

Get all field names for a specified Table

procedure GetTableNames(**var** Names: TRawUTF8DynArray);

Get all table names contained in this database file

procedure Lock; overload;

Enter the internal mutex without any cache flush

- same as Lock("");

procedure Lock(**const** aSQL: RawUTF8); overload;

Class function = bug in D2005 enter the internal mutex: called before any DB access

- provide the SQL statement about to be executed: handle proper caching

- if the SQL statement is void, assume a SELECT statement (no cache flush)

procedure LockAndFlushCache;

Flush the internal statement cache, and enter the internal mutex

- same as Lock('ALTER');

procedure RegisterSQLFunction(aDynArrayTypeInfo: pointer; aCompare: TDynArraySortCompare; **const** aFunctionName: RawUTF8=''); overload;

Add a SQL custom function for a dynamic array to the database

- the resulting SQL function will expect two parameters: the first is the BLOB field content, and the 2nd is the array element to search (as set with TDynArray.ElemSave() or with BinToBase64WithMagic(aDynArray.ElemSave())) if called via a Client and a JSON prepared parameter)

- if the function name is not specified, it will be retrieved from the type information (e.g. TReferenceDynArray will declare 'ReferenceDynArray')

- you should better use the already existing faster SQL functions

Byte/Word/Integer/Cardinal/Int64/CurrencyDynArrayContains() if possible (this implementation will allocate each dynamic array into memory before comparison, and will be therefore slower than those optimized versions - but it will be always faster than Client-Server query, in all cases)

procedure RegisterSQLFunction(aFunction: TSQLFunctionFunc; aFunctionParametersCount: Integer; **const** aFunctionName: RawUTF8); overload;

Add a SQL custom function to the SQLite3 database engine

- will do nothing if the same function name and parameters count have already been registered (you can register then same function name with several numbers of parameters)

- typical use may be:

Demo.RegisterSQLFunction(InternalSQLFunctionCharIndex, 2, 'CharIndex');

procedure RegisterSQLFunction(aFunction: TSQLDataBaseSQLFunction); overload;

Add a SQL custom function to the SQLite3 database engine

- the supplied aFunction instance will be used globally and freed by TSQLDataBase.Destroy destructor

- will do nothing if the same function name and parameters count have already been registered (you can register then same function name with several numbers of parameters)

- you may use the overloaded function, which is a wrapper around:

Demo.RegisterSQLFunction(
TSQLDataBaseSQLFunction.Create(InternalSQLFunctionCharIndex, 2, 'CharIndex'));

procedure RollBack;

Abort a transaction: restore the previous state of the database

procedure TransactionBegin(aBehavior: TSQLDataBaseTransactionBehaviour = tbDeferred);

Begin a transaction

- Execute SQL statements with Execute() procedure below
- must be ended with Commit on success
- must be aborted with Rollback after an ESQlite3Exception raised
- The default transaction behavior is tbDeferred

procedure UnLock;

Leave the internal mutex: called after any DB access

procedure UnLockJSON(const aJSONResult: RawUTF8; aResultCount: PtrInt);

Leave the internal mutex: called after any DB access

- caller must provide the JSON result for the SQL statement previously set by LockJSON()
- do proper caching of the JSON response for this SQL statement

property BackupBackgroundInProgress: boolean **read** GetBackupBackgroundInProgress;

Is set to TRUE while a BackupBackground() process is still running

- see also BackupBackgroundWaitUntilFinished() method

property BackupBackgroundLastFileName: TFileName **read** fBackupBackgroundLastFileName;

The latest BackupBackground() process file name

property BackupBackgroundLastTime: RawUTF8 **read** fBackupBackgroundLastTime;

How much time did the latest BackupBackground() finished process take

property BusyTimeout: Integer **read** fBusyTimeout **write** SetBusyTimeout;

Sets a busy handler that sleeps for a specified amount of time (in milliseconds) when a table is locked, before returning an error

property Cache: TSynCache **read** fCache;

Access to the internal JSON cache, used by ExecuteJSON() method

- see UseCache property and CacheFlush method

property CacheSize: cardinal **read** GetCacheSize **write** SetCacheSize;

Query or change the suggested maximum number of database disk pages that SQLite will hold in memory at once per open database file

- DBOpen method will set this cache size to a big 10000 default, which sounds reasonable in the context of a server application (will use up to 40 MB of memory cache, with the default PageSize of 4096 bytes)
- when you change the cache size using the cache_size pragma, the change only endures for the current session. The cache size reverts to the default value when the database is closed and reopened
- we do not handle negative values here (i.e. KB of RAM), since it won't work if the linked SQLite3 library is version 3.7.9 and earlier

property DB: TSQLite3DB **read** fDB;

Read-only access to the SQLite3 database handle

property FileName: TFileName **read** fFileName;

Read-only access to the SQLite3 database filename opened

property FileNameWithoutPath: TFileName **read** fFileNameWithoutPath;

Read-only access to the SQLite3 database filename opened without its path

property FileSize: Int64 **read** GetFileSize;

Return the total number of bytes in the database file
- computes PageSize*PageCount

property InternalState: PCardinal **read** fInternalState **write** fInternalState;

This integer pointer (if not nil) is incremented when any SQL statement changes the database contents (i.e. any not SELECT statement)
- this pointer is thread-safe updated, inside a critical section

property IsMemory: boolean **read** fIsMemory;

Equals TRUE if the SQLite3 database was created as ':memory:' (i.e. SQLITE_MEMORY_DATABASE_NAME)

property Limit[Category: TSQLLimitCategory]: integer **read** GetLimit **write** SetLimit;

Retrieve or define a limit on the current database connection
- see TSQLLimitCategory for a details of all available limits
- see [@http://www.sqlite.org/c3ref/limit.html](http://www.sqlite.org/c3ref/limit.html)

property LockingMode: TSQLLockingMode **read** GetLockingMode **write** SetLockingMode;

Query or change the SQLite3 file-based locking mode, i.e. the way it locks the file
- default ImNormal is ACID and safe
- ImExclusive gives better performance in case of a number of write transactions, so can be used to release a mORMot server power: but you won't be able to access the database file from outside the process (like a "normal" database engine)

property Log: TSynLogClass **read** fLog **write** fLog;

Access to the log class associated with this SQLite3 database engine
- can be customized, e.g. by overridden TSQLRestServerDB.SetLogClass()

property LogResultMaximumSize: integer **read** fLogResultMaximumSize **write** fLogResultMaximumSize;

Sets a maximum size (in bytes) to be logged as sllResult rows
- by default, is set to 512 bytes, which sounds a good compromise since it does not make sense to log all the JSON content retrieved from the database engine, when a huge SELECT is executed

property MemoryMappedMB: cardinal **read** GetMemoryMappedMB **write** SetMemoryMappedMB;

Enables or disables disk content access using memory-mapped I/O
- 0 to disable it (the default, because of potential disadvantages)
- set to a number of Mega Bytes value of memory for the mapping
- expects a SQLite3 engine version >= 3.7.17
- Memory-Mapped I/O is NOT compatible with password encryption as implemented in our SynSQLite3Static unit

property OpenV2Flags: Integer **read** fOpenV2Flags;

Reflects how the database connection was created in the constructor

property PageCount: cardinal **read** GetPageCount;

Return the total number of pages in the database file

property PageSize: cardinal **read** GetPageSize **write** SetPageSize;

Query or change the page size of the database

- the page size must be a power of two between 512 and 65536 inclusive
- DBOpen method will set the PageSize to 4096 (if the database is not encrypted), which sounds better than the default 1024 value - you should not have to set this property usually
- setting this property will only cause an immediate change in the page size if it is issued while the database is still empty, prior to the first CREATE TABLE statement; if this property is used to specify a new page size just prior to running the VACUUM command and if the database is not in WAL journal mode then VACUUM will change the page size to the new value for the newly created database file

property Password: RawUTF8 **read** fPassword;

Read-only access to the SQLite3 password used for encryption

- may be a JSON-serialized TSynSignerParams object, or will use AES-OFB-128 after SHAKE_128 with rounds=1000 and a fixed salt on plain password text

property SQLite3Library: TSQlite3Library **read** GetSQLite3Library;

The SQLite3 library which is currently running

- part of TSQlDatabase published properties, to publish e.g. Version

property Synchronous: TSQlSynchronousMode **read** GetSynchronous **write** SetSynchronous;

Query or change the SQLite3 file-based synchronization mode, i.e. the way it waits for the data to be flushed on hard drive

- default smFull is very slow, but achieve 100% ACID behavior
- smNormal is faster, and safe until a catastrophic hardware failure occurs
- smOff is the fastest, data should be safe if the application crashes, but database file may be corrupted in case of failure at the wrong time

property TransactionActive: boolean **read** fTransactionActive;

Return TRUE if a Transaction begun

property UseCache: boolean **read** GetUseCache **write** SetUseCache;

If this property is set, all ExecuteJSON() responses will be cached

- cache is flushed on any write access to the DB (any not SELECT statement)
- cache is consistent only if ExecuteJSON() Expand parameter is constant
- cache is used by TSQlDataBase.ExecuteJSON() and TSQlTableDB.Create()

property UseCacheSize: integer **read** fUseCacheSize **write** fUseCacheSize;

Cache size in JSON bytes, to be set before UseCache is set to true

- default is 16MB

property user_version: cardinal **read** GetUserVersion **write** SetUserVersion;

Retrieve or set the user_version stored in the SQLite3 database file

- user-version is a 32-bit signed integer stored in the database header
- it can be used to change the database in case of format upgrade (e.g. refresh some hand-made triggers)

property WALMode: Boolean **read** GetWALMode **write** SetWALMode;

Query or change the Write-Ahead Logging mode for the database

- beginning with version 3.7 of the SQLite3 engine, a new "Write-Ahead Log" option (hereafter referred to as "WAL") is optionally available
- WAL might be very slightly slower (perhaps 1% or 2% slower) than the traditional rollback-journal approach in applications that do mostly reads and seldom write; but WAL provides more concurrency as readers do not block writers and a writer does not block readers. Reading and writing can proceed concurrently. With our SQLite3 framework, it's not needed.
- by default, this option is not set: only implement if you really need it, but our SQLite3 framework use locked access to the database, so there should be no benefit of WAL for the framework; but if you call directly TSQLiteDatabase instances in your code, it may be useful to you

TSQLBlobStream = class(TStream)

Used to read or write a BLOB Incrementaly

- data is read/written directly from/to the SQLite3 BTree
- data can be written after a TSQLRequest.BindZero() call to reserve memory
- this TStream has a fixed size, but Position property can be used to rewind

Used for DI-2.2.1 (page 2558).

constructor Create(aDB: TSQLite3DB; **const** DBName, TableName, ColumnName: RawUTF8; RowID: Int64; ReadWrite: boolean);

Opens a BLOB located in row RowID, column ColumnName, table TableName in database DBName; in other words, the same BLOB that would be selected by:

SELECT ColumnName FROM DBName.TableName WHERE rowid = RowID;

destructor Destroy; **override**;

Release the BLOB object

function Read(**var** Buffer; Count: Longint): Longint; **override**;

Read Count bytes from the opened BLOB in Buffer

function Seek(Offset: Longint; Origin: Word): Longint; **override**;

Change the current read position

function Write(**const** Buffer; Count: Longint): Longint; **override**;

Write is allowed for in-place replacement (resizing is not allowed)

- Create() must have been called with ReadWrite=true

procedure ChangeRow(RowID: Int64);

Reuse this class instance with another row of the same table

- will update the stream size, and also rewind position to the beginning
- it is actually faster than creating a new TSQLBlobStream instance

property Handle: TSQLite3Blob **read** fBlob;

Read-only access to the BLOB object handle

TSQLiteDatabaseBackupThread = class(TThread)

Background thread used for TSQLiteDatabase.BackupBackground() process

constructor Create(Backup: TSQLite3Backup; Source, Dest: TSQLDatabase;
 StepPageNumber, StepSleepMS: Integer; SynLzCompress: boolean; OnProgress:
 TSQLDatabaseBackupEvent; OwnerDest: boolean=true); **reintroduce**;

Initialize the background thread

- execution is started immediately - caller may call the WaitFor inherited method to run the process in blocking mode

property BackupDestFile: TFileName **read** fBackupDestFile;

The backup target database file name

property DestDB: TSQLDatabase **read** fDestDB;

The destination database of the backup process

property FailureError: Exception **read** fError;

The raised exception in case of backupFailure notification

property SourceDB: TSQLDatabase **read** fSourceDB;

The source database of the backup process

property Step: TSQLDatabaseBackupEventStep **read** fStep;

The current state of the backup process

- only set before a call to TSQLDatabaseBackupEvent

property StepNumberToFinish: integer **read** fStepNumberToFinish;

The number of pages which remain before end of backup

- only set before a call to TSQLDatabaseBackupEvent with backupStep* event

property StepNumberTotal: integer **read** fStepNumberTotal;

The number of pages for the whole database

- only set before a call to TSQLDatabaseBackupEvent with backupStep* event

property StepSynLzCompress: boolean **read** fStepSynLzCompress;

If .dbsynlz compression would be done on the backup file

- would use FileSynLZ(), so compress in chunks of 128 MB

Types implemented in the SynSQLite3 unit

TOnSQLStoredProc = **procedure**(const Statement: TSQLRequest) **of object**;

Stored Procedure prototype, used by TSQLDataBase.Execute() below

- called for every row of a Statement

- the implementation may update the database directly by using a local or shared TSQLRequest

- the TSQLRequest may be shared and prepared before the call for even faster access than with a local TSQLRequest

- no TSQLDataBase or higher levels objects can be used inside this method, since all locking and try..finally protection is outside it

- can optionnaly trigger a ESQLite3Exception on any error

TSQLAuthorizerCallback = **function**(pUserData: Pointer; code: Integer; const zTab, zCol,
 zDb, zAuthContext: PAnsiChar): Integer; **cdecl**;

Compile-Time Authorization Callback prototype

- The authorizer callback is invoked as SQL statements are being compiled by sqlite3.prepare2() e.g.

- The authorizer callback should return SQLITE_OK to allow the action, SQLITE_IGNORE to disallow the specific action but allow the SQL statement to continue to be compiled, or SQLITE_DENY to cause the entire SQL statement to be rejected with an error.

- If the authorizer callback returns any value other than SQLITE_IGNORE, SQLITE_OK, or SQLITE_DENY then the sqlite3.prepare_v2() or equivalent call that triggered the authorizer will fail with an error message.
- The first pUserData parameter to the authorizer callback is a copy of the third parameter to the sqlite3.set_authorizer() interface
- The second parameter to the callback is an integer action code that specifies the particular action to be authorized:
- The third through sixth parameters to the callback are zero-terminated strings that contain additional details about the action to be authorized.
- Here is a list of handled code constant, and their associated zTab / zCol parameters:

const	zTab	zCol
SQLITE_CREATE_INDEX	Index Name	Table Name
SQLITE_CREATE_TABLE	Table Name	nil
SQLITE_CREATE_TEMP_INDEX	Index Name	Table Name
SQLITE_CREATE_TEMP_TABLE	Table Name	nil
SQLITE_CREATE_TEMP_TRIGGER	Trigger Name	Table Name
SQLITE_CREATE_TEMP_VIEW	View Name	nil
SQLITE_CREATE_TRIGGER	Trigger Name	Table Name
SQLITE_CREATE_VIEW	View Name	nil
SQLITE_DELETE	Table Name	nil
SQLITE_DROP_INDEX	Index Name	Table Name
SQLITE_DROP_TABLE	Table Name	nil
SQLITE_DROP_TEMP_INDEX	Index Name	Table Name
SQLITE_DROP_TEMP_TABLE	Table Name	nil
SQLITE_DROP_TEMP_TRIGGER	Trigger Name	Table Name
SQLITE_DROP_TEMP_VIEW	View Name	nil
SQLITE_DROP_TRIGGER	Trigger Name	Table Name
SQLITE_DROP_VIEW	View Name	nil
SQLITE_INSERT	Table Name	nil
SQLITE_PRAGMA	Pragma Name	1st arg or nil
SQLITE_READ	Table Name	Column Name
SQLITE_SELECT	nil	nil
SQLITE_TRANSACTION	Operation	nil
SQLITE_UPDATE	Table Name	Column Name
SQLITE_ATTACH	Filename	nil
SQLITE_DETACH	Database Name	nil
SQLITE_ALTER_TABLE	Database Name	Table Name
SQLITE_REINDEX	Index Name	nil
SQLITE_ANALYZE	Table Name	nil
SQLITE_CREATE_VTABLE	Table Name	Module Name
SQLITE_DROP_VTABLE	Table Name	Module Name
SQLITE_FUNCTION	nil	Function Name
SQLITE_SAVEPOINT	Operation	Savepoint Name

- The 5th parameter to the authorizer callback is the name of the database ('main', 'temp', etc.) if applicable.
- The 6th parameter to the authorizer callback is the name of the inner-most trigger or view that is responsible for the access attempt or nil if this access attempt is directly from top-level SQL code.

TSQLEasyHandler = function(user: pointer; count: integer): integer; cdecl;

SQLite3 callback prototype to handle SQLITE_BUSY errors

- The first argument to the busy handler is a copy of the user pointer which is the third argument to sqlite3.busy_handler().
- The second argument to the busy handler callback is the number of times that the busy handler has been invoked for this locking event.
- If the busy callback returns 0, then no additional attempts are made to access the database and SQLITE_BUSY or SQLITE_IOERR_BLOCKED is returned.
- If the callback returns non-zero, then another attempt is made to open the database for reading and the cycle repeats.

```
TSQCollateFunc = function(CollateParam: pointer; s1Len: integer; s1: pointer; s2Len: integer; s2: pointer) : integer; cdecl;
```

SQLite3 collation (i.e. sort and comparison) function prototype

- this function MUST use s1Len and s2Len parameters during the comparison: s1 and s2 are not zero-terminated
- used by sqlite3.create_collation low-level function

```
TSQCommitCallback = function(pArg: Pointer): Integer; cdecl;
```

Commit And Rollback Notification Callback function after sqlite3.commit_hook() or sqlite3.rollback_hook() registration

- The callback implementation must not do anything that will modify the database connection that invoked the callback. Any actions to modify the database connection must be deferred until after the completion of the sqlite3.step() call that triggered the commit or rollback hook in the first place. Note that sqlite3.prepare_v2() and sqlite3.step() both modify their database connections for the meaning of "modify" in this paragraph.
- When the commit hook callback routine returns zero, the COMMIT operation is allowed to continue normally. If the commit hook returns non-zero, then the COMMIT is converted into a ROLLBACK. The rollback hook is invoked on a rollback that results from a commit hook returning non-zero, just as it would be with any other rollback.
- For the purposes of this API, a transaction is said to have been rolled back if an explicit "ROLLBACK" statement is executed, or an error or constraint causes an implicit rollback to occur. The rollback callback is not invoked if a transaction is automatically rolled back because the database connection is closed.

```
TSQDatabaseBackupEvent = function(Sender: TSQDatabaseBackupThread): boolean of object;
```

Callback called asynchronously during TSQDatabase.BackupBackground()

- implementation should return TRUE to continue the process: if the method returns FALSE, backup will be aborted, and destination file deleted
- this method allows to monitor the backup process, thanks to TSQDatabaseBackupThread properties (especially the Step property)
- this method will be executed in the context of the associated TSQDatabaseBackupThread: so you should use Synchronize() to update the UI

```
TSQDatabaseBackupEventStep = ( backupNone, backupStart, backupSuccess, backupFailure, backupStepOk, backupStepBusy, backupStepLocked, backupStepSynLz );
```

Kind of event triggered during TSQDatabase.BackupBackground() process

- you can use (Sender.Step in backupAnyStep), to check for normal step, or (Sender.Step in backupFinished) to check for process end

```
TSQDataBaseTransactionBehaviour = ( tbDeferred, tbImmediate, tbExclusive );
```

TSQDataBase.TransactionBegin can be deferred, immediate, or exclusive

- tbDeferred means that no locks are acquired on the database until the database is first accessed. Thus with a deferred transaction, the BEGIN statement itself does nothing to the filesystem. Locks are not acquired until the first read or write operation. The first read operation against a database creates a SHARED lock and the first write operation creates a RESERVED lock. Because the acquisition of locks is deferred until they are needed, it is possible that another thread or process could create a separate transaction and write to the database after the BEGIN on the current thread has executed.
- If the transaction is tbImmediate, then RESERVED locks are acquired on all databases as soon as the BEGIN command is executed, without waiting for the database to be used. After a BEGIN IMMEDIATE, no other database connection will be able to write to the database or do a BEGIN

IMMEDIATE or BEGIN EXCLUSIVE. Other processes can continue to read from the database, however.

- A `tbExclusive` transaction causes EXCLUSIVE locks to be acquired on all databases. After a BEGIN EXCLUSIVE, no other database connection except for `read_uncommitted` connections will be able to read the database and no other connection without exception will be able to write the database until the transaction is complete.

TSQLEndDestroyPtr = procedure(p: pointer); cdecl;

Type for a custom destructor for the text or BLOB content

- set to `@sqlite3InternalFree` if a Value must be released via `FreeMem()`
- set to `@sqlite3InternalFreeObject` if a Value must be released via `TObject(p).Free`

TSQLEndFunctionFinal = procedure(Context: TSQLEndFunctionContext); cdecl;

SQLite3 user final aggregate callback prototype

TSQLEndFunctionFunc = procedure(Context: TSQLEndFunctionContext; argc: integer; var argv: TSQLEndValueArray); cdecl;

SQLite3 user function or aggregate callback prototype

- `argc` is the number of supplied parameters, which are available in `argv[]` (you can call `ErrorWrongNumberOfArgs(Context)` in case of unexpected number)
- use `sqlite3.value_*(argv[*])` functions to retrieve a parameter value
- then set the result using `sqlite3.result_*(Context,*)` functions

TSQLEnd3Backup = type PtrUInt;

Internally store a SQLite3 Backup process handle

TSQLEnd3Blob = type PtrUInt;

Internally store the SQLite3 blob handle

Used for DI-2.2.1 (page 2558).

TSQLEnd3DB = type PtrUInt;

Internally store the SQLite3 database handle

Used for DI-2.2.1 (page 2558).

TSQLEnd3ErrorCode = (secUnknown, secOK, secERROR, secINTERNAL, secPERM, secABORT, secBUSY, secLOCKED, secNOMEM, secREADONLY, secINTERRUPT, secIOERR, secCORRUPT, secNOTFOUND, secFULL, secCANTOPEN, secPROTOCOL, secEMPTY, secSCHEMA, secTOOBIG, secCONSTRAINT, secMISMATCH, secMISUSE, secNOLFS, secAUTH, secFORMAT, secRANGE, secNOTADB, secROW, secDONE);

The main possible return codes, including error codes

TSQLEnd3FunctionContext = type PtrUInt;

Internal store a SQLite3 Function Context Object

- The context in which an SQL function executes is stored in an `sqlite3.context` object, which is mapped to this `TSQLEnd3FunctionContext` type
- A pointer to an `sqlite3.context` object is always first parameter to application-defined SQL functions, i.e. a `TSQLEndFunctionFunc` prototype

Used for DI-2.2.1 (page 2558).

TSQLEnd3Statement = type PtrUInt;

Internally store the SQLite3 statement handle

- This object is variously known as a "prepared statement" or a "compiled SQL statement" or simply as a "statement".

- Create the object using `sqlite3.prepare_v2()` or a related function.
- Bind values to host parameters using the `sqlite3.bind_*` interfaces.
- Run the SQL by calling `sqlite3.step()` one or more times.
- Reset the statement using `sqlite3.reset()` then go back to "Bind" step. Do this zero or more times.
- Destroy the object using `sqlite3.finalize()`.

Used for DI-2.2.1 (page 2558).

TSQLite3Value = type PtrUInt;

Internally store a SQLite3 Dynamically Typed Value Object

- SQLite uses the `sqlite3.value` object to represent all values that can be stored in a database table, which are mapped to this `TSQLite3Value` type
- SQLite uses dynamic typing for the values it stores
- Values stored in `sqlite3.value` objects can be integers, floating point values, strings, BLOBs, or NULL

Used for DI-2.2.1 (page 2558).

TSQLite3ValueArray = array[0..63] of TSQLite3Value;

Internally store of SQLite3 values, as used by TSQLFunctionFunc

Used for DI-2.2.1 (page 2558).

TSQLLimitCategory = (lcLength, lcSQLLength, lcColumn, lcExprDepth, lcCompoundSelect, lcVDBEop, lcFunctionArg, lcAttached, lcLikePatternLength, lcVariableNumber, lcTriggerDepth);

Available Run-Time limit categories

- as expected by `sqlite3.limit()` function and `TSQLDatabase.Limit` property
- `lcLength` The maximum size of any string or BLOB or table row, in bytes.
- `lcSQLLength` The maximum length of an SQL statement, in bytes.
- `lcColumn` The maximum number of columns in a table definition or in the result set of a SELECT or the maximum number of columns in an index or in an ORDER BY or GROUP BY clause.
- `lcExprDepth` The maximum depth of the parse tree on any expression.
- `lcCompoundSelect` The maximum number of terms in a compound SELECT statement.
- `lcVDBEop` The maximum number of instructions in a virtual machine program used to implement an SQL statement. This limit is not currently enforced, though that might be added in some future release of SQLite.
- `lcFunctionArg` The maximum number of arguments on a function.
- `lcAttached` The maximum number of attached databases.
- `lcLikePatternLength` The maximum length of the pattern argument to the LIKE or GLOB operators.
- `lcVariableNumber` The maximum number of parameters in an SQL statement.
- `lcTriggerDepth` The maximum depth of recursion for triggers.

TSQLLockingMode = (lmNormal, lmExclusive);

Available file-level database connection locking-mode

- `lmNormal` locking-mode (the default unless overridden at compile-time using `SQLITE_DEFAULT_LOCKING_MODE`), a database connection unlocks the database file at the conclusion of each read or write transaction.
- when the locking-mode is set to `lmExclusive`, the database connection never releases file-locks. The first time the database is read in `lmExclusive` mode, a shared lock is obtained and held. The first time the database is written, an exclusive lock is obtained and held. Database locks obtained by a connection in `lmExclusive` mode may be released either by closing the database connection, or by setting the locking-mode back to `lmNormal` using this pragma and then accessing the database file (for read or write). Simply setting the locking-mode to `lmNormal` is not enough - locks are not

released until the next time the database file is accessed.

- ImExclusive gives much better write performance, and could be used when needed, in case of a heavy loaded mORMot server

```
TSQLErrorCallback = procedure(ProfileArg: Pointer; Profile: PUTF8Char;  
ProfileNanoSeconds: Int64); cdecl;
```

Callback function registered by sqlite3.profile()

- this procedure will be invoked as each SQL statement finishes
- warning: sqlite3.profile() function is considered experimental and is subject to change in future versions of SQLite

```
TSQLStatementCacheDynArray = array of TSQLStatementCache;
```

Used to store all prepared statement

```
TSQLSynchronousMode = ( smOff, smNormal, smFull );
```

Available file-level write access wait mode of the SQLite3 engine

- when synchronous is smFull (which is the default setting), the SQLite database engine will use the xSync method of the VFS to ensure that all content is safely written to the disk surface prior to continuing. This ensures that an operating system crash or power failure will not corrupt the database. FULL synchronous is very safe, but it is also slower.
- when synchronous is smNormal, the SQLite database engine will still sync at the most critical moments, but less often than in FULL mode. There is a very small (though non-zero) chance that a power failure at just the wrong time could corrupt the database in NORMAL mode. But in practice, you are more likely to suffer a catastrophic disk failure or some other unrecoverable hardware fault.
- when synchronous is smOff, SQLite continues without syncing as soon as it has handed data off to the operating system. If the application running SQLite crashes, the data will be safe, but the database might become corrupted if the operating system crashes or the computer loses power before that data has been written to the disk surface. On the other hand, some operations are as much as 50 or more times faster with synchronous OFF.

```
TSQLTraceCallback = procedure(Trace: TSQLTraceMask; UserData,P,X: pointer); cdecl;
```

Callback function registered by sqlite3.trace_v2()

- the Trace argument has one of the TSQLTraceMask items set, to indicate why the callback was invoked
- UserData argument is a copy of the context pointer, as provided at sqlite3.trace_v2() call
- P and X arguments are pointers whose meanings depend on Trace content: see TSQLTraceMask for the various use cases

```
TSQLTraceMask = set of (stmStmt, stmProfile, stmRow, stmClose);
```

Events monitored by sqlite3.trace_v2() tracing logic

- stmStmt callback is invoked when a prepared statement first begins running and possibly at other times during the execution of the prepared statement, such as at the start of each trigger subprogram. The P argument is a pointer to the prepared statement. The X argument is a pointer to a string which is the unexpanded SQL text of the prepared statement or an SQL comment that indicates the invocation of a trigger.
- stmProfile callback provides approximately the same information as was provided by the deprecated sqlite3.profile() callback. The P argument is a pointer to the prepared statement and the X argument points to a 64-bit integer which is the estimated of the number of nanosecond that the prepared statement took to run. The stmProfile callback is invoked when the statement finishes.
- stmRow callback is invoked whenever a prepared statement generates a single row of result. The P argument is a pointer to the prepared statement and the X argument is unused.
- stmClose callback is invoked when a database connection closes. The P argument is a pointer to the

database connection object and the X argument is unused.

```
TSQLUpdateCallback = procedure(pUpdateArg: Pointer; op: Integer; const zDb, zTbl:  
PUTF8Char; iRowID: Int64); cdecl;
```

Callback function invoked when a row is updated, inserted or deleted, after sqlite3.update_hook() registration

- The first pUpdateArg argument is a copy of the third argument to sqlite3.update_hook().
- The second op argument is one of SQLITE_INSERT, SQLITE_DELETE, or SQLITE_UPDATE, depending on the operation that caused the callback to be invoked.
- The third and fourth zDB / zTbl arguments contain pointers to the database and table name containing the affected row.
- The final iRowID parameter is the rowid of the row. In the case of an update, this is the rowid after the update takes place.
- The update hook implementation must not do anything that will modify the database connection that invoked the update hook. Any actions to modify the database connection must be deferred until after the completion of the sqlite3.step() call that triggered the update hook. Note that sqlite3.prepare_v2() and sqlite3.step() both modify their database connections for the meaning of "modify" in this paragraph.

Constants implemented in the SynSQLite3 unit

```
backupAnyStep = [backupStepOk, backupStepBusy, backupStepLocked, backupStepSynLz];
```

Identify the iterative step events during TSQLDatabase.BackupBackground()

- you can use (Sender.Step in backupAnyStep), to check for normal step

```
backupFinished = [backupSuccess, backupFailure];
```

Identify the end step events during TSQLDatabase.BackupBackground()

- you can use (Sender.Step in backupFinished) to check for process end

```
SQLDATABASE_NOCACHE: RawUTF8 = '/*nocache*/';
```

A magic text constant which will prevent any JSON result to be cached in TSQLDataBase, if present in the SQL statement

- to be used e.g. when you put some pointers as bound parameters

```
SQLITE3_MAGIC = $ABA5A5AB;
```

The "magic" number used to identify .dbsynlz compressed files, as created by TSQLDataBase.BackupSynLZ() or if SynLZCompress parameter is TRUE for the TSQLDataBase.BackupBackground() method

- note that the SynDBExplorer tool is able to recognize such files, and open them directly - or use the DBSynLZ.dpr command-line sample tool

```
SQLITE_ABORT = 4;
```

Sqlite_exec() return code: Callback routine requested an abort

```
SQLITE_ANY = 5;
```

Sqlite3.create_function don't care about text encoding

```
SQLITE_AUTH = 23;
```

Sqlite_exec() return code: Authorization denied

```
SQLITE_BLOB = 4;
```

Internal SQLite3 type as Blob

```
SQLITE_BUSY = 5;
```

Sqlite_exec() return code: The database file is locked

SQLITE_CANTOPEN = 14;

Sqlite_exec() return code: Unable to open the database file

SQLITE_CONSTRAINT = 19;

Sqlite_exec() return code: Abort due to constraint violation

SQLITE_CORRUPT = 11;

Sqlite_exec() return code: The database disk image is malformed

SQLITE_DONE = 101;

Sqlite3.step() return code: has finished executing

SQLITE_EMPTY = 16;

Sqlite_exec() return code: Database is empty

SQLITE_ERROR = 1;

Sqlite_exec() return code: SQL error or missing database - legacy generic code

SQLITE_ERRORS = [SQLITE_ERROR..SQLITE_ROW-1];

*Possible error codes for sqlite_exec() and sqlite3.step()
- as verified by sqlite3_check()*

SQLITE_FILE_HEADER: array[0..15] of AnsiChar = 'SQLite format 3';

The "magic" 16 bytes header stored at the beginning of every SQLite3 file

SQLITE_FLOAT = 2;

Internal SQLite3 type as Floating point value

SQLITE_FORMAT = 24;

Sqlite_exec() return code: Auxiliary database format error

SQLITE_FULL = 13;

Sqlite_exec() return code: Insertion failed because database is full

SQLITE_INTEGER = 1;

Internal SQLite3 type as Integer

SQLITE_INTERNAL = 2;

Sqlite_exec() return code: An internal logic error in SQLite

SQLITE_INTERRUPT = 9;

Sqlite_exec() return code: Operation terminated by sqlite3.interrupt()

SQLITE_IOERR = 10;

Sqlite_exec() return code: Some kind of disk I/O error occurred

SQLITE_LOCKED = 6;

Sqlite_exec() return code: A table in the database is locked

SQLITE_MEMORY_DATABASE_NAME = ':memory:';

Pseudo database file name used to create an in-memory database

- an SQLite database is normally stored in a single ordinary disk file - however, in certain circumstances, the database might be stored in memory, if you pass SQLITE_MEMORY_DATABASE_NAME to TSQLiteDatabase.Create() instead of a real disk file name

- this instance will cease to exist as soon as the database connection is closed, i.e. when calling TSQLDatabase.Free
- every ':memory:' database is distinct from every other - so, creating two TSQLDatabase instances each with the filename SQLITE_MEMORY_DATABASE_NAME will create two independent in-memory databases

SQLITE_MISMATCH = 20;

Sqlite_exec() return code: Data type mismatch

SQLITE_MISUSE = 21;

Sqlite_exec() return code: Library used incorrectly

SQLITE_NOLFS = 22;

Sqlite_exec() return code: Uses OS features not supported on host

SQLITE_NOMEM = 7;

Sqlite_exec() return code: A malloc() failed

SQLITE_NOTADB = 26;

Sqlite_exec() return code: File opened that is not a database file

SQLITE_NOTFOUND = 12;

Sqlite_exec() return code: (Internal Only) Table or record not found

SQLITE_NULL = 5;

Internal SQLite3 type as NULL

SQLITE_OK = 0;

Sqlite_exec() return code: no error occurred

SQLITE_OPEN_CREATE = \$00000004;

In conjunction with SQLITE_OPEN_READWRITE, optionally create the database file if it does not exist

- The database is opened for reading and writing if possible, or reading only if the file is write protected by the operating system
- In either case the database must already exist, otherwise an error is returned

SQLITE_OPEN_FULLMUTEX = \$00010000;

Ok for sqlite3_open_v2() If the SQLITE_OPEN_FULLMUTEX flag is set then the database connection opens in the serialized threading mode unless single-thread was previously selected at compile-time or start-time

- Ok for sqlite3.open_v2(), in conjunction with SQLITE_OPEN_READONLY, SQLITE_OPEN_READWRITE, (SQLITE_OPEN_READWRITE or SQLITE_OPEN_CREATE)

SQLITE_OPEN_MEMORY = \$00000080;

Ok for sqlite3_open_v2() If the SQLITE_OPEN_NOMUTEX flag is set, then the database will remain in memory

- Ok for sqlite3.open_v2(), in conjunction with SQLITE_OPEN_READONLY, SQLITE_OPEN_READWRITE, (SQLITE_OPEN_READWRITE or SQLITE_OPEN_CREATE)

SQLITE_OPEN_NOMUTEX = \$00008000;

Ok for sqlite3_open_v2() If the SQLITE_OPEN_NOMUTEX flag is set, then the database connection opens in the multi-thread threading mode as long as the single-thread mode has not been set at compile-time or start-time

- Ok for sqlite3.open_v2(), in conjunction with SQLITE_OPEN_READONLY, SQLITE_OPEN_READWRITE, (SQLITE_OPEN_READWRITE or SQLITE_OPEN_CREATE)

SQLITE_OPEN_PRIVATECACHE = \$00040000;

Ok for `sqlite3_open_v2()` The `SQLITE_OPEN_PRIVATECACHE` flag causes the database connection to not participate in shared cache mode even if it is enabled

- Ok for `sqlite3.open_v2()`, in conjunction with `SQLITE_OPEN_READONLY`, `SQLITE_OPEN_READWRITE`, (`SQLITE_OPEN_READWRITE` or `SQLITE_OPEN_CREATE`)

SQLITE_OPEN_READONLY = \$00000001;

The database is opened in read-only mode

- if the database does not already exist, an error is returned

- Ok for `sqlite3.open_v2()`

SQLITE_OPEN_READWRITE = \$00000002;

The database is opened for reading and writing if possible, or reading only if the file is write protected by the operating system

- In either case the database must already exist, otherwise an error is returned

- Ok for `sqlite3.open_v2()`

SQLITE_OPEN_SHARED_CACHE = \$00020000;

Ok for `sqlite3_open_v2()` The `SQLITE_OPEN_SHARED_CACHE` flag causes the database connection to be eligible to use shared cache mode, regardless of whether or not shared cache is enabled using `sqlite3.enable_shared_cache()`

- Ok for `sqlite3.open_v2()`, in conjunction with `SQLITE_OPEN_READONLY`, `SQLITE_OPEN_READWRITE`, (`SQLITE_OPEN_READWRITE` or `SQLITE_OPEN_CREATE`)

SQLITE_OPEN_URI = \$00000040;

URI filename interpretation is enabled if the `SQLITE_OPEN_URI` flag is set in the fourth argument to `sqlite3.open_v2()`, or if it has been enabled globally using the `SQLITE_CONFIG_URI` option with the `sqlite3.config()` method or by the `SQLITE_USE_URI` compile-time option.

- As of SQLite version 3.7.7, URI filename interpretation is turned off by default, but future releases of SQLite might enable URI filename interpretation by default

- Ok for `sqlite3.open_v2()`, in conjunction with `SQLITE_OPEN_READONLY`, `SQLITE_OPEN_READWRITE`, (`SQLITE_OPEN_READWRITE` or `SQLITE_OPEN_CREATE`)

SQLITE_PERM = 3;

`Sqlite_exec()` return code: Access permission denied

SQLITE_PROTOCOL = 15;

`Sqlite_exec()` return code: (Internal Only) Database lock protocol error

SQLITE_RANGE = 25;

`Sqlite_exec()` return code: 2nd parameter to `sqlite3.bind` out of range

SQLITE_READONLY = 8;

`Sqlite_exec()` return code: Attempt to write a readonly database

SQLITE_ROW = 100;

`Sqlite3.step()` return code: another result row is ready

SQLITE_SCHEMA = 17;

`Sqlite_exec()` return code: The database schema changed, and unable to be recompiled

SQLITE_STATIC = pointer(0);

DestroyPtr set to `SQLITE_STATIC` if data is constant and will never change

- SQLite assumes that the text or BLOB result is in constant space and does not copy the content of

the parameter nor call a destructor on the content when it has finished using that result

SQLITE_TEXT = 3;

Internal SQLite3 type as Text

SQLITE_TOOBIG = 18;

Sqlite_exec() return code: Too much data for one row of a table

SQLITE_TRANSIENT = pointer(-1);

DestroyPtr set to SQLITE_TRANSIENT for SQLite3 to make a private copy of the data into space obtained from from sqlite3.malloc() before it returns

- this is the default behavior in our framework

- note that we discovered that under Win64, sqlite3.result_text() expects SQLITE_TRANSIENT_VIRTUALTABLE=pointer(integer(-1)) and not pointer(-1)

SQLITE_TRANSIENT_VIRTUALTABLE = pointer(integer(-1));

DestroyPtr set to SQLITE_TRANSIENT_VIRTUALTABLE for setting results to SQLite3 virtual tables columns

- due to a bug of the SQLite3 engine under Win64

SQLITE_UTF16 = 4;

Text is UTF-16 encoded, using the system native byte order

SQLITE_UTF16BE = 3;

Text is UTF-16 BE encoded

SQLITE_UTF16LE = 2;

Text is UTF-16 LE encoded

SQLITE_UTF16_ALIGNED = 8;

Used by sqlite3.create_collation() only

SQLITE_UTF8 = 1;

Text is UTF-8 encoded

SQL_GET_TABLE_NAMES = 'SELECT name FROM sqlite_master WHERE type='table' AND name NOT LIKE 'sqlite_%';';

SQL statement to get all tables names in the current database file (taken from official SQLite3 documentation)

Functions or procedures implemented in the SynSQLite3 unit

Functions or procedures	Description	Page
CheckNumberOfArgs	Wrapper around sqlite3.result_error() validating the expected number of arguments	1714
ErrorCodeToText	Convert a TSQLite3ErrorCode item into the corresponding SQLite constant name	1714
ErrorWrongNumberOfArgs	Wrapper around sqlite3.result_error() to be called if wrong number of arguments	1714
ExceptionToSqlite3Err	Create a TSQLite3Module.pzErr UTF-8 text buffer according to the given Delphi exception	1714

Functions or procedures	Description	Page
IsSQLite3File	Check from the file beginning if sounds like a valid SQLite3 file	1714
IsSQLite3FileEncrypted	Check if sounds like an encrypted SQLite3 file	1715
JsonToSQLite3Context	Set a JSON value into a SQLite3 result context	1715
RawUTF8ToSQLite3Context	Set a UTF-8 string into a SQLite3 result context	1715
sqlite3InternalFree	An internal function which calls Freemem(p)	1715
sqlite3InternalFreeObject	An internal function which calls TObject(p).Free	1715
sqlite3InternalFreeRawByteString	An internal function which calls RawByteString(p) := ''	1715
SQLite3ValueToSQLVar	Set a SQLite3 value into a TSQLVar	1715
sqlite3_check	Test the result state of a sqlite3.*() function	1715
sqlite3_resultToErrorCode	Convert a SQLite3 result code into a TSQLite3ErrorCode item	1715
sqlite3_resultToErrorText	Convert a SQLite3 result code into the corresponding SQLite constant name	1715
SQLVarToSQLite3Context	Set a TSQLVar into a SQLite3 result context	1715
StatementCacheTotalTimeCompare	Comparison function using TSQLStatementCache.Timer.TimeInMicroSec	1716
VariantToSQLite3Context	Set a variant value into a SQLite3 result context	1716

function CheckNumberOfArgs(Context: TSQLite3FunctionContext; expected, sent: integer): boolean;

Wrapper around sqlite3.result_error() validating the expected number of arguments

function ErrorCodeToText(err: TSQLite3ErrorCode): RawUTF8;

Convert a TSQLite3ErrorCode item into the corresponding SQLite constant name

- e.g. ErrorCodeToText(secOK)='SQLITE_OK'

procedure ErrorWrongNumberOfArgs(Context: TSQLite3FunctionContext);

Wrapper around sqlite3.result_error() to be called if wrong number of arguments

procedure ExceptionToSQLite3Err(E: Exception; var pzErr: PUTF8Char);

Create a TSQLite3Module.pzErr UTF-8 text buffer according to the given Delphi exception

function IsSQLite3File(const FileName: TFileName; PageSize: PInteger=nil): boolean;

Check from the file beginning if sounds like a valid SQLite3 file

- returns true if a database file is encrypted or not
- optional retrieve the file page size from header

function IsSQLite3FileEncrypted(const FileName: TFileName): boolean;

Check if sounds like an encrypted SQLite3 file

procedure JsonToSQLite3Context(json: PUTF8Char; Context: TSQLite3FunctionContext);

Set a JSON value into a SQLite3 result context

- a JSON object or array would be returned at plain TEXT, or other simple JSON text or number would be returned as the corresponding SQLite3 value

procedure RawUTF8ToSQLite3Context(const Text: RawUTF8; Context: TSQLite3FunctionContext; VoidTextAsNull: boolean);

Set a UTF-8 string into a SQLite3 result context

- this function will use copy-on-write assignment of Text, with no memory allocation, then let sqlite3InternalFreeRawByteString release its reference count

procedure sqlite3InternalFree(p: pointer); cdecl;

An internal function which calls Freemem(p)

- can be used to free some PUTF8Char pointer allocated by Delphi Getmem()

procedure sqlite3InternalFreeObject(p: pointer); cdecl;

An internal function which calls TObject(p).Free

- can be used to free some Delphi class instance

procedure sqlite3InternalFreeRawByteString(p: pointer); cdecl;

An internal function which calls RawByteString(p) := ''

- can be used to free some Delphi class instance

- use a local tmp: pointer variable to prepare the reference count, e.g.

tmp := nil;

RawUTF8(tmp) := Text; // fast COW assignment

sqlite3.result_text(Context, tmp, length(Text)+1, sqlite3InternalFreeRawByteString);

procedure SQLite3ValueToSQLVar(Value: TSQLite3Value; var Res: TSQLVar);

Set a SQLite3 value into a TSQLVar

- will call the corresponding sqlite3.value_*() function to retrieve the data with the less overhead (e.g. memory allocation or copy) as possible

function sqlite3_check(DB: TSQLite3DB; aResult: integer; const SQL: RawUTF8=''): integer;

Test the result state of a sqlite3.() function*

- raise a ESQLite3Exception if the result state is within SQLITE_ERRORS

- return the result state otherwise (SQLITE_OK, SQLITE_ROW, SQLITE_DONE e.g.)

function sqlite3_resultToErrorCode(aResult: integer): TSQLite3ErrorCode;

Convert a SQLite3 result code into a TSQLite3ErrorCode item

function sqlite3_resultToErrorText(aResult: integer): RawUTF8;

Convert a SQLite3 result code into the corresponding SQLite constant name

- e.g. sqlite3_resultToErrorText(SQLITE_OK)='SQLITE_OK'

function SQLVarToSQLite3Context(const Res: TSQLVar; Context: TSQLite3FunctionContext): boolean;

Set a TSQLVar into a SQLite3 result context

- will call the corresponding sqlite3.result_*() function and return true, or will return false if the TSQLVar type is not handled

```
function StatementCacheTotalTimeCompare(const A,B): integer;
```

Comparison function using TSQLStatementCache.Timer.TimeInMicroSec

```
procedure VariantToSQLite3Context(const Value: Variant; Context:  
TSQLite3FunctionContext);
```

Set a variant value into a SQLite3 result context

- will call the corresponding sqlite3.result_*() function, using SQLVarToSQLite3Context() after a call to VariantToSQLVar()

Variables implemented in the SynSQLite3 unit

```
sqlite3: TSQLite3Library;
```

Global access to linked SQLite3 library API calls

- you should call sqlite3.open() instead of sqlite3_open() for instance
- points either to the statically linked sqlite3.obj, or to an external library (e.g. sqlite3.dll under Windows)
- your project should use EITHER SynSQLite3Static unit OR create a TSQLite3LibraryDynamic instance:

```
FreeAndNil(sqlite3); // release any previous instance  
sqlite3 := TSQLite3LibraryDynamic.Create;
```

- caller should free the sqlite3 instance only with
FreeAndNil(sqlite3);

to avoid issues with the automatic freeing in finalization section

```
SynSQLite3Log: TSynLogClass = TSynLog;
```

The TSynLog class used for logging for all our SynSQLite3 related functions

- you may override it with TSQLog, if available from mORMot.pas
- since not all exceptions are handled specifically by this unit, you may better use a common TSynLog class for the whole application or module

27.36. SynSQLite3RegEx.pas unit

Purpose: REGEXP function for SQLite3 Database using PCRE library

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the *SynSQLite3RegEx* unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynSQLite3</i>	SQLite3 Database engine direct access - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1653

Functions or procedures implemented in the *SynSQLite3RegEx* unit

Functions or procedures	Description	Page
CreateRegExpFunction	Register the REGEXP SQL function to a given SQLite3 engine instance	1717

```
function CreateRegExpFunction(DB: TSQLite3DB): boolean;
```

Register the REGEXP SQL function to a given SQLite3 engine instance

- allow execution of statements as such:

```
SELECT column FROM table WHERE column REGEXP '<here goes your expression>';
```

27.37. SynSQLite3Static.pas unit

Purpose: SQLite3 3.38.2 Database engine - statically linked for Windows/Linux

- this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

The *SynSQLite3Static* unit is quoted in the following items

SWRS #	Description	Page
DI-2.2.1	The <i>SQLite3</i> engine shall be embedded to the framework	2558

Units used in the *SynSQLite3Static* unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synapse projects - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynCrypto</i>	Fast cryptographic routines (hashing and cypher) - implements AES,XOR,ADLER32,MD5,RC4,SHA1,SHA256,SHA384,SHA512,SHA3 and JWT - optimized for speed (tuned assembler and SSE3/SSE4/AES-NI/PADLOCK support) - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1143
<i>SynSQLite3</i>	SQLite3 Database engine direct access - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1653

SynSQLite3Static class hierarchy

Objects implemented in the *SynSQLite3Static* unit

Objects	Description	Page
TSQLite3LibraryStatic	Access class to the static .obj SQLite3 engine	1718

TSQLite3LibraryStatic = class(TSQLite3Library)

Access class to the static .obj SQLite3 engine

- the initialization section of this unit calls:

```
sqlite3 := TSQLite3LibraryStatic.Create;
```

therefore, adding SynSQLite3Static to your uses clause is enough to use the statically linked SQLite3 engine with SynSQLite3

Used for DI-2.2.1 (page 2558).

constructor Create; **override**;

Fill the internal API reference s with the static .obj engine

destructor Destroy; **override**;

Unload the static library

Functions or procedures implemented in the *SynSQLite3Static* unit

Functions or procedures	Description	Page
ChangeSQLEncryptTablePassWord	Use this procedure to change the password for an existing SQLite3 database file	1719
IsOldSQLEncryptTable	Could be used to detect a database in old/deprecated/unsupported format (<1.18.4413)	1719
OldSQLEncryptTablePassWordToPlain	This function may be used to create a plain database file from an existing one encrypted with our old/deprecated/unsupported format (<1.18.4413)	1720

function ChangeSQLEncryptTablePassword(**const** FileName: TFileName; **const** OldPassWord, NewPassword: RawUTF8): boolean;

Use this procedure to change the password for an existing SQLite3 database file

- convenient and faster alternative to the sqlite3.rekey() API call
- conversion is done in-place at file level, with no SQL nor BTree pages involved, therefore it can process very big files with best possible speed
- the OldPassWord must be correct, otherwise the resulting file will be corrupted
- any password can be "" to mark no encryption as input or output
- the password may be a JSON-serialized TSynSignerParams object, or will use AES-OFB-128 after SHAKE_128 with rounds=1000 and a fixed salt on plain password text
- please note that this encryption is compatible only with SQLite3 files made with SynSQLiteStatic.pas unit (not external/official/wxsqlite3 dll)
- implementation is NOT compatible with the official SQLite Encryption Extension (SEE) file format, not the wxsqlite3 extension, but is (much) faster thanks to our SynCrypto AES-NI enabled unit
- if the key is not correct, a ESQlite3Exception will be raised with 'database disk image is malformed' (SQLITE_CORRUPT) at database opening
- see also IsSQLite3File/IsSQLite3FileEncrypted functions
- warning: this encryption is NOT compatible with our previous (<1.18.4413) cyphered format, which was much less safe (simple XOR on fixed tables), and was not working on any database size, making unclean patches to the official sqlite3.c amalgamation file, so is deprecated and unsupported any longer - see OldSQLEncryptTablePassWordToPlain() to convert your existing databases

function IsOldSQLEncryptTable(**const** FileName: TFileName): boolean;

Could be used to detect a database in old/deprecated/unsupported format (<1.18.4413)

- to call OldSQLEncryptTablePassWordToPlain + ChangeSQLEncryptTablePassWord and switch to the new format

```
procedure OldSQLEncryptTablePassWordToPlain(const FileName: TFileName; const  
OldPassWord: RawUTF8);
```

This function may be used to create a plain database file from an existing one encrypted with our old/deprecated/unsupported format (<1.18.4413)

- then call ChangeSQLEncryptTablePassWord() to convert to the new safer format

Variables implemented in the *SynSQLite3Static* unit

```
ForceSQLite3LegacyAES: boolean;
```

Global flag to use initial AES encryption scheme

- IV derivation was hardened in revision 1.18.4607 - set TRUE to this global constant to use the former implementation (theoretically slightly less resistant to brute force attacks) and convert existing databases

27.38. SynSSPI.pas unit

Purpose: Low level access to Windows SSPI/SChannel API for the Win32/Win64 platform

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

SynSSPI class hierarchy

Objects implemented in the *SynSSPI* unit

Objects	Description	Page
ESynSSPI	Exception class raised durint SSPI/SChannel process	1722
SecPkgContext_NamesW	Store the name associated with the context	1722
TSChannel_Cred	SChannel credential information	1722
TSecBuffer	Defines a SSPI buffer	1722
TSecBufferDesc	Describes a SSPI buffer	1722
TSecContext	SSPI context	1722
TSecHandle	SSPI context handle	1722
TSecPkgContext_NegotiationInfo	Store negotiation information about a SSPI package	1722
TSecPkgContext_Sizes	Store various working buffer sizes of a SSPI command	1722
TSecPkgContext_StreamSizes	Store various working buffer sizes of a SSPI stream	1722
TSecPkgCred_SupportedAlgs	Information about SSPI supported algorithm	1722
TSecPkgInfoW	Store information about a SSPI package	1722
TSecWinntAuthIdentityW	Information about SSPI Authority Identify	1722
TSynSSPIAbstract	Abstract parent class for SSPI / SChannel process	1722

TSecHandle = record

SSPI context handle

TSecContext = record

SSPI context

TSecBuffer = object(TObject)

Defines a SSPI buffer

TSecBufferDesc = object(TObject)

Describes a SSPI buffer

SecPkgContext_NamesW = record

Store the name associated with the context

TSecPkgInfoW = record

Store information about a SSPI package

TSecPkgContext_NegotiationInfo = record

Store negotiation information about a SSPI package

TSecPkgContext_Sizes = record

Store various working buffer sizes of a SSPI command

TSecPkgContext_StreamSizes = record

Store various working buffer sizes of a SSPI stream

TSecPkgCred_SupportedAlgs = record

Information about SSPI supported algorithm

TSecWinntAuthIdentityW = record

Information about SSPI Authority Identify

TSChannel_Cred = record

SChannel credential information

ESynSSPI = class(Exception)

Exception class raised durant SSPI/SChannel process

TSynSSPIAbstract = class(TObject)

Abstract parent class for SSPI / SChannel process

constructor Create(aConnectionID: Int64); **virtual;**

Initialize the process

property ConnectionID: Int64 **read** fContext.ID;

Read-only access to the associated connection ID, as provided to Create

property TLS: TSynSSPIModes **read** fTLS **write** fTLS;

The TLS modes supported by this instance

- only TLS 1.2 is supported by default, for security reasons

Types implemented in the SynSSPI unit

PSChannel_Cred = ^TSChannel_Cred;

Pointer to SChannel credential information

PSecPkgCred_SupportedAlgs = ^TSecPkgCred_SupportedAlgs;

Pointer to SSPI supported algorithm

PSecPkgInfow = ^TSecPkgInfow;

Pointer to information about a SSPI package

PSecWinntAuthIdentityW = ^TSecWinntAuthIdentityW;

Pointer to SSPI Authority Identify

TSecContextDynArray = array of TSecContext;

Dynamic array of SSPI contexts

- used to hold information between calls to ServerSSPIAuth

TSynSSPILog = procedure(const Fmt: TSSPIBuffer; const Args: array of const) of object;

Used for low-level logging

TSynSSPIMode = (tls10, tls11, tls12);

The supported TLS modes

- unsafe deprecated modes (e.g. SSL) are not defined at all

TSynSSPIModes = set of TSynSSPIMode;

Set of supported TLS modes

Constants implemented in the SynSSPI unit

SP_PROT_TLS1_2_SERVER = \$00000400;

TLS 1.2 should be the preferred safe default

Functions or procedures implemented in the SynSSPI unit

Functions or procedures	Description	Page
FreeSecContext	Free aSecContext on client or server side	1723
InvalidateSecContext	Sets aSecHandle fields to empty state for a given connection ID	1723
SecDecrypt	Decrypts a message	1724
SecEncrypt	Encrypts a message	1724

procedure FreeSecContext(var aSecContext: TSecContext);

Free aSecContext on client or server side

procedure InvalidateSecContext(var aSecContext: TSecContext; aConnectionID: Int64);

Sets aSecHandle fields to empty state for a given connection ID

```
function SecDecrypt(var aSecContext: TSecContext; var aEncrypted: TSSPIBuffer):  
TSSPIBuffer;
```

Decrypts a message

- aSecContext must be set e.g. from previous success call to ServerSSPIAuth or ClientSSPIAuth
- aEncrypted contains data that must be decrypted
- warning: aEncrypted is modified in-place during the process
- returns decrypted message

```
function SecEncrypt(var aSecContext: TSecContext; const aPlain: TSSPIBuffer):  
TSSPIBuffer;
```

Encrypts a message

- aSecContext must be set e.g. from previous success call to ServerSSPIAuth or ClientSSPIAuth
- aPlain contains data that must be encrypted
- returns encrypted message

27.39. SynSSPIAuth.pas unit

Purpose: Low level access to Windows Authentication for the Win32/Win64 platform

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the *SynSSPIAuth* unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynSSPI</i>	Low level access to Windows SSPI/SChannel API for the Win32/Win64 platform - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1721

Constants implemented in the *SynSSPIAuth* unit

```
SECPKGNAME_TLM = 'NTLM';
```

SSPI package names. Client always use Negotiate. Server detect Negotiate or NTLM requests and use appropriate package

Functions or procedures implemented in the *SynSSPIAuth* unit

Functions or procedures	Description	Page
ClientForceSPN	Force using aSecKerberosSPN for server identification.	1725
ClientSSPIAuth	Client-side authentication procedure	1726
ClientSSPIAuthWithPassword	Client-side authentication procedure with clear text password. This function must be used when application need to use different user credentials (not credentials of logged in user)	1726
SecPackageName	Returns name of the security package that has been used with the negotiation process	1726
ServerForceNTLM	Force NTLM authentication instead of Negotiate for browser authentication. Use case: SPNs not configured properly in domain	1726
ServerSSPIAuth	Server-side authentication procedure	1726
ServerSSPIAuthUser	Server-side function that returns authenticated user name	1726

```
procedure ClientForceSPN(const aSecKerberosSPN: RawUTF8);
```

Force using aSecKerberosSPN for server identification.

- aSecKerberosSPN is the Service Principal Name, registered in domain, e.g.
'mymormotservice/myserver.mydomain.tld@MYDOMAIN.TLD'

```
function ClientSSPIAuth(var aSecContext: TSecContext; const aInData: RawByteString;  
const aSecKerberosSPN: RawUTF8; out aOutData: RawByteString): Boolean;
```

Client-side authentication procedure

- aSecContext holds information between function calls
- aInData contains data received from server
- aSecKerberosSPN is the optional SPN domain name, e.g.
'mymormotservice/myserver.mydomain.tld'
- aOutData contains data that must be sent to server
- if function returns True, client must send aOutData to server and call function again with data, returned from server

```
function ClientSSPIAuthWithPassword(var aSecContext: TSecContext; const aInData:  
RawByteString; const aUserName: RawUTF8; const aPassword: RawUTF8; out aOutData:  
RawByteString): Boolean;
```

Client-side authentication procedure with clear text password. This function must be used when application need to use different user credentials (not credentials of logged in user)

- aSecContext holds information between function calls
- aInData contains data received from server
- aUserName is the domain and user name, in form of 'DomainName\UserName'
- aPassword is the user clear text password
- aOutData contains data that must be sent to server
- if function returns True, client must send aOutData to server and call function again with data, returned from server

```
function SecPackageName(var aSecContext: TSecContext): RawUTF8;
```

Returns name of the security package that has been used with the negotiation process

- aSecContext must be received from previous success call to ServerSSPIAuth or ClientSSPIAuth

```
procedure ServerForceNTLM(IsNTLM: boolean);
```

Force NTLM authentication instead of Negotiate for browser authentication. Use case: SPNs not configured properly in domain

- see for details <https://synapse.info/forum/viewtopic.php?id=931&p=3>

```
function ServerSSPIAuth(var aSecContext: TSecContext; const aInData: RawByteString;  
out aOutData: RawByteString): Boolean;
```

Server-side authentication procedure

- aSecContext holds information between function calls
- aInData contains data received from client
- aOutData contains data that must be sent to client
- if function returns True, server must send aOutData to client and call function again with data, returned from client

```
procedure ServerSSPIAuthUser(var aSecContext: TSecContext; out aUserName: RawUTF8);
```

Server-side function that returns authenticated user name

- aSecContext must be received from previous successful call to ServerSSPIAuth
- aUserName contains authenticated user name

Variables implemented in the *SynSSPIAuth* unit

```
SECPKGNAMEHTTPAUTHORIZATION: PAnsiChar;
```

HTTP header pattern received for SSPI authentication 'AUTHORIZATION: NTLM ' or 'AUTHORIZATION: NEGOTIATE '

SECPKGNAMEHTTPWWWAUTHENTICATE: RawUTF8;

*HTTP header to be set for SSPI authentication 'WWW-Authenticate: NTLM' or
'WWW-Authenticate: Negotiate';*

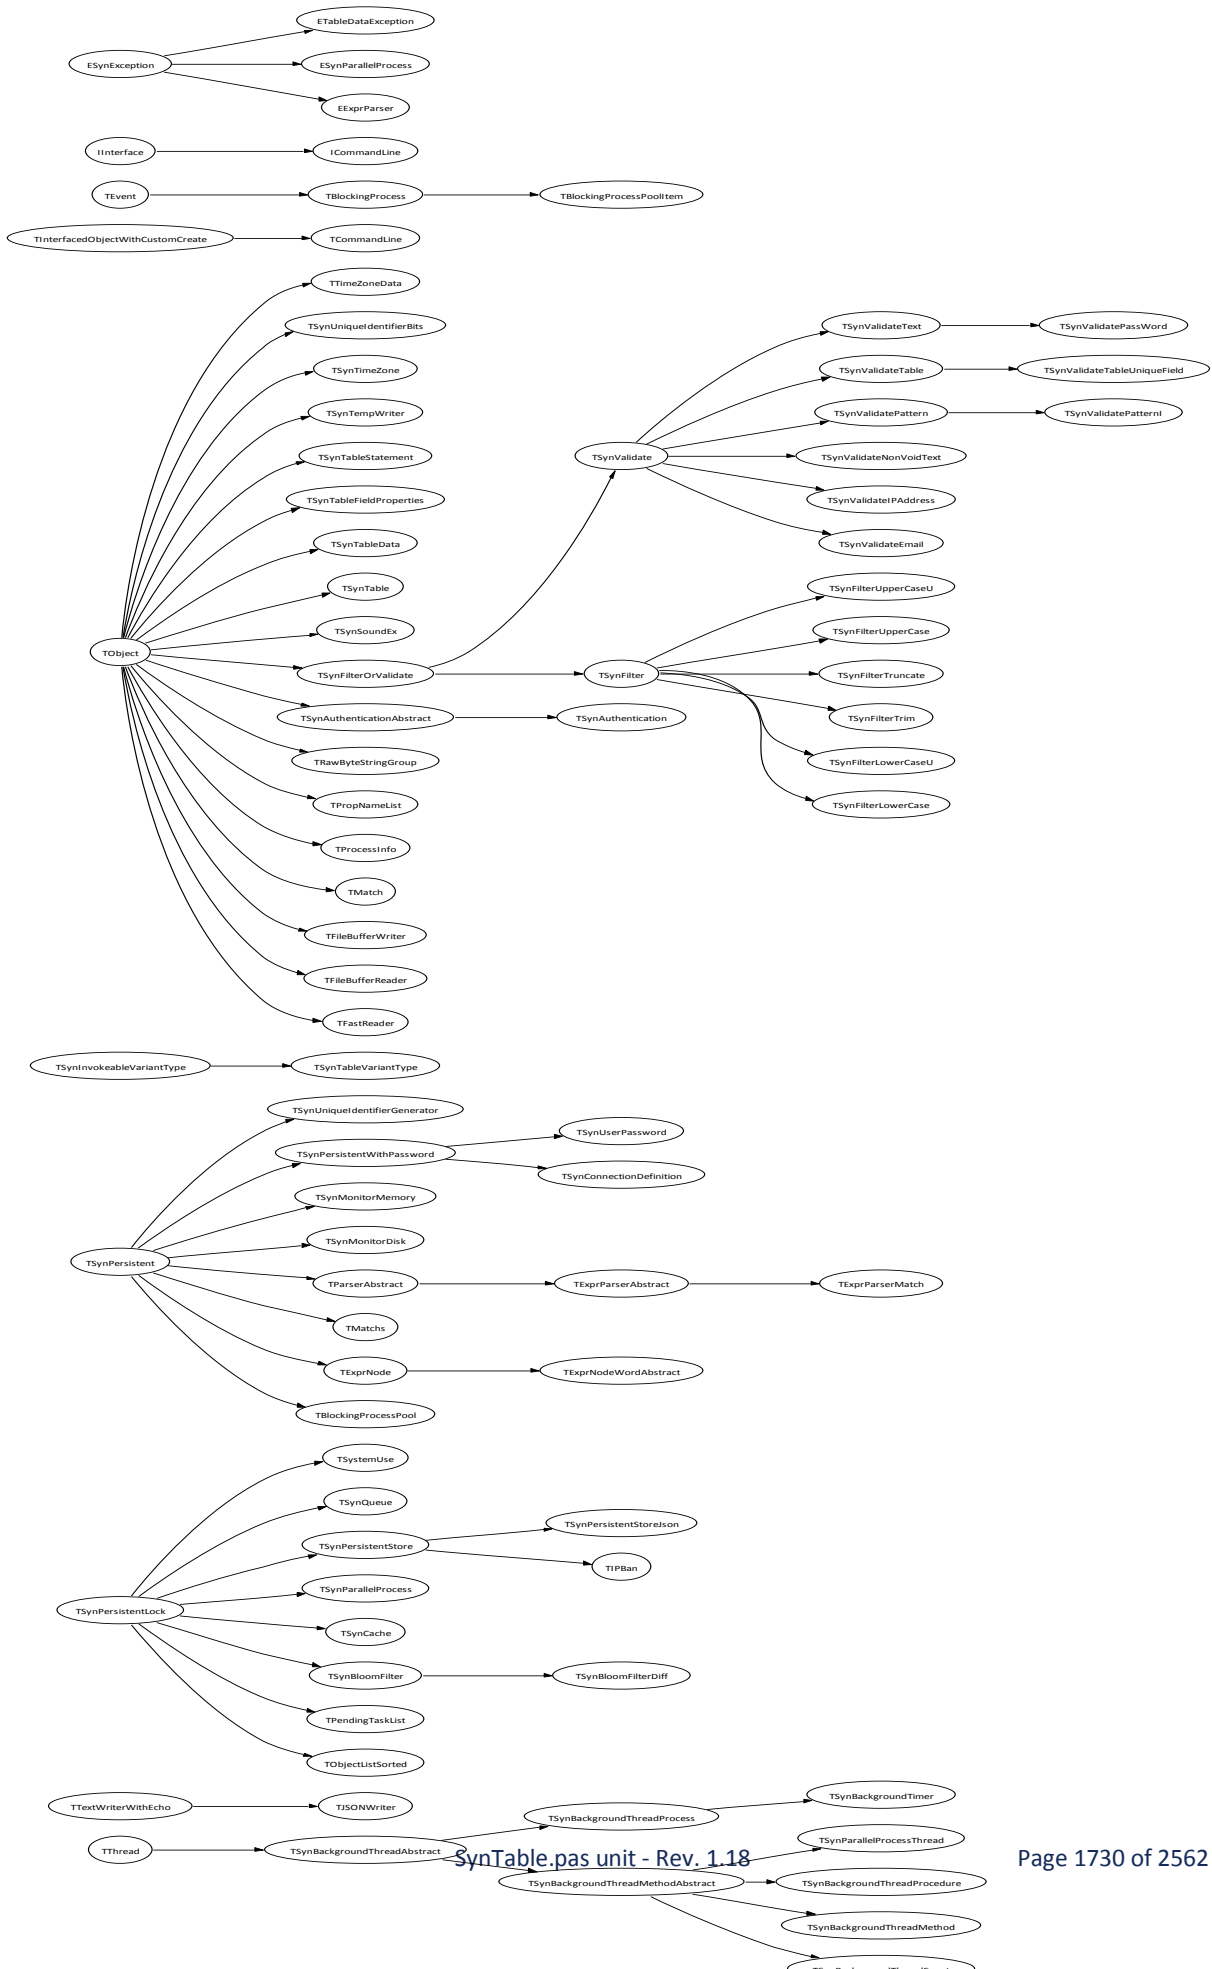

27.40. SynTable.pas unit

Purpose: Filter/database/cache/buffer/security/search/multithread/OS features

- as a complement to SynCommons, which tended to increase too much
- licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the *SynTable* unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718

SynTable class hierarchy

Objects implemented in the *SynTable* unit

Objects	Description	Page
EExprParser	Exception type used by TExprParser	1771
ESynParallelProcess	An exception which would be raised by TSynParallelProcess	1777
ETableDataException	Exception raised by all TSynTable related code	1791
ICommandLine	An interface to process the command line switches over a console	1789
TBlockingProcess	A semaphore used to wait for some process to be finished	1780
TBlockingProcessPool	Manage a pool of TBlockingProcessPoolItem instances	1781
TBlockingProcessPoolItem	A semaphore used in the TBlockingProcessPool	1781
TCommandLine	A class to process the command line switches, with console interactivity	1790
TDiskPartition	Stores information about a disk partition	1785
TExprNode	Stores an expression search engine node, as used by TExprParser	1771
TExprNodeWordAbstract	Abstract class to handle word search, as used by TExprParser	1772
TExprParserAbstract	Abstract class to parse a text expression into nodes	1772
TExprParserMatch	Search expression engine using TMatch for the actual word searches	1772
TFastReader	Safe decoding of a TFileBufferWriter content	1744
TFileBufferReader	This structure can be used to speed up reading from a file	1752
TFileBufferWriter	This class can be used to speed up writing to a file	1748
TIPBan	Optimized thread-safe storage of a list of IP v4 addresses	1771
TJSONWriter	Simple writer to a Stream, specialized for the JSON format and SQL export	1743
TMatch	Low-level structure used by IsMatch() for actual glob search	1734
TMatches	Stores several TMatch instances, from a set of glob patterns	1735
TMatchStore	TMatch descendant owning a copy of the Pattern string to avoid GPF issues	1735
TMemoryInfo	Hold low-level information about current memory usage	1787
TObjectListSorted	Maintain a thread-safe sorted list of TSynPersistentLock objects	1760
TParserAbstract	Parent class of TExprParserAbstract	1772
TPendingTaskList	Handle a list of tasks, stored as RawByteString, with a time stamp	1773

Objects	Description	Page
TPendingTaskListItem	Internal item definition, used by TPendingTaskList storage	1773
TProcessInfo	Low-level structure used to compute process memory and CPU usage	1782
TPropNameList	Simple stack-allocated type for handling a non-void type names list	1764
TRawByteStringGroup	Store several RawByteString content with optional concatenation	1762
TRawByteStringGroupValue	Item as stored in a TRawByteStringGroup instance	1762
TSortCompareTmp	Internal value used by TSynTableFieldProperties.SortCompare() method to avoid stack allocation	1794
TSQLVar	Memory structure used for database values by reference storage	1743
TSynAuthentication	Simple authentication class, implementing safe token/challenge security	1770
TSynAuthenticationAbstract	Abstract authentication class, implementing safe token/challenge security and a list of active sessions	1769
TSynBackgroundThreadAbstract	Abstract TThread with its own execution content	1774
TSynBackgroundThreadEvent	Allow background thread process of a method callback	1776
TSynBackgroundThreadMethod	Allow background thread process of a variable TThreadMethod callback	1776
TSynBackgroundThreadMethodAbstract	Abstract TThread able to run a method in its own execution content	1775
TSynBackgroundThreadProcedure	Allow background thread process of a procedure callback	1776
TSynBackgroundThreadProcess	TThread able to run a method at a given periodic pace	1777
TSynBackgroundTimer	TThread able to run one or several tasks at a periodic pace in a background thread	1778
TSynBackgroundTimerTask	Used by TSynBackgroundTimer internal registration list	1778
TSynBloomFilter	Implements a thread-safe Bloom Filter storage	1754
TSynBloomFilterDiff	Implements a thread-safe differential Bloom Filter storage	1756
TSynCache	Implement a cache of some key/value pairs, e.g. to improve reading speed	1757
TSynConnectionDefinition	Handle safe storage of any connection properties	1769
TSynFilter	Will define a transformation to be applied to a Record field content (typically a TSQLRecord)	1741
TSynFilterLowerCase	Convert the value into ASCII Lower Case characters	1741

Objects	Description	Page
TSynFilterLowerCaseU	Convert the value into WinAnsi Lower Case characters	1742
TSynFilterOrValidate	Will define a filter (transformation) or a validation process to be applied to a database Record content (typically a TSQLRecord)	1736
TSynFilterTrim	Trim any space character left or right to the value	1742
TSynFilterTruncate	Truncate a text above a given maximum length	1742
TSynFilterUpperCase	Convert the value into ASCII Upper Case characters	1741
TSynFilterUpperCaseU	Convert the value into WinAnsi Upper Case characters	1741
TSynMonitorDisk	Value object able to gather information about a system drive	1786
TSynMonitorMemory	Value object able to gather information about the current system memory	1785
TSynParallelProcess	Allow parallel execution of an index-based process in a thread pool	1777
TSynParallelProcessThread	Thread executing process for TSynParallelProcess	1777
TSynPersistentStore	Abstract high-level handling of (SynLZ-)compressed persisted storage	1761
TSynPersistentStoreJson	Implement binary persistence and JSON serialization (not deserialization)	1762
TSynPersistentWithPassword	Abstract TSynPersistent class allowing safe storage of a password	1767
TSynQueue	Thread-safe FIFO (First-In-First-Out) in-order queue of records	1758
TSynSoundEx	Fast search of a text value, using the Soundex approximation mechanism	1736
TSynTable	Store the description of a table with records, to implement a Database	1801
TSynTableData	Used to store a TSynTable record using our SBF compact binary format	1798
TSynTableFieldProperties	Store the type properties of a given field / database column	1795
TSynTableStatement	Used to parse a SELECT SQL statement, following the SQLite3 syntax	1793
TSynTableStatementSelect	One recognized SELECT expression for TSynTableStatement	1792
TSynTableStatementWhere	One recognized WHERE expression for TSynTableStatement	1792
TSynTableVariantType	A custom variant type used to have direct access to a record content	1804
TSynTempWriter	Implements a stack-based writable storage of binary content	1747
TSynTimeZone	Handle cross-platform time conversions, following Microsoft time zones	1787

Objects	Description	Page
TSynUniqueIdentifierBits	Map 64-bit integer unique identifier internal memory structure	1765
TSynUniqueIdentifierGenerator	Thread-safe 64-bit integer unique identifier computation	1766
TSynUserPassword	Could be used to store a credential pair, as user name and password	1768
TSynValidate	Will define a validation to be applied to a Record (typically a TSQLRecord) field content	1737
TSynValidateEmail	IP address validation to be applied to a Record field content (typically a TSQLRecord)	1737
TSynValidateIPAddress	IP v4 address validation to be applied to a Record field content (typically a TSQLRecord)	1737
TSynValidateNonVoidText	Text validation to ensure that to any text field would not be "	1739
TSynValidatePassword	Strong password validation for a Record field content (typically a TSQLRecord)	1741
TSynValidatePattern	Glob case-sensitive pattern validation of a Record field content	1738
TSynValidatePatternI	Glob case-insensitive pattern validation of a text field content (typically a TSQLRecord)	1738
TSynValidateTable	Will define a validation to be applied to a TSynTableFieldProperties field	1800
TSynValidateTableUniqueField	Will define a validation for a TSynTableFieldProperties Unique field	1800
TSynValidateText	To have existing RTTI for published properties text validation to be applied to any Record field content	1739
TSystemUse	Monitor CPU and RAM usage of one or several processes	1782
TSystemUseData	Store CPU and RAM usage for a given process	1782
TSystemUseProcess	Internal storage of CPU and RAM usage for one process	1782
TTimeZoneData	Used to store Time Zone information for a single area in TSynTimeZone	1787
TTimeZoneInfo	Used to store Time Zone bias in TSynTimeZone	1787
TUpdateFieldEvent	An opaque structure used for TSynTable.UpdateFieldEvent method	1799

TMatch = object(TObject)

Low-level structure used by IsMatch() for actual glob search

- you can use this object to prepare a given pattern, e.g. in a loop
- implemented as a fast brute-force state-machine without any heap allocation
- some common patterns ('exactmatch', 'startswith*', '*endwith', '*contained*') are handled with dedicated code, optionally with case-insensitive search
- consider using TMatches (or SetMatches/TMatchDynArray) if you expect to search for several patterns, or even TExprParserMatch for expression search

Search: TMatchSearchFunction;

Published for proper inlining

function Equals(const aAnother: TMatch): boolean;

Returns TRUE if this search pattern matches another

function Match(const aText: RawUTF8): boolean; overload;

Returns TRUE if the supplied content matches the prepared glob pattern

- this method is not thread-safe

function Match(aText: PUTF8Char; aTextLen: PtrInt): boolean; overload;

Returns TRUE if the supplied content matches the prepared glob pattern

- this method is not thread-safe

function MatchString(const aText: string): boolean;

Returns TRUE if the supplied VCL/LCL content matches the prepared glob pattern

- this method IS thread-safe, will use stack to UTF-8 temporary conversion if possible, and won't lock

function MatchThreadSafe(const aText: RawUTF8): boolean;

Returns TRUE if the supplied content matches the prepared glob pattern

- this method IS thread-safe, and won't lock

function PatternLength: integer;

Access to the pattern length as stored in PMax + 1

function PatternText: PUTF8Char;

Access to the pattern text as stored in Pattern

procedure Prepare(aPattern: PUTF8Char; aPatternLen: integer; aCaseInsensitive, aReuse: boolean); overload;

Initialize the internal fields for a given glob search pattern

- note that the aPattern buffer should remain in memory, since it will be pointed to by the Pattern private field of this object

procedure Prepare(const aPattern: RawUTF8; aCaseInsensitive, aReuse: boolean); overload;

Initialize the internal fields for a given glob search pattern

- note that the aPattern instance should remain in memory, since it will be pointed to by the Pattern private field of this object

procedure PrepareContains(**var** aPattern: RawUTF8; aCaseInsensitive: boolean);
 overload;

*Initialize low-level internal fields for '*aPattern*' search*

- this method is faster than a regular Prepare('*' + aPattern + '*')
- warning: the supplied aPattern variable may be modified in-place to be filled with some lookup buffer, for length(aPattern) in [2..31] range

procedure PrepareRaw(aPattern: PUTF8Char; aPatternLen: integer; aSearch: TMatchSearchFunction);

Initialize low-level internal fields for a custom search algorithm

TMatchStore = record

TMatch descendant owning a copy of the Pattern string to avoid GPF issues

Pattern: TMatch;

Access to the research criteria

- defined as a nested record (and not an object) to circumvent Delphi bug

PatternInstance: RawUTF8;

Pattern.Pattern PUTF8Char will point to this instance

TMatches = class(TSynPersistent)

Stores several TMatch instances, from a set of glob patterns

constructor Create(**const** aPatterns: TRawUTF8DynArray; CaseInsensitive: Boolean);
reintroduce; overload;

Add once some glob patterns to the internal TMach list

- aPatterns[] follows the IsMatch() syntax

function Match(aText: PUTF8Char; aLen: integer): integer; overload;

Search patterns in the supplied UTF-8 text buffer

function Match(**const** aText: RawUTF8): integer; overload;

Search patterns in the supplied UTF-8 text

- returns -1 if no filter has been subscribed
- returns -2 if there is no match on any previous pattern subscription
- returns fMatch[] index, i.e. >= 0 number on first matching pattern
- this method is thread-safe

function MatchString(**const** aText: string): integer;

Search patterns in the supplied VCL/LCL text

- could be used on a TFileName for instance
- will avoid any memory allocation if aText is small enough

procedure Subscribe(**const** aPatterns: TRawUTF8DynArray; CaseInsensitive: Boolean);
 overload; **virtual**;

Add once some glob patterns to the internal TMach list

- aPatterns[] follows the IsMatch() syntax

procedure Subscribe(**const** aPatternsCSV: RawUTF8; CaseInsensitive: Boolean);
 overload;

Add once some glob patterns to the internal TMach list
 - each CSV item in aPatterns follows the IsMatch() syntax

TSynSoundEx = object(TObject)

Fast search of a text value, using the Soundex approximation mechanism

- Soundex is a phonetic algorithm for indexing names by sound, as pronounced in a given language. The goal is for homophones to be encoded to the same representation so that they can be matched despite minor differences in spelling
 - this implementation is very fast and can be used e.g. to parse and search in a huge text buffer
 - this version also handles french and spanish pronunciations on request, which differs from default Soundex, i.e. English

function Ansi(A: PAnsiChar): boolean;

Return true if prepared value is contained in a ANSI text buffer by using the SoundEx comparison algorithm
 - search prepared value at every word beginning in A^

function Prepare(UpperValue: PAnsiChar; Lang: PSoundExValues): boolean; overload;

Prepare for a custom Soundex search
 - you can specify any language pronunciation from raw TSynSoundExValues array

function Prepare(UpperValue: PAnsiChar; Lang:
 TSynSoundExPronunciation=sndxEnglish): boolean; overload;

Prepare for a Soundex search
 - you can specify another language pronunciation than default english

function UTF8(U: PUTF8Char): boolean;

Return true if prepared value is contained in a text buffer (UTF-8 encoded), by using the SoundEx comparison algorithm
 - search prepared value at every word beginning in U^

TSynFilterOrValidate = class(TObject)

Will define a filter (transformation) or a validation process to be applied to a database Record content (typically a TSQLRecord)
 - the optional associated parameters are to be supplied JSON-encoded

constructor Create(**const** aParameters: RawUTF8=''); overload; **virtual**;

Initialize the filter (transformation) or validation instance
 - most of the time, optional parameters may be specified as JSON, possibly with the extended MongoDB syntax

constructor CreateUTF8(**const** Format: RawUTF8; **const** Args, Params: **array of const**);
 overload;

Initialize the filter or validation instance
 - this overloaded constructor will allow to easily set the parameters

```
function AddOnce(var aObjArray: TSynFilterOrValidateObjArray; aFreeIfAlreadyThere:
boolean=true): TSynFilterOrValidate;
```

Add the filter or validation process to a list, checking if not present

- if an instance with the same class type and parameters is already registered, will call `anInstance.Free` and return the existing instance
- if there is no similar instance, will add it to the list and return it

```
property Parameters: RawUTF8 read fParameters write SetParameters;
```

The optional associated parameters, supplied as JSON-encoded

```
TSynValidate = class(TSynFilterOrValidate)
```

Will define a validation to be applied to a Record (typically a TSQLRecord) field content

- a typical usage is to validate an email or IP address e.g.
- the optional associated parameters are to be supplied JSON-encoded

```
function Process(FieldIndex: integer; const Value: RawUTF8; var ErrorMsg: string):
boolean; virtual; abstract;
```

Perform the validation action to the specified value

- the value is expected to be UTF-8 text, as generated by `TPropInfo.GetValue` e.g.
- if the validation failed, must return `FALSE` and put some message in `ErrorMsg` (translated into the current language: you could e.g. use a `ResourceString` and a `SysUtils.Format()` call for automatic translation via the `mORMoti18n` unit - you can leave `ErrorMsg=""` to trigger a generic error message from class name ('"Validate email" rule failed' for `TSynValidateEmail` class e.g.)
- if the validation passed, will return `TRUE`

```
TSynValidateIPAddress = class(TSynValidate)
```

IP v4 address validation to be applied to a Record field content (typically a TSQLRecord)

- this version expects no parameter

```
function Process(aFieldIndex: integer; const Value: RawUTF8; var ErrorMsg: string):
boolean; override;
```

Perform the IP Address validation action to the specified value

```
TSynValidateEmail = class(TSynValidate)
```

IP address validation to be applied to a Record field content (typically a TSQLRecord)

- optional JSON encoded parameters are "AllowedTLD" or "ForbiddenTLD", expecting a CSV list of Top-Level-Domain (TLD) names, e.g.

```
'{"AllowedTLD":"com,org,net","ForbiddenTLD":"fr"}'
'{"AnyTLD:true,ForbiddenDomains":"mailinator.com,yopmail.com"}'
```

- this will process a validation according to RFC 822 (calling the `IsValidEmail()` function) then will check for the TLD to be in one of the Top-Level domains ('.com' and such) or a two-char country, and then will check the TLD according to `AllowedTLD` and `ForbiddenTLD`

```
function Process(aFieldIndex: integer; const Value: RawUTF8; var ErrorMsg: string):
boolean; override;
```

Perform the Email Address validation action to the specified value

- call `IsValidEmail()` function and check for the supplied TLD

property AllowedTLD: RawUTF8 read fAllowedTLD write fAllowedTLD;

A CSV list of allowed TLD

- if accessed directly, should be set as lower case values
- e.g. 'com,org,net'

property AnyTLD: boolean read fAnyTLD write fAnyTLD;

Allow any TLD to be allowed, even if not a generic TLD (.com,.net ...)

- this may be mandatory since already over 1,300 new gTLD names or "strings" could become available in the next few years: there is a growing list of new gTLDs available at <http://newgtlds.icann.org/en/program-status/delegated-strings>
- the only restriction is that it should be ascii characters

property ForbiddenDomains: RawUTF8 read fForbiddenDomains write fForbiddenDomains;

A CSV list of forbidden domain names

- if accessed directly, should be set as lower case values
- not only the TLD, but whole domains like 'cracks.ru,hotmail.com' or such

property ForbiddenTLD: RawUTF8 read fForbiddenTLD write fForbiddenTLD;

A CSV list of forbidden TLD

- if accessed directly, should be set as lower case values
- e.g. 'fr'

TSynValidatePattern = class(TSynValidate)

Glob case-sensitive pattern validation of a Record field content

- parameter is NOT JSON encoded, but is some basic TMatch glob pattern
- ? Matches any single characer
- * Matches any contiguous characters
- [abc] Matches a or b or c at that position
- [^abc] Matches anything but a or b or c at that position
- [!abc] Matches anything but a or b or c at that position
- [a-e] Matches a through e at that position
- [abcx-z] Matches a or b or c or x or y or or z, as does [a-cx-z]
- 'ma?ch.*' would match match.exe, mavch.dat, march.on, etc..
- 'this [e-n]s a [!zy]est' would match 'this is a test', but would not match 'this as a test' nor 'this is a zest'
- pattern check IS case sensitive (TSynValidatePatternI is not)
- this class is not as complete as PCRE regex for example, but code overhead is very small, and speed good enough in practice

function Process(aFieldIndex: integer; const Value: RawUTF8; var ErrorMsg: string): boolean; **override;**

Perform the pattern validation to the specified value

- pattern can be e.g. '[0-9][0-9]:[0-9][0-9]:[0-9][0-9]'
- this method will implement both TSynValidatePattern and TSynValidatePatternI, checking the current class

TSynValidatePatternI = class(TSynValidatePattern)

Glob case-insensitive pattern validation of a text field content (typically a TSQLRecord)

- parameter is NOT JSON encoded, but is some basic TMatch glob pattern
- same as TSynValidatePattern, but is NOT case sensitive

TSynValidateNonVoidText = class(TSynValidate)

Text validation to ensure that to any text field would not be "

function Process(aFieldIndex: integer; **const** Value: RawUTF8; **var** ErrorMsg: string): boolean; **override**;

Perform the non void text validation action to the specified value

TSynValidateText = class(TSynValidate)

To have existing RTTI for published properties text validation to be applied to any Record field content

- default MinLength value is 1, MaxLength is maxInt: so a blank TSynValidateText.Create("") is the same as TSynValidateNonVoidText

- MinAlphaCount, MinDigitCount, MinPunctCount, MinLowerCount and MinUpperCount allow you to specify the minimal count of respectively alphabetical [a-zA-Z], digit [0-9], punctuation [_!.,/:?%\$="#@(){}+~*], lower case or upper case characters

- expects optional JSON parameters of the allowed text length range as
 '{"MinLength":5,"MaxLength":10,"MinAlphaCount":1,"MinDigitCount":1,"MinPunctCount":1,"MinLowerCount":1,"MinUpperCount":1}'

function Process(aFieldIndex: integer; **const** Value: RawUTF8; **var** ErrorMsg: string): boolean; **override**;

Perform the text length validation action to the specified value

property MaxAlphaCount: cardinal **read** fProps[10] **write** fProps[10];

Maximal alphabetical character [a-zA-Z] count

- default is maxInt, i.e. no Maximum set

property MaxDigitCount: cardinal **read** fProps[11] **write** fProps[11];

Maximal digit character [0-9] count

- default is maxInt, i.e. no Maximum set

property MaxLeftTrimCount: cardinal **read** fProps[8] **write** fProps[8];

Maximal space count allowed on the Left side

- default is maxInt, i.e. any Left space allowed

property MaxLength: cardinal **read** fProps[1] **write** fProps[1];

Maximal length value allowed for the text content

- the length is calculated with UTF-16 Unicode codepoints, unless UTF8Length has been set to TRUE so that the UTF-8 byte count is checked

- default is maxInt, i.e. no maximum length is set

property MaxLowerCount: cardinal **read** fProps[13] **write** fProps[13];

Maximal alphabetical lower case character [a-z] count

- default is maxInt, i.e. no Maximum set

property MaxPunctCount: cardinal **read** fProps[12] **write** fProps[12];

Maximal punctuation sign [_!.,/:?%\$="#@(){}+~] count*

- default is maxInt, i.e. no Maximum set

property MaxRightTrimCount: cardinal read fProps[9] write fProps[9];

Maximal space count allowed on the Right side
- default is maxInt, i.e. any Right space allowed

property MaxSpaceCount: cardinal read fProps[15] write fProps[15];

Maximal space count inside the value text
- default is maxInt, i.e. any space number allowed

property MaxUpperCount: cardinal read fProps[14] write fProps[14];

Maximal alphabetical upper case character [A-Z] count
- default is maxInt, i.e. no Maximum set

property MinAlphaCount: cardinal read fProps[2] write fProps[2];

Minimal alphabetical character [a-zA-Z] count
- default is 0, i.e. no minimum set

property MinDigitCount: cardinal read fProps[3] write fProps[3];

Minimal digit character [0-9] count
- default is 0, i.e. no minimum set

property MinLength: cardinal read fProps[0] write fProps[0];

Minimal length value allowed for the text content
- the length is calculated with UTF-16 Unicode codepoints, unless UTF8Length has been set to TRUE so that the UTF-8 byte count is checked
- default is 1, i.e. a void text will not pass the validation

property MinLowerCount: cardinal read fProps[5] write fProps[5];

Minimal alphabetical lower case character [a-z] count
- default is 0, i.e. no minimum set

property MinPunctCount: cardinal read fProps[4] write fProps[4];

Minimal punctuation sign [_ !,./:;%\$="#{ }+~] count*
- default is 0, i.e. no minimum set

property MinSpaceCount: cardinal read fProps[7] write fProps[7];

Minimal space count inside the value text
- default is 0, i.e. any space number allowed

property MinUpperCount: cardinal read fProps[6] write fProps[6];

Minimal alphabetical upper case character [A-Z] count
- default is 0, i.e. no minimum set

property UTF8Length: boolean read fUTF8Length write fUTF8Length;

Defines if lengths parameters expects UTF-8 or UTF-16 codepoints number
- with default FALSE, the length is calculated with UTF-16 Unicode codepoints - MaxLength may not match the UCS4 glyphs number, in case of UTF-16 surrogates
- you can set this property to TRUE so that the UTF-8 byte count would be used for truncation againsts the MaxLength parameter

TSynValidatePassWord = class(TSynValidateText)

Strong password validation for a Record field content (typically a TSQLRecord)

- the following parameters are set by default to

```
'{"MinLength":5,"MaxLength":20,"MinAlphaCount":1,"MinDigitCount":1,  
"MinPunctCount":1,"MinLowerCount":1,"MinUpperCount":1,"MaxSpaceCount":0}'
```

- you can specify some JSON encoded parameters to change this default values, which will validate the text field only if it contains from 5 to 10 characters, with at least one digit, one upper case letter, one lower case letter, and one punctuation sign, with no space allowed inside

TSynFilter = class(TSynFilterOrValidate)

Will define a transformation to be applied to a Record field content (typically a TSQLRecord)

- here "filter" means that content would be transformed according to a set of defined rules

- a typical usage is to convert to lower or upper case, or trim any time or date value in a TDateTime field

- the optional associated parameters are to be supplied JSON-encoded

procedure Process(aFieldIndex: integer; **var** Value: RawUTF8); **virtual; abstract;**

Perform the transformation to the specified value

- the value is converted into UTF-8 text, as expected by TPropInfo.GetValue / TPropInfo.SetValue e.g.

TSynFilterUpperCase = class(TSynFilter)

Convert the value into ASCII Upper Case characters

- UpperCase conversion is made for ASCII-7 only, i.e. 'a'..'z' characters

- this version expects no parameter

procedure Process(aFieldIndex: integer; **var** Value: RawUTF8); **override;**

Perform the case conversion to the specified value

TSynFilterUpperCaseU = class(TSynFilter)

Convert the value into WinAnsi Upper Case characters

- UpperCase conversion is made for all latin characters in the WinAnsi code page only, e.g. 'e' acute will be converted to 'E'

- this version expects no parameter

procedure Process(aFieldIndex: integer; **var** Value: RawUTF8); **override;**

Perform the case conversion to the specified value

TSynFilterLowerCase = class(TSynFilter)

Convert the value into ASCII Lower Case characters

- LowerCase conversion is made for ASCII-7 only, i.e. 'A'..'Z' characters

- this version expects no parameter

procedure Process(aFieldIndex: integer; **var** Value: RawUTF8); **override;**

Perform the case conversion to the specified value

TSynFilterLowerCaseU = class(TSynFilter)

Convert the value into WinAnsi Lower Case characters

- LowerCase conversion is made for all latin characters in the WinAnsi code page only, e.g. 'E' acute will be converted to 'e'
- this version expects no parameter

procedure Process(aFieldIndex: integer; **var** Value: RawUTF8); **override**;

Perform the case conversion to the specified value

TSynFilterTrim = class(TSynFilter)

Trim any space character left or right to the value

- this versions expect no parameter

procedure Process(aFieldIndex: integer; **var** Value: RawUTF8); **override**;

Perform the space trimming conversion to the specified value

TSynFilterTruncate = class(TSynFilter)

Truncate a text above a given maximum length

- expects optional JSON parameters of the allowed text length range as '{MaxLength':10}

procedure Process(aFieldIndex: integer; **var** Value: RawUTF8); **override**;

Perform the length truncation of the specified value

property MaxLength: cardinal **read** fMaxLength **write** fMaxLength;

Maximal length value allowed for the text content

- the length is calculated with UTF-16 Unicode codepoints, unless UTF8Length has been set to TRUE so that the UTF-8 byte count is checked
- default is 0, i.e. no maximum length is forced

property UTF8Length: boolean **read** fUTF8Length **write** fUTF8Length;

Defines if MaxLength is stored as UTF-8 or UTF-16 codepoints number

- with default FALSE, the length is calculated with UTF-16 Unicode codepoints - MaxLength may not match the UCS4 glyphs number, in case of UTF-16 surrogates
- you can set this property to TRUE so that the UTF-8 byte count would be used for truncation againsts the MaxLength parameter

TSQLVar = record

Memory structure used for database values by reference storage

- used mainly by SynDB, mORMot, mORMotDB and mORMotSQLite3 units
- defines only TSQLDBFieldType data types (similar to those handled by SQLite3, with the addition of ftCurrency and ftDate)
- cleaner/lighter dedicated type than TValue or variant/TVarData, strong enough to be marshalled as JSON content
- variable-length data (e.g. UTF-8 text or binary BLOB) are never stored within this record, but VText/VBlob will point to an external (temporary) memory buffer
- date/time is stored as ISO-8601 text (with milliseconds if svoDateWithMS option is set and the database supports it), and currency as double or BCD in most databases

Options: TSQLVarOptions;

How this value should be processed

VType: TSQLDBFieldType

The type of the value stored

TJSONWriter = class(TTextWriterWithEcho)

Simple writer to a Stream, specialized for the JSON format and SQL export

- i.e. define some property/method helpers to export SQL resultset as JSON
- see mORMot.pas for proper class serialization via TJSONSerializer.WriteObject

ColNames: TRawUTF8DynArray;

Used internally to store column names and count for AddColumns

constructor Create(aStream: TStream; Expand, withID: boolean; **const** Fields: TSQLFieldIndexDynArray=nil; aBufSize: integer=8192; aStackBuffer: PTextWriterStackBuffer=nil); overload;

The data will be written to the specified Stream

- if no Stream is supplied, a temporary memory stream will be created (it's faster to supply one, e.g. any TSQLRest.TempMemoryStream)

constructor Create(aStream: TStream; Expand, withID: boolean; **const** Fields: TSQLFieldBits; aBufSize: integer=8192); overload;

The data will be written to the specified Stream

- if no Stream is supplied, a temporary memory stream will be created (it's faster to supply one, e.g. any TSQLRest.TempMemoryStream)

procedure AddColumns(aKnownRowCount: integer=0);

Write or init field names for appropriate JSON Expand later use

- ColNames[] must have been initialized before calling this procedure
- if aKnownRowCount is not null, a "rowCount":... item will be added to the generated JSON stream (for faster unserialization of huge content)

procedure CancelAllVoid;

Rewind the Stream position and write void JSON object

procedure ChangeExpandedFields(aWithID: boolean; **const** aFields: TSQLFieldIndexDynArray); overload;

Allow to change on the fly an expanded format column layout
- by definition, a non expanded format will raise a ESynException
- caller should then set ColNames[] and run AddColumns()

procedure EndJSONObject(aKnownRowCount, aRowCount: integer; aFlushFinal: boolean=true);

End the serialized JSON object
- cancel last ','
- close the JSON object '}' or '}]'
- write non expanded postlog (,"rowcount":...), if needed
- flush the internal buffer content if aFlushFinal=true

procedure TrimFirstRow;

The first data row is erased from the content
- only works if the associated storage stream is TMemoryStream
- expect not Expanded format

property Expand: boolean **read** fExpand **write** fExpand;

Is set to TRUE in case of Expanded format

property Fields: TSQLFieldIndexDynArray **read** fFields;

Read-Only access to the field bits set for each column to be stored

property StartDataPosition: integer **read** fStartDataPosition;

If not Expanded format, contains the Stream position of the first useful Row of data; i.e. 'val11' position in:

```
{ "fieldCount":1,"values":["col1","col2",val11,"val12",val21,..] }
```

property WithID: boolean **read** fWithID;

Is set to TRUE if the ID field must be appended to the resulting JSON
- this field is used only by TSQLRecord.GetJSONValues
- this field is ignored by TSQLTable.GetJSONValues

TFastReader = object(TObject)

Safe decoding of a TFileBufferWriter content
- similar to TFileBufferReader, but faster and only for in-memory buffer
- is also safer, since will check for reaching end of buffer
- raise a EFastReader exception on decoding error (e.g. if a buffer overflow may occur) or call OnErrorOverflow/OnErrorData event handlers

Last: PAnsiChar;

The last position in the buffer

OnErrorData: procedure(**const** fmt: RawUTF8; **const** args: array of **const**) of **object**;

Use this event to customize the ErrorData process

OnErrorOverflow: procedure of **object**;

Use this event to customize the ErrorOverflow process

P: PAnsiChar;

The current position in the memory

Tag: PtrInt;

Some opaque value, which may be a version number to define the binary layout

function CopySafe(out Dest; DataLen: PtrInt): boolean;

Copy data from the current position, and move ahead the specified bytes
 - this version won't call ErrorOverflow, but return false on error
 - returns true on read success

function EOF: boolean;

Returns TRUE if the current position is the end of the input stream

function Next(DataLen: PtrInt): pointer;

Returns the current position, and move ahead the specified bytes

function Next4: cardinal;

Read the next 4 bytes from the buffer as a 32-bit unsigned value

function Next8: Qword;

Read the next 8 bytes from the buffer as a 64-bit unsigned value

function NextByte: byte;

Read the next byte from the buffer

function NextByteEquals(Value: byte): boolean;

Consumes the next byte from the buffer, if matches a given value

function NextByteSafe(dest: pointer): boolean;

Read the next byte from the buffer, checking

function NextSafe(out Data: Pointer; DataLen: PtrInt): boolean;

Returns the current position, and move ahead the specified bytes

function PeekVarInt32(out value: PtrInt): boolean;

Try to read the next 32-bit signed value from the buffer
 - don't change the current position

function PeekVarUInt32(out value: PtrUInt): boolean;

Try to read the next 32-bit unsigned value from the buffer
 - don't change the current position

function ReadCompressed(Load: TAlgoCompressLoad=aclNormal; BufferOffset: integer=0): RawByteString;

Retrieve some TAlgoCompress buffer, appended via Write()
 - BufferOffset could be set to reserve some bytes before the uncompressed buffer

function ReadVarUInt32Array(var Values: TIntegerDynArray): PtrInt;

Retrieved cardinal values encoded with TFileBufferWriter.WriteVarUInt32Array
 - only supports wkUInt32, wkVarInt32, wkVarUInt32 kind of encoding

function RemainingLength: PtrUInt;

Returns remaining length (difference between Last and P)

function VarBlob: TValueResult; overload;

Read the next pointer and length value from the buffer

function VarInt32: integer;

Read the next 32-bit signed value from the buffer

function VarInt64: Int64;

Read the next 64-bit signed value from the buffer

function VarShortString: shortstring;

Read the next ShortString value from the buffer

function VarString: RawByteString;

Read the next RawByteString value from the buffer

function VarUInt32: cardinal;

Read the next 32-bit unsigned value from the buffer

function VarUInt32Safe(out Value: cardinal): boolean;

Read the next 32-bit unsigned value from the buffer

- this version won't call ErrorOverflow, but return false on error
- returns true on read success

function VarUInt64: QWord;

Read the next 64-bit unsigned value from the buffer

function VarUTF8: RawUTF8; overload;

Read the next RawUTF8 value from the buffer

function VarUTF8Safe(out Value: RawUTF8): boolean;

Read the next RawUTF8 value from the buffer

- this version won't call ErrorOverflow, but return false on error
- returns true on read success

procedure Copy(out Dest; DataLen: PtrInt);

Copy data from the current position, and move ahead the specified bytes

procedure ErrorData(const fmt: RawUTF8; const args: array of const);

Raise a EFastReader with an "incorrect data" error message

procedure ErrorOverflow;

Raise a EFastReader with an "overflow" error message

procedure Init(const Buffer: RawByteString); overload;

Initialize the reader from a RawByteString content

procedure Init(Buffer: pointer; Len: integer); overload;

Initialize the reader from a memory block

procedure NextDocVariantData(out Value: variant; CustomVariantOptions: PDocVariantOptions);

Read the JSON-serialized TDocVariant from the buffer

- matches TFileBufferWriter.WriteDocVariantData format

```
procedure NextVariant(var Value: variant; CustomVariantOptions:
PDocVariantOptions);
```

Read the next variant from the buffer
- is a wrapper around VariantLoad()

```
procedure Read(var DA: TDynArray; NoCheckHash: boolean=false);
```

Apply TDynArray.LoadFrom on the buffer
- will unserialize a previously appended dynamic array, e.g. as
aWriter.WriteDynArray(DA);

```
procedure VarBlob(out result: TValueResult); overload;
```

Read the next pointer and length value from the buffer

```
procedure VarNextInt(count: integer); overload;
```

Fast ignore the next count VarUInt32/VarInt32/VarUInt64/VarInt64 values
- don't raise any exception, so caller could check explicitly for any EOF

```
procedure VarNextInt; overload;
```

Fast ignore the next VarUInt32/VarInt32/VarUInt64/VarInt64 value
- don't raise any exception, so caller could check explicitly for any EOF

```
procedure VarUTF8(out result: RawUTF8); overload;
```

Read the next RawUTF8 value from the buffer

```
TSynTempWriter = object(TObject)
```

Implements a stack-based writable storage of binary content
- memory allocation is performed via a TSynTempBuffer

```
pos: PAnsiChar;
```

The current writable position in tmp.buf

```
function AsBinary: RawByteString;
```

Returns the buffer as a RawByteString instance

```
function Position: PtrInt;
```

Returns the current offset position in the internal buffer

```
function wrfillchar(count: integer; value: byte): PAnsiChar;
```

Append some fixed-value bytes as binary to the internal buffer
- returns a pointer to the first byte of the added memory chunk

```
procedure AsUTF8(var result: RawUTF8);
```

Returns the buffer as a RawUTF8 instance

```
procedure Done;
```

Finalize the temporary storage

```
procedure Init(maxsize: integer=0);
```

Initialize a new temporary buffer of a given number of bytes
- if maxsize is left to its 0 default value, the default stack-allocated memory size is used, i.e. 4 KB

procedure wr(const val; len: PtrInt);

Append some binary to the internal buffer
 - will raise an ESynException in case of potential overflow

procedure wrb(b: byte);

Append some 8-bit value as binary to the internal buffer

procedure writ(int: integer);

Append some 32-bit value as binary to the internal buffer

procedure wrptr(ptr: pointer);

Append some 32-bit/64-bit pointer value as binary to the internal buffer

procedure wrptrint(int: PtrInt);

Append some 32-bit/64-bit integer as binary to the internal buffer

procedure wrs(const str: RawByteString);

Append some string as binary to the internal buffer

procedure wrss(const str: shortstring);

Append some shortstring as binary to the internal buffer

procedure wrw(w: word);

Append some 16-bit value as binary to the internal buffer

TFileBufferWriter = class(TObject)

This class can be used to speed up writing to a file
 - big speed up if data is written in small blocks
 - also handle optimized storage of any dynamic array of Integer/Int64/RawUTF8
 - use TFileBufferReader or TFastReader for decoding of the stored binary

constructor Create(aClass: TStreamClass; BufLen: integer=4096); overload;

Initialize the buffer, using an internal TStream instance
 - parameter could be e.g. THeapMemoryStream or TRawByteStringStream
 - use Flush then TMemoryStream(Stream) to retrieve its content, or
 TRawByteStringStream(Stream).DataString

constructor Create(aStream: TStream; aTempBuf: pointer; aTempLen: integer);
 overload;

Initialize with a specified buffer and TStream class
 - use a specified external buffer (which may be allocated on stack), to avoid a memory allocation

constructor Create(aClass: TStreamClass; aTempBuf: pointer; aTempLen: integer);
 overload;

Initialize with a specified buffer
 - use a specified external buffer (which may be allocated on stack), to avoid a memory allocation
 - aStream parameter could be e.g. THeapMemoryStream or TRawByteStringStream

constructor Create(aFile: THandle; BufLen: integer=65536); overload;

Initialize the buffer, and specify a file handle to use for writing
 - use an internal buffer of the specified size

constructor Create(aStream: TStream; BufLen: integer=65536); overload;

Initialize the buffer, and specify a TStream to use for writing
- use an internal buffer of the specified size

constructor Create(const aFileName: TFileName; BufLen: integer=65536; Append: boolean=false); overload;

Initialize the buffer, and specify a file to use for writing
- use an internal buffer of the specified size
- would replace any existing file by default, unless Append is TRUE

destructor Destroy; **override**;

Release internal TStream (after AssignToHandle call)
- warning: an explicit call to Flush is needed to write the data pending in internal buffer

function DirectWritePrepare(len: PtrInt; out tmp: RawByteString): PAnsiChar;

Allows to write directly to a memory buffer
- caller should specify the maximum possible number of bytes to be written
- then write the data to the returned pointer, and call DirectWriteFlush

function Flush: Int64;

Write any pending data in the internal buffer to the file
- after a Flush, it's possible to call FileSeek64(aFile,...)
- returns the number of bytes written between two FLush method calls

function FlushAndCompress(nocompression: boolean=false; algo: TAlgoCompress=nil; BufferOffset: integer=0): RawByteString;

Write any pending data, then call algo.Compress() on the buffer
- expect the instance to have been created via
 TFileBufferWriter.Create(TRawByteStringStream)
- if algo is left to its default nil, will use global AlgoSynLZ
- features direct compression from internal buffer, if stream was not used
- BufferOffset could be set to reserve some bytes before the compressed buffer

procedure CancelAll; **virtual**;

Rewind the Stream to the position when Create() was called
- note that this does not clear the Stream content itself, just move back its writing position to its initial place

procedure DirectWriteFlush(len: PtrInt; const tmp: RawByteString);

Finalize a direct write to a memory buffer
- by specifying the number of bytes written to the buffer

procedure Write(const Text: RawByteString); overload;

Append some UTF-8 encoded text at the current position
- will write the string length (as VarUInt32), then the string content, as expected by the FromVarString() function

procedure Write(Data: pointer; DataLen: PtrInt); overload;

Append some data at the current position

procedure Write(const Value: variant); overload;

Append some variant value at the current position
- matches FromVarVariant() and VariantSave/VariantLoad format

procedure Write1(Data: Byte);

Append 1 byte of data at the current position

procedure Write2(Data: Word);

Append 2 bytes of data at the current position

procedure Write4(Data: integer);

Append 4 bytes of data at the current position

procedure Write4BigEndian(Data: integer);

Append 4 bytes of data, encoded as BigEndian, at the current position

procedure Write8(const Data8Bytes);

Append 8 bytes of data at the current position

procedure WriteBinary(const Data: RawByteString);

Append some content at the current position

- will write the binary data, without any length prefix

procedure WriteDocVariantData(const Value: variant);

Append some TDocVariant value at the current position, as JSON string

- matches TFastReader.NextDocVariantData format

procedure WriteDynArray(const DA: TDynArray);

Append some dynamic array at the current position

- will use the binary serialization as for:

`aWriter.WriteBinary(DA.SaveTo);`

but writing directly into the buffer, if possible

procedure WriteN(Data: Byte; Count: integer);

Append the same byte a given number of occurrences at the current position

procedure WriteRawUTF8Array(Values: PPtrUIntArray; ValuesCount: integer);

Append a RawUTF8 array of values, from its low-level memory pointer

- handled the fixed size strings array case in a very efficient way

procedure WriteRawUTF8DynArray(const Values: TRawUTF8DynArray; ValuesCount: integer);

Append the RawUTF8 dynamic array

- handled the fixed size strings array case in a very efficient way

procedure WriteRawUTF8List(List: TRawUTF8List; StoreObjectsAsVarUInt32: Boolean=false);

Append the RawUTF8List content

- if StoreObjectsAsVarUInt32 is TRUE, all Objects[] properties will be stored as VarUInt32

procedure WriteRecord(const Rec; RecTypeInfo: pointer);

Append some record at the current position, with binary serialization

- will use the binary serialization as for:

`aWriter.WriteBinary(RecordSave(Rec, RecTypeInfo));`

but writing directly into the buffer, if possible

procedure WriteShort(const Text: ShortString);

Append some UTF-8 encoded text at the current position

- will write the string length (as VarUInt32), then the string content

procedure WriteStream(aStream: TCustomMemoryStream; aStreamSize: Integer=-1);

Append a TStream content

- is StreamSize is left as -1, the Stream.Size is used
- the size of the content is stored in the resulting stream

procedure WriteVarInt32(Value: PtrInt);

Append an integer value using 32-bit variable-length integer encoding of the by-two complement of the given value

procedure WriteVarInt64(Value: Int64);

Append an integer value using 64-bit variable-length integer encoding of the by-two complement of the given value

procedure WriteVarUInt32(Value: PtrUInt);

Append a cardinal value using 32-bit variable-length integer encoding

procedure WriteVarUInt32Array(const Values: TIntegerDynArray; ValuesCount: integer; DataLayout: TFileBufferWriterKind);

Append cardinal values (NONE must be negative!) using 32-bit variable-length integer encoding or other specialized algorithm, depending on the data layout

procedure WriteVarUInt32Values(Values: PIntegerArray; ValuesCount: integer; DataLayout: TFileBufferWriterKind);

Append cardinal values (NONE must be negative!) using 32-bit variable-length integer encoding or other specialized algorithm, depending on the data layout

procedure WriteVarUInt64(Value: QWord);

Append an unsigned integer value using 64-bit variable-length encoding

procedure WriteVarUInt64DynArray(const Values: TInt64DynArray; ValuesCount: integer; Offset: Boolean);

Append UInt64 values using 64-bit variable length integer encoding

- if Offset is TRUE, then it will store the difference between two values using 64-bit variable-length integer encoding (in this case, a fixed-sized record storage is also handled separately)
- could be decoded later on via TFileBufferReader.ReadVarUInt64Array

procedure WriteXor(New,Old: PAnsiChar; Len: PtrInt; crc: PCardinal=nil);

Append "New[0..Len-1] xor Old[0..Len-1]" bytes

- as used e.g. by ZeroCompressXor/TSynBloomFilterDiff.SaveTo

property Stream: TStream **read** fStream;

The associated writing stream

property Tag: PtrInt **read** fTag **write** fTag;

Simple property used to store some integer content

property TotalWritten: Int64 **read** fTotalWritten;

Get the byte count written since last Flush

TFileBufferReader = object(TObject)

This structure can be used to speed up reading from a file

- use internally memory mapped files for a file up to 2 GB (Windows has problems with memory mapped files bigger than this size limit - at least with 32-bit executables) - but sometimes, Windows fails to allocate more than 512 MB for a memory map, because it does lack of contiguous memory space: in this case, we fall back on direct file reading
- maximum handled file size has no limit (but will use slower direct file reading)
- can handle sophisticated storage layout of TFileBufferWriter for dynamic arrays of Integer/Int64/RawUTF8
- is defined as an object or as a record, due to a bug in Delphi 2009/2010 compiler (at least): this structure is not initialized if defined as an object on the stack, but will be as a record :(

function CurrentMemory(DataLen: PtrUInt=0; PEnd: PPAncsiChar=nil): pointer;

Retrieve the current in-memory pointer

- if file was not memory-mapped, returns nil
- if DataLen>0, will increment the current in-memory position

function CurrentPosition: integer;

Retrieve the current in-memory position

- if file was not memory-mapped, returns -1

function FileSize: Int64;

Read-only access to the global file size

function MappedBuffer: PPAncsiChar;

Read-only access to the global mapped buffer binary

function OpenFrom(Stream: TStream): boolean; overload;

Initialize the buffer from an already existing Stream

- accept either TFileStream or TCustomMemoryStream kind of stream

function Read(out Text: RawByteString): integer; overload;

Read some buffer text at the current position

- returns the resulting text length, in bytes

function Read(Data: pointer; DataLen: PtrInt): integer; overload;

Read some bytes from the given reading position

- returns the number of bytes which was read
- if Data is nil, it won't read content but will forward reading position

function Read(out Text: RawUTF8): integer; overload;

Read some UTF-8 encoded text at the current position

- returns the resulting text length, in bytes

function ReadByte: PtrUInt;

Read one byte

- if reached end of file, don't raise any error, but returns 0

function ReadCardinal: cardinal;

Read one cardinal, which was written as fixed length

- if reached end of file, don't raise any error, but returns 0

function ReadPointer(DataLen: PtrUInt; var aTempData: RawByteString): pointer;

Retrieve a pointer to the current position, for a given data length

- if the data is available in the current memory mapped file, it will just return a pointer to it
- otherwise (i.e. if the data is split between to 1GB memory map buffers), data will be copied into the temporary aTempData buffer before retrieval

function ReadRawUTF8: RawUTF8;

Read some UTF-8 encoded text at the current position

- returns the resulting text

function ReadRawUTF8List(List: TRawUTF8List): boolean;

Retrieve the RawUTF8List content encoded with TFileBufferWriter.WriteRawUTF8List

- if StoreObjectsAsVarUInt32 was TRUE, all Objects[] properties will be retrieved as VarUInt32

function ReadStream(DataLen: PtrInt=-1): TCustomMemoryStream;

Create a TMemoryStream instance from the current position

- the content size is either specified by DataLen>=0, either available at the current position, as saved by TFileBufferWriter.WriteStream method
- if this content fit in the current 1GB memory map buffer, a TSynMemoryStream instance is returned, with no data copy (faster)
- if this content is not already mapped in memory, a separate memory map will be created (the returned instance is a TSynMemoryStreamMapped)

function ReadVarInt32: PtrInt;

Read one integer value encoded using our 32-bit variable-length integer, and the by-two complement

function ReadVarInt64: Int64;

Read one Int64 value encoded using our 64-bit variable-length integer

function ReadVarRawUTF8DynArray(var Values: TRawUTF8DynArray): PtrInt;

Retrieved RawUTF8 values encoded with TFileBufferWriter.WriteRawUTF8DynArray

- returns the number of items read into Values[] (may differ from length(Values))

function ReadVarUInt32: PtrUInt;

Read one cardinal value encoded using our 32-bit variable-length integer

function ReadVarUInt32Array(var Values: TIntegerDynArray): PtrInt;

Retrieved cardinal values encoded with TFileBufferWriter.WriteVarUInt32Array

- returns the number of items read into Values[] (may differ from length(Values), which will be resized, so could be void before calling)
- if the returned integer is negative, it is -Count, and testifies from wkFakeMarker and the content should be retrieved by the caller

function ReadVarUInt64: QWord;

Read one UInt64 value encoded using our 64-bit variable-length integer

function ReadVarUInt64Array(var Values: TInt64DynArray): PtrInt;

Retrieved Int64 values encoded with TFileBufferWriter.WriteVarUInt64DynArray

- returns the number of items read into Values[] (may differ from length(Values))

function Seek(Offset: PtrInt): boolean; overload;

Change the current reading position, from the beginning of the file

- returns TRUE if success, or FALSE if Offset is out of range

function Seek(Offset: Int64): boolean; overload;

Change the current reading position, from the beginning of the file
- returns TRUE if success, or FALSE if Offset is out of range

procedure Close;

Close all internal mapped files
- call Open() again to use the Read() methods

procedure ErrorInvalidContent;

Raise an exception in case of invalid content

procedure Open(aFile: THandle; aFileNotMapped: boolean=false);

Initialize the buffer, and specify a file to use for reading
- will try to map the whole file content in memory
- if memory mapping failed, or aFileNotMapped is true, methods will use default slower file API

procedure OpenFrom(aBuffer: pointer; aBufferSize: PtrUInt); overload;

Initialize the buffer from an already existing memory block
- may be e.g. a resource or a TMemoryStream

procedure OpenFrom(const aBuffer: RawByteString); overload;

Initialize the buffer from an already existing memory block

TSynBloomFilter = class(TSynPersistentLock)

Implements a thread-safe Bloom Filter storage

- a "Bloom Filter" is a space-efficient probabilistic data structure, that is used to test whether an element is a member of a set. False positive matches are possible, but false negatives are not. Elements can be added to the set, but not removed. Typical use cases are to avoid unnecessary slow disk or network access if possible, when a lot of items are involved.
- memory use is very low, when compared to storage of all values: fewer than 10 bits per element are required for a 1% false positive probability, independent of the size or number of elements in the set - for instance, storing 10,000,000 items presence with 1% of false positive ratio would consume only 11.5 MB of memory, using 7 hash functions
- use Insert() methods to add an item to the internal bits array, and Reset() to clear all bits array, if needed
- MayExist() function would check if the supplied item was probably set
- SaveTo() and LoadFrom() methods allow transmission of the bits array, for a disk/database storage or transmission over a network
- internally, several (hardware-accelerated) crc32c hash functions will be used, with some random seed values, to simulate several hashing functions
- Insert/MayExist/Reset methods are thread-safe

constructor Create(const aSaved: RawByteString; aMagic: cardinal=\$B1003F11);
reintroduce; overload;

Initialize the internal bits storage from a SaveTo() binary buffer
- this constructor will initialize the internal bits array calling LoadFrom()

constructor Create(aSize: integer; aFalsePositivePercent: double = 1); reintroduce; overload;

Initialize the internal bits storage for a given number of items

- by default, internal bits array size will be guess from a 1 % false positive rate - but you may specify another value, to reduce memory use
- this constructor would compute and initialize Bits and HashFunctions corresponding to the expected false positive ratio

function LoadFrom(const aSaved: RawByteString; aMagic: cardinal=\$B1003F11): boolean; overload;

Read the internal bits array from a binary buffer

- as previously serialized by the SaveTo method
- may be used to transmit or store the state of a dataset

function LoadFrom(P: PByte; PLen: integer; aMagic: cardinal=\$B1003F11): boolean; overload; virtual;

Read the internal bits array from a binary buffer

- as previously serialized by the SaveTo method
- may be used to transmit or store the state of a dataset

function MayExist(aValue: pointer; aValueLen: integer): boolean; overload;

Returns TRUE if the supplied items was probably set via Insert()

- some false positive may occur, but not much than FalsePositivePercent
- this method is thread-safe

function MayExist(const aValue: RawByteString): boolean; overload;

Returns TRUE if the supplied items was probably set via Insert()

- some false positive may occur, but not much than FalsePositivePercent
- this method is thread-safe

function SaveTo(aMagic: cardinal=\$B1003F11): RawByteString; overload;

Store the internal bits array into a binary buffer

- may be used to transmit or store the state of a dataset, avoiding to recompute all Insert() at program startup, or to synchronize networks nodes information and reduce the number of remote requests

procedure Insert(aValue: pointer; aValueLen: integer); overload; virtual;

Add an item in the internal bits array storage

- this method is thread-safe

procedure Insert(const aValue: RawByteString); overload;

Add an item in the internal bits array storage

- this method is thread-safe

procedure Reset; virtual;

Clear the internal bits array storage

- you may call this method after some time, if some items may have been removed, to reduce false positives
- this method is thread-safe

procedure SaveTo(aDest: TFileBufferWriter; aMagic: cardinal=\$B1003F11); overload;

Store the internal bits array into a binary buffer

- may be used to transmit or store the state of a dataset, avoiding to recompute all Insert() at program startup, or to synchronize networks nodes information and reduce the number of remote requests

property Bits: cardinal **read** fBits;

Number of bits stored in the internal bits array

property FalsePositivePercent: double **read** fFalsePositivePercent;

Expected percentage (1..100) of false positive results for MayExists()

property HashFunctions: cardinal **read** fHashFunctions;

How many hash functions would be applied for each Insert()

property Inserted: cardinal **read** GetInserted;

How many times the Insert() method has been called

property Size: cardinal **read** fSize;

Maximum number of items which are expected to be inserted

TSynBloomFilterDiff = **class**(TSynBloomFilter)

Implements a thread-safe differential Bloom Filter storage

- this inherited class is able to compute incremental serialization of its internal bits array, to reduce network use
 - an obfuscated revision counter is used to identify storage history

function DiffKnownRevision(const aDiff: RawByteString): Int64;

Retrieve the revision number from an incremental binary buffer

- returns 0 if the supplied binary buffer does not match this bloom filter

function LoadFromDiff(const aDiff: RawByteString): boolean;

Read the internal bits array from an incremental binary buffer

- as previously serialized by the SaveToDiff() method
 - may be used to transmit or store the state of a dataset
 - returns false if the supplied content is incorrect, e.g. if the known revision is deprecated

function SaveToDiff(const aKnownRevision: Int64): RawByteString;

Store the internal bits array into an incremental binary buffer

- here the difference from a previous SaveToDiff revision will be computed
 - if aKnownRevision is outdated (e.g. if equals 0), the whole bits array would be returned, and around 10 bits per item would be transmitted (for 1% false positive ratio)
 - incremental retrieval would then return around 10 bytes per newly added item since the last snapshot reference state (with 1% ratio, i.e. 7 hash functions)

procedure DiffSnapshot;

Use the current internal bits array state as known revision

- is done the first time SaveToDiff() is called, then after 1/32th of the filter size has been inserted (see SnapshotAfterInsertCount property), or after SnapShotAfterMinutes property timeout period

procedure Insert(aValue: pointer; aValueLen: integer); **override**;

Add an item in the internal bits array storage

- this overloaded thread-safe method would compute fRevision

procedure Reset; **override**;

Clear the internal bits array storage

- this overloaded thread-safe method would reset fRevision

property Revision: Int64 **read** fRevision;

The opaque revision number of this internal storage

- is in fact the Unix timestamp shifted by 31 bits, and an incremental counter: this pattern will allow consistent IDs over several ServPanels

property SnapshotAfterInsertCount: cardinal **read** fSnapshotAfterInsertCount **write** fSnapshotAfterInsertCount;

After how many Insert() the internal bits array storage should be promoted as known revision

- equals Size div 32 by default

property SnapShotAfterMinutes: cardinal **read** fSnapShotAfterMinutes **write** fSnapShotAfterMinutes;

After how many time the internal bits array storage should be promoted as known revision

- equals 30 minutes by default

TSynCache = class(TSynPersistentLock)

Implement a cache of some key/value pairs, e.g. to improve reading speed

- used e.g. by TSQLDataBase for caching the SELECT statements results in an internal JSON format (which is faster than a query to the SQLite3 engine)

- internally make use of an efficient hashing algorithm for fast response (i.e. TSynNameValue will use the TDynArrayHashed wrapper mechanism)

- this class is thread-safe if you use properly the associated Safe lock

constructor Create(aMaxCacheRamUsed: cardinal=16 shl 20; aCaseSensitive: boolean=false; aTimeoutSeconds: cardinal=0); **reintroduce**;

Initialize the internal storage

- aMaxCacheRamUsed can set the maximum RAM to be used for values, in bytes (default is 16 MB), after which the cache is flushed

- by default, key search is done case-insensitively, but you can specify another option here

- by default, there is no timeout period, but you may specify a number of seconds of inactivity (i.e. no Add call) after which the cache is flushed

function AddOrUpdate(const aKey, aValue: RawUTF8; aTag: PtrInt): boolean;

Add a Key/Value pair in the cache entries

- returns true if aKey was not existing yet, and aValue has been stored

- returns false if aKey did already exist in the internal cache, and its entry has been updated with the supplied aValue/aTag

- this method is thread-safe, using the Safe locker of this instance

function Count: integer;

Number of entries in the cache

function Find(const aKey: RawUTF8; aResultTag: PPtrInt=nil): RawUTF8;

Find a Key in the cache entries

- return '' if nothing found: you may call Add() just after to insert the expected value in the cache
- return the associated Value otherwise, and the associated integer tag if aResultTag address is supplied
- this method is not thread-safe, unless you call Safe.Lock before calling Find(), and Safe.Unlock after calling Add()

function Reset: boolean;

Called after a write access to the database to flush the cache

- set Count to 0
- release all cache memory
- returns TRUE if was flushed, i.e. if there was something in cache
- this method is thread-safe, using the Safe locker of this instance

procedure Add(const aValue: RawUTF8; aTag: PtrInt);

Add a Key and its associated value (and tag) to the cache entries

- you MUST always call Find() with the associated Key first
- this method is not thread-safe, unless you call Safe.Lock before calling Find(), and Safe.Unlock after calling Add()

property MaxRamUsed: cardinal read fMaxRamUsed;

The maximum RAM to be used for values, in bytes

- the cache is flushed when ValueSize reaches this limit
- default is 16 MB (16 shl 20)

property RamUsed: cardinal read fRamUsed;

The current global size of Values in RAM cache, in bytes

property Safe: PSynLocker read fSafe;

Access to the internal locker, for thread-safe process

- Find/Add methods calls should be protected as such:
cache.Safe.Lock;
try
... cache.Find/cache.Add ...
finally
cache.Safe.Unlock;
end;

property TimeoutSeconds: cardinal read fTimeoutSeconds;

After how many seconds between Add() calls the cache should be flushed

- equals 0 by default, meaning no time out

TSynQueue = class(TSynPersistentLock)

Thread-safe FIFO (First-In-First-Out) in-order queue of records

- uses internally a dynamic array storage, with a sliding algorithm (more efficient than the FPC or Delphi TQueue)

constructor Create(aTypeInfo: pointer); reintroduce; virtual;

Initialize the queue storage

- aTypeInfo should be a dynamic array TypeInfo() RTTI pointer, which would store the values within this TSynQueue instance

destructor Destroy; override;

Finalize the storage

- would release all internal stored values, and call WaitPopFinalize

function Capacity: integer;

Returns how much slots is currently reserved in memory

- the queue has an optimized auto-sizing algorithm, you can use this method to return its current capacity
- this method is thread-safe

function Count: Integer;

Returns how many items are currently stored in this queue

- this method is thread-safe

function Peek(out aValue): boolean;

Lookup one item from the queue, as FIFO (First-In-First-Out)

- returns true if aValue has been filled with a pending item, without removing it from the queue (as Pop method does)
- returns false if the queue is empty
- this method is thread-safe, since it will lock the instance

function Pending: boolean;

Returns true if there are some items currently pending in the queue

- slightly faster than checking Count=0, and much faster than Pop or Peek

function Pop(out aValue): boolean;

Extract one item from the queue, as FIFO (First-In-First-Out)

- returns true if aValue has been filled with a pending item, which is removed from the queue (use Peek if you don't want to remove it)
- returns false if the queue is empty
- this method is thread-safe, since it will lock the instance

function PopEquals(aAnother: pointer; aCompare: TDynArraySortCompare; out aValue): boolean;

Extract one matching item from the queue, as FIFO (First-In-First-Out)

- the current pending item is compared with aAnother value

function WaitPeekLocked(aTimeoutMS: integer; const aWhenIdle: TThreadMethod): pointer;

Waiting lookup of one item from the queue, as FIFO (First-In-First-Out)

- returns a pointer to a pending item within the specified aTimeoutMS time - the Safe.Lock is still there, so that caller could check its content, then call Pop() if it is the expected one, and eventually always call Safe.Unlock
- returns nil if nothing was pushed into the queue in time
- this method is thread-safe, but will lock the instance only if needed

```
function WaitPop(aTimeoutMS: integer; const aWhenIdle: TThreadMethod; out aValue;  
aCompared: pointer=nil; aCompare: TDynArraySortCompare=nil): boolean;
```

Waiting extract of one item from the queue, as FIFO (First-In-First-Out)

- returns true if aValue has been filled with a pending item within the specified aTimeoutMS time
- returns false if nothing was pushed into the queue in time, or if WaitPopFinalize has been called
- aWhenIdle could be assigned e.g. to VCL/LCL Application.ProcessMessages
- you can optionally compare the pending item before returning it (could be used e.g. when several threads are putting items into the queue)
- this method is thread-safe, but will lock the instance only if needed

```
procedure Clear;
```

Delete all items currently stored in this queue, and void its capacity

- this method is thread-safe, since it will lock the instance

```
procedure Push(const aValue);
```

Store one item into the queue

- this method is thread-safe, since it will lock the instance

```
procedure Save(out aDynArrayValues; aDynArray: PDynArray=nil);
```

Initialize a dynamic array with the stored queue items

- aDynArrayValues should be a variable defined as aTypeInfo from Create
- you can retrieve an optional TDynArray wrapper, e.g. for binary or JSON persistence
- this method is thread-safe, and will make a copy of the queue data

```
procedure WaitPopFinalize(aTimeoutMS: integer=100);
```

Ensure any pending or future WaitPop() returns immediately as false

- is always called by Destroy destructor
- could be also called e.g. from an UI OnClose event to avoid any lock
- this method is thread-safe, but will lock the instance only if needed

```
TObjectListSorted = class(TSynPersistentLock)
```

Maintain a thread-safe sorted list of TSynPersistentLock objects

- will use fast $O(\log(n))$ binary search for efficient search - it is a lighter alternative to TObjectListHashedAbstract/TObjectListPropertyHashed if hashing has a performance cost (e.g. if there are a few items, or deletion occurs regularly)
- in practice, insertion becomes slower after around 100,000 items stored
- expect to store only TSynPersistentLock inherited items, so that the process is explicitly thread-safe
- inherited classes should override the Compare and NewItem abstract methods

```
destructor Destroy; override;
```

Finalize the list

```
function Delete(const Value): boolean;
```

Remove a given TSynPersistentLock instance from a value

function FindLocked(**const** Value): pointer;

Search a given TSynPersistentLock instance from a value

- if returns not nil, caller should make result.Safe.Unlock once finished
- will use the TObjectListSortedCompare function for the search

function FindOrAddLocked(**const** Value; **out** added: boolean): pointer;

Search or add a given TSynPersistentLock instance from a value

- if returns not nil, caller should make result.Safe.Unlock once finished
- added is TRUE if a new void item has just been created
- will use the TObjectListSortedCompare function for the search

property Count: Integer **read** fCount;

How many items are actually stored

property ObjArray: TSynPersistentLockDynArray **read** fObjArray;

Low-level access to the stored items

- warning: use should be protected by Lock.Enter/Lock.Leave

TSynPersistentStore = **class**(TSynPersistentLock)

Abstract high-level handling of (SynLZ-)compressed persisted storage

- LoadFromReader/SaveToWriter abstract methods should be overridden with proper binary persistence implementation

constructor Create(**const** aName: RawUTF8); **reintroduce**; **overload**; **virtual**;

Initialize a void storage with the supplied name

constructor CreateFrom(**const** aBuffer: RawByteString; aLoad: TAlgoCompressLoad = ac1Normal);

Initialize a storage from a SaveTo persisted buffer

- raise a EFastReader exception on decoding error

constructor CreateFromBuffer(aBuffer: pointer; aBufferLen: integer; aLoad: TAlgoCompressLoad = ac1Normal);

Initialize a storage from a SaveTo persisted buffer

- raise a EFastReader exception on decoding error

constructor CreateFromFile(**const** aFileName: TFileName; aLoad: TAlgoCompressLoad = ac1Normal);

Initialize a storage from a SaveTo persisted buffer

- raise a EFastReader exception on decoding error

function LoadFromFile(**const** aFileName: TFileName; aLoad: TAlgoCompressLoad = ac1Normal): boolean;

Initialize the storage from a SaveToFile content

- actually call the LoadFromReader() virtual method for persistence
- returns false if the file is not found, true if the file was loaded without any problem, or raise a EFastReader exception on decoding error

function SaveTo(nocompression: boolean=false; BufLen: integer=65536; ForcedAlgo: TAlgoCompress=nil; BufferOffset: integer=0): RawByteString; **overload**;

Persist the content as a SynLZ-compressed binary blob

- just an overloaded wrapper

```
function SaveToFile(const aFileName: TFileName; nocompression: boolean=false;
  BufLen: integer=65536; ForcedAlgo: TAlgoCompress=nil): PtrUInt;
```

Persist the content as a SynLZ-compressed binary file

- to be retrieved later on via LoadFromFile method
- returns the number of bytes of the resulting file
- actually call the SaveTo method for persistence

```
procedure LoadFrom(const aBuffer: RawByteString; aLoad: TAlgoCompressLoad =
  ac1Normal); overload;
```

Fill the storage from a SaveTo persisted buffer

- actually call the LoadFromReader() virtual method for persistence
- raise a EFastReader exception on decoding error

```
procedure LoadFrom(aBuffer: pointer; aBufferLen: integer; aLoad: TAlgoCompressLoad
  = ac1Normal); overload; virtual;
```

Initialize the storage from a SaveTo persisted buffer

- actually call the LoadFromReader() virtual method for persistence
- raise a EFastReader exception on decoding error

```
procedure SaveTo(out aBuffer: RawByteString; nocompression: boolean=false; BufLen:
  integer=65536; ForcedAlgo: TAlgoCompress=nil; BufferOffset: integer=0); overload;
virtual;
```

Persist the content as a SynLZ-compressed binary blob

- to be retrieved later on via LoadFrom method
- actually call the SaveToWriter() protected virtual method for persistence
- you can specify ForcedAlgo if you want to override the default AlgoSynLZ
- BufferOffset could be set to reserve some bytes before the compressed buffer

```
property LoadFromLastUncompressed: integer read fLoadFromLastUncompressed;
```

After a LoadFrom(), contains the uncompressed data size read

```
property Name: RawUTF8 read fName;
```

One optional text associated with this storage

- you can define this field as published to serialize its value in log/JSON

```
property SaveToLastUncompressed: integer read fSaveToLastUncompressed;
```

After a SaveTo(), contains the uncompressed data size written

```
TSynPersistentStoreJson = class(TSynPersistentStore)
```

Implement binary persistence and JSON serialization (not deserialization)

```
function SaveToJSON(reformat: TTextWriterJSONFormat = jsonCompact): RawUTF8;
```

Serialize this instance as a JSON object

```
TRawByteStringGroupValue = record
```

Item as stored in a TRawByteStringGroup instance

```
TRawByteStringGroup = object(TObject)
```

Store several RawByteString content with optional concatenation

Count: integer;
How many items are currently stored in Values[]

LastFind: integer;
Naive but efficient cache for Find()

Position: integer;
The current size of data stored in Values[]

Values: TRawByteStringGroupValueDynArray;
Actual list storing the data

function AsBytes: TByteDynArray;
Return all content as a single TByteDynArray

function AsText: RawByteString;
Return all content as a single RawByteString
- will also compact the Values[] array into a single item (which is returned)

function Equals(const aAnother: TRawByteStringGroup): boolean;
Compare two TRawByteStringGroup instance stored text

function Find(aPosition: integer): PRawByteStringGroupValue; overload;
Returns a pointer to Values[] containing a given position
- returns nil if not found

function Find(aPosition, aLength: integer): pointer; overload;
Returns a pointer to Values[].Value containing a given position and length
- returns nil if not found

function FindAsText(aPosition, aLength: integer): RawByteString; overload;
Returns the text at a given position in Values[]
- text should be in a single Values[] entry

procedure Add(const aItem: RawByteString); overload;
Add a new item to Values[]

procedure Add(const aAnother: TRawByteStringGroup); overload;
Add another TRawByteStringGroup to Values[]

procedure Add(aItem: pointer; aItemLen: integer); overload;
Add a new item to Values[]

procedure AddFromReader(var aReader: TFastReader);
Add another TRawByteStringGroup previously serialized via WriteString()

procedure AppendTextAndClear(var aDest: RawByteString);
Append stored information into another RawByteString, and clear content

procedure Clear;
Clear any stored information

procedure Compact;
Compact the Values[] array into a single item
- is also used by AsText to compute a single RawByteString

procedure FindAsText(aPosition, aLength: integer; **out** aText: RawByteString);
overload;

Returns the text at a given position in Values[]
- text should be in a single Values[] entry

procedure FindAsVariant(aPosition, aLength: integer; **out** aDest: variant);

Returns the text at a given position in Values[]
- text should be in a single Values[] entry
- explicitly returns null if the supplied text was not found

procedure FindMove(aPosition, aLength: integer; aDest: pointer);

Copy the text at a given position in Values[]
- text should be in a single Values[] entry

procedure FindWrite(aPosition, aLength: integer; W: TTextWriter; Escape: TTextWriterKind=twJSONEscape; TrailingCharsToIgnore: integer=0);

Append the text at a given position in Values[], JSON escaped by default
- text should be in a single Values[] entry

procedure FindWriteBase64(aPosition, aLength: integer; W: TTextWriter; withMagic: boolean);

Append the blob at a given position in Values[], base-64 encoded
- text should be in a single Values[] entry

procedure RemoveLastAdd;

Low-level method to abort the latest Add() call
- warning: will work only once, if an Add() has actually been just called: otherwise, the behavior is unexpected, and may wrongly truncate data

procedure Write(W: TTextWriter; Escape: TTextWriterKind=twJSONEscape); overload;
Save all content into a TTextWriter instance

procedure WriteBinary(W: TFileBufferWriter); overload;
Save all content into a TFileBufferWriter instance

procedure WriteString(W: TFileBufferWriter);
Save all content as a string into a TFileBufferWriter instance
- storing the length as WriteVarUInt32() prefix

TPropNameList = **object**(TObject)

Simple stack-allocated type for handling a non-void type names list
- Delphi "object" is buggy on stack -> also defined as record with methods

Count: Integer;

How many items are currently in Values[]

Values: TRawUTF8DynArray;

The actual names storage

function AddPropName(**const** Value: RawUTF8): Boolean;

If Value is in Values[0..Count-1] using IdemPropNameU() returns FALSE
- otherwise, returns TRUE and add Value to Values[]
- any Value="" is rejected

```
function FindPropName(const Value: RawUTF8): Integer;
  Search for a Value within Values[0..Count-1] using IdemPropNameU()
```

```
procedure Init;
  Initialize the list
  - set Count := 0
```

```
TSynUniqueIdentifierBits = object(TObject)
  Map 64-bit integer unique identifier internal memory structure
  - as stored in TSynUniqueIdentifier = Int64 values, and computed by
    TSynUniqueIdentifierGenerator
  - bits 0..14 map a 15-bit increasing counter (collision-free)
  - bits 15..30 map a 16-bit process identifier
  - bits 31..63 map a 33-bit UTC time, encoded as seconds since Unix epoch
```

```
Value: TSynUniqueIdentifier;
  The actual 64-bit storage value
  - in practice, only first 63 bits are used
```

```
function AsVariant: variant;
  Convert this identifier as an explicit TDocVariant JSON object
  - returns e.g.
    {"Created": "2016-04-19T15:27:58", "Identifier": 1, "Counter": 1,
     "Value": 3137644716930138113, "Hex": "2B8B273F00008001"}
```

```
function Counter: word;
  15-bit counter (0..32767), starting with a random value
```

```
function CreateDateTime: TDateTime;
  Extract the UTC generation timestamp from the identifier as TDateTime
  - time is expressed in Coordinated Universal Time (UTC), not local time
```

```
function CreateTimeLog: TTimeLog;
  Extract the UTC generation timestamp from the identifier
  - time is expressed in Coordinated Universal Time (UTC), not local time
```

```
function CreateTimeUnix: TUnixTime;
  Low-endian 4-byte value representing the seconds since the Unix epoch
  - time is expressed in Coordinated Universal Time (UTC), not local time
  - it uses in fact a 33-bit resolution, so is "Year 2038" bug-free
```

```
function Equal(const Another: TSynUniqueIdentifierBits): boolean;
  Compare two Identifiers
```

```
function FromHexa(const hexa: RawUTF8): boolean;
  Fill this unique identifier back from a 16 chars hexadecimal string
  - returns TRUE if the supplied hexadecimal is on the expected format
  - returns FALSE if the supplied text is invalid
```

function ProcessID: TSynUniqueIdentifierProcess;

16-bit unique process identifier

- as specified to TSynUniqueIdentifierGenerator constructor

function ToHexa: RawUTF8;

Convert the identifier into a 16 chars hexadecimal string

procedure From(const AID: TSynUniqueIdentifier);

Fill this unique identifier structure from its TSynUniqueIdentifier value

- is just a wrapper around PInt64(@self)^

procedure FromDateTime(const aDateTime: TDateTime);

Fill this unique identifier with a fake value corresponding to a given timestamp

- may be used e.g. to limit database queries on a particular time range

- bits 0..30 would be 0, i.e. would set Counter = 0 and ProcessID = 0

procedure FromUnixTime(const aUnixTime: TUnixTime);

Fill this unique identifier with a fake value corresponding to a given timestamp

- may be used e.g. to limit database queries on a particular time range

- bits 0..30 would be 0, i.e. would set Counter = 0 and ProcessID = 0

procedure ToVariant(out result: variant);

Convert this identifier to an explicit TDocVariant JSON object

- returns e.g.

```
{ "Created": "2016-04-19T15:27:58", "Identifier": 1, "Counter": 1,
  "Value": 3137644716930138113, "Hex": "2B8B273F00008001" }
```

TSynUniqueIdentifierGenerator = class(TSynPersistent)

Thread-safe 64-bit integer unique identifier computation

- may be used on client side for something similar to a MongoDB ObjectID, but compatible with TSQLRecord.ID: TID properties, since it will contain a 63-bit unsigned integer, following our ORM expectations

- each identifier would contain a 16-bit process identifier, which is supplied by the application, and should be unique for this process at a given time

- identifiers may be obfuscated as hexadecimal text, using both encryption and digital signature

constructor Create(aIdentifier: TSynUniqueIdentifierProcess; const aSharedObfuscationKey: RawUTF8=''); **reintroduce**;

Initialize the generator for the given 16-bit process identifier

- you can supply an obfuscation key, which should be shared for the whole system, so that you may use FromObfuscated/ToObfuscated methods

destructor Destroy; **override**;

Finalize the generator structure

function ComputeNew: Int64; **overload**;

Return a new unique ID, type-casted to an Int64

function FromObfuscated(**const** aObfuscated: TSynUniqueIdentifierObfuscated; **out** aIdentifier: TSynUniqueIdentifier): boolean;

Retrieve a TSynUniqueIdentifier from 24 chars cyphered hexadecimal text
 - any file extension (e.g. '.jpeg') would be first deleted from the supplied obfuscated text
 - returns true if the supplied obfuscated text has the expected layout and a valid digital signature
 - returns false if the supplied obfuscated text is invalid

function ToObfuscated(**const** aIdentifier: TSynUniqueIdentifier): TSynUniqueIdentifierObfuscated;

Map a TSynUniqueIdentifier as 24 chars cyphered hexadecimal text
 - cyphering includes simple key-based encryption and a CRC-32 digital signature

procedure ComputeFromDateTime(**const** aDateTime: TDateTime; **out** result: TSynUniqueIdentifierBits);

Return an unique ID matching this generator pattern, at a given timestamp
 - may be used e.g. to limit database queries on a particular time range

procedure ComputeFromUnixTime(**const** aUnixTime: TUnixTime; **out** result: TSynUniqueIdentifierBits);

Return an unique ID matching this generator pattern, at a given timestamp
 - may be used e.g. to limit database queries on a particular time range

procedure ComputeNew(**out** result: TSynUniqueIdentifierBits); overload;

Return a new unique ID
 - this method is very optimized, and would use very little CPU

property ComputedCount: Int64 **read** GetComputedCount;

How many times ComputeNew method has been called

property CryptoCRC: cardinal **read** fCryptoCRC;

Some 32-bit value, derivated from aSharedObfuscationKey as supplied to the class constructor
 - FromObfuscated and ToObfuscated methods will validate their hexadecimal content with this value to secure the associated CRC
 - may be used e.g. as system-depending salt

property Identifier: TSynUniqueIdentifierProcess **read** fIdentifier;

The process identifier, associated with this generator

property Safe: TSynLocker **read** fSafe;

Direct access to the associated mutex

TSynPersistentWithPassword = class(TSynPersistent)

Abstract TSynPersistent class allowing safe storage of a password
 - the associated Password, e.g. for storage or transmission encryption will be persisted encrypted with a private key (which can be customized)
 - if default simple symmetric encryption is not enough, you may define a custom TSynPersistentWithPasswordUserCrypt callback, e.g. to SynCrypto's CryptDataForCurrentUser, for hardened password storage
 - a published property should be defined as such in inherited class:

property PasswordPropertyName: RawUTF8 **read** fPassword **write** fPassword;

- use the PasswordPlain property to access to its uncyphered value

destructor Destroy; **override**;

Finalize the instance

class function ComputePassword(PlainPassword: pointer; PlainPasswordLen: integer; CustomKey: cardinal=0): RawUTF8; overload;

This class method could be used to compute the encrypted password from a binary digest, ready to be stored as JSON, according to a given private key

- just a wrapper around ComputePassword(BinToBase64URI())

class function ComputePassword(const PlainPassword: RawUTF8; CustomKey: cardinal=0): RawUTF8; overload;

This class method could be used to compute the encrypted password, ready to be stored as JSON, according to a given private key

class function ComputePlainPassword(const CypheredPassword: RawUTF8; CustomKey: cardinal=0; const AppSecret: RawUTF8=''): RawUTF8;

This class method could be used to decrypt a password, stored as JSON, according to a given private key

- may trigger a ESynException if the password was stored using a custom TSynPersistentWithPasswordUserCrypt callback, and the current user doesn't match the expected user stored in the field

function GetPasswordFieldAddress: pointer;

Low-level function used to identify if a given field is a Password

- this method is used e.g. by TJSONSerializer.WriteObject to identify the password field, since its published name is set by the inherited classes

property Key: cardinal **read** GetKey **write** fKey;

The private key used to cypher the password storage on serialization

- application can override the default 0 value at runtime

property PasswordPlain: RawUTF8 **read** GetPassWordPlain **write** SetPassWordPlain;

Access to the associated unencrypted Password value

- read may trigger a ESynException if the password was stored using a custom TSynPersistentWithPasswordUserCrypt callback, and the current user doesn't match the expected user stored in the field

TSynUserPassword = **class**(TSynPersistentWithPassword)

Could be used to store a credential pair, as user name and password

- password will be stored with TSynPersistentWithPassword encryption

property Password: RawUTF8 **read** FPassword **write** FPassword;

The associated encrypted password

- use the PasswordPlain public property to access to the unencrypted password

property UserName: RawUTF8 **read** FUserName **write** FUserName;

The associated user name

TSynConnectionDefinition = class(TSynPersistentWithPassword)

Handle safe storage of any connection properties

- would be used by SynDB.pas to serialize TSQLDBConnectionProperties, or by mORMot.pas to serialize TSQLRest instances
- the password will be stored as Base64, after a simple encryption as defined by TSynPersistentWithPassword
- typical content could be:

```
{
  "Kind": "TSQLDBSQLite3ConnectionProperties",
  "ServerName": "server",
  "DatabaseName": "",
  "User": "",
  "Password": "PtvlPA=="
}
```

- the "Kind" value will be used to let the corresponding TSQLRest or TSQLDBConnectionProperties NewInstance*() class methods create the actual instance, from its class name

constructor CreateFromJSON(const JSON: RawUTF8; Key: cardinal=0); **virtual;**

Unserialize the database definition from JSON

- as previously serialized with the SaveToJSON method
- you can specify a custom Key used for password encryption, if the default value is not safe enough for you
- this method won't use JSONToObject() so avoid any dependency to mORMot.pas

function SaveToJSON: RawUTF8; **virtual;**

Serialize the database definition as JSON

- this method won't use ObjectToJSON() so avoid any dependency to mORMot.pas

property DatabaseName: RawUTF8 **read** fDatabaseName **write** fDatabaseName;

The associated database name (if any), or additional options

property Kind: string **read** fKind **write** fKind;

The class name implementing the connection or TSQLRest instance

- will be used to instantiate the expected class type

property Password: RawUTF8 **read** fPassword **write** fPassword;

The associated Password, e.g. for storage or transmission encryption

- will be persisted encrypted with a private key
- use the PasswordPlain property to access to its uncyphered value

property ServerName: RawUTF8 **read** fServerName **write** fServerName;

The associated server name (or file, for SQLite3) to be connected to

property User: RawUTF8 **read** fUser **write** fUser;

The associated User Identifier (if any)

TSynAuthenticationAbstract = class(TObject)

Abstract authentication class, implementing safe token/challenge security and a list of active sessions

- do not use this class, but plain TSynAuthentication

constructor Create;

Initialize the authentication scheme

destructor Destroy; **override**;

Finalize the authentication

class function ComputeHash(Token: Int64; **const** UserName, Password: RawUTF8): cardinal; **virtual**;

To be used to compute a Hash on the client side, for a given Token

- the token should have been retrieved from the server, and the client should compute and return this hash value, to perform the authentication challenge and create the session
- internal algorithm is not cryptographic secure, but fast and safe

function CreateSession(**const** User: RawUTF8; Hash: cardinal): integer; **virtual**;

Create a new session

- should return 0 on authentication error, or an integer session ID
- this method will check the User name and password, and create a new session

function CurrentToken: Int64;

Returns the current identification token

- to be sent to the client for its authentication challenge

function SessionExists(aID: integer): boolean;

Check if the session exists in the internal list

procedure AuthenticateUser(**const** aName, aPassword: RawUTF8); **virtual**;

Register one credential for a given user

- this abstract method will raise an exception: inherited classes should implement them as expected

procedure DisauthenticateUser(**const** aName: RawUTF8); **virtual**;

Unregister one credential for a given user

- this abstract method will raise an exception: inherited classes should implement them as expected

procedure RemoveSession(aID: integer);

Delete a session

property SessionsCount: integer **read** fSessionsCount;

The number of current opened sessions

property UsersCount: integer **read** GetUsersCount;

The number of registered users

TSynAuthentication = class(TSynAuthenticationAbstract)

Simple authentication class, implementing safe token/challenge security

- maintain a list of user / name credential pairs, and a list of sessions
- is not meant to handle authorization, just plain user access validation
- used e.g. by TSQLDBConnection.RemoteProcessMessage (on server side) and TSQLDBProxyConnectionPropertiesAbstract (on client side) in SynDB.pas

constructor Create(const aUserName: RawUTF8=''; const aPassword: RawUTF8=''); reintroduce;

Initialize the authentication scheme
- you can optionally register one user credential

procedure AuthenticateUser(const aName, aPassword: RawUTF8); override;

Register one credential for a given user

procedure DisauthenticateUser(const aName: RawUTF8); override;

Unregister one credential for a given user

TIPBan = class(TSynPersistentStore)

Optimized thread-safe storage of a list of IP v4 addresses
- can be used e.g. as white-list or black-list of clients
- will maintain internally a sorted list of 32-bit integers for fast lookup
- with optional binary persistence

function Add(const aIP: RawUTF8): boolean;

Register one IP to the list

function Delete(const aIP: RawUTF8): boolean;

Unregister one IP to the list

function DynArrayLocked: TDynArray;

Creates a TDynArray wrapper around the stored list of values
- could be used e.g. for binary persistence
- warning: caller should make Safe.Unlock when finished

function Exists(const aIP: RawUTF8): boolean;

Returns true if the IP is in the list

property Count: integer read fCount;

How many IPs are currently banned

property IP4: TIntegerDynArray read fIP4;

Low-level access to the internal IPv4 list
- 32-bit unsigned values are sorted, for fast $O(\log(n))$ binary search

EExprParser = class(ESynException)

Exception type used by TExprParser

TExprNode = class(TSynPersistent)

Stores an expression search engine node, as used by TExprParser

constructor Create(nodeType: TExprNodeType); reintroduce;

Initialize a node for the search engine

destructor Destroy; override;

Recursively destroys the linked list of nodes (i.e. Next)

function Last: TExprNode;

Browse all nodes until Next = nil

property Next: TExprNode read fNext;

Points to the next node in the parsed tree

property NodeType: TExprNodeType read fNodeType;

What is actually stored in this node

TExprNodeWordAbstract = **class**(TExprNode)

Abstract class to handle word search, as used by TExprParser

constructor Create(aOwner: TParserAbstract; **const** aWord: RawUTF8); **reintroduce**;
virtual;

You should override this virtual constructor for proper initialization

TParserAbstract = **class**(TSynPersistent)

Parent class of TExprParserAbstract

constructor Create; **override**;

Initialize an expression parser

destructor Destroy; **override**;

Finalize the expression parser

function Parse(**const** aExpression: RawUTF8): TExprParserResult;

Initialize the parser from a given text expression

class function ParseError(**const** aExpression: RawUTF8): RawUTF8;

Try this parser class on a given text expression

- returns '' on success, or an explicit error message (e.g. 'Missing parenthesis')

property Expression: RawUTF8 read fExpression;

The associated text expression used to define the search

property WordCount: integer read fWordCount;

How many words did appear in the search expression

TExprParserAbstract = **class**(TParserAbstract)

Abstract class to parse a text expression into nodes

- you should inherit this class to provide actual text search

- searched expressions can use parenthesis and &=AND -=WITHOUT +=OR operators, e.g. '((w1 & w2) - w3) + w4' means ((w1 and w2) without w3) or w4

- no operator is handled like a AND, e.g. 'w1 w2' = 'w1 & w2'

TExprParserMatch = **class**(TExprParserAbstract)

Search expression engine using TMatch for the actual word searches

constructor Create(aCaseSensitive: boolean = true); **reintroduce**;

Initialize the search engine

function Search(**const** aText: RawUTF8): boolean; **overload**;

Returns TRUE if the expression is within the text buffer

function Search(aText: PUTF8Char; aTextLen: PtrInt): boolean; overload;

Returns TRUE if the expression is within the text buffer

TPendingTaskListItem = packed record

Internal item definition, used by TPendingTaskList storage

Task: RawByteString;

The associated task, stored by representation as raw binary

Timestamp: Int64;

The task should be executed when TPendingTaskList.GetTimestamp reaches this value

TPendingTaskList = class(TSynPersistentLock)

Handle a list of tasks, stored as RawByteString, with a time stamp

- internal time stamps would be GetTickCount64 by default, so have a resolution of about 16 ms under Windows
- you can add tasks to the internal list, to be executed after a given delay, using a post/peek like algorithm
- execution delays are not expected to be accurate, but are best guess, according to NextTask call
- this implementation is thread-safe, thanks to the Safe internal locker

constructor Create; **override;**

Initialize the list memory and resources

function NextPendingTask: RawByteString; **virtual;**

Retrieve the next pending task

- returns "" if there is no scheduled task available at the current time
- returns the next task as defined corresponding to its specified delay

procedure AddTask(aMillisecondsDelayFromNow: integer; **const** aTask: RawByteString); **virtual;**

Append a task, specifying a delay in milliseconds from current time

procedure AddTasks(**const** aMillisecondsDelays: array of integer; **const** aTasks: array of RawByteString);

Append several tasks, specifying a delay in milliseconds between tasks

- first supplied delay would be computed from the current time, then it would specify how much time to wait between the next supplied task

procedure Clear; **virtual;**

Flush all pending tasks

property Count: integer **read** GetCount;

How many pending tasks are currently defined

property Task: TPendingTaskListItemDynArray read fTask;

Direct low-level access to the internal task list

- warning: this dynamic array length is the list capacity: use Count property to retrieve the exact number of stored items
- use Safe.Lock/TryLock with a try ... finally Safe.Unlock block for thread-safe access to this array
- items are stored in increasing Timestamp, i.e. the first item is the next one which would be returned by the NextPendingTask method

property Timestamp: Int64 read GetTimestamp;

Access to the internal TPendingTaskListItem.Timestamp stored value

- corresponding to the current time
- default implementation is to return GetTickCount64, with a 16 ms typical resolution under Windows

TSynBackgroundThreadAbstract = class(TThread)

Abstract TThread with its own execution content

- you should not use this class directly, but use either TSynBackgroundThreadMethodAbstract / TSynBackgroundThreadEvent / TSynBackgroundThreadMethod and provide a much more convenient callback

constructor Create(const aThreadName: RawUTF8; OnBeforeExecute: TNotifyThreadEvent=nil; OnAfterExecute: TNotifyThreadEvent=nil; CreateSuspended: boolean=false); **reintroduce;**

Initialize the thread

- you could define some callbacks to nest the thread execution, e.g. assigned to TSQLRestServer.BeginCurrentThread/EndCurrentThread, or at least set OnAfterExecute to TSynLogFamily.OnThreadEnded

destructor Destroy; **override;**

Release used resources

procedure Start;

Method to be called to start the thread

- Resume is deprecated in the newest RTL, since some OS - e.g. Linux - do not implement this pause/resume feature; we define here this method for older versions of Delphi

procedure Terminate; **reintroduce;**

Reintroduced to call TerminatedSet

procedure TerminatedSet; **virtual;**

Properly terminate the thread

- called by reintroduced Terminate

procedure WaitForNotExecuting(maxMS: integer=500);

Wait for Execute/ExecuteLoop to be ended (i.e. fExecute<>exRun)

property Pause: boolean read fExecuteLoopPause write SetExecuteLoopPause;

Temporary stop the execution of ExecuteLoop, until set back to false

- may be used e.g. by TSynBackgroundTimer to delay the process of background tasks

property ProcessEvent: TEvent read fProcessEvent;

Access to the low-level associated event used to notify task execution to the background thread
- you may call ProcessEvent.SetEvent to trigger the internal process loop

property Terminated;

Defined as public since may be used to terminate the processing methods

TSynBackgroundThreadMethodAbstract = class(TSynBackgroundThreadAbstract)

Abstract TThread able to run a method in its own execution content

- typical use is a background thread for processing data or remote access, while the UI will be still responsive by running OnIdle event in loop: see e.g. how TSQLRestClientURI.OnIdle handle this in mORMot.pas unit

- you should not use this class directly, but inherit from it and override the Process method, or use either TSynBackgroundThreadEvent / TSynBackgroundThreadMethod and provide a much more convenient callback

constructor Create(aOnIdle: TOnIdleSynBackgroundThread; const aThreadName: RawUTF8; OnBeforeExecute: TNotifyThreadEvent=nil; OnAfterExecute: TNotifyThreadEvent=nil); reintroduce;

Initialize the thread

- if aOnIdle is not set (i.e. equals nil), it will simply wait for the background process to finish until RunAndWait() will return

- you could define some callbacks to nest the thread execution, e.g. assigned to TSQLRestServer.BeginCurrentThread/EndCurrentThread

destructor Destroy; override;

Finalize the thread

function RunAndWait(OpaqueParam: pointer): boolean;

Launch Process abstract method asynchronously in the background thread

- wait until process is finished, calling OnIdle() callback in the meanwhile

- any exception raised in background thread will be translated in the caller thread

- returns false if self is not set, or if called from the same thread as it is currently processing (to avoid race condition from OnIdle() callback)

- returns true when the background process is finished

- OpaqueParam will be used to specify a thread-safe content for the background process

- this method is thread-safe, that is it will wait for any started process already launch by another thread: you may call this method from any thread, even if its main purpose is to be called from the main UI thread

property OnAfterProcess: TNotifyThreadEvent read fOnAfterProcess write fOnAfterProcess;

Optional callback event triggered in Execute after each Process

property OnBeforeProcess: TNotifyThreadEvent read fOnBeforeProcess write fOnBeforeProcess;

Optional callback event triggered in Execute before each Process

property OnIdle: TOnIdleSynBackgroundThread read fOnIdle write fOnIdle;

Set a callback event to be executed in loop during remote blocking process, e.g. to refresh the UI during a somewhat long request

- you can assign a callback to this property, calling for instance Application.ProcessMessages, to execute the remote request in a background thread, but let the UI still be reactive: the TLoginForm.OnIdleProcess and OnIdleProcessForm methods of mORMotUILogin.pas will match this property expectations
- if OnIdle is not set (i.e. equals nil), it will simply wait for the background process to finish until RunAndWait() will return

property OnIdleBackgroundThreadActive: Boolean read GetOnIdleBackgroundThreadActive;

- TRUE if the background thread is active, and OnIdle event is called during process*
- to be used e.g. to ensure no re-entrance from User Interface messages

TSynBackgroundThreadEvent = class(TSynBackgroundThreadMethodAbstract)

Allow background thread process of a method callback

constructor Create(aOnProcess: TOnProcessSynBackgroundThread; aOnIdle: TOnIdleSynBackgroundThread; **const** aThreadName: RawUTF8); **reintroduce**;

Initialize the thread

- if aOnIdle is not set (i.e. equals nil), it will simply wait for the background process to finish until RunAndWait() will return

property OnProcess: TOnProcessSynBackgroundThread read fOnProcess write fOnProcess;

Provide a method handler to be execute in the background thread

- triggered by RunAndWait() method - which will wait until finished
- the OpaqueParam as specified to RunAndWait() will be supplied here

TSynBackgroundThreadMethod = class(TSynBackgroundThreadMethodAbstract)

Allow background thread process of a variable TThreadMethod callback

procedure RunAndWait(Method: TThreadMethod); **reintroduce**;

Run once the supplied TThreadMethod callback

- use this method, and not the inherited RunAndWait()

TSynBackgroundThreadProcedure = class(TSynBackgroundThreadMethodAbstract)

Allow background thread process of a procedure callback

constructor Create(aOnProcess: TOnProcessSynBackgroundThreadProc; aOnIdle: TOnIdleSynBackgroundThread; **const** aThreadName: RawUTF8); **reintroduce**;

Initialize the thread

- if aOnIdle is not set (i.e. equals nil), it will simply wait for the background process to finish until RunAndWait() will return

property OnProcess: TOnProcessSynBackgroundThreadProc **read** fOnProcess **write** fOnProcess;

Provide a procedure handler to be execute in the background thread
- triggered by RunAndWait() method - which will wait until finished
- the OpaqueParam as specified to RunAndWait() will be supplied here

ESynParallelProcess = **class**(ESynException)

An exception which would be raised by TSynParallelProcess

TSynParallelProcessThread = **class**(TSynBackgroundThreadMethodAbstract)

Thread executing process for TSynParallelProcess

TSynParallelProcess = **class**(TSynPersistentLock)

Allow parallel execution of an index-based process in a thread pool
- will create its own thread pool, then execute any method by splitting the work into each thread

constructor Create(ThreadPoolCount: integer; **const** ThreadName: RawUTF8;
OnBeforeExecute: TNotifyThreadEvent=nil; OnAfterExecute: TNotifyThreadEvent=nil;
MaxThreadPoolCount: integer = 32); **reintroduce**; **virtual**;

Initialize the thread pool
- you could define some callbacks to nest the thread execution, e.g. assigned to
TSQLRestServer.BeginCurrentThread/EndCurrentThread
- up to MaxThreadPoolCount=32 threads could be setup (you may allow a bigger value, but
interest of this thread pool is to have its process saturating each CPU core)
- if ThreadPoolCount is 0, no thread would be created, and process would take place in the
current thread

destructor Destroy; **override**;

Finalize the thread pool

procedure ParallelRunAndWait(**const** Method: TSynParallelProcessMethod; MethodCount:
integer; **const** OnMainThreadIdle: TNotifyEvent = nil);

Run a method in parallel, and wait for the execution to finish
- will split Method[0..MethodCount-1] execution over the threads
- in case of any exception during process, an ESynParallelProcess exception would be raised by
this method
- if OnMainThreadIdle is set, the current thread (which is expected to be e.g. the main UI thread)
won't process anything, but call this event during waiting for the background threads

property ParallelRunCount: integer **read** fParallelRunCount;

How many threads have been activated

property ThreadName: RawUTF8 **read** fThreadName;

Some text identifier, used to distinguish each owned thread

property ThreadPoolCount: integer **read** fThreadPoolCount;

How many threads are currently in this instance thread pool

TSynBackgroundThreadProcess = **class**(TSynBackgroundThreadAbstract)

TThread able to run a method at a given periodic pace

constructor Create(const aThreadName: RawUTF8; aOnProcess: TOnSynBackgroundThreadProcess; aOnProcessMS: cardinal; aOnBeforeExecute: TNotifyThreadEvent=nil; aOnAfterExecute: TNotifyThreadEvent=nil; aStats: TSynMonitorClass=nil; CreateSuspended: boolean=false); reintroduce; virtual;

Initialize the thread for a periodic task processing

- aOnProcess would be called when ProcessEvent.SetEvent is called or aOnProcessMS milliseconds period was elapse since last process
- if aOnProcessMS is 0, will wait until ProcessEvent.SetEvent is called
- you could define some callbacks to nest the thread execution, e.g. assigned to TSQLRestServer.BeginCurrentThread/EndCurrentThread

destructor Destroy; override;

Finalize the thread

property OnException: TNotifyEvent read fOnException write fOnException;

Event callback executed when OnProcess did raise an exception

- supplied Sender parameter is the raised Exception instance

property OnProcess: TOnSynBackgroundThreadProcess read fOnProcess;

Access to the implementation event of the periodic task

property OnProcessMS: cardinal read fOnProcessMS write fOnProcessMS;

Access to the delay, in milliseconds, of the periodic task processing

property Stats: TSynMonitor read fStats;

Processing statistics

- may be nil if aStats was nil in the class constructor

TSynBackgroundTimerTask = record

Used by TSynBackgroundTimer internal registration list

TSynBackgroundTimer = class(TSynBackgroundThreadProcess)

TThread able to run one or several tasks at a periodic pace in a background thread

- as used e.g. by TSQLRest.TimerEnable/TimerDisable methods, via the inherited TSQLRestBackgroundTimer
- each process can have its own FIFO of text messages
- if you expect to update some GUI, you should rather use a TTimer component (with a period of e.g. 200ms), since TSynBackgroundTimer will use its own separated thread

constructor Create(const aThreadName: RawUTF8; aOnBeforeExecute: TNotifyThreadEvent=nil; aOnAfterExecute: TNotifyThreadEvent=nil; aStats: TSynMonitorClass=nil); reintroduce; virtual;

Initialize the thread for a periodic task processing

- you could define some callbacks to nest the thread execution, e.g. assigned to TSQLRestServer.BeginCurrentThread/EndCurrentThread, as made by TSQLRestBackgroundTimer.Create

destructor Destroy; override;

Finalize the thread

function DeQueue(aOnProcess: TOnSynBackgroundTimerProcess; **const** aMsg: RawUTF8): boolean;

Remove a message from the processing list

- supplied message will be searched in the internal FIFO list associated with aOnProcess, then removed from the list if found
- aOnProcess should have been registered by a previous call to Enable() method
- returns true on success, false if the supplied message was not registered

function Disable(aOnProcess: TOnSynBackgroundTimerProcess): boolean;

Undefine a task running on a periodic number of seconds

- aOnProcess should have been registered by a previous call to Enable() method
- returns true on success, false if the supplied task was not registered
- for background process on a mORMot service, consider using TSQLRestServer TimerEnable/TimerDisable methods, and their TSynBackgroundTimer thread

function EnQueue(aOnProcess: TOnSynBackgroundTimerProcess; **const** aMsgFmt: RawUTF8; **const** Args: **array of const**; aExecuteNow: boolean=false): boolean; overload;

Add a message to be processed during the next execution of a task

- supplied message will be added to the internal FIFO list associated with aOnProcess, then supplied to as aMsg parameter for each call
- if aExecuteNow is true, won't wait for the next aOnProcessSecs occurrence
- aOnProcess should have been registered by a previous call to Enable() method
- returns true on success, false if the supplied task was not registered

function EnQueue(aOnProcess: TOnSynBackgroundTimerProcess; **const** aMsg: RawUTF8; aExecuteNow: boolean=false): boolean; overload;

Add a message to be processed during the next execution of a task

- supplied message will be added to the internal FIFO list associated with aOnProcess, then supplied to as aMsg parameter for each call
- if aExecuteNow is true, won't wait for the next aOnProcessSecs occurrence
- aOnProcess should have been registered by a previous call to Enable() method
- returns true on success, false if the supplied task was not registered

function ExecuteNow(aOnProcess: TOnSynBackgroundTimerProcess): boolean;

Execute a task without waiting for the next aOnProcessSecs occurrence

- aOnProcess should have been registered by a previous call to Enable() method
- returns true on success, false if the supplied task was not registered

function Processing: boolean;

Returns true if there is currently one task processed

procedure Enable(aOnProcess: TOnSynBackgroundTimerProcess; aOnProcessSecs: cardinal);

Define a process method for a task running on a periodic number of seconds

- for background process on a mORMot service, consider using TSQLRest TimerEnable/TimerDisable methods, and its associated BackgroundTimer thread

procedure WaitUntilNotProcessing(timeoutsecs: integer=10);

Wait until no background task is processed

property Task: TSynBackgroundTimerTaskDynArray **read** fTask;

Low-level access to the internal task list

property TaskLock: TSynLocker read fTaskLock;

Low-level access to the internal task mutex

TBlockingProcess = class(TEvent)

A semaphore used to wait for some process to be finished

- used e.g. by TBlockingCallback in mORMot.pas
- once created, process would block via a WaitFor call, which would be released when NotifyFinished is called by the process background thread

constructor Create(aTimeoutMs: integer); reintroduce; overload; virtual;

Initialize the semaphore instance

- specify a time out milliseconds period after which blocking execution should be handled as failure (if 0 is set, default 3000 would be used)
- an associated mutex would be created and owned by this instance

constructor Create(aTimeoutMs: integer; aSafe: PSynLocker); reintroduce; overload; virtual;

Override to reset associated params initialize the semaphore instance

- specify a time out milliseconds period after which blocking execution should be handled as failure (if 0 is set, default 3000 would be used)
- an associated mutex shall be supplied

destructor Destroy; override;

Finalize the instance

function NotifyFinished(alreadyLocked: boolean=false): boolean; virtual;

Should be called by the background process when it is finished

- the caller would then let its WaitFor method return
- returns TRUE on success (i.e. status was not evRaised or evTimeout)
- if the instance is already locked (e.g. when retrieved from TBlockingProcessPool.FromCallLocked), you may set alreadyLocked=TRUE

function Reset: boolean; virtual;

Just a wrapper to reset the internal Event state to evNone

- may be used to re-use the same TBlockingProcess instance, after a successful WaitFor/NotifyFinished process
- returns TRUE on success (i.e. status was not evWaiting), setting the current state to evNone, and the Call property to 0
- if there is a WaitFor currently in progress, returns FALSE

function WaitFor: TBlockingEvent; reintroduce; overload; virtual;

Called to wait for NotifyFinished() to be called, or trigger timeout

- returns the final state of the process, i.e. evRaised or evTimeOut

function WaitFor(TimeoutMS: integer): TBlockingEvent; reintroduce; overload;

Called to wait for NotifyFinished() to be called, or trigger timeout

- returns the final state of the process, i.e. evRaised or evTimeOut

procedure Lock;

Just a wrapper around fSafe^.Lock

procedure Unlock;

Just a wrapper around fSafe^.Unlock

property Event: TBlockingEvent **read** fEvent;

The current state of process

- use Reset method to re-use this instance after a WaitFor process

property TimeoutMs: integer **read** fTimeoutMS;

The time out period, in ms, as defined at constructor level

TBlockingProcessPoolItem = **class**(TBlockingProcess)

A semaphore used in the TBlockingProcessPool

- such semaphore have a Call field to identify each execution

property Call: TBlockingProcessPoolCall **read** fCall;

An unique identifier, when owned by a TBlockingProcessPool

- Reset would restore this field to its 0 default value

TBlockingProcessPool = **class**(TSynPersistent)

Manage a pool of TBlockingProcessPoolItem instances

- each call will be identified via a TBlockingProcessPoolCall unique value

- to be used to emulate e.g. blocking execution from an asynchronous event-driven DDD process

- it would also allow to re-use TEvent system resources

constructor Create(aClass: TBlockingProcessPoolItemClass=nil); **reintroduce**;

Set TBlockingProcessPoolItem.Call initialize the pool, for a given implementation class

destructor Destroy; **override**;

Finalize the pool

- would also force all pending WaitFor to trigger a evTimeout

function FromCall(call: TBlockingProcessPoolCall; locked: boolean=false):
TBlockingProcessPoolItem; **virtual**;

Retrieve a TBlockingProcess from its call identifier

- may be used e.g. from the callback of the asynchronous process to set some additional parameters to the inherited TBlockingProcess, then call NotifyFinished to release the caller WaitFor

- if leavelocked is TRUE, the returned instance would be locked: caller should execute result.Unlock or NotifyFinished(true) after use

function NewProcess(aTimeoutMs: integer): TBlockingProcessPoolItem; **virtual**;

Book a TBlockingProcess from the internal pool

- returns nil on error (e.g. the instance is destroying)

- or returns the blocking process instance corresponding to this call; its Call property would identify the call for the asynchronous callback, then after WaitFor, the Reset method should be run to release the mutex for the pool

TSystemUseData = packed record

Store CPU and RAM usage for a given process
 - as used by TSystemUse class

Kernel: single;

Percent of current Kernel-space CPU usage for this process

Timestamp: TDateTime;

When the data has been sampled

User: single;

Percent of current User-space CPU usage for this process

VirtualKB: cardinal;

How many KB of virtual memory are used by this process

WorkKB: cardinal;

How many KB of working memory are used by this process

TProcessInfo = object(TObject)

Low-level structure used to compute process memory and CPU usage

function Init: boolean;

Initialize the system/process resource tracking

function PerProcess(PID: cardinal; Now: PDateTime; **out** Data: TSystemUseData; **var** PrevKernel, PrevUser: Int64): boolean;

Retrieve CPU and RAM usage for a given process

function PerSystem(**out** Idle, Kernel, User: currency): boolean;

Percent of current Idle/Kernel/User CPU usage for all processes

function Start: boolean;

To be called before PerSystem() or PerProcess() iteration

TSystemUseProcess = record

Internal storage of CPU and RAM usage for one process

TSystemUse = class(TSynPersistentLock)

Monitor CPU and RAM usage of one or several processes

- you should execute BackgroundExecute on a regular pace (e.g. every second) to gather low-level CPU and RAM information for the given set of processes
- is able to keep an history of latest sample values
- use Current class function to access a process-wide instance

constructor Create(const aProcessID: array of integer; aHistoryDepth: integer=60); reintroduce; overload; virtual;

Track the CPU and RAM usage of the supplied set of Process ID

- any aProcessID[]=0 will be replaced by the current process ID
- you can specify the number of sample values for the History() method
- you should then execute the BackgroundExecute method of this instance in a VCL timer or from a TSynBackgroundTimer.Enable() registration

constructor Create(aHistoryDepth: integer=60); reintroduce; overload; virtual;

Track the CPU and RAM usage of the current process

- you can specify the number of sample values for the History() method
- you should then execute the BackgroundExecute method of this instance in a VCL timer or from a TSynBackgroundTimer.Enable() registration

class function Current(aCreateIfNone: boolean=true): TSystemUse;

Access to a global instance, corresponding to the current process

- its HistoryDepth will be of 60 items

function Data(aProcessID: integer=0): TSystemUseData; overload;

Returns the detailed CPU and RAM usage percent of the supplied process

- aProcessID=0 will return information from the current process
- returns Timestamp=0 if the Process ID was not registered via Create/Subscribe

function Data(out aData: TSystemUseData; aProcessID: integer=0): boolean; overload;

Returns the detailed CPU and RAM usage percent of the supplied process

- aProcessID=0 will return information from the current process
- returns -1 if the Process ID was not registered via Create/Subscribe

function History(aProcessID: integer=0; aDepth: integer=0): TSingleDynArray; overload;

Returns total (Kernel+User) CPU usage percent history of the supplied process

- aProcessID=0 will return information from the current process
- returns nil if the Process ID was not registered via Create/Subscribe
- returns the sample values as an array, starting from the last to the oldest
- you can customize the maximum depth, with aDepth < HistoryDepth

function HistoryData(aProcessID: integer=0; aDepth: integer=0): TSystemUseDataDynArray; overload;

Returns detailed CPU and RAM usage history of the supplied process

- aProcessID=0 will return information from the current process
- returns nil if the Process ID was not registered via Create/Subscribe
- returns the sample values as an array, starting from the last to the oldest
- you can customize the maximum depth, with aDepth < HistoryDepth

function HistoryText(aProcessID: integer=0; aDepth: integer=0; aDestMemoryMB: PRawUTF8=nil): RawUTF8;

Returns total (Kernel+User) CPU usage percent history of the supplied process, as a string of two digits values

- aProcessID=0 will return information from the current process
- returns "" if the Process ID was not registered via Create/Subscribe
- you can customize the maximum depth, with aDepth < HistoryDepth
- the memory history (in MB) can be optionally returned in aDestMemoryMB

function HistoryVariant(aProcessID: integer=0; aDepth: integer=0): variant;

Returns total (Kernel+User) CPU usage percent history of the supplied process

- aProcessID=0 will return information from the current process
- returns null if the Process ID was not registered via Create/Subscribe
- returns the sample values as a TDocVariant array, starting from the last to the oldest, with two digits precision (as currency values)
- you can customize the maximum depth, with aDepth < HistoryDepth

function KB(aProcessID: integer=0): cardinal; overload;

Returns the total (Work+Paged) RAM use of the supplied process, in KB

- aProcessID=0 will return information from the current process
- returns 0 if the Process ID was not registered via Create/Subscribe

function Percent(aProcessID: integer=0): single; overload;

Returns the total (Kernel+User) CPU usage percent of the supplied process

- aProcessID=0 will return information from the current process
- returns -1 if the Process ID was not registered via Create/Subscribe

function PercentKernel(aProcessID: integer=0): single; overload;

Returns the Kernel-space CPU usage percent of the supplied process

- aProcessID=0 will return information from the current process
- returns -1 if the Process ID was not registered via Create/Subscribe

function PercentSystem(out Idle,Kernel,User: currency): boolean;

Percent of current Idle/Kernel/User CPU usage for all processes

function PercentUser(aProcessID: integer=0): single; overload;

Returns the User-space CPU usage percent of the supplied process

- aProcessID=0 will return information from the current process
- returns -1 if the Process ID was not registered via Create/Subscribe

function Unsubscribe(aProcessID: integer): boolean;

Remove a Process ID from the internal tracking list

procedure BackgroundExecute(Sender: TSynBackgroundTimer; Event: TWaitResult; const Msg: RawUTF8);

A TSynBackgroundThreadProcess compatible event

- matches TOnSynBackgroundTimerProcess callback signature
- to be supplied e.g. to a TSynBackgroundTimer.Enable method so that it will run every few seconds and retrieve the CPU and RAM use

procedure OnTimerExecute(Sender: TObject);

A VCL's TTimer.OnTimer compatible event

- to be run every few seconds and retrieve the CPU and RAM use:

```
tmrSystemUse.Interval := 10000; // every 10 seconds
tmrSystemUse.OnTimer := TSystemUse.Current.OnTimerExecute;
```

procedure Subscribe(aProcessID: integer);

Add a Process ID to the internal tracking list

property HistoryDepth: integer read fHistoryDepth;

How many items are stored internally, and returned by the History() method

property OnMeasured: TOnSystemUseMeasured **read** fOnMeasured **write** fOnMeasured;

Executed when TSystemUse.BackgroundExecute finished its measurement

property Timer: TSynBackgroundTimer **read** fTimer **write** fTimer;

Low-level access to the associated timer running BackgroundExecute

- equals nil if has been associated to no timer

property UnsubscribeProcessOnAccessError: boolean **read** fUnsubscribeProcessOnAccessError **write** fUnsubscribeProcessOnAccessError;

If any unexisting (e.g. closed/killed) process should be unregistered

- e.g. if OpenProcess() API call fails

TDiskPartition = packed record

Stores information about a disk partition

mounted: TFileName;

Where this partition has been mounted

- e.g. 'C:' or '/home'

- you can use GetDiskInfo(mounted) to retrieve current space information

name: RawUTF8;

The name of this partition

- is the Volume name under Windows, or the Device name under POSIX

size: QWord;

Total size (in bytes) of this partition

TSynMonitorMemory = class(TSynPersistent)

Value object able to gather information about the current system memory

constructor Create(aTextNoSpace: boolean); **reintroduce**;

Initialize the class, and its nested TSynMonitorOneSize instances

destructor Destroy; **override**;

Finalize the class, and its nested TSynMonitorOneSize instances

class function FreeAsText(nospace: boolean=false): ShortString;

Some text corresponding to current 'free/total' memory information

- returns e.g. '10.3 GB / 15.6 GB'

class function PhysicalAsText(nospace: boolean=false): TShort16;

How many physical memory is currently installed, as text (e.g. '32 GB');

class function ToJSON: RawUTF8;

Returns a JSON object with the current system memory information

- numbers would be given in KB (Bytes shl 10)

class function ToVariant: variant;

Fill a TDocVariant with the current system memory information

- numbers would be given in KB (Bytes shl 10)

property AllocatedReserved: TSynMonitorOneSize **read** GetAllocatedReserved;

Total of allocated memory reserved by the program

property AllocatedUsed: TSynMonitorOneSize **read** GetAllocatedUsed;

Total of allocated memory used by the program

property MemoryLoadPercent: integer **read** GetMemoryLoadPercent;

Percent of memory in use for the system

property PagingFileFree: TSynMonitorOneSize **read** GetPagingFileFree;

Free of paging file for the system

property PagingFileTotal: TSynMonitorOneSize **read** GetPagingFileTotal;

Total of paging file for the system

property PhysicalMemoryFree: TSynMonitorOneSize **read** GetPhysicalMemoryFree;

Free of physical memory for the system

property PhysicalMemoryTotal: TSynMonitorOneSize **read** GetPhysicalMemoryTotal;

Total of physical memory for the system

property VirtualMemoryFree: TSynMonitorOneSize **read** GetVirtualMemoryFree;

Free of virtual memory for the system

- property not defined under Linux, since not applying to this OS

property VirtualMemoryTotal: TSynMonitorOneSize **read** GetVirtualMemoryTotal;

Total of virtual memory for the system

- property not defined under Linux, since not applying to this OS

TSynMonitorDisk = class(TSynPersistent)

Value object able to gather information about a system drive

constructor Create; **override**;

Initialize the class, and its nested TSynMonitorOneSize instances

destructor Destroy; **override**;

Finalize the class, and its nested TSynMonitorOneSize instances

class function FreeAsText: RawUTF8;

Some text corresponding to current 'free/total' disk information

- could return e.g. 'D: 64.4 GB / 213.4 GB'

property AvailableSize: TSynMonitorOneSize **read** GetAvailable;

Space currently available on this disk for the current user

- may be less then FreeSize, if user quotas are specified (only taken into account under Windows)

property FreeSize: TSynMonitorOneSize **read** GetFree;

Free space currently available on this disk

property Name: TFileName **read** GetName;

The disk name

property TotalSize: TSynMonitorOneSize **read** GetTotal;

Total space

property VolumeName: TFileName **read** fVolumeName **write** fVolumeName;

The volume name (only available on Windows)

TMemoryInfo = **record**

Hold low-level information about current memory usage

- as filled by GetMemoryInfo()

TTimeZoneInfo = **record**

Used to store Time Zone bias in TSynTimeZone

- map how low-level information is stored in the Windows Registry

TTimeZoneData = **object**(TObject)

Used to store Time Zone information for a single area in TSynTimeZone

- Delphi "object" is buggy on stack -> also defined as record with methods

TSynTimeZone = **class**(TObject)

Handle cross-platform time conversions, following Microsoft time zones

- is able to retrieve accurate information from the Windows registry, or from a binary compressed file on other platforms (which should have been saved from a Windows system first)

- each time zone will be identified by its TzId string, as defined by Microsoft for its Windows Operating system

constructor Create;

Initialize the internal storage

- but no data is available, until Load* methods are called

constructor CreateDefault(dummy: integer=0);

Retrieve the time zones from Windows registry, or from a local file

- under Linux, the file should be located with the executable, renamed with a .tz extension - may have been created via SaveToFile(""), or from a 'TSynTimeZone' bound resource "dummy" parameter exists only to disambiguate constructors for C++

destructor Destroy; **override**;

Finalize the instance

class function Default: TSynTimeZone;

Will retrieve the default shared TSynTimeZone instance

- locally created via the CreateDefault constructor

- this is the usual entry point for time zone process, calling e.g.

aLocalTime := TSynTimeZone.Default.NowToLocal(aTimeZoneID);

function Displays: TStrings;

Returns a TStringList of all Display text values

- could be used to fill any VCL component to select the time zone

- order in Displays[] array follows the Zone[].display information

```
function GetBiasForDateTime(const Value: TDateTime; const TzId: TTimeZoneID; out Bias: integer; out HaveDaylight: boolean; DateIsUTC: boolean=false): boolean;
```

Retrieve the time bias (in minutes) for a given date/time on a TzId

```
function GetDisplay(const TzId: TTimeZoneID): RawUTF8;
```

Retrieve the display text corresponding to a TzId
- returns "" if the supplied TzId is not recognized

```
function Ids: TStringList;
```

Returns a TStringList of all TzID values
- could be used to fill any VCL component to select the time zone
- order in Ids[] array follows the Zone[].id information

```
function LocalToUtc(const LocalDateTime: TDateTime; const TzID: TTimeZoneID): TDateTime;
```

Compute the UTC date/time for a given local TzId value
- by definition, a local time may correspond to two UTC times, during the time bias period, so the returned value is informative only, and any stored value should be following UTC

```
function NowToLocal(const TzId: TTimeZoneID): TDateTime;
```

Compute the current date/time corrected for a given TzId

```
function SaveToBuffer: RawByteString;
```

Write then time zone information into a compressed memory buffer

```
function UtcToLocal(const UtcDateTime: TDateTime; const TzId: TTimeZoneID): TDateTime;
```

Compute the UTC date/time corrected for a given TzId

```
procedure LoadFromBuffer(const Buffer: RawByteString);
```

Read time zone information from a compressed memory buffer

```
procedure LoadFromFile(const FileName: TFileName='');
```

Read time zone information from a compressed file
- if no file name is supplied, a ExecutableName.tz file would be used

```
procedure LoadFromRegistry;
```

Read time zone information from the Windows registry

```
procedure LoadFromResource(Instance: THandle=0);
```

Read time zone information from a 'TSynTimeZone' resource
- the resource should contain the SaveToBuffer compressed binary content
- is no resource matching the TSynTimeZone class name and ResType=10 do exist, nothing would be loaded
- the resource could be created as such, from a Windows system:
 TSynTimeZone.Default.SaveToFile('TSynTimeZone.data');
then compile the resource as expected, with a brcc32 .rc entry:
 TSynTimeZone 10 "TSynTimeZone.data"
- you can specify a library (dll) resource instance handle, if needed

```
procedure SaveToFile(const FileName: TFileName);
```

Write then time zone information into a compressed file
- if no file name is supplied, a ExecutableName.tz file would be created

property Zone: TTimeZoneDataDynArray **read** fZone;

Direct access to the low-level time zone information

property Zones: TDynArrayHashed **read** fZones;

Direct access to the wrapper over the time zone information array

Interface ICommandLine = **interface**(IInterface)

An interface to process the command line switches over a console

- as implemented e.g. by TCommandLine class
- can implement any process, optionally with console interactivity

function AsArray: TRawUTF8DynArray;

Returns all command line values as an array of UTF-8 text

- i.e. won't interpret the various switches in the input parameters
- as created e.g. by TCommandLine.CreateFromArray constructor

function AsDate(**const** Switch: RawUTF8; **Default**: TDateTime; **const** Prompt: **string**): TDateTime;

Returns a command line switch ISO-8601 value as date value

- here dates are expected to be encoded with ISO-8601, i.e. YYYY-MM-DD
- you can specify a prompt text, when asking for any missing switch

function AsEnum(**const** Switch, **Default**: RawUTF8; TypeInfo: pointer; **const** Prompt: **string**): integer;

Returns a command line switch value as enumeration ordinal

- RTTI will be used to check for the enumeration text, or plain integer value will be returned as ordinal value
- you can specify a prompt text, when asking for any missing switch

function AsInt(**const** Switch: RawUTF8; **Default**: Int64; **const** Prompt: **string**): Int64;

Returns a command line switch value as integer

- you can specify a prompt text, when asking for any missing switch

function AsJSON(**Format**: TTextWriterJSONFormat): RawUTF8;

Serialize all recognized switches as UTF-8 JSON text

function AsString(**const** Switch: RawUTF8; **const** Default, Prompt: **string**): **string**;

Returns a command line switch value as VCL string text

- you can specify a prompt text, when asking for any missing switch

function AsUTF8(**const** Switch, **Default**: RawUTF8; **const** Prompt: **string**): RawUTF8;

Returns a command line switch value as UTF-8 text

- you can specify a prompt text, when asking for any missing switch

function NoPrompt: boolean;

Equals TRUE if the -noprompt switch has been supplied

- may be used to force pure execution without console interaction, e.g. when run from another process

```
procedure Text(const Fmt: RawUTF8; const Args: array of const; Color: TConsoleColor=ccLightGray);
```

Write some console text, with an optional color
- will output the text even if NoPrompt is TRUE

```
procedure TextColor(Color: TConsoleColor);
```

Change the console text color
- do nothing if NoPrompt is TRUE

```
TCommandLine = class(TInterfacedObjectWithCustomCreate)
```

A class to process the command line switches, with console interactivity
- is able to redirect all Text() output to an internal UTF-8 storage, in addition or instead of the console (to be used e.g. from a GUI)
- implements ICommandLine interface

```
constructor Create(const switches: variant; aNoConsole: boolean=true); reintroduce; overload;
```

Initialize the internal storage with some ready-to-use switches
- will also set the NoPrompt option, and set the supplied NoConsole value
- may be used e.g. from a graphical interface instead of console mode

```
constructor Create(const NameValuePairs: array of const; aNoConsole: boolean=true); reintroduce; overload;
```

Initialize the internal storage with some ready-to-use name/value pairs
- will also set the NoPrompt option, and set the supplied NoConsole value
- may be used e.g. from a graphical interface instead of console mode

```
constructor Create; overload; override;
```

Initialize the internal storage from the command line
- will parse "-switch1 value1 -switch2 value2" layout
- stand-alone "-switch1 -switch2 value2" will create switch1=true value

```
constructor CreateFromArray(firstParam: integer);
```

Initialize the internal storage from the command line
- will set paramstr(firstParam)..paramstr(paramcount) in fValues as array
- may be used e.g. for "val1 val2 val3" command line layout

```
function AsArray: TRawUTF8DynArray;
```

Returns all command line values as an array of UTF-8 text
- i.e. won't interpret the various switches in the input parameters
- as created e.g. by TCommandLine.CreateFromArray constructor

```
function AsDate(const Switch: RawUTF8; Default: TDateTime; const Prompt: string): TDateTime;
```

Returns a command line switch ISO-8601 value as date value
- here dates are expected to be encoded with ISO-8601, i.e. YYYY-MM-DD
- you can specify a prompt text, when asking for any missing switch

function AsEnum(**const** Switch, **Default**: RawUTF8; TypeInfo: pointer; **const** Prompt: **string**): integer;

Returns a command line switch value as enumeration ordinal

- RTTI will be used to check for the enumeration text, or plain integer value will be returned as ordinal value
- you can specify a prompt text, when asking for any missing switch

function AsInt(**const** Switch: RawUTF8; **Default**: Int64; **const** Prompt: **string**): Int64;

Returns a command line switch value as integer

- you can specify a prompt text, when asking for any missing switch

function AsJSON(Format: TTextWriterJSONFormat): RawUTF8;

Serialize all recognized switches as UTF-8 JSON text

function AsString(**const** Switch: RawUTF8; **const** Default, Prompt: **string**): **string**;

Returns a command line switch value as VCL string text

- you can specify a prompt text, when asking for any missing switch

function AsUTF8(**const** Switch, **Default**: RawUTF8; **const** Prompt: **string**): RawUTF8;

Returns a command line switch value as UTF-8 text

- you can specify a prompt text, when asking for any missing switch

function ConsoleText(**const** LineFeed: RawUTF8=sLineBreak): RawUTF8;

Returns the UTF-8 text as inserted by Text() calls

- line feeds will be included to the ConsoleLines[] values

function NoPrompt: boolean;

Equals TRUE if the -noprompt switch has been supplied

- may be used to force pure execution without console interaction, e.g. when run from another process

procedure Text(**const** Fmt: RawUTF8; **const** Args: **array of const**; Color: TConsoleColor=ccLightGray);

Write some console text, with an optional color

- will output the text even if NoPrompt=TRUE, but not if NoConsole=TRUE
- will append the text to the internal storage, available from ConsoleText

procedure TextColor(Color: TConsoleColor);

Change the console text color

- do nothing if NoPrompt is TRUE

property ConsoleLines: TRawUTF8DynArray **read** fLines;

Low-level access to the internal UTF-8 console lines storage

property NoConsole: boolean **read** fNoConsole **write** SetNoConsole;

If Text() should be redirected to ConsoleText internal storage

- and don't write anything to the console
- should be associated with NoProperty = TRUE property

property Values: TDocVariantData **read** fValues;

Low-level access to the internal switches storage

ETableDataException = **class**(ESynException)

Exception raised by all TSynTable related code

TSynTableStatementSelect = record

One recognized SELECT expression for TSynTableStatement

Alias: RawUTF8;

The optional column alias, e.g. 'MaxID' for 'max(id) as MaxID'

Field: integer;

The column SELECTed for the SQL statement, in the expected order
- contains 0 for ID/RowID, or the RTTI field index + 1

FunctionKnown: (funcNone, funcCountStar, funcDistinct, funcMax);

If the function needs a special process
- e.g. funcCountStar for the special Count(*) expression or funcDistinct, funcMax for distinct(...)/max(...) aggregation

FunctionName: RawUTF8;

The optional function applied to the SELECTed column
- e.g. Max(RowID) would store 'Max' and SelectField[0]=0
- but Count(*) would store 'Count' and SelectField[0]=0, and set FunctionIsCountStar = TRUE

SubField: RawUTF8;

MongoDB-like sub field e.g. 'mainfield.subfield1.subfield2'
- still identifying 'mainfield' in Field index, and setting SubField='.subfield1.subfield2'

ToBeAdded: integer;

An optional integer to be added
- recognized from .. +123 .. -123 patterns in the select

TSynTableStatementWhere = record

One recognized WHERE expression for TSynTableStatement

Field: integer;

The index of the field used for the WHERE expression
- WhereField=0 for ID, 1 for field # 0, 2 for field #1, and so on... (i.e. WhereField = RTTI field index +1)

FunctionName: RawUTF8;

The SQL function name associated to a Field and Value
- e.g. 'INTEGERDYNARRAYCONTAINS' and Field=0 for IntegerDynArrayContains(RowID,10) and ValueInteger=10
- Value does not contain anything

JoinedOR: boolean;

Expressions are evaluated as AND unless this field is set to TRUE

NotClause: boolean;

If this expression is preceded by a NOT modifier

Operator: TSynTableStatementOperator;

The operator of the WHERE expression

ParenthesisAfter: RawUTF8;

Any ')' after the actual expression

ParenthesisBefore: RawUTF8;

Any '(' before the actual expression

SubField: RawUTF8;

MongoDB-like sub field e.g. 'mainfield.subfield1.subfield2'

- still identifying 'mainfield' in Field index, and setting SubField='.subfield1.subfield2'

Value: RawUTF8;

The value used for the WHERE expression

ValueInteger: integer;

An integer representation of WhereValue (used for ID check e.g.)

ValueSBF: TSBFString;

Used to fast compare with SBF binary compact formatted data

ValueSQL: PUTF8Char;

The raw value SQL buffer used for the WHERE expression

ValueSQLLen: integer;

The raw value SQL buffer length used for the WHERE expression

ValueVariant: variant;

The value used for the WHERE expression, encoded as Variant

- may be a TDocVariant for the IN operator

TSynTableStatement = class(TObject)

Used to parse a SELECT SQL statement, following the SQLite3 syntax

- handle basic REST commands, i.e. a SELECT over a single table (no JOIN) with its WHERE clause, and result column aliases
- handle also aggregate functions like "SELECT Count(*) FROM TableName"
- will also parse any LIMIT, OFFSET, ORDER BY, GROUP BY statement clause

constructor Create(const SQL: RawUTF8; GetFieldIndex: TSynTableFieldIndex;
 SimpleFieldsBits: TSQLFieldBits=[0..MAX_SQLFIELDS-1]; FieldProp:
 TSynTableFieldProperties=nil);

Parse the given SELECT SQL statement and retrieve the corresponding parameters into this class read-only properties

- the supplied GetFieldIndex() method is used to populate the SelectedFields and Where[].Field properties
- SimpleFieldsBits is used for '*' field names
- SQLStatement is left '' if the SQL statement is not correct
- if SQLStatement is set, the caller must check for TableName to match the expected value, then use the Where[] to retrieve the content
- if FieldProp is set, then the Where[].ValueSBF property is initialized with the SBF equivalence of the Where[].Value

procedure SelectFieldBits(**var** Fields: TSQLFieldBits; **var** withID: boolean;
 SubFields: PRawUTF8Array=**nil**);

Compute the SELECT column bits from the SelectFields array
 - optionally set Select[].SubField into SubFields[Select[].Field] (e.g. to include specific fields from MongoDB embedded document)

property GroupByField: TSQLFieldIndexDynArray **read** fGroupByField;

Recognize an GROUP BY clause with one or several fields
 - here 0 = ID, otherwise RTTI field index +1

property HasSelectSubFields: boolean **read** fHasSelectSubFields;

If any Select[].SubField was actually set

property Limit: integer **read** fLimit;

The number specified by the optional LIMIT ... clause
 - set to 0 by default (meaning no LIMIT clause)

property Offset: integer **read** fOffset;

The number specified by the optional OFFSET ... clause
 - set to 0 by default (meaning no OFFSET clause)

property OrderByDesc: boolean **read** fOrderByDesc;

False for default ASC order, true for DESC attribute

property OrderByField: TSQLFieldIndexDynArray **read** fOrderByField;

Recognize an ORDER BY clause with one or several fields
 - here 0 = ID, otherwise RTTI field index +1

property Select: TSynTableStatementSelectDynArray **read** fSelect;

The column SELECTed for the SQL statement, in the expected order

property SelectFunctionCount: integer **read** fSelectFunctionCount;

If the SELECTed expression of this SQL statement have any function defined

property SQLStatement: RawUTF8 **read** fSQLStatement;

The SELECT SQL statement parsed
 - equals '' if the parsing failed

property TableName: RawUTF8 **read** fTableName;

The retrieved table name

property Where: TSynTableStatementWhereDynArray **read** fWhere;

The WHERE clause of this SQL statement

property WhereHasParenthesis: boolean **read** fWhereHasParenthesis;

If the WHERE clause contains any () parenthesis expression

property WhereHasSubFields: boolean **read** fWhereHasSubFields;

If the WHERE clause contains any Where[].SubField

property Writer: TJSONWriter **read** fWriter **write** fWriter;

Optional associated writer

TSortCompareTmp = record

Internal value used by TSynTableFieldProperties.SortCompare() method to avoid stack allocation

TSynTableFieldProperties = class(TObject)

Store the type properties of a given field / database column

FieldNumber: integer;

Number of the field in the table (starting at 0)

FieldSize: integer;

The fixed-length size, or -1 for a varInt, -2 for a variable string

FieldType: TSynTableFieldType;

Kind of field (defines both value type and storage to be used)

Filters: TSynObjectList;

All TSynValidate instances registered per each field

Name: RawUTF8;

The field name

Offset: integer;

Contains the offset of this field, in case of fixed-length field

- normally, fixed-length fields are stored in the beginning of the record storage: in this case, a value ≥ 0 will point to the position of the field value of this field
- if the value is < 0 , its absolute will be the field number to be counted after TSynTable.fFieldVariableOffset (-1 for first item)

Options: TSynTableFieldOptions;

Options of this field

OrderedIndex: TIntegerDynArray;

If allocated, contains the storage indexes of every item, in sorted order

- only available if tfoIndex is in Options
- the index is not the per-ID index, but the "physical" index, i.e. the index value used to retrieve data from low-level (and faster) method

OrderedIndexCount: integer;

Number of items in OrderedIndex[]

- is set to 0 when the content has been modified (mark force recreate)

OrderedIndexNotSorted: boolean;

If set to TRUE after an OrderedIndex[] refresh but with not sorting

- OrderedIndexSort(0,OrderedIndexCount-1) must be called before using the OrderedIndex[] array
- you should call OrderedIndexRefresh method to ensure it is sorted

OrderedIndexReverse: TIntegerDynArray;

If allocated, contains the reverse storage index of OrderedIndex

- i.e. OrderedIndexReverse[OrderedIndex[i]] := i;
- used to speed up the record update procedure with huge number of records

Validates: TSynObjectList;

All TSynValidate instances registered per each field

constructor CreateFrom(**var** RD: TFileBufferReader);

Read entry from a specified file reader

destructor Destroy; **override**;

Release associated memory and objects

function AddFilterOrValidate(aFilter: TSynFilterOrValidate):
TSynFilterOrValidate;

Register a custom filter or validation rule to the class for this field

- this will be used by Filter() and Validate() methods
- will return the specified associated TSynFilterOrValidate instance
- a TSynValidateTableUniqueField is always added by TSynTable.AfterFieldModif if tfoUnique is set in Options

function GetBoolean(RecordBuffer: pointer): Boolean;

Decode the value from a record buffer into an Boolean

- will call Owner.GetData to retrieve then decode the field SBF content

function GetCurrency(RecordBuffer: pointer): Currency;

Decode the value from a record buffer into an currency value

- will call Owner.GetData to retrieve then decode the field SBF content

function GetDouble(RecordBuffer: pointer): Double;

Decode the value from a record buffer into an floating-point value

- will call Owner.GetData to retrieve then decode the field SBF content

function GetInt64(RecordBuffer: pointer): Int64;

Decode the value from a record buffer into an Int64

- will call Owner.GetData to retrieve then decode the field SBF content

function GetInteger(RecordBuffer: pointer): Integer;

Decode the value from a record buffer into an integer

- will call Owner.GetData to retrieve then decode the field SBF content

function GetJSON(FieldBuffer: pointer; W: TTextWriter): pointer;

Decode the value from our SBF compact binary format into UTF-8 JSON

- returns the next FieldBuffer value

function GetLength(FieldBuffer: pointer): Integer;

Retrieve the binary length (in bytes) of some SBF compact binary format

function GetRawUTF8(RecordBuffer: pointer): RawUTF8;

Decode the value from a record buffer into a RawUTF8 string

- will call Owner.GetData to retrieve then decode the field SBF content

function GetValue(FieldBuffer: pointer): RawUTF8;

Decode the value from our SBF compact binary format into UTF-8 text

- this method does not check for FieldBuffer to be not nil -> caller should check this explicitly

function GetVariant(FieldBuffer: pointer): Variant; **overload**;

Decode the value from our SBF compact binary format into a Variant

```
function OrderedIndexMatch(WhereSBFValue: pointer; var MatchIndex:
TIntegerDynArray; var MatchIndexCount: integer; Limit: Integer=0): Boolean;
```

Retrieve one or more "physical" indexes matching a WHERE Statement

- is faster than O(1) GetIterating(), because will use O(log(n)) binary search using the OrderedIndex[] array
- returns the resulting indexes as a sorted list in MatchIndex/MatchIndexCount
- if the indexes are already present in the list, won't duplicate them
- WhereSBFValue must be a valid SBF formatted field buffer content
- the Limit parameter is similar to the SQL LIMIT clause: if greater than 0, an upper bound on the number of rows returned is placed (e.g. set Limit=1 to only retrieve the first match)
- GetData property must have been set with a method returning a pointer to the field data for a given index (this index is not the per-ID index, but the "physical" index, i.e. the index value used to retrieve data from low-level (and fast) GetData method)
- in this method, indexes are not the per-ID indexes, but the "physical" indexes, i.e. each index value used to retrieve data from low-level (and fast) GetData method

```
function OrderedIndexUpdate(aOldIndex, aNewIndex: integer; aOldRecordData,
aNewRecordData: pointer): boolean;
```

Will update then sort the array of indexes used for the field index

- the OrderedIndex[] array is first refreshed according to the aOldIndex, aNewIndex parameters: aOldIndex=-1 for Add, aNewIndex=-1 for Delete, or both >= 0 for update
- call with both indexes = -1 will sort the existing OrderedIndex[] array
- GetData property must have been set with a method returning a pointer to the field data for a given index (this index is not the per-ID index, but the "physical" index, i.e. the index value used to retrieve data from low-level (and fast) GetData method)
- aOldRecordData and aNewRecordData can be specified in order to guess if the field data has really been modified (speed up the update a lot to only sort indexed fields if its content has been really modified)
- returns FALSE if any parameter is invalid

```
function SBF(const Value: Variant): TSBFString; overload;
```

Create some SBF compact binary format from a Variant value

```
function SBF(const Value: RawUTF8): TSBFString; overload;
```

Create some SBF compact binary format from a Delphi binary value

- expect a RawUTF8 string: will be converted to WinAnsiString before storage, for tftWinAnsi
- will return "" if the field type doesn't match a string

```
function SBF(Value: pointer; ValueLen: integer): TSBFString; overload;
```

Create some SBF compact binary format from a BLOB memory buffer

- will return "" if the field type doesn't match tftBlobInternal

```
function SBF(const Value: Int64): TSBFString; overload;
```

Create some SBF compact binary format from a Delphi binary value

- will encode any byte, word, integer, cardinal, Int64 value
- will return "" if the field type doesn't match an integer

```
function SBF(const Value: Boolean): TSBFString; overload;
```

Create some SBF compact binary format from a Delphi binary value

- will return "" if the field type doesn't match a boolean

function SBF(const Value: Integer): TSBFString; overload;

Create some SBF compact binary format from a Delphi binary value

- will encode any byte, word, integer, cardinal value
- will return "" if the field type doesn't match an integer

function SBFCurr(const Value: Currency): TSBFString;

Create some SBF compact binary format from a Delphi binary value

- will return "" if the field type doesn't match a currency
- we can't use SBF() method name because of Currency/Double ambiguity

function SBFFloat(const Value: Double): TSBFString;

Create some SBF compact binary format from a Delphi binary value

- will return "" if the field type doesn't match a floating-point
- we can't use SBF() method name because of Currency/Double ambiguity

function SBFFFromRawUTF8(const aValue: RawUTF8): TSBFString;

Convert any UTF-8 encoded value into our SBF compact binary format

- can be used e.g. from a WHERE clause, for fast comparison in TSynTableStatement.WhereValue content using OrderedIndex[]
- is the reverse of GetValue/GetRawUTF8 methods above

function SortCompare(P1,P2: PUTF8Char): PtrInt;

Low-level binary comparison used by IDSort and TSynTable.IterateJSONValues

- P1 and P2 must point to the values encoded in our SBF compact binary format

function Validate(RecordBuffer: pointer; RecordIndex: integer): string;

Check the registered constraints

- returns "" on success
- returns an error message e.g. if a tftUnique constraint failed
- RecordIndex=-1 in case of adding, or the physical index of the updated record

procedure GetVariant(FieldBuffer: pointer; var result: Variant); overload;

Decode the value from our SBF compact binary format into a Variant

procedure OrderedIndexRefresh;

Will force refresh the OrderedIndex[] array

- to be called e.g. if OrderedIndexNotSorted = TRUE, if you want to access to the OrderedIndex[] array

procedure SaveTo(WR: TFileBufferWriter);

Save entry to a specified file writer

property SBFDefault: TSBFString read fDefaultFieldData;

Some default SBF compact binary format content

TSynTableData = object(TObject)

Used to store a TSynTable record using our SBF compact binary format

- this object can be created on the stack
- it is mapped into a variant TVarData, to be retrieved by the TSynTable.Data method - but direct allocation of a TSynTableData on the stack is faster (due to the Variant overhead)
- is defined either as an object either as a record, due to a bug in Delphi 2009/2010 compiler (at least): this structure is not initialized if defined as an object on the stack, but will be as a record :(

function GetFieldSBFValue(aField: TSynTableFieldProperties): TSBFString;

Get a field value for a specified field, into SBF-encoded data

- this method is faster than the other, because it won't look for the field name nor make any variant conversion

function GetFieldValue(aField: TSynTableFieldProperties): Variant;

Get a field value for a specified field

- this method is faster than Field[], because it won't look for the field name

function ValidateSBFValue(RecordIndex: integer): string;

Check the registered constraints according to a record SBF buffer

- returns "" on success

- returns an error message e.g. if a tftUnique constraint failed

- RecordIndex=-1 in case of adding, or the physical index of the updated record

procedure FilterSBFValue;

Filter the SBF buffer record content with all registered filters

- all field values are filtered in-place, following our SBF compact binary format encoding for this record

procedure Init(aTable: TSynTable; aID: Integer=0); overload;

Initialize a record data content for a specified table

- a void content is set

procedure Init(aTable: TSynTable; aID: Integer; RecordBuffer: pointer;
RecordBufferLen: integer); overload;

Initialize a record data content for a specified table

- the specified SBF content is store inside this TSynTableData

procedure SetFieldSBFValue(aField: TSynTableFieldProperties; const Value: TSBFString);

Set a field value for a specified field, from SBF-encoded data

- this method is faster than the other, because it won't look for the field name nor make any variant conversion

procedure SetFieldValue(aField: TSynTableFieldProperties; const Value: Variant);

Set a field value for a specified field

- this method is faster than Field[], because it won't look for the field name

property Field[const FieldName: RawUTF8]: Variant read GetField write SetField;

Set or retrieve a field value from a variant data

property ID: integer read VID write VID;

The associated record ID

property SBF: TSBFString read VValue;

The record content, SBF compact binary format encoded

property Table: TSynTable read VTable write VTable;

The associated TSynTable instance

TUpdateFieldEvent = record

An opaque structure used for TSynTable.UpdateFieldEvent method

AvailableFields: TSQLFieldBits;

The list of existing field in the previous data

Count: integer;

The number of record added

IDs: TIntegerDynArray;

The list of IDs added

- this list is already in increasing order, because GetIterating was called with the ioID order

NewIndexes: TIntegerDynArray;

Previous indexes: NewIndexes[oldIndex] := newIndex

Offsets64: TInt64DynArray;

The offset of every record added

- follows the IDs[] order

WR: TFileBufferWriter;

Where to write the updated data

TSynValidateTable = class(TSynValidate)

Will define a validation to be applied to a TSynTableFieldProperties field

- a typical usage is to validate a value to be unique in the table (implemented in the

TSynValidateTableUniqueField class)

- the optional associated parameters are to be supplied JSON-encoded

- ProcessField and ProcessRecordIndex properties will be filled before Process method call by TSynTableFieldProperties.Validate()

property ProcessField: TSynTableFieldProperties **read** fProcessField **write** fProcessField;

The associated TSQLRest instance

- this value is filled by TSynTableFieldProperties.Validate with its self value to be used for the validation

- it can be used in the overridden Process method

property ProcessRecordIndex: integer **read** fProcessRecordIndex **write** fProcessRecordIndex;

The associated record index (in case of update)

- is set to -1 in case of adding, or the physical index of the updated record

- this value is filled by TSynTableFieldProperties.Validate

- it can be used in the overridden Process method

TSynValidateTableUniqueField = class(TSynValidateTable)

Will define a validation for a TSynTableFieldProperties Unique field

- implement constraints check e.g. if tfoUnique is set in Options

- it will check that the field value is not void

- it will check that the field value is not a duplicate

function Process(aFieldIndex: integer; **const** Value: RawUTF8; **var** ErrorMsg: string): boolean; **override**;

Perform the unique field validation action to the specified value

- duplication value check will use the ProcessField and ProcessRecordIndex properties, which will be filled before call by TSynTableFieldProperties.Validate()
- aFieldIndex parameter is not used here, since we have already the ProcessField property set
- here the Value is expected to be UTF-8 text, as converted from our SBF compact binary format via e.g. TSynTableFieldProperties.GetValue / GetRawUTF8: this is mandatory to have the validation rule fit with other TSynValidateTable classes

TSynTable = **class**(TObject)

Store the description of a table with records, to implement a Database

- can be used with several storage engines, for instance TSynBigTableRecord
- each record can have up to 64 fields
- a mandatory ID field must be handled by the storage engine itself
- will handle the storage of records into our SBF compact binary format, in which fixed-length fields are stored leftmost side, then variable-length fields follow

constructor Create(**const** aTableName: RawUTF8);

Create a table definition instance

destructor Destroy; **override**;

Release used memory

function AddField(**const** aName: RawUTF8; aType: TSynTableFieldType; aOptions: TSynTableFieldOptions=[]): TSynTableFieldProperties;

Add a field description to the table

- warning: the class responsible of the storage itself must process the data already stored when a field is created, e.g. in TSynBigTableRecord.AddFieldUpdate method
- physical order does not necessary follow the AddField() call order: for better performance, it will try to store fixed-sized record first, multiple of 4 bytes first (access is faster if dat is 4 byte aligned), then variable-length after fixed-sized fields; in all case, a field indexed will be put first

function CreateJSONWriter(JSON: TStream; Expand, withID: boolean; **const** Fields: TSQLFieldIndexDynArray): TJSONWriter; **overload**;

Create a TJSONWriter, ready to be filled with GetJSONValues(W) below

- will initialize all TJSONWriter.ColNames[] values according to the specified Fields index list, and initialize the JSON content

function CreateJSONWriter(JSON: TStream; Expand, withID: boolean; **const** Fields: TSQLFieldBits): TJSONWriter; **overload**;

Create a TJSONWriter, ready to be filled with GetJSONValues(W) below

- will initialize all TJSONWriter.ColNames[] values according to the specified Fields bit set, and initialize the JSON content

function Data(aID: integer=0; RecordBuffer: pointer=nil; RecordBufferLen: Integer=0): **Variant**; **overload**;

Create a Variant able to access any field content via late binding

- i.e. you can use Var.Name to access the 'Name' field of record Var
- if you leave ID and RecordBuffer void, a void record is created

function DataLength(RecordBuffer: pointer): integer;

Return the total length of the given record buffer, encoded in our SBF compact binary format

function GetData(RecordBuffer: PUTF8Char; Field: TSynTableFieldProperties): pointer;

Retrieve to the corresponding data address of a given field

function IterateJSONValues(Sender: TObject; Opaque: pointer; ID: integer; Data: pointer; DataLen: integer): boolean;

Can be used to retrieve all values matching a prepared TSynTableStatement

- this method matches the TSynBigTableIterateEvent callback definition
- Sender will be the TSynBigTable instance, and Opaque will point to a TSynTableStatement instance (with all fields initialized, including Writer)

function UpdateFieldEvent(Sender: TObject; Opaque: pointer; ID, Index: integer; Data: pointer; DataLen: integer): boolean;

This Event is to be called for all data records (via a GetIterating method) after any AddfieldUpdate, to refresh the data

- Opaque is in fact a pointer to a TUpdateFieldEvent record, and will contain all parameters set by TSynBigTableRecord.AddFieldUpdate, including a TFileBufferWriter instance to use to write the recreated data
- it will work with either any newly added field, handly also field data order change in SBF record (e.g. when a fixed-sized field has been added on a record containing variable-length fields)

function UpdateFieldRecord(RecordBuffer: PUTF8Char; var AvailableFields: TSQLFieldBits): TSBFString;

Update a record content after any AddfieldUpdate, to refresh the data

- AvailableFields must contain the list of existing fields in the previous data

function Validate(RecordBuffer: pointer; RecordIndex: integer): string;

Check the registered constraints according to a record SBF buffer

- returns "" on success
- returns an error message e.g. if a tftUnique constraint failed
- RecordIndex=-1 in case of adding, or the physical index of the updated record

procedure FieldIndexModify(aOldIndex, aNewIndex: integer; aOldRecordData, aNewRecordData: pointer);

Event which must be called by the storage engine when some values are modified

- if aOldIndex and aNewIndex are both ≥ 0 , the corresponding aOldIndex will be replaced by aNewIndex value (i.e. called in case of a data Update)
- if aOldIndex is -1 and aNewIndex is ≥ 0 , aNewIndex refers to a just created item (i.e. called in case of a data Add)
- if aOldIndex is ≥ 0 and aNewIndex is -1, aNewIndex refers to a just deleted item (i.e. called in case of a data Delete)
- will update then sort all existing TSynTableFieldProperties.OrderedIndex values
- the GetDataBuffer protected virtual method must have been overridden to properly return the record data for a given "physical/stored" index
- aOldRecordData and aNewRecordData can be specified in order to guess if the field data has really been modified (speed up the update a lot to only sort indexed fields if its content has been really modified)

procedure Filter(**var** RecordBuffer: TSBFString);

Filter the SBF buffer record content with all registered filters

- all field values are filtered in-place, following our SBF compact binary format encoding for this record

procedure GetJSONValues(aID: integer; RecordBuffer: PUTF8Char; W: TJSONWriter);

Return the UTF-8 encoded JSON objects for the values contained in the specified RecordBuffer encoded in our SBF compact binary format, according to the Expand/WithID/Fields parameters of W

- if W.Expand is true, JSON data is an object, for direct use with any Ajax or .NET client:

```
{ "col1":val11, "col2": "val12" }
```

- if W.Expand is false, JSON data is serialized (as used in TSQLTableJSON)

```
{ "fieldCount":1, "values":["col1", "col2", val11, "val12", val21, .. ] }
```

- only fields with a bit set in W.Fields will be appended

- if W.WithID is true, then the first ID field value is included

procedure LoadFrom(**var** RD: TFileBufferReader);

Create a table definition instance from a specified file reader

procedure SaveTo(WR: TFileBufferWriter);

Save field properties to a specified file writer

procedure UpdateFieldData(RecordBuffer: PUTF8Char; RecordBufferLen, FieldIndex: integer; **var** result: TSBFString; **const** NewFieldData: TSBFString='');

Update a record content

- return the updated record data, in our SBF compact binary format

- if NewFieldData is not specified, a default 0 or '' value is appended

- if NewFieldData is set, it must match the field value kind

- warning: this method will update result in-place, so RecordBuffer MUST be <> pointer(result) or data corruption may occur

property AddedField: TList **read** fAddedField **write** fAddedField;

List of TSynTableFieldProperties added via all AddField() call

- this list will allow TSynBigTableRecord.AddFieldUpdate to refresh the data on disk according to the new field configuration

property DefaultRecordData: TSBFString **read** fDefaultRecordData;

Return a default content for ALL record fields

- uses our SBF compact binary format

property Field[Index: integer]: TSynTableFieldProperties **read** GetFieldType;

Retrieve the properties of a given field

- returns nil if the specified Index is out of range

property FieldCount: integer **read** GetFieldCount;

Number of fields in this table

property FieldFromName[**const** aName: RawUTF8]: TSynTableFieldProperties **read** GetFieldFromName;

Retrieve the properties of a given field

- returns nil if the specified Index is out of range

property FieldIndexFromName[const aName: RawUTF8]: integer read
 GetFieldIndexFromName;

Retrieve the index of a given field
 - returns -1 if the specified Index is out of range

property FieldList: TObjectList read fField;

Read-only access to the Field list

property FieldVariableOffset: PtrUInt read fFieldVariableOffset;

Offset of the first variable length value field

property GetRecordData: TSynTableGetRecordData read fGetRecordData write
 fGetRecordData;

*Event used for proper data retrieval of a given record buffer, according to the physical/storage
 index value (not per-ID index)*
 - if not set, field indexes won't work
 - will be mapped e.g. to TSynBigTable.GetPointerFromPhysicalIndex

property HasUniqueIndexes: boolean read fFieldHasUniqueIndexes;

True if any field has a tfoUnique option set

property TableName: RawUTF8 read fTableName write fTableName;

The internal Table name used to identify it (e.g. from JSON or SQL)
 - similar to the SQL Table name

TSynTableVariantType = class(TSynInvokeableVariantType)

A custom variant type used to have direct access to a record content
 - use TSynTable.Data method to retrieve such a Variant
 - this variant will store internally a SBF compact binary format representation of the record
 content
 - uses internally a TSynTableData object

class function ToID(const V: Variant): integer;

Retrieve the ID value associated to a record content

class function ToSBF(const V: Variant): TSBFString;

Retrieve the SBF compact binary format representation of a record content

class function ToTable(const V: Variant): TSynTable;

Retrieve the TSynTable instance associated to a record content

procedure Clear(var V: TVarData); **override**;

Clear the content

procedure Copy(var Dest: TVarData; const Source: TVarData; const Indirect: Boolean);
override;

Copy two record content

Types implemented in the SynTable unit

PRawByteStringGroup = ^TRawByteStringGroup;

Pointer reference to a TRawByteStringGroup

PSQLFieldBits = ^TSQLFieldBits;

Points to a bit set used for all available fields in a Table

PSynTableData = ^TSynTableData;

A pointer to structure used to store a TSynTable record

PSynUniqueIdentifierBits = ^TSynUniqueIdentifierBits;

Points to a 64-bit integer identifier, as computed by TSynUniqueIdentifierGenerator

- may be used to access the identifier internals, from its stored Int64 or TSynUniqueIdentifier value

PSynValidate = ^TSynValidate;

Points to a TSynValidate variable

- used e.g. as optional parameter to TSQLRecord.Validate/FilterAndValidate

TBlockingEvent = (evNone, evWaiting, evTimeOut, evRaised);

The current state of a TBlockingProcess instance

TBlockingProcessPoolCall = **type** integer;

Used to identify each TBlockingProcessPool call

- allow to match a given TBlockingProcessPoolItem semaphore

TBlockingProcessPoolItemClass = **class of** TBlockingProcessPoolItem;

Class-reference type (metaclass) of a TBlockingProcess

TCompareOperator = (soEqualTo, soNotEqualTo, soLessThan, soLessThanOrEqualTo, soGreaterThan, soGreaterThanOrEqualTo, soBeginWith, soContains, soSoundsLikeEnglish, soSoundsLikeFrench, soSoundsLikeSpanish);

SQL Query comparison operators

- used e.g. by CompareOperator() functions in SynTable.pas or vt_BestIndex() in mORMotSQLite3.pas

TConsoleColor = (ccBlack, ccBlue, ccGreen, ccCyan, ccRed, ccMagenta, ccBrown, ccLightGray, ccDarkGray, ccLightBlue, ccLightGreen, ccLightCyan, ccLightRed, ccLightMagenta, ccYellow, ccWhite);

Available console colors (under Windows at least)

TDeltaError = (dsSuccess, dsCrcCopy, dsCrcComp, dsCrcBegin, dsCrcEnd, dsCrcExtract, dsFlag, dsLen);

Result of function DeltaExtract()

TDiskPartitions = **array of** TDiskPartition;

Stores information about several disk partitions

TEmoji = (eNone, eGrinning, eGrin, eJoy, eSmiley, eSmile, eSweat_smile, eLaughing, eInnocent, eSmiling_imp, eWink, eBlush, eYum, eRelieved, eHeart_eyes, eSunglasses, eSmirk, eNeutral_face, eExpressionless, eUnamused, eSweat, ePensive, eConfused, eConfounded, eKissing, eKissing_heart, eKissing_smiling_eyes, eKissing_closed_eyes, eStuck_out_tongue, eStuck_out_tongue_winking_eye, eStuck_out_tongue_closed_eyes, eDisappointed, eWorried, eAngry, ePout, eCry, ePersevere, eTriumph, eDisappointed_relieved, eFrowning, eAnguished, eFearful, eWeary, eSleepy, eTired_face, eGrimacing, eSob, eOpen_mouth, eHushed, eCold_sweat, eScream, eAstonished, eFlushed, eSleeping, eDizzy_face, eNo_mouth, eMask, eSmile_cat, eJoy_cat, eSmiley_cat, eHeart_eyes_cat, eSmirk_cat, eKissing_cat, ePouting_cat, eCrying_cat_face, eScream_cat, eSlightly_frowning_face, eSlightly_smiling_face, eUpside_down_face, eRoll_eyes, eNo_good, eOk_woman, eBow, eSee_no_evil, eHear_no_evil, eSpeak_no_evil, eRaising_hand, eRaised_hands, eFrowning_woman, ePerson_with_pouting_face, ePray);

Map the first Unicode page of Emojis, from U+1F600 to U+1F64F

- naming comes from github/Markdown :identifiers:

TExprNodeType = (entWord, entNot, entOr, entAnd);

Identify an expression search engine node type, as used by TExprParser

TExprNodeWordClass = **class of** TExprNodeWordAbstract;

Class-reference type (metaclass) for a TExprNode

- allow to customize the actual searching process for entWord

TExprParserResult = (eprSuccess, eprNoExpression, eprMissingParenthesis, eprTooManyParenthesis, eprMissingFinalWord, eprInvalidExpression, eprUnknownVariable, eprUnsupportedOperator, eprInvalidConstantOrVariable);

Results returned by TExprParserAbstract.Parse method

TFileBufferWriterKind = (wkUInt32, wkVarUInt32, wkVarInt32, wkSorted, wkOffsetU, wkOffsetI, wkFakeMarker);

Available kind of integer array storage, corresponding to the data layout

- wkUInt32 will write the content as "plain" 4 bytes binary (this is the preferred way if the integers can be negative)
- wkVarUInt32 will write the content using our 32-bit variable-length integer encoding
- wkVarInt32 will write the content using our 32-bit variable-length integer encoding and the by-two complement (0=0,1=1,2=-1,3=2,4=-2...)
- wkSorted will write an increasing array of integers, handling the special case of a difference of similar value (e.g. 1) between two values - note that this encoding is efficient only if the difference is main < 253
- wkOffsetU and wkOffsetI will write the difference between two successive values, handling constant difference (Unsigned or Integer) in an optimized manner
- wkFakeMarker won't be used by WriteVarUInt32Array, but to notify a custom encoding

TMatchDynArray = **array of** TMatch;

Use SetMatches() to initialize such an array from a CSV pattern text

TNotifyThreadEvent = **procedure**(Sender: TThread) **of object**;

Event prototype used e.g. by TSynBackgroundThreadAbstract callbacks

- a similar signature is defined in SynCrtSock and LVCL.Classes

TNullableBoolean = **type variant**;

Define a variant published property as a nullable boolean

- either a varNull or a varBoolean value will be stored in the variant
- either a NULL or a 0/1 INTEGER value will be stored in the database
- the property should be defined as such:

property Bool: TNullableBoolean **read** fBool **write** fBool;

TNullableCurrency = **type variant**;

Define a variant published property as a nullable decimal value

- either a varNull or a varCurrency value will be stored in the variant
- either a NULL or a FLOAT value will be stored in the database
- the property should be defined as such:

property Cur: TNullableCurrency **read** fCur **write** fCur;

TNullableDateTime = **type variant**;

Define a variant published property as a nullable date/time value

- either a varNull or a varDate value will be stored in the variant
- either a NULL or a ISO-8601 TEXT value will be stored in the database
- the property should be defined as such:
property Dat: TNullableDateTime **read** fDat **write** fDat;

TNullableFloat = type variant;

Define a variant published property as a nullable floating point value

- either a varNull or a varDouble value will be stored in the variant
- either a NULL or a FLOAT value will be stored in the database
- the property should be defined as such:
property Flt: TNullableFloat **read** fFlt **write** fFlt;

TNullableInteger = type variant;

Define a variant published property as a nullable integer

- either a varNull or a varInt64 value will be stored in the variant
- either a NULL or an INTEGER value will be stored in the database
- the property should be defined as such:
property Int: TNullableInteger **read** fInt **write** fInt;

TNullableTimeLog = type variant;

Define a variant published property as a nullable timestamp value

- either a varNull or a varInt64 value will be stored in the variant
- either a NULL or a TTimeLog INTEGER value will be stored in the database
- the property should be defined as such:
property Tim: TNullableTimrency **read** fTim **write** fTim;

TNullableUTF8Text = type variant;

Define a variant published property as a nullable UTF-8 encoded text

- either a varNull or varString (RawUTF8) will be stored in the variant
- either a NULL or a TEXT value will be stored in the database
- the property should be defined as such:
property Txt: TNullableUTF8Text **read** fTxt **write** fTxt;

or for a fixed-width VARCHAR (in external databases), here of 32 max chars:

property Txt: TNullableUTF8Text **index** 32 **read** fTxt **write** fTxt;

- warning: prior to Delphi 2009, since the variant will be stored as RawUTF8 internally, you should not use directly the field value as a VCL string=AnsiString like string(aField) but use VariantToString(aField)

TOnIdleSynBackgroundThread = procedure(Sender: TSynBackgroundThreadAbstract;
 ElapsedMS: Integer) **of object**;

Idle method called by TSynBackgroundThreadAbstract in the caller thread during remote blocking process in a background thread

- typical use is to run Application.ProcessMessages, e.g. for TSQLRestClientURI.URI() to provide a responsive UI even in case of slow blocking remote access
- provide the time elapsed (in milliseconds) from the request start (can be used e.g. to popup a temporary message to wait)
- is call once with ElapsedMS=0 at request start
- is call once with ElapsedMS=-1 at request ending

- see TLoginForm.OnIdleProcess and OnIdleProcessForm in mORMotUILogin.pas

TOnProcessSynBackgroundThread = procedure(Sender: TSynBackgroundThreadEvent; ProcessOpaqueParam: pointer) **of object**;

Background process method called by TSynBackgroundThreadEvent

- will supply the OpaqueParam parameter as provided to RunAndWait() method when the Process virtual method will be executed

TOnProcessSynBackgroundThreadProc = procedure(ProcessOpaqueParam: pointer);

Background process procedure called by TSynBackgroundThreadProcedure

- will supply the OpaqueParam parameter as provided to RunAndWait() method when the Process virtual method will be executed

TOnSynBackgroundThreadProcess = procedure(Sender: TSynBackgroundThreadProcess; Event: TWaitResult) **of object**;

Event callback executed periodically by TSynBackgroundThreadProcess

- Event is wrTimeout after the OnProcessMS waiting period
- Event is wrSignaled if ProcessEvent.SetEvent has been called

TOnSynBackgroundTimerProcess = procedure(Sender: TSynBackgroundTimer; Event: TWaitResult; **const** Msg: RawUTF8) **of object**;

Event callback executed periodically by TSynBackgroundThreadProcess

- Event is wrTimeout after the OnProcessMS waiting period
- Event is wrSignaled if ProcessEvent.SetEvent has been called
- Msg is '' if there is no pending message in this task FIFO
- Msg is set for each pending message in this task FIFO

TOnSystemUseMeasured = procedure(ProcessID: integer; **const** Data: TSystemUseData) **of object**;

Event handler which may be executed by TSystemUse.BackgroundExecute

- called just after the measurement of each process CPU and RAM consumption
- run from the background thread, so should not directly make VCL calls, unless BackgroundExecute is run from a VCL timer

TPendingTaskListItemDynArray = array of TPendingTaskListItem;

Internal list definition, used by TPendingTaskList storage

TRawByteStringGroupValueDynArray = array of TRawByteStringGroupValue;

Items as stored in a TRawByteStringGroup instance

TSBFString = type RawByteString;

An custom RawByteString type used to store internally a data in our SBF compact binary format

TSQLDBFieldType = (ftUnknown, ftNull, ftInt64, ftDouble, ftCurrency, ftDate, ftUTF8, ftBlob);

Handled field/parameter/column types for abstract database access

- this will map JSON-compatible low-level database-level access types, not high-level Delphi types as TSQLFieldType defined in mORMot.pas
- it does not map either all potential types as defined in DB.pas (which are there for compatibility with old RDBMS, and are not abstract enough)
- those types can be mapped to standard SQLite3 generic types, i.e. NULL, INTEGER, REAL, TEXT, BLOB (with the addition of a ftCurrency and ftDate type, for better support of most DB engines) see @<http://www.sqlite.org/datatype3.html>
- the only string type handled here uses UTF-8 encoding (implemented using our RawUTF8 type), for

cross-Delphi true Unicode process

TSQLDBFieldTypeArray = array[0..MAX_SQLFIELDS-1] of TSQLDBFieldType;

Array of field/parameter/column types for abstract database access

- this array as a fixed size, ready to handle up to MAX_SQLFIELDS items

TSQLDBFieldTypeDynArray = array of TSQLDBFieldType;

Array of field/parameter/column types for abstract database access

TSQLDBFieldTypes = set of TSQLDBFieldType;

Set of field/parameter/column types for abstract database access

TSQLFieldBits = set of 0..MAX_SQLFIELDS-1;

Used to store bit set for all available fields in a Table

- with current MAX_SQLFIELDS value, 64 bits uses 8 bytes of memory

- see also IsZero() and IsEqual() functions

- you can also use ALL_FIELDS as defined in mORMot.pas

TSQLFieldIndex = SmallInt;

Used to store a field index in a Table

- note that -1 is commonly used for the ID/RowID field so the values should be signed

- even if ShortInt (-128..127) may have been enough, we define a 16 bit safe unsigned integer to let the source compile with Delphi 5

TSQLFieldIndexDynArray = array of TSQLFieldIndex;

-32768..32767 used to store field indexes in a Table

- same as TSQLFieldBits, but allowing to store the proper order

TSQLParamType = (sptUnknown, sptInteger, sptFloat, sptText, sptBlob, sptDateTime);

Generic parameter types, as recognized by SQLParamContent() and ExtractInlineParameters() functions

TSQLParamTypeDynArray = array of TSQLParamType;

Array of parameter types, as recognized by SQLParamContent() and ExtractInlineParameters() functions

TSQLVarDynArray = array of TSQLVar;

Dynamic array of database values by reference storage

TSQLVarOption = (svoDateWithMS);

How TSQLVar may be processed

- by default, ftDate will use seconds resolution unless svoDateWithMS is set

TSQLVarOptions = set of TSQLVarOption;

Defines how TSQLVar may be processed

TSynAuthenticationClass = class of TSynAuthenticationAbstract;

Class-reference type (metaclass) of an authentication class

TSynBackgroundThreadProcessStep = (flagIdle, flagStarted, flagFinished, flagDestroying);

State machine status of the TSynBackgroundThreadAbstract process

TSynBackgroundThreadProcessSteps = set of TSynBackgroundThreadProcessStep;

State machine statuses of the TSynBackgroundThreadAbstract process

TSynBackgroundTimerTaskDynArray = **array of** TSynBackgroundTimerTask;
Stores TSynBackgroundTimer internal registration list

TSynFilterClass = **class of** TSynFilter;
Class-reference type (metaclass) of a record filter (transformation)

TSynFilterOrValidateClass = **class of** TSynFilterOrValidate;
Class-reference type (metaclass) for a TSynFilter or a TSynValidate

TSynParallelProcessMethod = **procedure**(IndexStart, IndexStop: integer) **of object**;
Callback implementing some parallelized process for TSynParallelProcess
 - if 0<=IndexStart<=IndexStop, it should execute some process

TSynSoundExPronunciation = (sndxEnglish, sndxFrench, sndxSpanish, sndxNone);
Available pronunciations for our fast Soundex implementation

TSynTableFieldBits = **set of** 0..63;
Used to store bit set for all available fields in a Table
 - with current format, maximum field count is 64

TSynTableFieldIndex = **function**(const PropName: RawUTF8): integer **of object**;
Function prototype used to retrieve the index of a specified property name
 - 'ID' is handled separately: here must be available only the custom fields

TSynTableFieldOption = (tfoIndex, tfoUnique, tfoCaseInsensitive);
Available option types for a field property
 - tfoIndex is set if an index must be created for this field
 - tfoUnique is set if field values must be unique (if set, the tfoIndex will be always forced)
 - tfoCaseInsensitive can be set to make no difference between 'a' and 'A' (by default, comparison is case-sensitive) - this option has an effect not only if tfoIndex or tfoUnique is set, but also for iterating search

TSynTableFieldOptions = **set of** TSynTableFieldOption;
Set of option types for a field

TSynTableFieldType = (tftUnknown, tftBoolean, tftUInt8, tftUInt16, tftUInt24, tftInt32, tftInt64, tftCurrency, tftDouble, tftVarUInt32, tftVarInt32, tftVarUInt64, tftWinAnsi, tftUTF8, tftBlobInternal, tftBlobExternal, tftVarInt64);

The available types for any TSynTable field property
 - this is used in our so-called SBF compact binary format (similar to BSON or Protocol Buffers)
 - those types are used for both storage and JSON conversion
 - basic types are similar to SQLite3, i.e. Int64/Double/UTF-8/Blob
 - storage can be of fixed size, or of variable length
 - you can specify to use WinAnsi encoding instead of UTF-8 for string storage (it can use less space on disk than UTF-8 encoding)
 - BLOB fields can be either internal (i.e. handled by TSynTable like a RawByteString text storage), either external (i.e. must be stored in a dedicated storage structure - e.g. another TSynBigTable instance)

TSynTableFieldTypes = **set of** TSynTableFieldType;
Set of available field types for TSynTable

TSynTableGetRecordData = **function**(Index: integer; var aTempData: RawByteString):
 pointer **of object**;
Function prototype used to retrieve the RECORD data of a specified Index

- the index is not the per-ID index, but the "physical" index, i.e. the index value used to retrieve data from low-level (and faster) method
- should return nil if Index is out of range
- caller must provide a temporary storage buffer to be used optionally

```
TSynTableStatementOperator = ( opEqualTo, opNotEqualTo, opLessThan,
opLessThanOrEqualTo, opGreaterThan, opGreaterThanOrEqualTo, opIn, opIsNull,
opIsNotNull, opLike, opContains, opFunction );
```

The recognized operators for a TSynTableStatement where clause

```
TSynTableStatementSelectDynArray = array of TSynTableStatementSelect;
```

The recognized SELECT expressions for TSynTableStatement

```
TSynTableStatementWhereDynArray = array of TSynTableStatementWhere;
```

The recognized WHERE expressions for TSynTableStatement

```
TSynUniqueIdentifier = type Int64;
```

64-bit integer unique identifier, as computed by TSynUniqueIdentifierGenerator

- they are increasing over time (so are much easier to store/shard/balance than UUID/GUID), and contain generation time and a 16-bit process ID
- mapped by TSynUniqueIdentifierBits memory structure
- may be used on client side for something similar to a MongoDB ObjectID, but compatible with TSQLRecord.ID: TID properties

```
TSynUniqueIdentifierObfuscated = type RawUTF8;
```

A 24 chars cyphered hexadecimal string, mapping a TSynUniqueIdentifier

- has handled by TSynUniqueIdentifierGenerator.ToObfuscated/FromObfuscated

```
TSynUniqueIdentifierProcess = type word;
```

16-bit unique process identifier, used to compute TSynUniqueIdentifier

- each TSynUniqueIdentifierGenerator instance is expected to have its own unique process identifier, stored as a 16 bit integer 1..65535 value

```
TSystemUseDataDynArray = array of TSystemUseData;
```

Store CPU and RAM usage history for a given process

- as returned by TSystemUse.History

```
TSystemUseProcessDynArray = array of TSystemUseProcess;
```

Internal storage of CPU and RAM usage for a set of processes

```
TTextWriterHTMLEscape = set of ( heHtmlEscape, heEmojiToUTF8);
```

Tune AddHtmlEscapeWiki/AddHtmlEscapeMarkdown wrapper functions process

- heHtmlEscape will escape any HTML special chars, e.g. & into &
- heEmojiToUTF8 will convert any Emoji text into UTF-8 Unicode character, recognizing e.g. :joy: or :) in the text

```
TTimeZoneDataDynArray = array of TTimeZoneData;
```

Used to store the Time Zone information of a TSynTimeZone class

```
TTimeZoneID = type RawUTF8;
```

Text identifier of a Time Zone, following Microsoft Windows naming

Constants implemented in the SynTable unit

```
DELTA_BUF_DEFAULT = 2 shl 20;
```

2MB as internal chunks/window default size for DeltaCompress()

- will use up to 9 MB of RAM during DeltaCompress() - none in DeltaExtract()

DELTA_LEVEL_BEST = 500;

Brutal pattern search depth for DeltaCompress()

- may become very slow, with minor benefit, on huge content

DELTA_LEVEL_FAST = 100;

Normal pattern search depth for DeltaCompress()

- gives good results on most content

PARSER_STOPCHAR = ['&', '+', '-', '(', ')'];

May be used when overriding TExprParserAbstract.ParseNextWord method

SOUNDEX_BITS = 4;

Number of bits to use for each interesting soundex char

- default is to use 8 bits, i.e. 4 soundex chars, which is the standard approach

- for a more detailed soundex, use 4 bits resolution, which will compute up to 7 soundex chars in a cardinal (that's our choice)

SQLDBFIELDTYPE_TO_DELPHITYPE: array[TSQLDBFieldType] of RawUTF8 = ('???' , '???' , 'Int64', 'Double', 'Currency', 'TDateTime', 'RawUTF8', 'TSQLERawBlob');

Convert identified field types into high-level ORM types

- as will be implemented in unit mORMot.pas

SYNTABLESTATEMENTWHEREID = 0;

Used by TSynTableStatement.WhereField for "SELECT .. FROM TableName WHERE ID=?"

Functions or procedures implemented in the SynTable unit

Functions or procedures	Description	Page
AddFieldIndex	Add a field index to an array of field indexes	1817
AddHtmlEscapeMarkdown	Convert minimal Markdown text into proper HTML	1817
AddHtmlEscapewiki	Convert some wiki-like text into proper HTML	1817
CompareOperator	Low-level text comparison according to a specified operator	1818
CompareOperator	Low-level floating-point comparison according to a specified operator	1818
CompareOperator	Low-level integer comparison according to a specified operator	1818
ConsoleKeyPressed	Low-level access to the keyboard state of a given key	1818
ConsoleReadBody	Read all available content from stdin	1818
ConsoleShowFatalException	Could be used in the main program block of a console application to handle unexpected fatal exceptions	1819
ConsoleWaitForEnterKey	Will wait for the ENTER key to be pressed, processing Synchronize() pending notifications, and the internal Windows Message loop (on this OS)	1819
ConsoleWrite	Write some text to the console using a given color	1819

Functions or procedures	Description	Page
ConsoleWrite	Write some text to the console using a given color	1819
DateTimeToSQL	Convert a date/time to a ISO-8601 string format for SQL '?' inlined parameters	1819
DateToSQL	Convert a date to a ISO-8601 string format for SQL '?' inlined parameters	1820
DateToSQL	Convert a date to a ISO-8601 string format for SQL '?' inlined parameters	1820
DeltaCompress	Compute difference of two binary buffers	1820
DeltaCompress	Compute difference of two binary buffers	1820
DeltaCompress	Compute difference of two binary buffers	1820
DeltaExtract	Apply the delta binary as computed by DeltaCompress()	1820
DeltaExtract	Low-level apply the delta binary as computed by DeltaCompress()	1820
DeltaExtractSize	Returns how many bytes a DeltaCompress() result will expand to	1820
DeltaExtractSize	Returns how many bytes a DeltaCompress() result will expand to	1820
EmojiFromDots	Conversion of github/Markdown :identifiers: into UTF-8 Emoji sequences	1821
EmojiFromDots	Low-level conversion of github/Markdown :identifiers: into UTF-8 Emoji sequences	1821
EmojiFromText	Recognize github/Markdown compatible text of Emojis	1821
EmojiParseDots	Low-level parser of github/Markdown compatible text of Emojis	1821
EmojiToDots	Conversion of UTF-8 Emoji sequences into github/Markdown :identifiers:	1821
EmojiToDots	Low-level conversion of UTF-8 Emoji sequences into github/Markdown :identifiers:	1821
EnumAllProcesses	A wrapper around EnumProcesses() PsAPI call	1821
EnumProcessName	A wrapper around QueryFullProcessImageNameW/GetModuleFileNameEx PsAPI call	1821
ExtractInlineParameters	This function will extract inlined :(1234): parameters into Types[]/Values[]	1821
FieldBitsToIndex	Convert a TSQLFieldBits set of bits into an array of integers	1821
FieldBitsToIndex	Convert a TSQLFieldBits set of bits into an array of integers	1821
FieldIndexToBits	Convert an array of field indexes into a TSQLFieldBits set of bits	1822
FieldIndexToBits	Convert an array of field indexes into a TSQLFieldBits set of bits	1822

Functions or procedures	Description	Page
FillZero	Fast initialize a TSQLFieldBits with 0	1822
FilterMatches	Apply the CSV-supplied glob patterns to an array of RawUTF8	1822
FixedWaitFor	Allow to fix TEvent.WaitFor() method for Kylix	1822
FixedWaitForever	Allow to fix TEvent.WaitFor(Event,INFINITE) method for Kylix	1822
GetDiskInfo	Retrieve low-level information about a given disk partition	1822
GetDiskPartitions	Retrieve low-level information about all mounted disk partitions of the system	1822
GetDiskPartitionsText	Retrieve low-level information about all mounted disk partitions as text	1822
GetMemoryInfo	Retrieve low-level information about current memory usage	1822
HtmlEscapeMarkdown	Escape some Markdown-marked text into HTML	1822
HtmlEscapeWiki	Escape some wiki-marked text into HTML	1823
InlineParameter	Returns a string value as inlined '(:"value"):' text	1823
InlineParameter	Returns a 64-bit value as inlined ':(1234):' text	1823
IPToCardinal	Convert an IPv4 'x.x.x.x' text into its 32-bit value	1823
IPToCardinal	Convert an IPv4 'x.x.x.x' text into its 32-bit value, 0 or localhost	1823
IPToCardinal	Convert an IPv4 'x.x.x.x' text into its 32-bit value	1823
IsEqual	Fast comparison of two TSQLFieldBits values	1823
IsMatch	Return TRUE if the supplied content matches a glob pattern	1823
IsMatchString	Return TRUE if the supplied content matches a glob pattern, using VCL strings	1823
Iso8601ToSQL	Convert a Iso8601 encoded string into a ISO-8601 string format for SQL '?' inlined parameters	1824
IsValidEmail	Return TRUE if the supplied content is a valid email address	1824
IsValidIP4Address	Return TRUE if the supplied content is a valid IP v4 address	1824
IsValidUTF8	Returns TRUE if the supplied buffer has valid UTF-8 encoding	1824
IsValidUTF8	Returns TRUE if the supplied buffer has valid UTF-8 encoding	1824
IsValidUTF8	Returns TRUE if the supplied buffer has valid UTF-8 encoding	1824
IsZero	Returns TRUE if no bit inside this TSQLFieldBits is set	1824
MatchAdd	Add one TMach if not already registered in the Several[] dynamic array	1824
MatchAny	Returns TRUE if Match=nil or if any Match[].Match(Text) is TRUE	1824

Functions or procedures	Description	Page
MatchExists	Search if one TMach is already registered in the Several[] dynamic array	1824
NullableBoolean	Creates a nullable Boolean value from a supplied constant	1824
NullableBooleanIsEmptyOrNull	Same as VarIsEmpty(V) or VarIsEmpty(V), but faster	1824
NullableBooleanToValue	Check if a TNullableBoolean is null, or return its value	1825
NullableBooleanToValue	Check if a TNullableBoolean is null, or return its value	1825
NullableCurrency	Creates a nullable Currency value from a supplied constant	1825
NullableCurrencyIsEmptyOrNull	Same as VarIsEmpty(V) or VarIsEmpty(V), but faster	1825
NullableCurrencyToValue	Check if a TNullableCurrency is null, or return its value	1825
NullableCurrencyToValue	Check if a TNullableCurrency is null, or return its value	1825
NullableDateTime	Creates a nullable TDateTime value from a supplied constant	1825
NullableDateTimeIsEmptyOrNull	Same as VarIsEmpty(V) or VarIsEmpty(V), but faster	1825
NullableDateTimeToValue	Check if a TNullableDateTime is null, or return its value	1825
NullableDateTimeToValue	Check if a TNullableDateTime is null, or return its value	1825
NullableFloat	Creates a nullable floating-point value from a supplied constant	1825
NullableFloatIsEmptyOrNull	Same as VarIsEmpty(V) or VarIsEmpty(V), but faster	1826
NullableFloatToValue	Check if a TNullableFloat is null, or return its value	1826
NullableFloatToValue	Check if a TNullableFloat is null, or return its value	1826
NullableInteger	Creates a nullable integer value from a supplied constant	1826
NullableIntegerIsEmptyOrNull	Same as VarIsEmpty(V) or VarIsEmpty(V), but faster	1826
NullableIntegerToValue	Check if a TNullableInteger is null, or return its value	1826
NullableIntegerToValue	Check if a TNullableInteger is null, or return its value	1826
NullableTimeLog	Creates a nullable TTimeLog value from a supplied constant	1826
NullableTimeLogIsEmptyOrNull	Same as VarIsEmpty(V) or VarIsEmpty(V), but faster	1826

Functions or procedures	Description	Page
NullableTimeLogToValue	Check if a TNullableTimeLog is null, or return its value	1826
NullableTimeLogToValue	Check if a TNullableTimeLog is null, or return its value	1826
NullableUTF8Text	Creates a nullable UTF-8 encoded text value from a supplied constant	1827
NullableUTF8TextIsEmptyOrNull	Same as VarIsEmpty(V) or VarIsNullOrEmpty(V), but faster	1827
NullableUTF8TextToValue	Check if a TNullableUTF8Text is null, or return its value	1827
NullableUTF8TextToValue	Check if a TNullableUTF8Text is null, or return its value	1827
SearchFieldIndex	Search a field index in an array of field indexes	1827
SetMatches	Fill the Match[0..MatchMax] static array with all glob patterns supplied as CSV	1827
SetMatches	Fill the Match[] dynamic array with all glob patterns supplied as CSV	1827
SoundExAnsi	Retrieve the Soundex value of a text word, from Ansi buffer	1827
SoundExAnsi	Retrieve the Soundex value of a text word, from Ansi buffer	1827
SoundExUTF8	Retrieve the Soundex value of a text word, from UTF-8 buffer	1828
SQLParamContent	Guess the content type of an UTF-8 SQL value, in :(...): format	1828
SQLToDateTime	Decode a SQL '?' inlined parameter (i.e. with JSON_SQLDATE_MAGIC prefix)	1828
SQLVarLength	Returns the stored size of a TSQLVar database value	1828
StringToConsole	Direct conversion of a VCL string into a console OEM-encoded String	1828
SynTableVariantVarType	Initialize TSynTableVariantType if needed, and return the corresponding VType	1828
SystemInfoJson	Returns a JSON object containing basic information about the computer	1828
TextBackground	Change the console text background color	1828
TextColor	Change the console text writing color	1829
TextToSQLDBFieldType	Guess the correct TSQLDBFieldType from the UTF-8 representation of a value	1829
TimeLogToSQL	Convert a TTimeLog value into a ISO-8601 string format for SQL '?' inlined parameters	1829
ToSBFStr	Convert any AnsiString content into our SBF compact binary format storage	1829

Functions or procedures	Description	Page
Utf8ToConsole	Direct conversion of a UTF-8 encoded string into a console OEM-encoded String	1829
VariantToSQLVar	Convert any Variant into a database value	1829
VariantTypeToSQLDBFieldType	Guess the correct TSQLDBFieldType from a variant value	1829
VariantVTypeToSQLDBFieldType	Guess the correct TSQLDBFieldType from a variant type	1829
ZeroCompress	RLE compression of a memory buffer containing mostly zeros	1829
ZeroCompressXor	RLE compression of XORed memory buffers resulting in mostly zeros	1830
ZeroDecompress	RLE uncompression of a memory buffer containing mostly zeros	1830
ZeroDecompressOr	RLE uncompression and ORing of a memory buffer containing mostly zeros	1830

function AddFieldIndex(**var** Indexes: TSQLFieldIndexDynArray; Field: integer): integer;

Add a field index to an array of field indexes

- returns the index in Indexes[] of the newly appended Field value

procedure AddHtmlEscapeMarkdown(W: TTextWriter; P: PUTF8Char; esc: TTextWriterHTMLEscape=[heEmojiToUTF8]);

Convert minimal Markdown text into proper HTML

- see <https://enterprise.github.com/downloads/en/markdown-cheatsheet.pdf>

- convert all #13#10 into <p>...</p>, *.* into ..., **..** into ..., `...` into <code>...</code>, backslash spaces \\ * _ and so on, [title](http://...) and detect plain http:// as

- create unordered lists from trailing * + - chars, blockquotes from trailing > char, and code line from 4 initial spaces

- as with default Markdown, won't escape HTML special chars (i.e. you can write plain HTML in the supplied text) unless esc is set otherwise

- only inline-style links and images are supported yet (not reference-style); tables aren't supported either

procedure AddHtmlEscapeWiki(W: TTextWriter; P: PUTF8Char; esc: TTextWriterHTMLEscape=[heHtmlEscape,heEmojiToUTF8]);

Convert some wiki-like text into proper HTML

- convert all #13#10 into <p>...</p>, *.* into ..., +..+ into ..., `..` into <code>...</code>, and http://... as

- escape any HTML special chars, and Emoji tags as specified with esc

```
function CompareOperator(FieldType: TSynTableFieldType; SBF, SBFEnd: PUTF8Char;  
Value: Int64; Oper: TCompareOperator): boolean; overload;
```

Low-level integer comparison according to a specified operator

- SBF must point to the values encoded in our SBF compact binary format
- Value must contain the plain integer value
- Value can be a Currency accessed via a PInt64
- will work only for tftBoolean, tftUInt8, tftUInt16, tftUInt24, tftInt32, tftInt64 and tftCurrency field types
- will handle only soEqualTo...soGreaterThanOrEqualTo operators
- if SBFEnd is not nil, it will test for all values until SBF>=SBFEnd (can be used for tftArray)
- returns true if both values match, or false otherwise

```
function CompareOperator(SBF, SBFEnd: PUTF8Char; Value: double; Oper:  
TCompareOperator): boolean; overload;
```

Low-level floating-point comparison according to a specified operator

- SBF must point to the values encoded in our SBF compact binary format
- Value must contain the plain floating-point value
- will work only for tftDouble field type
- will handle only soEqualTo...soGreaterThanOrEqualTo operators
- if SBFEnd is not nil, it will test for all values until SBF>=SBFEnd (can be used for tftArray)
- returns true if both values match, or false otherwise

```
function CompareOperator(FieldType: TSynTableFieldType; SBF, SBFEnd: PUTF8Char;  
Value: PUTF8Char; ValueLen: integer; Oper: TCompareOperator; CaseSensitive: boolean):  
boolean; overload;
```

Low-level text comparison according to a specified operator

- SBF must point to the values encoded in our SBF compact binary format
- Value must contain the plain text value, in the same encoding (either WinAnsi either UTF-8, as FieldType defined for the SBF value)
- will work only for tftWinAnsi and tftUTF8 field types
- will handle all kind of operators - including soBeginWith, soContains and soSoundsLike* - but soSoundsLike* won't make use of the CaseSensitive parameter
- for soSoundsLikeEnglish, soSoundsLikeFrench and soSoundsLikeSpanish operators, Value is not a real PUTF8Char but a prepared PSynSoundEx
- if SBFEnd is not nil, it will test for all values until SBF>=SBFEnd (can be used for tftArray)
- returns true if both values match, or false otherwise

```
function ConsoleKeyPressed(ExpectedKey: Word): Boolean;
```

Low-level access to the keyboard state of a given key

```
function ConsoleReadBody: RawByteString;
```

Read all available content from stdin

- could be used to retrieve some file piped to the command line
- the content is not converted, so will follow the encoding used for storage

procedure ConsoleShowFatalException(E: Exception; WaitForEnterKey: boolean=true);

Could be used in the main program block of a console application to handle unexpected fatal exceptions

- typical use may be:

```
begin
  try
    ... // main console process
  except
    on E: Exception do
      ConsoleShowFatalException(E);
  end;
end.
```

procedure ConsoleWaitForEnterKey;

Will wait for the ENTER key to be pressed, processing Synchronize() pending notifications, and the internal Windows Message loop (on this OS)

- to be used e.g. for proper work of console applications with interface-based service implemented as optExecInMainThread

procedure ConsoleWrite(const Fmt: RawUTF8; const Args: array of const; Color: TConsoleColor=ccLightGray; NoLineFeed: boolean=false); overload;

Write some text to the console using a given color

procedure ConsoleWrite(const Text: RawUTF8; Color: TConsoleColor=ccLightGray; NoLineFeed: boolean=false; NoColor: boolean=false); overload;

Write some text to the console using a given color

function DateTimeToSQL(DT: TDateTime; WithMS: boolean=false): RawUTF8;

Convert a date/time to a ISO-8601 string format for SQL '?' inlined parameters

- if DT=0, returns ''
- if DT contains only a date, returns the date encoded as '\uFFFF1YYYY-MM-DD'
- if DT contains only a time, returns the time encoded as '\uFFFF1Thh:mm:ss'
- otherwise, returns the ISO-8601 date and time encoded as '\uFFFF1YYYY-MM-DDThh:mm:ss' (JSON_SQLDATE_MAGIC will be used as prefix to create '\uFFFF1...' pattern)
- if WithMS is TRUE, will append '.sss' for milliseconds resolution
- to be used e.g. as in:
aRec.CreateAndFillPrepare(Client, 'Datum<=?', [DateTimeToSQL(Now)]);
- see TimeLogToSQL() if you are using TTimeLog/TModTime/TCreateTime values

function DateToSQL(Date: TDateTime): RawUTF8; overload;

Convert a date to a ISO-8601 string format for SQL '?' inlined parameters

- will return the date encoded as '\uFFFF1YYYY-MM-DD' - therefore '(:'\uFFFF12012-05-04'):' pattern will be recognized as a sftDateTime inline parameter in SQLParamContent() / ExtractInlineParameters() functions (JSON_SQLDATE_MAGIC will be used as prefix to create '\uFFFF1...' pattern)
- to be used e.g. as in:
aRec.CreateAndFillPrepare(Client, 'Datum=?', [DateToSQL(EncodeDate(2012,5,4))]);

function DateToSQL(Year,Month,Day: cardinal): RawUTF8; overload;

Convert a date to a ISO-8601 string format for SQL '?' inlined parameters

- will return the date encoded as '\uFFFF1YYYY-MM-DD' - therefore '("\uFFFF12012-05-04"):' pattern will be recognized as a sftDateTime inline parameter in SQLParamContent() / ExtractInlineParameters() functions (JSON_SQLDATE_MAGIC will be used as prefix to create '\uFFFF1...' pattern)
- to be used e.g. as in:
 aRec.CreateAndFillPrepare(Client,'Datum=?',[DateToSQL(2012,5,4)]);

function DeltaCompress(New, Old: PAnsiChar; NewSize, OldSize: integer; Level: integer=DELTA_LEVEL_FAST; BufSize: integer=DELTA_BUF_DEFAULT): RawByteString; overload;

Compute difference of two binary buffers

- returns '=' for equal buffers, or an optimized binary delta
- DeltaExtract() could be used later on to compute New from Old

function DeltaCompress(New, Old: PAnsiChar; NewSize, OldSize: integer; **out** Delta: PAnsiChar; Level: integer=DELTA_LEVEL_FAST; BufSize: integer=DELTA_BUF_DEFAULT): integer; overload;

Compute difference of two binary buffers

- returns '=' for equal buffers, or an optimized binary delta
- DeltaExtract() could be used later on to compute New from Old + Delta
- caller should call Freemem(Delta) once finished with the output buffer

function DeltaCompress(**const** New, Old: RawByteString; Level: integer=DELTA_LEVEL_FAST; BufSize: integer=DELTA_BUF_DEFAULT): RawByteString; overload;

Compute difference of two binary buffers

- returns '=' for equal buffers, or an optimized binary delta
- DeltaExtract() could be used later on to compute New from Old + Delta

function DeltaExtract(Delta,Old,New: PAnsiChar): TDeltaError; overload;

Low-level apply the delta binary as computed by DeltaCompress()

- New should already be allocated with DeltaExtractSize(Delta) bytes
- as such, expect Delta, Old and New to be <> nil, and Delta <> '='
- return dsSuccess if was uncompressed to aOutUpd as expected

function DeltaExtract(**const** Delta,Old: RawByteString; **out** New: RawByteString): TDeltaError; overload;

Apply the delta binary as computed by DeltaCompress()

- decompression don't use any RAM, will perform crc32c check, and is very fast
- return dsSuccess if was uncompressed to aOutUpd as expected

function DeltaExtractSize(Delta: PAnsiChar): integer; overload;

Returns how many bytes a DeltaCompress() result will expand to

function DeltaExtractSize(**const** Delta: RawByteString): integer; overload;

Returns how many bytes a DeltaCompress() result will expand to

procedure EmojiFromDots(P: PUTF8Char; W: TTextWriter); overload;

Low-level conversion of github/Markdown :identifiers: into UTF-8 Emoji sequences

function EmojiFromDots(const text: RawUTF8): RawUTF8; overload;

Conversion of github/Markdown :identifiers: into UTF-8 Emoji sequences

function EmojiFromText(P: PUTF8Char; len: PtrInt): TEmoji;

Recognize github/Markdown compatible text of Emojis

- for instance 'sunglasses' text buffer will return eSunglasses
- returns eNone if no case-insensitive match was found

function EmojiParseDots(var P: PUTF8Char; W: TTextWriter=nil): TEmoji;

Low-level parser of github/Markdown compatible text of Emojis

- supplied P^ should point to ':'
- will append the recognized UTF-8 Emoji if P contains e.g. :joy: or :)
- will append ':' if no Emoji text is recognized, and return eNone
- will try both EMOJI_AFTERDOTS[] and EMOJI_RTTL[] reference set
- if W is nil, won't append anything, but just return the recognized TEmoji

procedure EmojiToDots(P: PUTF8Char; W: TTextWriter); overload;

Low-level conversion of UTF-8 Emoji sequences into github/Markdown :identifiers:

function EmojiToDots(const text: RawUTF8): RawUTF8; overload;

Conversion of UTF-8 Emoji sequences into github/Markdown :identifiers:

function EnumAllProcesses(out Count: Cardinal): TCardinalDynArray;

A wrapper around EnumProcesses() PsAPI call

function EnumProcessName(PID: Cardinal): RawUTF8;

A wrapper around QueryFullProcessImageNameW/GetModuleFileNameEx PsAPI call

function ExtractInlineParameters(const SQL: RawUTF8; var Types: TSQLParamTypeDynArray; var Values: TRawUTF8DynArray; var maxParam: integer; var Nulls: TSQLFieldBits): RawUTF8;

This function will extract inlined :(1234): parameters into Types[]/Values[]

- will return the generic SQL statement with ? place holders for inlined parameters and setting Values with SQLParamContent() decoded content
- will set maxParam=0 in case of no inlined parameters
- recognized types are sptInteger, sptFloat, sptDateTime ('\uFFFF1...'), sptUTF8Text and sptBlob ('\uFFFF0...')
- sptUnknown is returned on invalid content

procedure FieldBitsToIndex(const Fields: TSQLFieldBits; var Index: TSQLFieldIndexDynArray; MaxLength: integer=MAX_SQLFIELDS; IndexStart: integer=0); overload;

Convert a TSQLFieldBits set of bits into an array of integers

function FieldBitsToIndex(const Fields: TSQLFieldBits; MaxLength: integer=MAX_SQLFIELDS): TSQLFieldIndexDynArray; overload;

Convert a TSQLFieldBits set of bits into an array of integers

function FieldIndexToBits(const Index: TSQLFieldIndexDynArray): TSQLFieldBits; overload;

Convert an array of field indexes into a TSQLFieldBits set of bits

procedure FieldIndexToBits(**const** Index: TSQLFieldIndexDynArray; **var** Fields: TSQLFieldBits); overload;

Convert an array of field indexes into a TSQLFieldBits set of bits

procedure FillZero(**var** Fields: TSQLFieldBits); overload;

Fast initialize a TSQLFieldBits with 0

- is optimized for 64, 128, 192 and 256 max bits count (i.e. MAX_SQLFIELDS)
- will work also with any other value

procedure FilterMatches(**const** CSVPattern: RawUTF8; CaseInsensitive: boolean; **var** Values: TRawUTF8DynArray);

Apply the CSV-supplied glob patterns to an array of RawUTF8

- any text not matching the pattern will be deleted from the array

function FixedWaitFor(Event: TEvent; Timeout: LongWord): TWaitResult;

Allow to fix TEvent.WaitFor() method for Kylix

- under Windows or with FPC, will call original TEvent.WaitFor() method

procedure FixedWaitForever(Event: TEvent);

Allow to fix TEvent.WaitFor(Event,INFINITE) method for Kylix

- under Windows or with FPC, will call original TEvent.WaitFor() method

function GetDiskInfo(**var** aDriveFolderOrFile: TFileName; **out** aAvailableBytes, aFreeBytes, aTotalBytes: QWord ; aVolumeName: PFileName = nil): boolean;

Retrieve low-level information about a given disk partition

- as used by TSynMonitorDisk and GetDiskPartitionsText()
- only under Windows the Quotas are applied separately to aAvailableBytes in respect to global aFreeBytes

function GetDiskPartitions: TDiskPartitions;

Retrieve low-level information about all mounted disk partitions of the system

- returned partitions array is sorted by "mounted" ascending order

function GetDiskPartitionsText(nocache: boolean=false; withfreespace: boolean=false; nospace: boolean=false): RawUTF8;

Retrieve low-level information about all mounted disk partitions as text

- returns e.g. under Linux '/' /dev/sda3 (19 GB), /boot /dev/sda2 (486.8 MB), /home /dev/sda4 (0.9 TB)' or under Windows 'C:\ System (115 GB), D:\ Data (99.3 GB)'
- uses internally a cache unless nocache is true
- includes the free space if withfreespace is true - e.g. '(80 GB / 115 GB)'

function GetMemoryInfo(**out** info: TMemoryInfo; withalloc: boolean): boolean;

Retrieve low-level information about current memory usage

- as used by TSynMonitorMemory
- under BSD, only memtotal/memfree/percent are properly returned
- allocreserved and allocused are set only if withalloc is TRUE

function HtmlEscapeMarkdown(**const** md: RawUTF8; esc: TTextWriterHTMLEscape=[heEmojiToUTF8]): RawUTF8;

Escape some Markdown-marked text into HTML

- just a wrapper around AddHtmlEscapeMarkdown() process

```
function HtmlEscapeWiki(const wiki: RawUTF8; esc:
TTextWriterHTMLEscape=[heHtmlEscape,heEmojiToUTF8]): RawUTF8;
```

Escape some wiki-marked text into HTML

- just a wrapper around AddHtmlEscapeWiki() process

```
function InlineParameter(ID: Int64): shortstring; overload;
```

Returns a 64-bit value as inlined '{(1234):' text

```
function InlineParameter(const value: RawUTF8): RawUTF8; overload;
```

Returns a string value as inlined '{"value"}:' text

```
function IPToCardinal(const aIP: RawUTF8; out aValue: cardinal): boolean; overload;
```

Convert an IPv4 'x.x.x.x' text into its 32-bit value

- returns TRUE if the text was a valid IPv4 text, unserialized as 32-bit aValue
- returns FALSE on parsing error, also setting aValue=0
- "" or '127.0.0.1' will also return false

```
function IPToCardinal(const aIP: RawUTF8): cardinal; overload;
```

Convert an IPv4 'x.x.x.x' text into its 32-bit value, 0 or localhost

- returns <> 0 value if the text was a valid IPv4 text, 0 on parsing error
- "" or '127.0.0.1' will also return 0

```
function IPToCardinal(P: PUTF8Char; out aValue: cardinal): boolean; overload;
```

Convert an IPv4 'x.x.x.x' text into its 32-bit value

- returns TRUE if the text was a valid IPv4 text, unserialized as 32-bit aValue
- returns FALSE on parsing error, also setting aValue=0
- "" or '127.0.0.1' will also return false

```
function IsEqual(const A,B: TSQLFieldBits): boolean; overload;
```

Fast comparison of two TSQLFieldBits values

- is optimized for 64, 128, 192 and 256 max bits count (i.e. MAX_SQLFIELDS)
- will work also with any other value

```
function IsMatch(const Pattern, Text: RawUTF8; CaseInsensitive: boolean=false):
boolean;
```

Return TRUE if the supplied content matches a glob pattern

- ? Matches any single characer
- * Matches any contiguous characters
- [abc] Matches a or b or c at that position
- [^abc] Matches anything but a or b or c at that position
- [!abc] Matches anything but a or b or c at that position
- [a-e] Matches a through e at that position
- [abcx-z] Matches a or b or c or x or y or or z, as does [a-cx-z]
- 'ma?ch.*' would match match.exe, mavch.dat, march.on, etc..
- 'this [e-n]s a [!zy]est' would match 'this is a test', but would not match 'this as a test' nor 'this is a zest'
- consider using TMatch or TMatches if you expect to reuse the pattern

```
function IsMatchString(const Pattern, Text: string; CaseInsensitive: boolean=false):
boolean;
```

Return TRUE if the supplied content matches a glob pattern, using VCL strings

- is a wrapper around IsMatch() with fast UTF-8 conversion

function Iso8601ToSQL(const S: RawByteString): RawUTF8;

Convert a Iso8601 encoded string into a ISO-8601 string format for SQL '?' inlined parameters
- follows the same pattern as DateToSQL or DateTimeToSQL functions, i.e. will return the date or time encoded as '\uFFFF1YYYY-MM-DDThh:mm:ss' - therefore '(:("\uFFFF12012-05-04T20:12:13")):' pattern will be recognized as a sftDateTime inline parameter in SQLParamContent() / ExtractInlineParameters() (JSON_SQLDATE_MAGIC will be used as prefix to create '\uFFFF1...' pattern)
- in practice, just append the JSON_SQLDATE_MAGIC prefix to the supplied text

function IsValidEmail(P: PUTF8Char): boolean;

Return TRUE if the supplied content is a valid email address
- follows RFC 822, to validate local-part@domain email format

function IsValidIPAddress(P: PUTF8Char): boolean;

Return TRUE if the supplied content is a valid IP v4 address

function IsValidUTF8(const source: RawUTF8): Boolean; overload;

Returns TRUE if the supplied buffer has valid UTF-8 encoding
- will also refuse #0 characters within the buffer
- on Haswell AVX2 Intel/AMD CPUs, will use very efficient ASM

function IsValidUTF8(source: PUTF8Char; sourcelen: PtrInt): Boolean; overload;

Returns TRUE if the supplied buffer has valid UTF-8 encoding
- will also refuse #0 characters within the buffer
- on Haswell AVX2 Intel/AMD CPUs, will use very efficient ASM

function IsValidUTF8(source: PUTF8Char): Boolean; overload;

Returns TRUE if the supplied buffer has valid UTF-8 encoding
- will stop when the buffer contains #0
- on Haswell AVX2 Intel/AMD CPUs, will use very efficient ASM

function IsZero(const Fields: TSQLFieldBits): boolean; overload;

Returns TRUE if no bit inside this TSQLFieldBits is set
- is optimized for 64, 128, 192 and 256 max bits count (i.e. MAX_SQLFIELDS)
- will work also with any other value

function MatchAdd(const One: TMatch; var Several: TMatchDynArray): boolean;

Add one TMach if not already registered in the Several[] dynamic array

function MatchAny(const Match: TMatchDynArray; const Text: RawUTF8): boolean;

Returns TRUE if Match=nil or if any Match[].Match(Text) is TRUE

function MatchExists(const One: TMatch; const Several: TMatchDynArray): boolean;

Search if one TMach is already registered in the Several[] dynamic array

function NullableBoolean(Value: boolean): TNullableBoolean;

Creates a nullable Boolean value from a supplied constant
- FPC does not allow direct assignment to a TNullableBoolean = type variant variable: use this function to circumvent it

function NullableBooleanIsEmptyOrNull(const V: TNullableBoolean): Boolean;

Same as VarIsEmpty(V) or VarIsNull(V), but faster
- FPC VarIsNull() seems buggy with varByRef variants, and does not allow direct transtyping from a TNullableBoolean = type variant variable: use this function to circumvent those limitations

function NullableBooleanToValue(**const** V: TNullableBoolean): Boolean; overload;

Check if a TNullableBoolean is null, or return its value

- returns false if V is null or empty, or the stored Boolean value

function NullableBooleanToValue(**const** V: TNullableBoolean; **out** Value: Boolean): Boolean; overload;

Check if a TNullableBoolean is null, or return its value

- returns FALSE if V is null or empty, or TRUE and set the Boolean value

function NullableCurrency(**const** Value: currency): TNullableCurrency;

Creates a nullable Currency value from a supplied constant

- FPC does not allow direct assignment to a TNullableCurrency = type variant variable: use this function to circumvent it

function NullableCurrencyIsEmptyOrNull(**const** V: TNullableCurrency): Boolean;

Same as VarIsEmpty(V) or VarIsEmpty(V), but faster

- FPC VarIsNull() seems buggy with varByRef variants, and does not allow direct transtyping from a TNullableCurrency = type variant variable: use this function to circumvent those limitations

function NullableCurrencyToValue(**const** V: TNullableCurrency): currency; overload;

Check if a TNullableCurrency is null, or return its value

- returns 0 if V is null or empty, or the stored Currency value

function NullableCurrencyToValue(**const** V: TNullableCurrency; **out** Value: currency): boolean; overload;

Check if a TNullableCurrency is null, or return its value

- returns FALSE if V is null or empty, or TRUE and set the Currency value

function NullableDateTime(**const** Value: TDateTime): TNullableDateTime;

Creates a nullable TDateTime value from a supplied constant

- FPC does not allow direct assignment to a TNullableDateTime = type variant variable: use this function to circumvent it

function NullableDateTimeIsEmptyOrNull(**const** V: TNullableDateTime): Boolean;

Same as VarIsEmpty(V) or VarIsEmpty(V), but faster

- FPC VarIsNull() seems buggy with varByRef variants, and does not allow direct transtyping from a TNullableDateTime = type variant variable: use this function to circumvent those limitations

function NullableDateTimeToValue(**const** V: TNullableDateTime; **out** Value: TDateTime): boolean; overload;

Check if a TNullableDateTime is null, or return its value

- returns FALSE if V is null or empty, or TRUE and set the DateTime value

function NullableDateTimeToValue(**const** V: TNullableDateTime): TDateTime; overload;

Check if a TNullableDateTime is null, or return its value

- returns 0 if V is null or empty, or the stored DateTime value

function NullableFloat(**const** Value: double): TNullableFloat;

Creates a nullable floating-point value from a supplied constant

- FPC does not allow direct assignment to a TNullableFloat = type variant variable: use this function to circumvent it

function NullableFloatIsEmptyOrNull(**const** V: TNullableFloat): Boolean;

Same as VarIsNullOrEmpty(V) or VarIsNullOrEmpty(V), but faster

- FPC VarIsNull() seems buggy with varByRef variants, and does not allow direct transtyping from a TNullableFloat = type variant variable: use this function to circumvent those limitations

function NullableFloatToValue(**const** V: TNullableFloat): double; overload;

Check if a TNullableFloat is null, or return its value

- returns 0 if V is null or empty, or the stored Float value

function NullableFloatToValue(**const** V: TNullableFloat; **out** Value: double): boolean; overload;

Check if a TNullableFloat is null, or return its value

- returns FALSE if V is null or empty, or TRUE and set the Float value

function NullableInteger(**const** Value: Int64): TNullableInteger;

Creates a nullable integer value from a supplied constant

- FPC does not allow direct assignment to a TNullableInteger = type variant variable: use this function to circumvent it

function NullableIntegerIsEmptyOrNull(**const** V: TNullableInteger): Boolean;

Same as VarIsNullOrEmpty(V) or VarIsNullOrEmpty(V), but faster

- FPC VarIsNull() seems buggy with varByRef variants, and does not allow direct transtyping from a TNullableInteger = type variant variable: use this function to circumvent those limitations

function NullableIntegerToValue(**const** V: TNullableInteger; **out** Value: Int64): Boolean; overload;

Check if a TNullableInteger is null, or return its value

- returns FALSE if V is null or empty, or TRUE and set the Integer value

function NullableIntegerToValue(**const** V: TNullableInteger): Int64; overload;

Check if a TNullableInteger is null, or return its value

- returns 0 if V is null or empty, or the stored Integer value

function NullableTimeLog(**const** Value: TTimeLog): TNullableTimeLog;

Creates a nullable TTimeLog value from a supplied constant

- FPC does not allow direct assignment to a TNullableTimeLog = type variant variable: use this function to circumvent it

function NullableTimeLogIsEmptyOrNull(**const** V: TNullableTimeLog): Boolean;

Same as VarIsNullOrEmpty(V) or VarIsNullOrEmpty(V), but faster

- FPC VarIsNull() seems buggy with varByRef variants, and does not allow direct transtyping from a TNullableTimeLog = type variant variable: use this function to circumvent those limitations

function NullableTimeLogToValue(**const** V: TNullableTimeLog): TTimeLog; overload;

Check if a TNullableTimeLog is null, or return its value

- returns 0 if V is null or empty, or the stored TimeLog value

function NullableTimeLogToValue(**const** V: TNullableTimeLog; **out** Value: TTimeLog): boolean; overload;

Check if a TNullableTimeLog is null, or return its value

- returns FALSE if V is null or empty, or TRUE and set the TimeLog value

function NullableUTF8Text(const Value: RawUTF8): TNullableUTF8Text;

Creates a nullable UTF-8 encoded text value from a supplied constant

- FPC does not allow direct assignment to a TNullableUTF8 = type variant variable: use this function to circumvent it

function NullableUTF8TextIsEmptyOrNull(const V: TNullableUTF8Text): Boolean;

Same as VarIsEmpty(V) or VarIsEmpty(V), but faster

- FPC VarIsNull() seems buggy with varByRef variants, and does not allow direct transtyping from a TNullableUTF8Text = type variant variable: use this function to circumvent those limitations

function NullableUTF8TextToValue(const V: TNullableUTF8Text): RawUTF8; overload;

Check if a TNullableUTF8Text is null, or return its value

- returns "" if V is null or empty, or the stored UTF8-encoded text value

function NullableUTF8TextToValue(const V: TNullableUTF8Text; out Value: RawUTF8): boolean; overload;

Check if a TNullableUTF8Text is null, or return its value

- returns FALSE if V is null or empty, or TRUE and set the UTF8Text value

function SearchFieldIndex(var Indexes: TSQLFieldIndexDynArray; Field: integer): integer;

Search a field index in an array of field indexes

- returns the index in Indexes[] of the given Field value, -1 if not found

function SetMatches(const CSVPattern: RawUTF8; CaseInsensitive: boolean; out Match: TMatchDynArray): integer; overload;

Fill the Match[] dynamic array with all glob patterns supplied as CSV

- returns how many patterns have been set in Match[]

- note that the CSVPattern instance should remain in memory, since it will be pointed to by the Match[].Pattern private field

function SetMatches(CSVPattern: PUTF8Char; CaseInsensitive: boolean; Match: PMatch; MatchMax: integer): integer; overload;

Fill the Match[0..MatchMax] static array with all glob patterns supplied as CSV

- note that the CSVPattern instance should remain in memory, since it will be pointed to by the Match[].Pattern private field

function SoundExAnsi(A: PAnsiChar; next: PPAnsiChar=nil; Lang: TSynSoundExPronunciation=sndxEnglish): cardinal; overload;

Retrieve the Soundex value of a text word, from Ansi buffer

- Return the soundex value as an easy to use cardinal value, 0 if the incoming string contains no valid word

- if next is defined, its value is set to the end of the encoded word (so that you can call again this function to encode a full sentence)

function SoundExAnsi(A: PAnsiChar; next: PPAnsiChar; Lang: PSoundExValues): cardinal; overload;

Retrieve the Soundex value of a text word, from Ansi buffer

- Return the soundex value as an easy to use cardinal value, 0 if the incoming string contains no valid word

- if next is defined, its value is set to the end of the encoded word (so that you can call again this function to encode a full sentence)

function SoundExUTF8(U: PUTF8Char; next: PPUTF8Char=nil; Lang: TSynSoundExPronunciation=sndxEnglish): cardinal;

Retrieve the Soundex value of a text word, from UTF-8 buffer

- Return the soundex value as an easy to use cardinal value, 0 if the incoming string contains no valid word
- if next is defined, its value is set to the end of the encoded word (so that you can call again this function to encode a full sentence)
- very fast: all UTF-8 decoding is handled on the fly

function SQLParamContent(P: PUTF8Char; out ParamType: TSQLParamType; out ParamValue: RawUTF8; out wasNull: boolean): PUTF8Char;

Guess the content type of an UTF-8 SQL value, in :(...): format

- will be used e.g. by ExtractInlineParameters() to un-inline a SQL statement
- sftInteger is returned for an INTEGER value, e.g. :(1234):
- sftFloat is returned for any floating point value (i.e. some digits separated by a '.' character), e.g. :(12.34): or :(12E-34):
- sftUTF8Text is returned for :("text"): or :('text'):, with double quoting inside the value
- sftBlob will be recognized from the ':("\uFFFF0base64encodedbinary"):' pattern, and return raw binary (for direct blob parameter assignment)
- sftDateTime will be recognized from ':(\uFFF1"2012-05-04"):' pattern, i.e. JSON_SQLDATE_MAGIC-prefixed string as returned by DateToSQL() or DateTimeToSQL() functions
- sftUnknown is returned on invalid content, or if wasNull is set to TRUE
- if ParamValue is not nil, the pointing RawUTF8 string is set with the value inside :(...): without double quoting in case of sftUTF8Text
- wasNull is set to TRUE if P was ':(null):' and ParamType is sftUnknwown

function SQLToDateTime(const ParamValueWithMagic: RawUTF8): TDateTime;

Decode a SQL '?' inlined parameter (i.e. with JSON_SQLDATE_MAGIC prefix)

- as generated by DateToSQL/DateTimeToSQL/TimeLogToSQL functions

function SQLVarLength(const Value: TSQLVar): integer;

Returns the stored size of a TSQLVar database value

- only returns VBlobLen / StrLen(VText) size, 0 otherwise

function StringToConsole(const S: string): RawByteString;

Direct conversion of a VCL string into a console OEM-encoded String

- under Windows, will use the CP_OEMCP encoding
- under Linux, will expect the console to be defined with UTF-8 encoding

function SynTableVariantVarType: cardinal;

Initialize TSynTableVariantType if needed, and return the corresponding VType

function SystemInfoJson: RawUTF8;

Returns a JSON object containing basic information about the computer

- including Host, User, CPU, OS, freemem, freedisk...

procedure TextBackground(Color: TConsoleColor);

Change the console text background color

procedure TextColor(Color: TConsoleColor);

Change the console text writing color

- you should call this procedure to initialize StdOut global variable, if you manually initialized the Windows console, e.g. via the following code:

```
AllocConsole;  
TextColor(ccLightGray); // initialize internal console context
```

function TextToSQLDBFieldType(json: PUTF8Char): TSQLDBFieldType;

Guess the correct TSQLDBFieldType from the UTF-8 representation of a value

function TimeLogToSQL(const Timestamp: TTimeLog): RawUTF8;

Convert a TTimeLog value into a ISO-8601 string format for SQL '?' inlined parameters

- handle TTimeLog bit-encoded Int64 format

- follows the same pattern as DateToSQL or DateTimeToSQL functions, i.e. will return the date or time encoded as '\uFFFF1YYYY-MM-DDThh:mm:ss' - therefore '("\uFFFF12012-05-04T20:12:13"):' pattern will be recognized as a sftDateTime inline parameter in SQLParamContent() / ExtractInlineParameters() (JSON_SQLDATE_MAGIC will be used as prefix to create '\uFFFF1...' pattern)

- to be used e.g. as in:

```
aRec.CreateAndFillPrepare(Client, 'Datum<=?', [TimeLogToSQL(TimeLogNow)]);
```

procedure ToSBFStr(const Value: RawByteString; out Result: TSBFString);

Convert any AnsiString content into our SBF compact binary format storage

function Utf8ToConsole(const S: RawUTF8): RawByteString;

Direct conversion of a UTF-8 encoded string into a console OEM-encoded String

- under Windows, will use the CP_OEMCP encoding

- under Linux, will expect the console to be defined with UTF-8 encoding

procedure VariantToSQLVar(const Input: variant; var temp: RawByteString; var Output: TSQLVar);

Convert any Variant into a database value

- ftBlob kind won't be handled by this function

- complex variant types would be converted into ftUTF8 JSON object/array

function VariantTypeToSQLDBFieldType(const V: Variant): TSQLDBFieldType;

Guess the correct TSQLDBFieldType from a variant value

function VariantVTypeToSQLDBFieldType(VType: cardinal): TSQLDBFieldType;

Guess the correct TSQLDBFieldType from a variant type

procedure ZeroCompress(P: PAnsiChar; Len: integer; Dest: TFileBufferWriter);

RLE compression of a memory buffer containing mostly zeros

- will store the number of consecutive zeros instead of plain zero bytes

- used for spare bit sets, e.g. TSynBloomFilter serialization

- will also compute the crc32c of the supplied content

- use ZeroDecompress() to expand the compressed result

- resulting content would be at most 14 bytes bigger than the input

- you may use this function before SynLZ compression

procedure ZeroCompressXor(New,Old: PAnsiChar; Len: cardinal; Dest: TFileBufferWriter);

RLE compression of XORed memory buffers resulting in mostly zeros

- will perform ZeroCompress(Dest^ := New^ xor Old^) without any temporary memory allocation
- is used e.g. by TSynBloomFilterDiff.SaveToDiff() in incremental mode
- will also compute the crc32c of the supplied content

procedure ZeroDecompress(P: PByte; Len: integer; **out** Dest: RawByteString);

RLE uncompression of a memory buffer containing mostly zeros

- returns Dest="" if P^ is not a valid ZeroCompress() function result
- used for spare bit sets, e.g. TSynBloomFilter serialization
- will also check the crc32c of the supplied content

function ZeroDecompressOr(P,Dest: PAnsiChar; Len, DestLen: integer): boolean;

RLE uncompression and ORing of a memory buffer containing mostly zeros

- will perform Dest^ := Dest^ or ZeroDecompress(P^) without any temporary memory allocation
- is used e.g. by TSynBloomFilterDiff.LoadFromDiff() in incremental mode
- returns false if P^ is not a valid ZeroCompress/ZeroCompressXor() result
- will also check the crc32c of the supplied content

Variables implemented in the SynTable unit

EMOJI_AFTERDOTS: array['('..' '|'] of TEmoji;

To recognize simple :) :(| :/ :D :o :p :s characters as smileys

EMOJI_RTTI: PShortString;

Low-level access to TEmoji RTTI - used when inlining EmojiFromText()

EMOJI_TAG: array[TEmoji] of RawUTF8;

Github/Markdown compatible tag of Emojis, including trailing and ending :

- e.g. ':grinning:' or ':person_with_pouting_face:'

EMOJI_TEXT: array[TEmoji] of RawUTF8;

Github/Markdown compatible text of Emojis

- e.g. 'grinning' or 'person_with_pouting_face'

EMOJI_UTF8: array[TEmoji] of RawUTF8;

The Unicode character matching a given Emoji, after UTF-8 encoding

NullableBooleanNull: TNullableBoolean **absolute** NullVarData;

A nullable boolean value containing null

NullableCurrencyNull: TNullableCurrency **absolute** NullVarData;

A nullable currency value containing null

NullableDateTimeNull: TNullableDateTime **absolute** NullVarData;

A nullable TDateTime value containing null

NullableFloatNull: TNullableFloat **absolute** NullVarData;

A nullable float value containing null

NullableIntegerNull: TNullableInteger **absolute** NullVarData;

A nullable integer value containing null

`NullableTimeLogNull: TNullableTimeLog absolute NullVarData;`

A nullable TTimeLog value containing null

`NullableUTF8TextNull: TNullableUTF8Text absolute NullVarData;`

A nullable UTF-8 encoded text value containing null

`StdOut: THandle;`

Low-level handle used for console writing

- may be overridden when console is redirected
- is initialized when TextColor() is called

`TSynPersistentWithPasswordUserCrypt: function(const Data,AppServer: RawByteString;
Encrypt: boolean): RawByteString;`

Function prototype to customize TSynPersistent class password storage

- is called when 'user1:base64pass1,user2:base64pass2' layout is found, and the current user logged on the system is user1 or user2
- you should not call this low-level method, but assign e.g. from SynCrypto:
`TSynPersistentWithPasswordUserCrypt := CryptDataForCurrentUser;`

27.41. SynTaskDialog.pas unit

Purpose: Implement TaskDialog window (native on Vista/Seven, emulated on XP)

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

SynTaskDialog class hierarchy

Objects implemented in the *SynTaskDialog* unit

Objects	Description	Page
TEmulatedTaskDialog	The actual form class used for emulation	1832
TSynButton	A generic Button to be used in the User Interface	1836
TTaskDialog	Implements a TaskDialog	1833
TTaskDialogEx	A wrapper around the TTaskDialog.Execute method	1835
TTaskDialogImplementation	Structure for low-level access to the task dialog implementation	1833

TEmulatedTaskDialog = class(TForm)

The actual form class used for emulation

Combo: TComboBox;

The Task Dialog selection list

Edit: TEdit;

The Task Dialog optional query editor

Element: array[tdeContent..tdeMainInstruction] of TLabel;

The labels corresponding to the Task Dialog main elements

Owner: PTaskDialog;

The Task Dialog structure which created the form

Verif: TCheckBox;

The Task Dialog optional checkbox

TTaskDialogImplementation = record

Structure for low-level access to the task dialog implementation

- points either to the HWND handle of the new TaskDialog API or to the emulation dialog

TTaskDialog = object(TObject)

Implements a TaskDialog

- will use the new TaskDialog API under Vista/Seven, and emulate it with pure Delphi code and standard themed VCL components under XP or 2K
- create a TTaskDialog object/record on the stack will initialize all its string parameters to "" (it's a SHAME that since Delphi 2009, objects are not initialized any more: we have to define this type as object before Delphi 2009, and as record starting with Delphi 2009)
- set the appropriate string parameters, then call Execute() with all additional parameters
- RadioRes/SelectionRes/VerifyChecked will be used to reflect the state after dialog execution
- here is a typical usage:

```
var Task: TTaskDialog;
begin
  Task.Inst := 'Saving application settings';
  Task.Content := 'This is the content';
  Task.Radios := 'Store settings in registry'#10'Store settings in XML file';
  Task.Verify := 'Do no ask for this setting next time';
  Task.VerifyChecked := true;
  Task.Footer := 'XML file is perhaps a better choice';
  Task.Execute([],0,[],tiQuestion,tfiInformation,mrRad1);
  ShowMessage(IntToStr(Task.RadioRes)); // mrRad1=Registry, mrRad2=XML
  if Task.VerifyChecked then
    ShowMessage(Task.Verify);
end;
```

Buttons: string;

A #13#10 or #10 separated list of custom buttons

- they will be identified with an ID number starting at 100 (so you may use mrBtn1, mrBtn2, mrBtn3... mrBtn9 constants)
- by default, the buttons will be created at the dialog bottom, just like the common buttons
- if tdfUseCommandLinks flag is set, the custom buttons will be created as big button in the middle of the dialog window; in this case, any '\n' will be converted as note text (shown with smaller text under native Vista/Seven TaskDialog, or as popup hint within Delphi emulation)
- see the AddButton() wrapper method for an easy access

Content: string;

The dialog's primary content content text

- any '\n' will be converted into a line feed

Dialog: TTaskDialogImplementation;

Low-level access to the task dialog implementation

Footer: string;

The footer content text

- any '\n' will be converted into a line feed

Info: string;

The expanded information content text

- any '\n' will be converted into a line feed
- the Delphi emulation will always show the Info content (there is no collapse/expand button)

InfoCollapse: string;

The button caption to be displayed when the information is expanded

- not used under XP: the Delphi emulation will always show the Info content

InfoExpanded: string;

The button caption to be displayed when the information is collapsed

- not used under XP: the Delphi emulation will always show the Info content

Inst: string;

The main instruction (first line on top of window)

- any '\n' will be converted into a line feed
- if left void, the text is taken from the current dialog icon kind

Query: string;

Some text to be edited

- if tdfQuery is in the flags, will contain the default query text
- if Selection is set, the

RadioRes: integer;

The selected radio item

- first is numeroted 0

Radios: string;

A #13#10 or #10 separated list of custom radio buttons

- they will be identified with an ID number starting at 200 (so you may use mrRad1, mrRad2, mrRad3... mrRad9 constants)
- aRadioDef parameter can be set to define the default selected value
- '\n' will be converted as note text (shown with smaller text under native Vista/Seven TaskDialog, or as popup hint within Delphi emulation)

Selection: string;

A #13#10 or #10 separated list of items to be selected

- if set, a Combo Box will be displayed to select
- if tdfQuery is in the flags, the combo box will be in edition mode, and the user will be able to edit the Query text or fill the field with one item of the selection
- this selection is not handled via the Vista/Seven TaskDialog, but with our Delphi emulation code (via a TComboBox)

SelectionRes: integer;

After execution, contains the selected item from the Selection list

Title: string;

The main title of the dialog window

- if left void, the title of the application main form is used

Verify: string;

The text of the bottom most optional checkbox

VerifyChecked: BOOL;

Reflect the the bottom most optional checkbox state

- if Verify is not "", should be set before execution
- after execution, will contain the final checkbox state

function Execute(aCommonButtons: TCommonButtons=[]; aButtonDef: integer=0; aFlags: TTaskDialogFlags=[]; aDialogIcon: TTaskDialogIcon=tiInformation; aFooterIcon: TTaskDialogFooterIcon=tfiWarning; aRadioDef: integer=0; aWidth: integer=0; aParent: HWND=0; aNonNative: boolean=false; aEmulateClassicStyle: boolean = false; aOnButtonClicked: TTaskDialogButtonClickedEvent=nil): integer;

Launch the TaskDialog form

- some common buttons can be set via aCommonButtons
- in emulation mode, aFlags will handle only tdfUseCommandLinks, tdfUseCommandLinksNoIcon, and tdfQuery options
- will return 0 on error, or the Button ID (e.g. mrOk for the OK button or mrBtn1/100 for the first custom button defined in Buttons string)
- if Buttons was defined, aButtonDef can set the selected Button ID
- if Radios was defined, aRadioDef can set the selected Radio ID
- aDialogIcon and aFooterIcon are used to specify the displayed icons
- aWidth can be used to force a custom form width (in pixels)
- aParent can be set to any HWND - by default, Application.DialogHandle
- if aNonNative is TRUE, the Delphi emulation code will always be used
- aEmulateClassicStyle can be set to enforce conformity with the non themed user interface - see @<https://synopse.info/forum/viewtopic.php?pid=2867#p2867>
- aOnButtonClicked can be set to a callback triggered when a button is clicked

procedure AddButton(const ACaption: string; const ACommandLinkHint: string = '');;

Wrapper method able to add a custom button to the Task Dialog

- will add the expected content to the Buttons text field

procedure SetElementText(element: TTaskDialogElement; const Text: string);

Allow a OnButtonClicked callback to change the Task Dialog main elements

- note that tdeVerif could be modified only in emulation mode, since the API does not give any runtime access to the checkbox caption
- other elements will work in both emulated and native modes

TTaskDialogEx = object(TObject)

A wrapper around the TTaskDialog.Execute method

- used to provide a "flat" access to task dialog parameters

Base: TTaskDialog;

The associated main TTaskDialog instance

ButtonDef: integer;

The default button ID

CommonButtons: TCommonButtons;

Some common buttons to be displayed

DialogIcon: TTaskDialogIcon;

Used to specify the dialog icon

EmulateClassicStyle: boolean;

Can be used to enforce conformity with the non themed user interface

Flags: TTaskDialogFlags;

The associated configuration flags for this Task Dialog
- in emulation mode, aFlags will handle only tdfUseCommandLinks,
tdfUseCommandLinksNoIcon, and tdfQuery options

FooterIcon: TTaskDialogFooterIcon;

Used to specify the footer icon

NonNative: boolean;

If TRUE, the Delphi emulation code will always be used

OnButtonClicked: TTaskDialogButtonClickedEvent;

This event handler will be fired on a button dialog click

RadioDef: integer;

The default radio button ID

Width: integer;

Can be used to force a custom form width (in pixels)

function Execute(aParent: HWND=0): integer;

Main (and unique) method showing the dialog itself
- is in fact a wrapper around the TTaskDialog.Execute method

procedure Init;

Will initialize the dialog parameters
- can be used to display some information with less parameters:

```
var TaskEx: TTaskDialogEx;  
...  
TaskEx.Init;  
TaskEx.Base.Title := 'Task Dialog Test';  
TaskEx.Base.Inst := 'Callback Test';  
TaskEx.Execute;
```

TSynButton = class(TSynButtonParent)

A generic Button to be used in the User Interface
- is always a Themed button: under Delphi 6, since TBitBtn is not themed, it will be a row TButton
with no glyph... never mind...

constructor CreateKind(Owner: TWinControl; Btn: TCommonButton; Left, Right, Width, Height: integer);

Create a standard button instance
- ModalResult/Default/Cancel properties will be set as expected for this kind of button

procedure DoDropDown;

Drop down the associated Popup Menu

procedure SetBitmap(Bmp: TBitmap);

Set the glyph of the button
- set nothing under Delphi 6

```
property DropDownMenu: TSynPopupMenu read fDropDownMenu write fDropDownMenu;
```

The associated Popup Menu to drop down

Types implemented in the *SynTaskDialog* unit

```
TCommonButton = ( cbOK, cbYes, cbNo, cbCancel, cbRetry, cbClose );
```

The standard kind of common buttons handled by the Task Dialog

```
TCommonButtons = set of TCommonButton;
```

Set of standard kind of common buttons handled by the Task Dialog

```
TSynPopupMenu = TPopupMenu;
```

A generic VCL popup menu

```
TTaskDialogButtonClickedEvent = procedure(Sender: PTaskDialog; AButtonID: integer; var  
ACanClose: Boolean) of object;
```

This callback will be triggered when a task dialog button is clicked

- to prevent the task dialog from closing, the application must set ACanClose to FALSE, otherwise the task dialog is closed and the button ID is returned via the original TTaskDialog.Execute() result

```
TTaskDialogElement = ( tdeContent, tdeExpandedInfo, tdeFooter, tdeMainInstruction,  
tdeEdit, tdeVerif );
```

The visual components of this Task Dialog

- map low-level TDE_CONTENT...TDE_MAIN_INSTRUCTION constants and the query editor and checkbox
- tdeEdit is for the query editor
- tdeVerif is for the checkbox

```
TTaskDialogFlag = ( tdfEnableHyperLinks, tdfUseHIconMain, tdfUseHIconFooter,  
tdfAllowDialogCancellation, tdfUseCommandLinks, tdfUseCommandLinksNoIcon,  
tdfExpandFooterArea, tdfExpandByDefault, tdfVerificationFlagChecked,  
tdfShowProgressBar, tdfShowMarqueeProgressBar, tdfCallbackTimer,  
tdfPositionRelativeToWindow, tdfRTLLayout, tdfNoDefaultRadioButton,  
tdfCanBeMinimized, tdfQuery, tdfQueryMasked, tdfQueryFieldFocused );
```

The available configuration flags for the Task Dialog

- most are standard TDF_* flags used for Vista/Seven native API (see [http://msdn.microsoft.com/en-us/library/bb787473\(v=vs.85\).aspx](http://msdn.microsoft.com/en-us/library/bb787473(v=vs.85).aspx) for TASKDIALOG_FLAGS)
- tdfQuery and tdfQueryMasked are custom flags, implemented in pure Delphi code to handle input query
- our emulation code will handle only tdfUseCommandLinks, tdfUseCommandLinksNoIcon, and tdfQuery options

```
TTaskDialogFlags = set of TTaskDialogFlag;
```

Set of available configuration flags for the Task Dialog

```
TTaskDialogFooterIcon = ( tfiBlank, tfiWarning, tfiQuestion, tfiError, tfiInformation,  
tfiShield );
```

The available footer icons for the Task Dialog

```
TTaskDialogIcon = ( tiBlank, tiWarning, tiQuestion, tiError, tiInformation, tiNotUsed,  
tiShield );
```

The available main icons for the Task Dialog

Constants implemented in the *SynTaskDialog* unit

`mrBtn1 = 100;`

Match the 1st custom button ID

`mrBtn2 = 101;`

Match the 2nd custom button ID

`mrBtn3 = 102;`

Match the 3rd custom button ID

`mrBtn4 = 103;`

Match the 4th custom button ID

`mrBtn5 = 104;`

Match the 5th custom button ID

`mrBtn6 = 105;`

Match the 6th custom button ID

`mrBtn7 = 106;`

Match the 7th custom button ID

`mrBtn8 = 107;`

Match the 8th custom button ID

`mrBtn9 = 108;`

Match the 9th custom button ID

`mrRad1 = 200;`

Match the 1st custom radio ID

`mrRad2 = 201;`

Match the 2nd custom radio ID

`mrRad3 = 202;`

Match the 3rd custom radio ID

`mrRad4 = 203;`

Match the 4th custom radio ID

`mrRad5 = 204;`

Match the 5th custom radio ID

`mrRad6 = 205;`

Match the 6th custom radio ID

`mrRad7 = 206;`

Match the 7th custom radio ID

`mrRad8 = 207;`

Match the 8th custom radio ID

`mrRad9 = 208;`

Match the 9th custom radio ID

Functions or procedures implemented in the *SynTaskDialog* unit

Functions or procedures	Description	Page
UnAmp	Return the text without the '&' characters within	1839

```
function UnAmp(const s: string): string;
```

Return the text without the '&' characters within

Variables implemented in the *SynTaskDialog* unit

```
BitmapArrow: TBitmap;
```

Will map a generic Arrow picture from SynTaskDialog.res

```
BitmapOK: TBitmap;
```

Will map a generic OK picture from SynTaskDialog.res

```
DefaultFont: TFont;
```

Will map a default font, according to the available

- if Calibri is installed, will use it
- will fall back to Tahoma otherwise

```
DefaultTaskDialog: TTaskDialogEx = ( DialogIcon: tiInformation; FooterIcon: tfiWarning);
```

A default Task Dialog wrapper instance

- can be used to display some information with less parameters, just like the TTaskDialogEx.Init method:

```
var TaskEx: TTaskDialogEx;
...
TaskEx := DefaultTaskDialog;
TaskEx.Base.Title := 'Task Dialog Test';
TaskEx.Base.Inst := 'Callback Test';
TaskEx.Execute;
```

```
TaskDialogIndirect: function(AConfig: pointer; Res: PInteger; ResRadio: PInteger; VerifyFlag: PBOOL): HRESULT; stdcall;
```

Is filled once in the initialization block below

- you can set this reference to nil to force Delphi dialogs even on Vista/Seven (e.g. make sense if TaskDialogBiggerButtons=true)

27.42. SynTests.pas unit

Purpose: Unit test functions used by Synopse projects

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the SynTests unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynLog</i>	Logging functions used by Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1368
<i>SynTable</i>	Filter/database/cache/buffer/security/search/multithread/OS features - as a complement to SynCommons, which tended to increase too much - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1728

SynTests class hierarchy

Objects implemented in the SynTests unit

Objects	Description	Page
TSynTest	Abstract parent class for both tests suit (TSynTests) and cases (TSynTestCase)	1841
TSynTestCase	A class implementing a test case	1842
TSynTestFailed	Information about a failed test	1845
TSynTestMethodInfo	How published method information is stored within TSynTest	1840
TSynTests	A class used to run a suit of test cases	1845
TSynTestsLogged	This overridden class will create a .log file in case of a test case failure	1847

TSynTestMethodInfo = record

How published method information is stored within TSynTest

IdentTestName: RawUTF8;

Ready-to-be-displayed 'Ident - TestName' text, as UTF-8

Method: TSynTestEvent;

Direct access to the method execution

MethodIndex: integer;

The index of this method in the TSynTestCase

MethodName: RawUTF8;

Raw method name, as defined in pascal code (not uncamelcased)

Test: TSynTest;

The test case holding this method

TestName: string;

The uncamelcased method name

TSynTest = class(TSynPersistent)

Abstract parent class for both tests suit (TSynTests) and cases (TSynTestCase)

- purpose of this ancestor is to have RTTI for its published methods, and to handle a class text identifier, or uncamelcase its class name if no identifier was defined
- sample code about how to use this test framework is available in the "Sample\07 - SynTest" folder

constructor Create(const Ident: string = ''); reintroduce; virtual;

Create the test instance

- if an identifier is not supplied, the class name is used, after T[Syn][Test] left trim and un-camel-case
- this constructor will add all published methods to the internal test list, accessible via the Count/TestName/TestMethod properties

procedure Add(const aMethod: TSynTestEvent; const aMethodName: RawUTF8; const aIdent: string);

Register a specified test to this class instance

- Create will register all published methods of this class, but your code may initialize its own set of methods on need

property Count: Integer read GetCount;

Return the number of tests associated with this class

- i.e. the number of registered tests by the Register() method PLUS the number of published methods defined within this class

property Ident: string read GetIdent;

The test name

- either the Ident parameter supplied to the Create() method, either a uncameled text from the class name

property InternalTestsCount: integer read fInternalTestsCount;

Return the number of published methods defined within this class as tests

- i.e. the number of tests added by the Create() constructor from RTTI
- any TestName/TestMethod[] index higher or equal to this value has been added by a specific call to the Add() method

property Options: TSynTestOptions read fOptions write fOptions;

Allows to tune the test case process

TSynTestCase = class(TSynTest)

A class implementing a test case

- should handle a test unit, i.e. one or more tests
- individual tests are written in the published methods of this class

constructor Create(Owner: TSynTests; const Ident: string = ''); reintroduce;
virtual;

Create the test case instance

- must supply a test suit owner
- if an identifier is not supplied, the class name is used, after T[Syn][Test] left trim and un-camel-case

destructor Destroy; override;

Clean up the instance

- will call CleanUp, even if already done before

function CheckEqual(a,b: pointer; const msg: RawUTF8 = ''): Boolean; overload;

Used by the published methods to run test assertion against pointers/classes

- if a<>b, will fail and include '#<>#' text before the supplied msg

function CheckEqual(a,b: Int64; const msg: RawUTF8 = ''): Boolean; overload;

Used by the published methods to run test assertion against integers

- if a<>b, will fail and include '#<>#' text before the supplied msg

function CheckEqual(const a,b: RawUTF8; const msg: RawUTF8 = ''): Boolean; overload;

Used by the published methods to run test assertion against UTF-8 strings

- if a<>b, will fail and include '#<>#' text before the supplied msg

function CheckFailed(condition: Boolean; const msg: string = ''): Boolean;

Used by the published methods to run a test assertion

- condition must equals TRUE to pass the test
- function return TRUE if the condition failed, in order to allow the caller to stop testing with such code:
 if CheckFailed(A=10) then exit;

function CheckMatchAny(const Value: RawUTF8; const Values: array of RawUTF8;
 CaseSensitive: Boolean=true; ExpectedResult: Boolean=true; const msg: string = ''):
 Boolean;

Perform a string comparison with several value

- test passes if (Value=Values[0]) or (Value=Value[1]) or (Value=Values[2])... and ExpectedResult=true

function CheckNot(condition: Boolean; **const** msg: string = ''): Boolean;

Used by the published methods to run a test assertion

- condition must equals FALSE to pass the test
- function return TRUE if the condition failed, in order to allow the caller to stop testing with such code:
if CheckNot(A<>10) then exit;

function CheckNotEqual(a,b: pointer; **const** msg: RawUTF8 = ''): Boolean; overload;

Used by the published methods to run test assertion against pointers/classes

- if a=b, will fail and include '#=#' text before the supplied msg

function CheckNotEqual(**const** a,b: RawUTF8; **const** msg: RawUTF8 = ''): Boolean; overload;

Used by the published methods to run test assertion against UTF-8 strings

- if a=b, will fail and include '#=#' text before the supplied msg

function CheckNotEqual(a,b: Int64; **const** msg: RawUTF8 = ''): Boolean; overload;

Used by the published methods to run test assertion against integers

- if a=b, will fail and include '#=#' text before the supplied msg

function CheckSame(**const** Value1,Value2: double; **const** Precision: double=DOUBLE_SAME; **const** msg: string = ''): Boolean;

Used by the published methods to run a test assertion about two double values

- includes some optional precision argument

function NotifyTestSpeed(**const** ItemNameFmt: RawUTF8; **const** ItemNameArgs: array of **const**; ItemCount: integer; SizeInBytes: cardinal=0; Timer: PPrecisionTimer=nil; OnlyLog: boolean=false): TSynMonitorOneMicroSec; overload;

Will add to the console a formatted message with a speed estimation

function NotifyTestSpeed(**const** ItemName: string; ItemCount: integer; SizeInBytes: cardinal=0; Timer: PPrecisionTimer=nil; OnlyLog: boolean=false): TSynMonitorOneMicroSec; overload;

Will add to the console a message with a speed estimation

- speed is computed from the method start
- returns the number of microsec of the (may be specified) timer
- OnlyLog will compute and append the info to the log, but not on the console
- warning: this method is not thread-safe if a local Timer is not specified

class function RandomAnsi7(CharCount: Integer): RawByteString;

Create a temporary string random content, using ASCII 7 bit content

class function RandomIdentifier(CharCount: Integer): RawByteString;

Create a temporary string random content, using A..Z,_,0..9 chars only

class function RandomString(CharCount: Integer): RawByteString;

Create a temporary string random content, WinAnsi (code page 1252) content

class function RandomTextParagraph(WordCount: Integer; LastPunctuation: AnsiChar='.'; **const** RandomInclude: RawUTF8=''): RawUTF8;

Create a temporary string, containing some fake text, with paragraphs

class function RandomUnicode(CharCount: Integer): SynUnicode;
Create a temporary UTF-16 string random content, using WinAnsi (code page 1252) content

class function RandomURI(CharCount: Integer): RawByteString;
Create a temporary string random content, using uri-compatible chars only

class function RandomUTF8(CharCount: Integer): RawUTF8;
Create a temporary UTF-8 string random content, using WinAnsi (code page 1252) content

procedure AddConsole(const msg: string; OnlyLog: boolean=false);
Append some text to the current console
- OnlyLog will compute and append the info to the log, but not on the console

class procedure AddRandomTextParagraph(WR: TTextWriter; WordCount: Integer;
LastPunctuation: AnsiChar='.'; const RandomInclude: RawUTF8=''; NoLineFeed:
boolean=false);
Add containing some "bla bli blo blu" fake text, with paragraphs

procedure Check(condition: Boolean; const msg: string = '');
Used by the published methods to run a test assertion
- condition must equals TRUE to pass the test

procedure CheckLogTime(condition: boolean; const msg: RawUTF8; const args: array of
const; level: TSynLogInfo=sllTrace);
Used by published methods to write some timing on associated log
- at least one CheckLogTimeStart method call should happen to reset the internal timer
- condition must equals TRUE to pass the test
- the supplied message would be appended, with its timing
- warning: this method is not thread-safe

procedure CheckLogTimeStart;
Used by published methods to start some timing on associated log
- call this once, before one or several consecutive CheckLogTime()
- warning: this method is not thread-safe

procedure CheckUTF8(condition: Boolean; const msg: RawUTF8); overload;
Used by the published methods to run a test assertion, with an UTF-8 error message
- condition must equals TRUE to pass the test

procedure CheckUTF8(condition: Boolean; const msg: RawUTF8; const args: array of
const); overload;
*Used by the published methods to run a test assertion, with a error message computed via
FormatUTF8()*
- condition must equals TRUE to pass the test

procedure TestFailed(const msg: string);
This method is triggered internally - e.g. by Check() - when a test failed

property Assertions: integer read fAssertions;
The number of assertions (i.e. Check() method call) for this test case

property AssertionsFailed: integer read fAssertionsFailed;
The number of assertions (i.e. Check() method call) for this test case

property Ident: **string** read GetIdent;

The test name

- either the Ident parameter supplied to the Create() method, either an uncamed text from the class name

property Owner: TSynTests read fOwner;

The test suit which owns this test case

TSynTestFailed = record

Information about a failed test

Error: string;

The contextual message associated with this failed test

IdentTestName: RawUTF8;

Ready-to-be-displayed 'TestCaselIdent - TestName' text, as UTF-8

TestName: string;

The uncamelcased method name

TSynTests = class(TSynTest)

A class used to run a suit of test cases

CustomVersions: string;

You can put here some text to be displayed at the end of the messages

- some internal versions, e.g.
- every line of text must explicitly BEGIN with #13#10

RunTimer: TPrecisionTimer;

Contains the run elapsed time

TestTimer: TPrecisionTimer;

Contains the run elapsed time

TotalTimer: TPrecisionTimer;

Contains the run elapsed time

constructor Create(const Ident: **string** = ''); **override;**

Create the test suit

- if an identifier is not supplied, the class name is used, after T[Syn][Test] left trim and un-camel-case
- this constructor will add all published methods to the internal test list, accessible via the Count/TestName/TestMethod properties

destructor Destroy; **override;**

Finalize the class instance

- release all registered Test case instance

function Run: Boolean; **virtual**;

Call of this method will run all associated tests cases

- function will return TRUE if all test passed
- all failed test cases will be added to the Failed[] list - which is cleared at the beginning of the run
- Assertions and AssertionsFailed counter properties are reset and computed during the run
- you may override this method to provide additional information, e.g.

```
function TMySynTests.Run: Boolean;
begin // need SynSQLite3.pas unit in the uses clause
  CustomVersions := format(#13#10#13#10'%s'#13#10'    %s'#13#10' +
    'Using mORMot %s'#13#10'    %s %s', [OSVersionText, CpuInfoText,
    SYNOPSIS_FRAMEWORK_FULLVERSION, sqlite3.ClassName, sqlite3.Version]);
  result := inherited Run;
end;
```

procedure AddCase(TestCase: TSynTestCaseClass); **overload**;

Register a specified Test case from its class name

- an instance of the supplied class will be created during Run
- the published methods of the children must call this method in order to add test cases
- example of use (code from a TSynTests published method):

```
AddCase(TOneTestCase);
```

procedure AddCase(const TestCase: array of TSynTestCaseClass); **overload**;

Register a specified Test case from its class name

- an instance of the supplied classes will be created during Run
- the published methods of the children must call this method in order to add test cases
- example of use (code from a TSynTests published method):

```
AddCase([TOneTestCase]);
```

class procedure RunAsConsole(const CustomIdent: string=''; withLogs: TSynLogInfos=[sllLastError,sllError,sllException,sllExceptionOS]; options: TSynTestOptions=[]); **virtual**;

You can call this class method to perform all the tests on the Console

- it will create an instance of the corresponding class, with the optional identifier to be supplied to its constructor
- if the executable was launched with a parameter, it will be used as file name for the output - otherwise, tests information will be written to the console
- it will optionally enable full logging during the process
- a typical use will first assign the same log class for the whole framework, if the mORMot.pas unit is to be used - in such case, before calling RunAsConsole(), the caller should execute:

```
TSynLogTestLog := TSQLLog;
TMyTestsClass.RunAsConsole('My Automated Tests', LOG_VERBOSE);
```

procedure SaveToFile(const DestPath: TFileName; const FileName: TFileName='');

Save the debug messages into an external file

- if no file name is specified, the current Ident is used

property Assertions: integer read fAssertions;

The number of assertions (i.e. Check() method call) in all tests
- this property is set by the Run method above

property AssertionsFailed: integer read fAssertionsFailed;

The number of assertions (i.e. Check() method call) which failed in all tests
- this property is set by the Run method above

property CurrentMethodInfo: PSynTestMethodInfo read fCurrentMethodInfo;

Method information currently running
- is set by Run and available within TTestCase methods

property Failed[Index: integer]: TSynTestFailed read GetFailed;

Retrieve the information associated with a failure

property FailedCount: integer read GetFailedCount;

Number of failed tests after the last call to the Run method

TSynTestsLogged = class(TSynTests)

This overridden class will create a .log file in case of a test case failure
- inherits from TSynTestsLogged instead of TSynTests in order to add logging to your test suite (via a dedicated TSynLogTest instance)

constructor Create(const Ident: string = ''); **override;**

Create the test instance and initialize associated LogFile instance
- this will allow logging of all exceptions to the LogFile

destructor Destroy; **override;**

Release associated memory

property LogFile: TSynLog read fLogFile;

The .log file generator created if any test case failed

Types implemented in the SynTests unit

PSynTestMethodInfo = ^TSynTestMethodInfo;

Pointer access to published method information

TSynTestCaseClass = class of TSynTestCase;

Class-reference type (metaclass) of a test case

TSynTestEvent = procedure of object;

The prototype of an individual test
- to be used with TSynTest descendants

TSynTestOption = (tcoLogEachCheck);

Allows to tune TSynTest process
- tcoLogEachCheck will log as sllCustom4 each non void Check() message

TSynTestOptions = set of TSynTestOption;

Set of options to tune TSynTest process

27.43. SynVirtualDataSet.pas unit

Purpose: DB VCL read-only virtual dataset

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the SynVirtualDataSet unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynTable</i>	Filter/database/cache/buffer/security/search/multithread/OS features - as a complement to SynCommons, which tended to increase too much - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1728

SynVirtualDataSet class hierarchy

Objects implemented in the SynVirtualDataSet unit

Objects	Description	Page
TDocVariantArrayDataSet	Read-only virtual TDataSet able to access a dynamic array of TDocVariant	1849
TSynVirtualDataSet	Read-only virtual TDataSet able to access any content	1848

TSynVirtualDataSet = class(TDataSet)

Read-only virtual TDataSet able to access any content

constructor Create(Owner: TComponent); **override;**

Class function BcdRead(P: PUTF8Char; var aValue; out aValid: Boolean): PUTF8Char; this overridden constructor will compute an unique Name property

function CreateBlobStream(Field: TField; Mode: TBlobStreamMode): TStream; **override;**

Get BLOB column data for the current active row
- handle ftBlob,ftMemo,ftWideMemo via GetRowFieldData()

function GetBlobStream(Field: TField;RowIndex: integer): TStream;

Get BLOB column data for a given row (may not the active row)
- handle ftBlob,ftMemo,ftWideMemo via GetRowFieldData()

function GetFieldData(Field: TField; Buffer: pointer): Boolean; **override;**

Get column data for the current active row
- handle ftBoolean,ftInteger,ftLargeint,ftFloat,ftCurrency,ftDate,ftTime,ftDateTime,ftString,ftWideString kind of fields via GetRowFieldData()

function Locate(const KeyFields: string; const KeyValues: Variant; Options: TLocateOptions) : boolean; **override**;

Searching a dataset for a specified record and making it the active record
- will call SearchForField protected virtual method for actual lookup

TDocVariantArrayDataSet = **class**(TSynVirtualDataSet)

Read-only virtual TDataSet able to access a dynamic array of TDocVariant
- could be used e.g. from the result of TMongoCollection.FindDocs() to avoid most temporary conversion into JSON or TClientDataSet buffers

constructor Create(Owner: TComponent; const Data: TVariantDynArray; const ColumnNames: array of RawUTF8; const ColumnTypes: array of TSQLDBFieldType); **reintroduce**;

Initialize the virtual TDataSet from a dynamic array of TDocVariant
- you can set the expected column names and types matching the results document layout - if no column information is specified, the first TDocVariant will be used as reference

Types implemented in the SynVirtualDataSet unit

TBCDBuffer = array[0..66] of AnsiChar;

A string buffer, used by InternalBCDToBuffer to store its output text

TRecordBuffer = PChar;

Defined as TRecordBuffer = PByte in newer DB.pas

Constants implemented in the SynVirtualDataSet unit

ftDefaultMemo = ftMemo;

*Map the best ft*Memo type available, depending on the Delphi compiler version*

ftDefaultVCLString = ftString;

Map the VCL string type, depending on the Delphi compiler version

Functions or procedures implemented in the SynVirtualDataSet unit

Functions or procedures	Description	Page
AddBcd	Append a TBcd value as text to the output buffer	1850
BCDToCurr	Convert a TBcd value into a currency	1850
BCDToString	Convert a TBcd value into a VCL string text	1850
BCDToUTF8	Convert a TBcd value into a RawUTF8 text	1850
BCDToUTF8	Convert a TBcd value into a RawUTF8 text	1850
DataSetToJSON	Export all rows of a TDataSet into JSON	1850
InternalBCDToBuffer	Convert a TBcd value as text to the output buffer	1850
ToDataSet	Convert a dynamic array of TDocVariant result into a VCL DataSet	1850

procedure AddBcd(WR: TTextWriter; **const** AValue: TBcd);

Append a TBcd value as text to the output buffer

- very optimized for speed

function BCDToCurr(**const** AValue: TBcd; **var** Curr: Currency): boolean;

Convert a TBcd value into a currency

- purepascal version included in latest Delphi versions is slower than this

function BCDToString(**const** AValue: TBcd): string;

Convert a TBcd value into a VCL string text

- will call fast InternalBCDToBuffer function

function BCDToUTF8(**const** AValue: TBcd): RawUTF8; overload;

Convert a TBcd value into a RawUTF8 text

- will call fast InternalBCDToBuffer function

procedure BCDToUTF8(**const** AValue: TBcd; **var** result: RawUTF8); overload;

Convert a TBcd value into a RawUTF8 text

- will call fast InternalBCDToBuffer function

function DataSetToJSON(Data: TDataSet): RawUTF8;

Export all rows of a TDataSet into JSON

- will work for any kind of TDataSet

function InternalBCDToBuffer(**const** AValue: TBcd; **out** ADest: TBCDBuffer; **var** PBeg: PAnsiChar): integer;

Convert a TBcd value as text to the output buffer

- buffer is to be array[0..66] of AnsiChar

- returns the resulting text start in PBeg, and the length as function result

- does not handle negative sign and 0 value - see AddBcd() function use case

- very optimized for speed

function ToDataSet(aOwner: TComponent; **const** Data: TVariantDynArray; **const** ColumnNames: array of RawUTF8; **const** ColumnTypes: array of TSQLDBFieldType): TDocVariantArrayDataSet; overload;

Convert a dynamic array of TDocVariant result into a VCL DataSet

- this function is just a wrapper around TDocVariantArrayDataSet.Create()

- the TDataSet will be opened once created

27.44. SynWinSock.pas unit

Purpose: Low level access to network Sockets for the Win32 platform

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

SynWinSock class hierarchy

Objects implemented in the SynWinSock unit

Objects	Description	Page
TIPv6_mreq		1851
TPollFD	Polling request data structure for poll/WSAPoll	1851

TIPv6_mreq = record

ipv6mr_interface: integer;
IPv6 multicast address.

padding: integer;
Interface index.

TPollFD = record

Polling request data structure for poll/WSAPoll

events: SHORT;
Types of events poller cares about
- mainly POLLIN and/or POLLOUT

fd: TSocket;
File descriptor to poll

revents: SHORT;
Types of events that actually occurred
- caller could just reset revents := 0 to reuse the structure

Constants implemented in the SynWinSock unit

AI_CANONNAME = \$2;
Socket address will be used in bind() call.

AI_NUMERICHOST = \$4;

Return canonical name in first ai_canonname.

AI_PASSIVE = \$1;

POLLERR = \$0001;

Poll/WSAPoll flag error condition (always implicitly polled for)

POLLHUP = \$0002;

Poll/WSAPoll flag hung up (always implicitly polled for)

POLLIN = POLLRDNORM or POLLRDBAND;

Poll/WSAPoll flag when there is data to read

POLLNVAL = \$0004;

Poll/WSAPoll flag invalid polling request (always implicitly polled for)

POLLOUT = \$0010;

Poll/WSAPoll flag when writing now will not block

POLLPRI = \$0400;

Poll/WSAPoll flag when there is urgent data to read

POLLRDBAND = \$0200;

Poll/WSAPoll flag when priority data may be read

POLLRDNORM = \$0100;

POLLWRBAND = \$0020;

Poll/WSAPoll flag when priority data may be written

POLLWRNORM = \$0010;

Poll/WSAPoll flag when writing now will not block

Functions or procedures implemented in the SynWinSock unit

Functions or procedures	Description	Page
poll	Poll the file descriptors described by the NFDS structures starting at fds	1852

function poll(fds: PPollFD; nfds, timeout: integer): integer;

Poll the file descriptors described by the NFDS structures starting at fds

- under Windows, will call WSAPoll() emulation API - see

<https://blogs.msdn.microsoft.com/wndp/2006/10/26>

- if TIMEOUT is nonzero and not -1, allow TIMEOUT milliseconds for an event to occur; if TIMEOUT is -1, block until an event occurs

- returns the number of file descriptors with events, zero if timed out, or -1 for errors

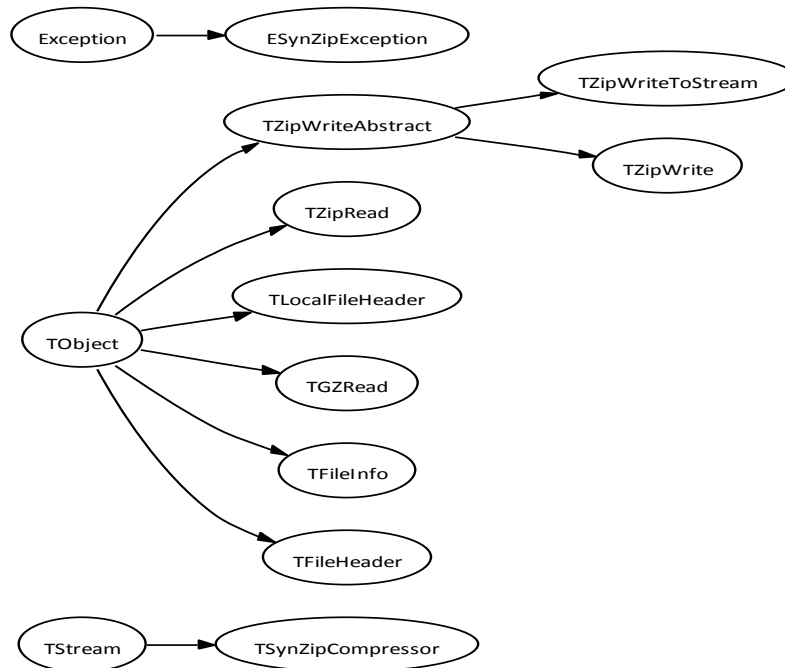

- before Vista, will return -1 since the API extension was not yet defined

- in practice, this API is actually slightly SLOWER than optimized Select() :(

27.45. SynZip.pas unit

Purpose: Low-level access to ZLib compression (1.2.5 engine version)

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

SynZip class hierarchy

Objects implemented in the SynZip unit

Objects	Description	Page
ESynZipException	Exception raised internally in case of Zip errors	1854
TFileHeader	Directory file information structure, as used in .zip file format	1854
TFileInfo	Generic file information structure, as used in .zip file format	1854
TGZRead	Simple wrapper class to decompress a .gz file into memory or stream/file	1856
TLastHeader	Last header structure, as used in .zip file format	1855
TLocalFileHeader	Internal file information structure, as used in .zip file format	1855
TSynZipCompressor	A simple TStream descendant for compressing data into a stream	1856
TZipEntry	Stores an entry of a file inside a .zip archive	1857
TZipRead	Read-only access to a .zip archive file	1857
TZipWrite	Write-only access for creating a .zip archive file	1859
TZipWriteAbstract	Abstract write-only access for creating a .zip archive	1859

Objects	Description	Page
TZipWriteToStream	Write-only access for creating a .zip archive into a stream	1860
TZStream	The internal memory structure as expected by the ZLib library	1854

ESynZipException = **class**(Exception)

Exception raised internally in case of Zip errors

TZStream = **record**

The internal memory structure as expected by the ZLib library

TFileInfo = **object**(TObject)

Generic file information structure, as used in .zip file format

- used in any header, contains info about following block

extraLen: word;

Length(name)

flags: word;

14

nameLen: word;

Size of uncompressed data

zcrc32: dword;

Time in dos format

zfullSize: dword;

Size of compressed data

zlastMod: integer;

0=Z_STORED 8=Z_DEFLATED 12=BZ2 14=LZMA

zzipMethod: word;

0

zzipSize: dword;

Crc32 checksum of uncompressed data

function SameAs(aInfo: PFileInfo): boolean;

0

procedure SetAlgoID(Algorithm: integer);

1..15 (1=SynLZ e.g.) from flags

TFileHeader = **object**(TObject)

Directory file information structure, as used in .zip file format

- used at the end of the zip file to recap all entries

```
extFileAttr: dword;
```

0 = binary; 1 = text

```
fileInfo: TFileInfo;
```

0314 = OS + version

```
firstDiskNo: word;
```

0

```
intFileAttr: word;
```

0

```
localHeadOff: dword;
```

Dos file attributes

```
madeBy: word;
```

02014b50 PK#1#2

```
function IsFolder: boolean;
```

@TLocalFileHeader

```
TLocalFileHeader = object(TObject)
```

Internal file information structure, as used in .zip file format

- used locally inside the file stream, followed by the name and then the data

```
fileInfo: TFileInfo;
```

04034b50 PK#3#4

```
TLastHeader = record
```

Last header structure, as used in .zip file format

- this header ends the file and is used to find the TFileHeader entries

```
commentLen: word;
```

@TFileHeader

```
headerDisk: word;
```

0

```
headerOffset: dword;
```

SizeOf(TFileHeaders + names)

```
headerSize: dword;
```

1

```
thisDisk: word;
```

06054b50 PK#5#6

```
thisFiles: word;
```

0

```
totalFiles: word;
```

```
1
```

```
TGZRead = object(TObject)
```

Simple wrapper class to decompress a .gz file into memory or stream/file

```
crc32: cardinal;
```

Modulo 2³² by gzip design

```
function Init(gz: PAnsiChar; gzLen: ZipPtrInt): boolean;
```

Read and validate the .gz header

- on success, return true and fill complen/uncomplen/crc32c properties

```
function ToFile(const filename: TFileName; tempBufSize: integer=0): boolean;
```

Uncompress the .gz content into a file

```
function ToMem: ZipString;
```

Uncompress the .gz content into a memory buffer

- warning: won't work as expected if uncomplen32 was truncated to 2³²

```
function ToStream(stream: TStream; tempBufSize: integer=0): boolean;
```

Uncompress the .gz content into a stream

```
function ZStreamDone: boolean;
```

Any successful call to ZStreamStart should always run ZStreamDone

- return true if the crc and the uncompressed size are ok

```
function ZStreamNext: integer;
```

Will uncompress into dest/destsize buffer as supplied to ZStreamStart

- return the number of bytes uncompressed (<=destsize)

- return 0 if the input stream is finished

```
function ZStreamStart(dest: pointer; destsize: integer): boolean;
```

Allow low level iterative decompression using an internal TZStream structure

```
function ZStreamStarted: boolean;
```

Return true if ZStreamStart() has been successfully called

```
TSynZipCompressor = class(TStream)
```

A simple TStream descendant for compressing data into a stream

- this simple version don't use any internal buffer, but rely on Zip library buffering system

- the version in SynZipFiles is much more powerful, but this one is sufficient for most common cases (e.g. for on the fly .gz backup)

```
constructor Create(outStream: TStream; CompressionLevel: Integer; Format:  
TSynZipCompressorFormat = szcfRaw);
```

Create a compression stream, writting the compressed data into the specified stream (e.g. a file stream)

```
destructor Destroy; override;
```

Release memory

function Read(var Buffer; Count: Longint): Longint; **override**;

This method will raise an error: it's a compression-only stream

function Seek(Offset: Longint; Origin: Word): Longint; **override**;

Used to return the current position, i.e. the real byte written count

- for real seek, this method will raise an error: it's a compression-only stream

function SizeIn: cardinal;

The number of byte written, i.e. the current uncompressed size

function SizeOut: cardinal;

The number of byte sent to the destination stream, i.e. the current compressed size

function Write(const Buffer; Count: Longint): Longint; **override**;

Add some data to be compressed

procedure Flush;

Write all pending compressed data into outStream

property CRC: cardinal **read** fCRC;

The current CRC of the written data, i.e. the uncompressed data CRC

TZipEntry = record

Stores an entry of a file inside a .zip archive

data: PAnsiChar;

Points to the compressed data in the .zip archive, mapped in memory

infoDirectory: PFileHeader;

The information of this file, as stored at the end of the .zip archive

- may differ from infoLocal^ content, depending of the zipper tool used

infoLocal: PFileInfo;

The information of this file, as stored locally in the .zip archive

- note that infoLocal^.zipSize/zfullSize/zcrc32 may be 0 if the info was stored in a "data descriptor" block after the data: in this case, you should use TZipRead.RetrieveFileInfo() instead of this structure

storedName: PAnsiChar;

Name of the file inside the .zip archive

- not ASCIIZ: length = infoLocal.nameLen

zipName: TFileName;

Name of the file inside the .zip archive

- converted from DOS/OEM or UTF-8 into generic (Unicode) string

TZipRead = class(TObject)

Read-only access to a .zip archive file

- can open directly a specified .zip file (will be memory mapped for fast access)

- can open a .zip archive file content from a resource (embedded in the executable)

- can open a .zip archive file content from memory

Count: integer;

The number of files inside a .zip archive

Entry: array of TZipEntry;

The files inside the .zip archive

constructor Create(aFile: THandle; ZipStartOffset: cardinal=0; Size: cardinal=0); overload;

Open a .zip archive file from its File Handle

constructor Create(BufZip: PByteArray; Size: cardinal); overload;

Open a .zip archive file directly from memory

constructor Create(const aFileName: TFileName; ZipStartOffset: cardinal=0; Size: cardinal=0); overload;

Open a .zip archive file as Read Only

constructor Create(Instance: THandle; const ResName: string; ResType: PChar); overload;

Open a .zip archive file directly from a resource

destructor Destroy; override;

Release associated memory

function NameToIndex(const aName: TFileName): integer;

Get the index of a file inside the .zip archive

function RetrieveFileInfo(Index: integer; var Info: TFileInfo): boolean;

Retrieve information about a file

- in some cases (e.g. for a .zip created by latest Java JRE), infoLocal^.zipSize/zfullSize/zcrc32 may equal 0: this method is able to retrieve the information either from the ending "central directory", or by searching the "data descriptor" block
- returns TRUE if the Index is correct and the info was retrieved
- returns FALSE if the information was not successfully retrieved

function UnZip(const aName: TFileName): ZipString; overload;

Uncompress a file stored inside the .zip archive into memory

function UnZip(const aName, DestDir: TFileName; DestDirIsFileName: boolean=false): boolean; overload;

Uncompress a file stored inside the .zip archive into a destination directory

function UnZip(aIndex: integer): ZipString; overload;

Uncompress a file stored inside the .zip archive into memory

function UnZip(aIndex: integer; aDest: TStream): boolean; overload;

Uncompress a file stored inside the .zip archive into a stream

function UnZip(aIndex: integer; const DestDir: TFileName; DestDirIsFileName: boolean=false): boolean; overload;

Uncompress a file stored inside the .zip archive into a destination directory

function UnZipAll(DestDir: TFileName): integer;

- Uncompress all fields stored inside the .zip archive into the supplied destination directory*
- returns -1 on success, or the index in Entry[] of the failing file

TZipWriteAbstract = class(TObject)

Abstract write-only access for creating a .zip archive

- update can be done manually by using a TZipRead instance and the AddFromZip() method

Count: integer;

The total number of entries

Entry: array of record intName: ZipString; fhr: TFileHeader; end;

The resulting file entries, ready to be written as a .zip catalog

- those will be appended after the data blocks at the end of the .zip file

constructor Create;

The file name, as stored in the .zip internal directory

- the path delimiter is forced to '/' just before writing to disk, as requested by 4.4.17 of reference

PKware appnote the corresponding file header initialize the .zip archive

- a new .zip file content is prepared

destructor Destroy; override;

Release associated memory, and close destination archive

procedure AddDeflated(const aZipName: TFileName; Buf: pointer; Size: integer; CompressLevel: integer=6; FileAge: integer=1+1 shl 5+30 shl 9); overload;

Compress (using the deflate method) a memory buffer, and add it to the zip file

- by default, the 1st of January, 2010 is used if not date is supplied

procedure AddFromZip(Source: TZipRead; EntryIndex: integer);

Add a file from an already compressed zip entry

procedure AddStored(const aZipName: TFileName; Buf: pointer; Size: integer; FileAge: integer=1+1 shl 5+30 shl 9);

Add a memory buffer to the zip file, without compression

- content is stored, not deflated (in that case, no deflate code is added to the executable)

- by default, the 1st of January, 2010 is used if not date is supplied

procedure Append(const Content: ZipString);

Append a file content into the destination file

- useful to add the initial Setup.exe file, e.g.

TZipWrite = class(TZipWriteAbstract)

Write-only access for creating a .zip archive file

- not to be used to update a .zip file, but to create a new one

Handle: integer;

The associated file handle

constructor Create(const aFileName: TFileName); overload;

Initialize the .zip file

- a new .zip file content is created

constructor CreateFrom(const aFileName: TFileName; dummy: integer=0);

Initialize an existing .zip file in order to add some content to it

- warning: AddStored/AddDeflated() won't check for duplicate zip entries
- this method is very fast, and will increase the .zip file in-place (the old content is not copied, new data is appended at the file end)
- "dummy" parameter exists only to disambiguate constructors for C++

destructor Destroy; **override**;

Release associated memory, and close destination file

procedure AddDeflated(const aFileName: TFileName; RemovePath: boolean=true;
CompressLevel: integer=6; ZipName: TFileName=''); overload;

Compress (using the deflate method) a file, and add it to the zip file

procedure AddFolder(const FolderName: TFileName; const Mask:
TFileName=ZIP_FILES_ALL; Recursive: boolean=true; CompressLevel: integer=6);

Compress (using the deflate method) all files within a folder, and add it to the zip file

- if Recursive is TRUE, would include files from nested sub-folders

TZipWriteToStream = **class**(TZipWriteAbstract)

Write-only access for creating a .zip archive into a stream

constructor Create(aDest: TStream);

Initialize the .zip archive

- a new .zip file content is prepared

Types implemented in the SynZip unit

PLastHeader = ^TLastHeader;

0

TSynZipCompressorFormat = (szcfRaw, szcfZip, szcfGZ);

The format used for storing data

TZLong = cardinal;

Statically linked with old 32-bit TZStream

ZipPtrUInt = cardinal;

As available in FPC

ZipString = **type** AnsiString;

Define a raw storage string type, used for data buffer management

Constants implemented in the SynZip unit

DEF_MEM_LEVEL = 8;

32K LZ77 window

ZIP_FILES_ALL = '*. *';

Operating-system dependent wildchar to match all files in a folder

Functions or procedures implemented in the SynZip unit

Functions or procedures	Description	Page
Check	Low-level check of the code returned by the ZLib library	1861
CompressDeflate	(un)compress a data content using the Deflate algorithm (i.e. "raw deflate")	1861
CompressGZip	(un)compress a data content using the gzip algorithm	1862
CompressMem	In-memory ZLib DEFLATE compression	1862
CompressStream	ZLib DEFLATE compression from memory into a stream	1862
CompressString	Compress some data, with a proprietary format (including CRC)	1862
CompressZLib	(un)compress a data content using the zlib algorithm	1862
CRC32string	Just hash aString with CRC32 algorithm	1862
DeflateInit	Prepare the internal memory structure as expected by the ZLib library for compression	1862
EventArchiveZip	A TSynLogArchiveEvent handler which will compress older .log files into .zip archive files	1862
GZFile	Compress a file content into a new .gz file	1862
GZRead	Uncompress a .gz file content	1862
StreamInit	Initialize the internal memory structure as expected by the ZLib library	1863
UnCompressMem	In-memory ZLib INFLATE decompression	1863
UnCompressStream	ZLib INFLATE decompression from memory into a stream	1863
UncompressString	Uncompress some data, with a proprietary format (including CRC)	1863
UnCompressZipString	ZLib INFLATE decompression from memory into a AnsiString (ZipString) variable	1863

function Check(const Code: Integer; const ValidCodes: array of Integer; const Context: string=''): integer;

Low-level check of the code returned by the ZLib library

function CompressDeflate(var DataRawByteString; Compress: boolean): AnsiString;

(un)compress a data content using the Deflate algorithm (i.e. "raw deflate")

- as expected by THttpSocket.RegisterCompress

- will use internally a level compression of 1, i.e. fastest available (content of 4803 bytes is compressed into 700, and time is 440 us instead of 220 us)

- deflate content encoding is pretty inconsistent in practice, so slightly slower CompressGZip() is preferred - <http://stackoverflow.com/a/9186091>

function CompressGZip(**var** DataRawByteString; Compress: boolean): AnsiString;

(un)compress a data content using the gzip algorithm

- as expected by THttpSocket.RegisterCompress
- will use internally a level compression of 1, i.e. fastest available (content of 4803 bytes is compressed into 700, and time is 440 us instead of 220 us)

function CompressMem(src, dst: pointer; srcLen, dstLen: integer; CompressionLevel: integer=6; ZlibFormat: Boolean=false) : integer;

In-memory ZLib DEFLATE compression

- by default, will use the deflate/.zip header-less format, but you may set ZlibFormat=true to add an header, as expected by zlib (and pdf)

function CompressStream(src: pointer; srcLen: integer; tmp: TStream; CompressionLevel: integer=6; ZlibFormat: Boolean=false; TempBufSize: integer=0): cardinal;

ZLib DEFLATE compression from memory into a stream

- by default, will use the deflate/.zip header-less format, but you may set ZlibFormat=true to add an header, as expected by zlib (and pdf)

function CompressString(**const** data: ZipString; failIfGrow: boolean = false; CompressionLevel: integer=6) : ZipString;

Compress some data, with a proprietary format (including CRC)

function CompressZLib(**var** DataRawByteString; Compress: boolean): AnsiString;

(un)compress a data content using the zlib algorithm

- as expected by THttpSocket.RegisterCompress
- will use internally a level compression of 1, i.e. fastest available (content of 4803 bytes is compressed into 700, and time is 440 us instead of 220 us)
- zlib content encoding is pretty inconsistent in practice, so slightly slower CompressGZip() is preferred - <http://stackoverflow.com/a/9186091>

function CRC32string(**const** aString: ZipString): cardinal;

Just hash aString with CRC32 algorithm

- crc32 is better than Adler32 for short strings

function DeflateInit(**var** Stream: TStream; CompressionLevel: integer; ZlibFormat: Boolean): Boolean; overload;

Prepare the internal memory structure as expected by the ZLib library for compression

function EventArchiveZip(**const** aOldLogFileName, aDestinationPath: TFileName): boolean;

A TSynLogArchiveEvent handler which will compress older .log files into .zip archive files

- resulting file will be named YYYYMM.zip and will be located in the aDestinationPath directory, i.e. TSynLogFamily.ArchivePath+'\\log\\YYYYMM.zip'

function GZFile(**const** orig, destgz: TFileName; CompressionLevel: Integer=6): boolean;

Compress a file content into a new .gz file

- will use TSynZipCompressor for minimal memory use during file compression

function GZRead(gz: PAnsiChar; gzLen: integer): ZipString;

Uncompress a .gz file content

- return "" if the .gz content is invalid (e.g. bad crc)

procedure StreamInit(**var** Stream: TZStream); overload;

Initialize the internal memory structure as expected by the ZLib library

function UnCompressMem(src, dst: pointer; srcLen, dstLen: integer; ZlibFormat: Boolean=false) : integer;

In-memory ZLib INFLATE decompression

- by default, will use the deflate/.zip header-less format, but you may set ZlibFormat=true to add an header, as expected by zlib (and pdf)

function UnCompressStream(src: pointer; srcLen: integer; tmp: TStream; checkCRC: PCardinal; ZlibFormat: Boolean=false; TempBufSize: integer=0): cardinal;

ZLib INFLATE decompression from memory into a stream

- return the number of bytes written into the stream
- if checkCRC is not nil, it will contain the crc32; if aStream is nil, it will only calculate the crc of the the uncompressed memory block
- by default, will use the deflate/.zip header-less format, but you may set ZlibFormat=true to add an header, as expected by zlib (and pdf)

function UncompressString(**const** data: ZipString) : ZipString;

Uncompress some data, with a proprietary format (including CRC)

- return "" in case of a decompression failure

function UnCompressZipString(src: pointer; srcLen: integer; **out** data: ZipString; checkCRC: PCardinal; ZlibFormat: Boolean; TempBufSize: integer=0): cardinal;

ZLib INFLATE decompression from memory into a AnsiString (ZipString) variable

- return the number of bytes written into the string
- if checkCRC is not nil, it will contain the crc32; if aStream is nil, it will only calculate the crc of the the uncompressed memory block
- by default, will use the deflate/.zip header-less format, but you may set ZlibFormat=true to add an header, as expected by zlib (and pdf)

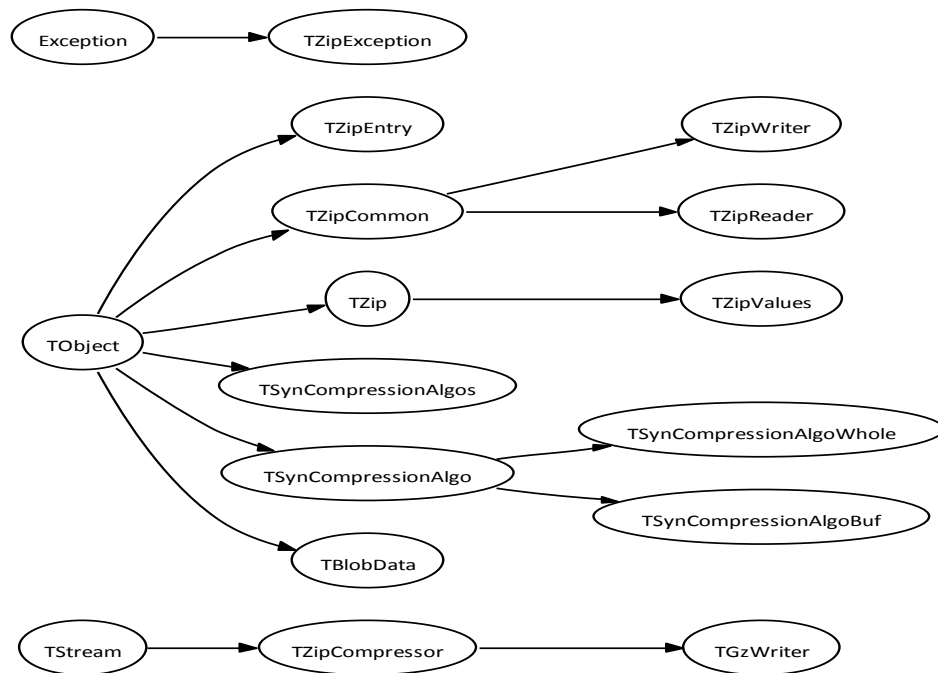

27.46. SynZipFiles.pas unit

Purpose: High-level access to .zip archive file compression

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the *SynZipFiles* unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynZip</i>	Low-level access to ZLib compression (1.2.5 engine version) - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1853

SynZipFiles class hierarchy

Objects implemented in the *SynZipFiles* unit

Objects	Description	Page
TSynCompressionAlgoBuf	Template class for 64KB chunked (not whole) algorithm (SynLZ, LZO...) which forces storing as uncompressed if compression ratio has no gain	1865
TSynCompressionAlgoWhole	Template class for whole algorithm (SynLZ, LZO...) which forces storing as uncompressed if compression ratio has no gain	1865
TZip	TZip handles ZIP standard files on disk	1866

Objects	Description	Page
TZipReader	Databuf: AnsiChar	1865

TSynCompressionAlgoBuf = class(TSynCompressionAlgo)

Template class for 64KB chunked (not whole) algorithm (SynLZ, LZO...) which forces storing as uncompressed if compression ratio has no gain

destructor Destroy; **override;**

Free fCompressBuf memory if allocated

function Compress(InP: pointer; InLen: cardinal; CRC: PCardinal): cardinal;
override;

Compress InP[InLen] into OutStream + update CRC, return compressed length

function UnCompress(InP: pointer; InLen: cardinal; OutP: pointer): cardinal;
override;

Uncompress InP[InLen] into OutP, return uncompressed length

function UnCompressedLength(InP: pointer; InLen: cardinal): cardinal; **override;**

Return uncompressed length of InP[InLen] for proper mem allocation

procedure CompressInit(OutStream: TStream); **override;**

Initialize compression into OutStream

TSynCompressionAlgoWhole = class(TSynCompressionAlgo)

Template class for whole algorithm (SynLZ, LZO...) which forces storing as uncompressed if compression ratio has no gain

function Compress(InP: pointer; InLen: cardinal; CRC: PCardinal): cardinal;
override;

Compress InP[InLen] into OutStream + update CRC, return compressed length

function UnCompress(InP: pointer; InLen: cardinal; OutP: pointer): cardinal;
override;

Uncompress InP[InLen] into OutP, return uncompressed length

function UnCompressedLength(InP: pointer; InLen: cardinal): cardinal; **override;**

Return uncompressed length of InP[InLen] for proper mem allocation

TZipReader = class(TZipCommon)

Databuf: AnsiChar

function GetData(aIndex: integer; aStream: TStream=nil; CheckCRC: boolean=false;
asBlobDataStored: boolean=false; withAlgoDataLen: boolean=false): PAnsiChar;

Force Count=0

function SameAs(aReader: TZipReader): boolean;

Save uncompressed to stream

```
procedure DeleteLastEntry;
```

TBlobData->aStream

```
procedure GetBlobData(aIndex: integer; aStream: TStream); overload;
```

PBlobData(result)

```
procedure SaveToStream(aStream: TStream);
```

Don't use inside TZipValues: already done in Create

```
TZip = class(TObject)
```

TZip handles ZIP standard files on disk

```
function MarkDeletedBefore(aDate: TDateTime; aBackup: TZip=nil): boolean;
```

Before any ZipCreate

```
function SameAs(aZip: TZip): boolean;
```

Flushed at Destroy

```
procedure ZipClose;
```

Use Zip.Write() to send data before ZipClose

Types implemented in the *SynZipFiles* unit

```
PBlobData = ^TBlobData;
```

Used to transfert Blob Data from/to Client without compress/uncompress:

Constants implemented in the *SynZipFiles* unit

```
BLOBDATA_HEADSIZE = sizeof(TBlobData)-sizeof(AnsiChar);
```

Points to next bloc

Functions or procedures implemented in the *SynZipFiles* unit

Functions or procedures	Description	Page
GZRead	Create a TBlobData in aStream - can use encryption with algo 7=AES+Zip-chunked and 8=AES+SynLz-chunked	1866

```
function GZRead(const aFileName: TFileName): RawByteString; overload;
```

Create a TBlobData in aStream - can use encryption with algo 7=AES+Zip-chunked and 8=AES+SynLz-chunked

Variables implemented in the *SynZipFiles* unit

```
BlobDataNull: TBlobData;
```

Before any AddValue

27.47. SynCrossPlatformCrypto.pas unit

Purpose: Cryptographic cross-platform units

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

SynCrossPlatformCrypto class hierarchy

Objects implemented in the SynCrossPlatformCrypto unit

Objects	Description	Page
TSHA256	Class for SHA256 hashing	1867
TSHAHash	Internal work buffer for SHA256 hashing	1867

TSHAHash = record

Internal work buffer for SHA256 hashing

TSHA256 = class(TObject)

Class for SHA256 hashing

constructor Create;

Initialize SHA256 context for hashing

function Finalize: **string**;

*Finalize and compute the resulting SHA256 hash Digest of all data affected to Update() method
- returns the data as Hexadecimal*

procedure Update(**const** ascii: **string**); overload;

Update the SHA256 context with 8 bit ascii data (e.g. UTF-8)

procedure Update(**const** buf: **array of byte**); overload;

Update the SHA256 context with some data

Types implemented in the SynCrossPlatformCrypto unit

TSHA256Buffer = array[0..63] of hash32;

Internal buffer for SHA256 hashing

Functions or procedures implemented in the SynCrossPlatformCrypto unit

Functions or procedures	Description	Page
crc32	Compute the zlib/deflate crc32 hash value on a supplied buffer	1868
crc32ascii	Compute the zlib/deflate crc32 hash value on a supplied ASCII-7 buffer	1868

Functions or procedures	Description	Page
SHA256	Compute SHA256 hexa digest of a supplied buffer	1868
SHA256	Compute SHA256 hexa digest of a supplied 8 bit ascii data (e.g. UTF-8)	1868

function crc32(aCrc32: hash32; **const** buf: **array of** byte): hash32;

Compute the zlib/deflate crc32 hash value on a supplied buffer

function crc32ascii(aCrc32: hash32; **const** buf: **string**): hash32;

Compute the zlib/deflate crc32 hash value on a supplied ASCII-7 buffer

function SHA256(**const** buf: **string**): **string**; overload;

Compute SHA256 hexa digest of a supplied 8 bit ascii data (e.g. UTF-8)

function SHA256(**const** buf: **array of** byte): **string**; overload;

Compute SHA256 hexa digest of a supplied buffer

Variables implemented in the *SynCrossPlatformCrypto* unit

crc32tab: array[byte] of hash32;

Table used by crc32() function

- table content is created from code in initialization section below

27.48. SynCrossPlatformJSON.pas unit

Purpose: Minimum standard-alone cross-platform JSON process using variants

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

SynCrossPlatformJSON class hierarchy

Objects implemented in the *SynCrossPlatformJSON* unit

Objects	Description	Page
EJSONException	Exception used during standard-alone cross-platform JSON process	1869
TJSONTable	Handle a JSON result table, as returned by mORMot's server	1871
TJSONTableObject	Handle a JSON result table, as returned by mORMot's server	1872
TJSONVariant	Low-level class used to register TJSONVariantData as custom type	1871
TJSONVariantData	Stores any JSON object or array as variant	1869
TPublishedMethod	Used e.g. by TSynTest for each test case	1872

EJSONException = class(Exception)

Exception used during standard-alone cross-platform JSON process

TJSONVariantData = object(TObject)

Stores any JSON object or array as variant

- this structure is not very optimized for speed or memory use, but is simple and strong enough for our client-side purpose
- it is in fact already faster (and using less memory) than DBXJSON and SuperObject / XSuperObject libraries - of course, mORMot's TDocVariant is faster, as dwsJSON is in some cases, but those are not cross-platform

Names: TStringDynArray;

Names of this jsonObject

Values: TVariantDynArray;

Values of this jsonObject or jsonArray

function AddItem: PJSONVariantData;

Add a void TJSONVariantData to the jsonArray and return a pointer to it

function Data(const aName: string): PJSONVariantData;

Access to a nested TJSONVariantData item

- returns nil if aName was not found, or not a true TJSONVariantData item

function EnsureData(const aPath: string): PJSONVariantData;

Access to a nested TJSONVariantData item, creating it if necessary

- aPath can be specified with any depth, e.g. 'level1.level2.level3'

- if the item does not exist or is not a true TJSONVariantData, a new one will be created, and returned as pointer

function FromJSON(const JSON: string): boolean;

Fill this document from a JSON array or object

function NameIndex(const aName: string): integer;

Search for a name in this jsonObject

function ToJSON: string;

Convert this document into JSON array or object

function ToNewObject: TObject;

Create an instance, and fill its published properties from this JSON object

- it should contain some "ClassName" properties, i.e. JSON should have been created by ObjectToJSON(Instance,true) and the class should have been registered with RegisterClassForJSON()

function ToObject(Instance: TObject): boolean;

Fill the published properties of supplied class from this JSON object

procedure AddNameValue(const aName: string; const aValue: variant);

Add a name/value pair to the jsonObject

- raise a EJSONException if the instance is a jsonArray

procedure AddValue(const aValue: variant);

Add a value to the jsonArray

- raise a EJSONException if the instance is a jsonObject

procedure Clear;

Delete all internal stored data

- basically the same as Finalize(aJsonVariantData) + aJsonVariantData.Init

- you should call this method before calling overloaded Init several times

procedure Init(const JSON: string); overload;

Initialize the low-level memory structure with a given JSON content

- you should call Clear before calling overloaded Init several times

procedure Init; overload;

Initialize the low-level memory structure

- you should call Clear before calling overloaded Init several times

procedure InitFrom(const aValues: TVariantDynArray); overload;

Initialize the low-level memory structure with a given array of variant
 - you should call Clear before calling overloaded Init several times

procedure SetPath(const aPath: string; const aValue: variant);

Set a value of this jsonObject to a given path
 - aPath can be specified with any depth, e.g. 'level1.level2.level3'

property Count: integer **read** GetCount;

Number of items in this jsonObject or jsonArray
 - returns 0 if this instance is not a TJSONVariant custom variant

property Item[aIndex: integer]: variant **read** GetItem **write** SetItem;

Access by index to a value of this jsonArray
 - will return UnAssigned if aIndex is not correct or this is not a jsonArray

property Kind: TJSONVariantKind **read** GetKind;

Kind of document this TJSONVariantData contains
 - returns jvUndefined if this instance is not a TJSONVariant custom variant

property Value[const aName: string]: variant **read** GetValue **write** SetValue;

Access by name to a value of this jsonObject
 - value is returned as (varVariant or varByRef) for best speed
 - will return UnAssigned if aName is not correct or this is not a jsonObject

property ValueCopy[const aName: string]: variant **read** GetValueCopy;

Access by name to a value of this jsonObject
 - value is returned as a true copy (not varByRef) so this property is slower but safer than Value[], if the owning TJSONVariantData disappears
 - will return UnAssigned if aName is not correct or this is not a jsonObject

TJSONVariant = class(TInvokeableVariantType)

Low-level class used to register TJSONVariantData as custom type

- allows late binding to values, e.g.
 jsonvar.avalue := jsonvar.avalue+1;
 - due to an issue with FPC implementation, you can only read properties, not set them, so you should write:
 TJSONVariantData(jsonvar)['avalue'] := jsonvar.avalue+1;

TJSONTable = class(TObject)

Handle a JSON result table, as returned by mORMot's server
 - handle both expanded and non expanded layout
 - will be used e.g. on client side for variant-based ORM data parsing

constructor Create(const aJSON: string);

Parse the supplied JSON content

function FieldIndex(const FieldName: string): integer;

Case-insensitive search for a field name

function Step(SeekFirst: boolean=false): boolean;

To be called in a loop to iterate through all data rows
- if returned true, Value[] contains the fields of this row

function StepValue(var RowValues: variant; SeekFirst: boolean=false): boolean;

To be called in a loop to iterate through all data rows
- if returned true, RowValues contains this row as TJSONVariant

property FieldNames: TStringDynArray **read** fFieldNames;

The recognized field names

property JSON: string **read** fJSON;

The associated JSON content

property RowValues: TVariantDynArray **read** fRowValues;

After Step() returned true, can be used to retrieve a field value by index

property Value[const FieldName: string]: variant **read** Get;

After Step() returned true, can be used to retrieve a field value by name

TJSONTableObject = **class**(TJSONTable)

Handle a JSON result table, as returned by mORMot's server
- handle both expanded and non expanded layout
- this class is able to use RTTI to fill all published properties of a TObject

function StepObject(Instance: TObject; SeekFirst: boolean=false): boolean; **virtual**;

To be called in a loop to iterate through all data rows
- if returned true, Object published properties will contain this row

TPublishedMethod = **record**

Used e.g. by TSynTest for each test case

Types implemented in the SynCrossPlatformJSON unit

NativeInt = integer;

Delphi 2009 NativeUInt is buggy

TByteDynArray = **array of** byte;

This type is used to store BLOB content

TJSONVariantKind = (jvUndefined, jvObject, jvArray);

Which kind of document the TJSONVariantData contains

TPublishedMethodDynArray = **array of** TPublishedMethod;

As filled by GetPublishedMethods()

TRTTIPropInfo = PPropInfo;

An abstract type used for RTTI property information

TRTTITypeInfo = PPropInfo;

An abstract type used for RTTI type information

TUTF8Buffer = UTF8String;

This type will store UTF-8 encoded buffer (also on NextGen platform)

Constants implemented in the *SynCrossPlatformJSON* unit

JSON_BASE64_MAGIC: array[0..2] of byte = (\$ef,\$bf,\$b0);

Special code to mark Base64 binary content in JSON string

- Unicode special char U+FFFF0 is UTF-8 encoded as EF BF B0 bytes
- prior to Delphi 2009, it won't work as expected since U+FFFF0 won't be able to be converted into U+FFFF0

JSON_BASE64_MAGIC_LEN = sizeof(JSON_BASE64_MAGIC) div sizeof(char);

Size, in platform chars, of our special code to mark Base64 binary content in JSON string

- equals 1 since Delphi 2009 (UTF-16 encoded), or 3 for older versions (UTF-8 encoded) of the compiler compiler

Functions or procedures implemented in the *SynCrossPlatformJSON* unit

Functions or procedures	Description	Page
AppendChar	This function is faster than <code>str := str+chr !</code>	1874
Base64JSONStringToBytes	Decode a Base64-encoded string	1874
BytesToBase64JSONString	Base-64 encode a BLOB into string	1874
CreateClassForJSON	Create a class instance from its name	1875
DateTimeToIso8601	Compute the unquoted ISO-8601 text representation of a date/time value	1875
DateTimeToJSON	Compute the ISO-8601 JSON text representation of a date/time value	1875
DoubleQuoteStr	Convert the supplied text as "text", as expected by SQL standard	1875
DoubleToJSON	Compute the JSON representation of a floating-point value	1875
GetInstanceProp	Retrieve the value of a published property as variant	1875
GetPropsInfo	Retrieve the published properties type information about a given class	1875
GetPublishedMethods	Retrieve all the published methods of a given class, using RTTI	1875
IdemPropName	Check that two ASCII-7 latin text do match	1875
IdemPropName	Check that two ASCII-7 latin text do match	1875
Iso8601ToDateTime	Convert unquoted ISO-8601 text representation into a date/time value	1875
JSONToNewObject	Create a new object and fill its published properties from the supplied JSON object, which should include "ClassName":"..." properties	1875
JSONToObject	Fill an object published properties from the supplied JSON object	1876
JSONToObjectList	Create a list of object published properties from the supplied JSON object	1876
JSONToValue	Compute a variant from its JSON representation	1876

Functions or procedures	Description	Page
JSONVariant	Create a TJSONVariant instance from a given JSON content	1876
JSONVariant	Create a TJSONVariant TJSONVariant array from a supplied array of values	1876
JSONVariantData	Access to a TJSONVariant instance members	1876
JSONVariantDataSafe	Access to a TJSONVariant instance members	1876
JSONVariantFromConst	Create a TJSONVariant TJSONVariant array from a supplied array of values	1876
NowToIso8601	Compute the ISO-8601 JSON text representation of the current date/time value	1877
ObjectToJSON	Compute the JSON representation of an object published properties	1877
RegisterClassForJSON	Register the class types to be created from its name	1877
RTTIPropInfoTypeName	Return a string corresponding to the type name, as stored in the RTTI	1877
SetInstanceProp	Set the value of a published property from a variant	1877
ShortStringToString	Convert ASCII-7 latin text, encoded as a shortstring buffer, into a string	1877
StartWithPropName	Check that two ASCII-7 latin text do match	1877
StringToJSON	Compute the quoted JSON string corresponding to the supplied text	1877
UTF8FileToString	Read an UTF-8 (JSON) file into a native string	1877
ValueToJSON	Compute the JSON representation of a variant value	1877
VarRecToValue	Convert an "array of const" parameter value into its string representation	1877

procedure AppendChar(**var** str: **string**; chr: Char);

This function is faster than str := str+chr !

function Base64JSONStringToBytes(**const** JSONString: **string**; **var** Bytes: TByteDynArray; withBase64Magic: boolean=true): boolean;

Decode a Base64-encoded string

- default withBase64Magic=TRUE will expect the string to start with our JSON_BASE64_MAGIC marker

function BytesToBase64JSONString(**const** Bytes: TByteDynArray; withBase64Magic: boolean=true): **string**;

Base-64 encode a BLOB into string

- default withBase64Magic=TRUE will include our JSON_BASE64_MAGIC marker

function CreateClassForJSON(const ClassName: string): TObject;

Create a class instance from its name

- the class should have been registered previously via RegisterClassForJSON()
- if the supplied class name is not found, will return nil

function DateTimeToIso8601(Value: TDateTime): string;

Compute the unquoted ISO-8601 text representation of a date/time value

- e.g. 'YYYY-MM-DD' 'Thh:mm:ss' or 'YYYY-MM-DDThh:mm:ss'
- if Date is 0, will return ''

function DateTimeToJSON(Value: TDateTime): string;

Compute the ISO-8601 JSON text representation of a date/time value

- e.g. "YYYY-MM-DD" "Thh:mm:ss" or "YYYY-MM-DDThh:mm:ss"
- if Date is 0, will return ""

procedure DoubleQuoteStr(var text: string);

Convert the supplied text as "text", as expected by SQL standard

procedure DoubleToJSON(Value: double; var result: string);

Compute the JSON representation of a floating-point value

function GetInstanceProp(Instance: TObject; PropInfo: TRTTIPropInfo; StoreClassName: boolean = False): variant;

Retrieve the value of a published property as variant

procedure GetPropsInfo(TypeInfo: TRTTITypeInfo; var PropNames: TStringDynArray; var PropRTTI: TRTTIPropInfoDynArray);

Retrieve the published properties type information about a given class

procedure GetPublishedMethods(Instance: TObject; out Methods: TPublishedMethodDynArray);

Retrieve all the published methods of a given class, using RTTI

function IdemPropName(const PropName1, PropName2: string): boolean; overload;

Check that two ASCII-7 latin text do match

function IdemPropName(PropName1: PByteArray; const PropName2: string): boolean; overload;

Check that two ASCII-7 latin text do match

- first parameter is expected to be a shortstring low-level buffer - as such, this overloaded function would work with NEXTGEN encoded RTTI

function Iso8601ToDateTime(const Value: string): TDateTime;

Convert unquoted ISO-8601 text representation into a date/time value

- e.g. 'YYYY-MM-DD' 'Thh:mm:ss' or 'YYYY-MM-DDThh:mm:ss'

function JSONToNewObject(const JSON: string): pointer;

Create a new object and fill its published properties from the supplied JSON object, which should include "ClassName": "... " properties

- JSON should have been created with ObjectToJSON(Instance,true) and the class should have been registered with RegisterClassForJSON()

function JSONToObject(Instance: TObject; **const** JSON: **string**): **boolean**;

Fill an object published properties from the supplied JSON object
 - handle only simple types of properties, not nested class instances

function JSONToObjectList(ItemClass: TClass; **const** JSON: **string**): TObjectList;

Create a list of object published properties from the supplied JSON object
 - handle only simple types of properties, not nested class instances

function JSONToValue(**const** JSON: **string**): **variant**;

Compute a variant from its JSON representation
 - will work for simple types, or TJSONVariant object or array

function JSONVariant(**const** values: TVariantDynArray): **variant**; overload;

Create a TJSONVariant TJSONVariant array from a supplied array of values

function JSONVariant(**const** JSON: **string**): **variant**; overload;

Create a TJSONVariant instance from a given JSON content

- typical usage may be:

```
var doc: variant;
    json: string;
begin
  doc := JSONVariant('{"test":1234,"name":"Joh\n\r"}');
  assert(doc.test=1234); // access via late binding
  assert(doc.name='Joh\n'#13);
  assert(doc.name2=null); // unknown properties returns null
  json := doc; // to convert a TJSONVariant to JSON, just assign to a string
  assert(json='{"test":1234,"name":"Joh\n\r"}');
end;
```

- note that FPC does not allow to set values by late-binding

function JSONVariantData(**const** JSONVariant: **variant**): PJSONVariantData;

Access to a TJSONVariant instance members

- e.g. Kind, Count, Names[] or Values[]
 - will raise an exception if the supplied variant is not a TJSONVariant
 - this function is safer than TJSONVariant(JSONVariant)

function JSONVariantDataSafe(**const** JSONVariant: **variant**; ExpectedKind: TJSONVariantKind=JVUndefined): PJSONVariantData;

Access to a TJSONVariant instance members

- e.g. Kind, Count, Names[] or Values[]
 - will return a read-only fake TJSONVariant with Kind=JVUndefined if the supplied variant is not a TJSONVariant
 - if ExpectedKind is JVArray or JVObject, it would return a fake TJSONVariant with Kind=JVUndefined if the JSONVariant kind does not match - so you can write:

```
var _a: integer;
    _arr: PJSONVariantData;
...
_arr := JSONVariantDataSafe(_variant, JVArray);
SetLength(result, _arr.Count);
for _a := 0 to _arr.Count-1 do
  result[_a] := _arr.Values[_a];
```

in the above code, _arr.Count will be 0 if _variant.Kind<>JVArray

- this function is safer than TJSONVariant(JSONVariant)

function JSONVariantFromConst(**const** constValues: **array of variant**): **variant**;

Create a TJSONVariant TJSONVariant array from a supplied array of values

function NowToIso8601: **string**;

Compute the ISO-8601 JSON text representation of the current date/time value
- e.g. "2015-06-27T20:59:29"

function ObjectToJSON(Instance: TObject; StoreClassName: boolean=false): **string**;

Compute the JSON representation of an object published properties
- handle only simple types of properties, not nested class instances
- any TList/TObjectList/TCollection will be serialized as JSON array

procedure RegisterClassForJSON(const Classes: array of TClass);

Register the class types to be created from its name
- used e.g. by JSONToNewObject() or TJSONVariantData.ToNewObject

function RTTIPropInfoTypeName(PropInfo: TRTTIPropInfo): **string**;

Return a string corresponding to the type name, as stored in the RTTI
- e.g. 'TDateTime', 'TByteDynArray', 'TModTime', 'TCreateTime'

procedure SetInstanceProp(Instance: TObject; PropInfo: TRTTIPropInfo; const Value: variant);

Set the value of a published property from a variant

function ShortStringToString(Buffer: PByteArray): **string**;

Convert ASCII-7 latin text, encoded as a shortstring buffer, into a string
- as such, this function would work with NEXTGEN encoded RTTI

function StartWithPropName(const PropName1, PropName2: **string**): **boolean**;

Check that two ASCII-7 latin text do match

function StringToJSON(const Text: **string**): **string**;

Compute the quoted JSON string corresponding to the supplied text

function UTF8FileToString(const aFileName: TFileName): **string**;

Read an UTF-8 (JSON) file into a native string
- file should be existing, otherwise an exception is raised

function ValueToJSON(const Value: variant): **string**;

Compute the JSON representation of a variant value
- will work for simple types, or TJSONVariant object or array

function VarRecToValue(const V: TVarRec; out wasString: **boolean**): **string**;

Convert an "array of const" parameter value into its string representation

Variables implemented in the *SynCrossPlatformJSON* unit

JSONVariantType: TInvokeableVariantType;

The custom variant type definition registered for TJSONVariant

Purpose: Minimum stand-alone cross-platform REST process for mORMot client
- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Unit Name	Description	Page
<i>SynCrossPlatformCrypto</i>	Cryptographic cross-platform units - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1867
<i>SynCrossPlatformJSON</i>	Minimum stand-alone cross-platform JSON process using variants - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1869
<i>SynCrossPlatformSpecific</i>	System-specific cross-platform units - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1900

Objects	Description	Page
---------	-------------	------

Objects	Description	Page
ERestException	Exception type raised when working with REST access	1879
EServiceException	Exception type raised when working with interface-based service process	1880
IServiceAbstract	All generated client interfaces will inherit from this abstract parent	1885
TServiceClientAbstract	Abstract ancestor to all client-side interface-based services	1885
TServiceClientAbstractClientDriven	Abstract ancestor to all sicClientDriven interface-based services	1886
TSQLAuthGroup	Table containing the available user access rights for authentication	1884
TSQLAuthUser	Table containing the Users registered for authentication	1884
TSQLModel	Store the database model	1882
TSQLModelInfo	Store information of one TSQLRecord class	1880
TSQLModelInfoPropInfo	Store information of one TSQLRecord published property	1880
TSQLRecord	Abstract ORM class to access remote tables	1882
TSQLRest	Abstract REST access class	1887
TSQLRestClientHTTP	REST client via HTTP	1893
TSQLRestClientURI	REST client access class	1891
TSQLRestLogClientThread	Thread used to asynchronously log to a remote client	1892
TSQLRestRoutingAbstract	Class used to determine the protocol of interface-based services	1886
TSQLRestRoutingJSON_RPC	JSON/RPC protocol for interface-based services	1887
TSQLRestRoutingREST	Default simple REST protocol for interface-based services	1886
TSQLRestServerAuthentication	Abstract class used for client authentication	1893
TSQLRestServerAuthenticationDefault	MORMot secure RESTful authentication scheme	1893
TSQLRestServerAuthenticationNone	MORMot weak RESTful authentication scheme	1893
TSQLTableJSON	Handle a JSON result table, as returned by mORMot's REST server ORM	1880

ERestException = class(Exception)
Exception type raised when working with REST access

TSQLTableJSON = class(TJSONTableObject)

Handle a JSON result table, as returned by mORMot's REST server ORM

- this class is expected to work with TSQLRecord instances only
- it will let any "RowID" JSON key match TSQLRecord.ID property

function FillOne(aValue: TSQLRecord; aSeekFirst: boolean=false): boolean;

To be called in a loop to iterate through all data rows

- if returned true, Object published properties will contain this row

EServiceException = class(ERestException)

Exception type raised when working with interface-based service process

TSQLModelInfoPropInfo = class(TObject)

Store information of one TSQLRecord published property

Kind: TSQLFieldKind;

The property field type

Name: string;

The name of the published property

- e.g. 'FirstName'

RTTI: TRTTIPropInfo;

RTTI information about the published property

TypeName: string;

The property type name, as retrieved from RTTI

constructor CreateFrom(aRTTI: TRTTIPropInfo);

Initialize the instance

TSQLModelInfo = class(TObject)

Store information of one TSQLRecord class

AllFields: TSQLFieldBits;

Specifies all fields, including simple and BLOB fields

BlobFields: TSQLFieldBits;

Specifies the BLOB fields

CreateTimeFields: TSQLFieldBits;

Specifies the TCreateTime fields

HasKind: TSQLFieldKinds;

Contains all published properties kind

HasTimeFields: boolean;

TRUE if has TModTime or TCreateTime fields

ModAndCreateTimeFields: TSQLFieldBits;

Specifies the TModTime and TCreateTime fields

ModTimeFields: TSQLFieldBits;

Specifies the TModTime fields

Name: **string**;

The short name of the class

- i.e. 'People' for TSQLRecordPeople

Prop: TSQLModelInfoPropInfoDynArray;

Information about every published property

- first is always the ID field

RecordFields: TSQLFieldBits;

Specifies the Record fields

SimpleFields: TSQLFieldBits;

Specifies the "simple" fields, i.e. all non BLOB fields

Table: TSQLRecordClass;

The TSQLRecord class type itself

VariantFields: TSQLFieldBits;

Specifies the Variant fields

constructor CreateFromRTTI(aTable: TSQLRecordClass);

Initialize the class member for the supplied TSQLRecord

destructor Destroy; **override**;

Finalize the memory used

function FieldBitsToFieldNames(const FieldBits: TSQLFieldBits): **string**;

Return the corresponding field names

function FieldNamesToFieldBits(const FieldNames: **string**; IncludeModTimeFields: boolean): TSQLFieldBits;

FieldNames="" to retrieve simple fields, '' all fields, or as specified*

function SQLSelect(const FieldNames: **string**): **string**;

Compute the 'SELECT ... FROM ...' corresponding to the supplied fields

function ToJSON(Value: TSQLRecord; const Fields: TSQLFieldBits): **string**; **overload**;

Save the specified record as JSON

function ToJSONAdd(Client: TSQLRest; Value: TSQLRecord; ForceID: boolean; const FieldNames: **string**): **string**;

Save the specified record as JSON for record adding

function ToJSONUpdate(Client: TSQLRest; Value: TSQLRecord; const FieldNames: **string**; ForceID: boolean): **string**;

Save the specified record as JSON for record update

procedure ComputeFieldsBeforeWrite(aClient: TSQLRest; Value: TSQLRecord; AndCreate: Boolean);

Set TModTime and TCreateFields

TSQLModel = class(TObject)

Store the database model

constructor Create(const Tables: array of TSQLRecordClass; const aRoot: string = 'root');

Initialize the Database Model

- set the Tables to be associated with this Model, as TSQLRecord classes
- set the optional Root URI path of this Model - default is 'root'

destructor Destroy; override;

Finalize the memory used

function GetTableIndex(const aTableName: string): integer; overload;

Get index of aTable in Tables[], returns -1 if not found

function GetTableIndex(aTable: TSQLRecordClass): integer; overload;

Get index of aTable in Tables[], returns -1 if not found

function GetTableIndexExisting(aTable: TSQLRecordClass): integer;

Get index of aTable in Tables[], raise an ERestException if not found

function InfoExisting(aTable: TSQLRecordClass): TSQLModelInfo;

Get the RTTI information for the specified class or raise an ERestException

procedure Add(Table: TSQLRecordClass);

Register a new Table class to this Model

property Info: TSQLModelInfoDynArray read fInfo;

The RTTI information for each class

property Root: string read fRoot;

The Root URI path of this Database Model

TSQLRecord = class(TPersistent)

Abstract ORM class to access remote tables

- in comparison to mORMot.pas TSQLRecord published fields, dynamic arrays shall be defined as variant (since SynCrossPlatformJSON do not serialize)
- inherit from TPersistent to have RTTI for its published properties (SmartMobileStudio does not allow {\$M+} in the source)

constructor Create(aClient: TSQLRest; const FieldNames, SQLWhere: string; const BoundsSQLWhere: array of const); overload;

This constructor loads a record from a REST instance

- you can bind parameters by using ? in the SQLWhere clause
- use DateTimeToSQL() for date/time database fields
- FieldNames="" retrieve simple fields, '*' all fields, or as specified

constructor Create(aClient: TSQLRest; aID: TID; ForUpdate: boolean=false); overload;

This constructor loads a record from a REST instance from its ID

constructor Create; overload; **virtual**;

This constructor initializes the record

constructor CreateAndFillPrepare(aClient: TSQLRest; **const** FieldNames, SQLWhere: **string**; **const** BoundsSQLWhere: **array of const**);

This constructor ask the server for a list of matching records

- you can bind parameters by using ? in the SQLWhere clause
- use DateTimeToSQL() for date/time database fields
- FieldNames="" retrieve simple fields, '*' all fields, or as specified
- then you can also loop through all rows with

```
while Rec.FillOne do
  dosomethingwith(Rec);
```

constructor CreateFromVariant(**const** aValue: **variant**);

This constructor will loads a record from its variant representation

- will call internally the FromJSON() method

destructor Destroy; **override**;

Finalize the record memory

function FillOne: **boolean**;

Fill all published properties of this object with the next available row of data, as returned by CreateAndFillPrepare() constructor

function FillRewind: **boolean**;

Go to the first data row, as returned by CreateAndFillPrepare(), then fill all published properties of this object

- you can use it e.g. as:

```
while Rec.FillOne do
  dosomethingwith(Rec);
if Rec.FillRewind then
  repeat
    dosomeotherthingwith(Rec);
  until not Rec.FillOne;
```

function FromJSON(**const** aJSON: **string**): **boolean**;

Fill the specified record from the supplied JSON

function FromVariant(**const** aValue: **variant**): **boolean**;

Fill the specified record from its variant representation

function RecordClass: TSQLRecordClass;

Return the class type of this TSQLRecord

function ToJSON(aModel: TSQLModel; aFieldNames: **string**=''): **string**;

Get the object properties as JSON

- FieldNames="" to retrieve simple fields, '*' all fields, or as specified

function ToVariant: **variant**;

Get the object properties as a TJSONVariant document

property FillTable: TSQLTableJSON **read** fFill;

Contains the TSQLTableJSON instance after CreateAndFillPrepare()

property ID: TID read fID write fID;

Stores the record's primary key

property InternalState: cardinal read fInternalState;

Internal state counter of the mORMot server at last access time
- can be used to check if retrieved data may be out of date

TSQLAuthGroup = class(TSQLRecord)

Table containing the available user access rights for authentication

- is added here since should be part of the model
- no wrapper is available to handle AccessRights, since for security reasons it is not available remotely from client side

property AccessRights: string read fAccessRights write fAccessRights;

A textual representation of a TSQLAccessRights buffer

property Ident: string read fIdent write fIdent stored AS_UNIQUE;

The access right identifier, ready to be displayed
- the same identifier can be used only once (this column is marked as unique via a "stored AS_UNIQUE" (i.e. "stored false") attribute)

property SessionTimeout: integer read fSessionTimeOut write fSessionTimeOut;

The number of minutes a session is kept alive

TSQLAuthUser = class(TSQLRecord)

Table containing the Users registered for authentication

property Data: TSQLRawBlob read fData write fData;

Some custom data, associated to the User
- Server application may store here custom data
- its content is not used by the framework but 'may' be used by your application

property DisplayName: string read fDisplayName write fDisplayName;

The User Name, as may be displayed or printed

property GroupRights: TID read fGroup write fGroup;

The associated access rights of this user in TSQLAuthGroup
- access rights are managed by group
- note that 'Group' field name is not allowed by SQLite

property LogonName: string read fLogonName write fLogonName stored AS_UNIQUE;

The User identification Name, as entered at log-in
- the same identifier can be used only once (this column is marked as unique via a "stored AS_UNIQUE" - i.e. "stored false" - attribute), and therefore indexed in the database (e.g. hashed in TSQLRestStorageInMemory)

property PasswordHashHexa: string read fPasswordHashHexa write fPasswordHashHexa;

The hexa encoded associated SHA-256 hash of the password

property PasswordPlain: **string write** SetPasswordPlain;

Able to set the PasswordHashHexa field from a plain password content
 - in fact, PasswordHashHexa := SHA256('salt'+PasswordPlain) in UTF-8

TServiceClientAbstract = class(TInterfacedObject)

Abstract ancestor to all client-side interface-based services

- any overridden class will in fact call the server to execute its methods
 - inherited classes are in fact the main entry point for all interface-based services, without any interface use:

```
aCalculator := TServiceCalculator.Create(aClient);
try
  aIntegerResult := aCalculator.Add(10,20);
finally
  aCalculator.Free;
end;
```

- under SmartMobileStudio, calling Free is mandatory only for sicClientDriven mode (to release the server-side associated session), so e.g. for a sicShared instance, you can safely write:

```
aIntegerResult := TServiceCalculator.Create(aClient).Add(10,20);
```

- as you already noted, server-side interface-based services are in fact consumed without any interface in this cross-platform unit!

constructor Create(aClient: TSQLRestClientURI); **virtual**;

Initialize the fake instance

- this method will synchronously (i.e. blocking) check the server contract according to the one expected by the client
 - overridden constructors will set the parameters expected by the server

property Client: TSQLRestClientURI **read** GetClient;

The associated TSQLRestClientURI instance

property ContractExpected: **string read** GetContractExpected;

The published service contract, as expected by both client and server

property InstanceImplementation: TServiceInstanceImplementation **read** GetInstanceImplementation;

How this instance lifetime is expected to be handled

property ServiceName: **string read** GetServiceName;

The unmangled remote service name

property ServiceURI: **string read** GetServiceURI;

The URI to access to the remote service

IServiceAbstract = interface(IInterface)

All generated client interfaces will inherit from this abstract parent

property Client: TSQLRestClientURI **read** GetClient;

The associated TSQLRestClientURI instance

property ContractExpected: **string read** GetContractExpected;

The published service contract, as expected by both client and server

property InstanceImplementation: TServiceInstanceImplementation **read** GetInstanceImplementation;

How this instance lifetime is expected to be handled

property RunningInstance: TServiceClientAbstract **read** GetRunningInstance;

The client class instance currently implementing this interface

property ServiceName: **string** **read** GetServiceName;

The unmangled remote service name

property ServiceURI: **string** **read** GetServiceURI;

The URI to access to the remote service

TServiceClientAbstractClientDriven = **class**(TServiceClientAbstract)

Abstract ancestor to all sicClientDriven interface-based services

- since server-side life-time is driven by the client, this kind of class expects an explicit call to aService.Free (even on SmartMobileStudio)

constructor Create(aClient: TSQLRestClientURI); **override**;

Initialize the fake instance and create the remote per-client session

- raise an EServiceException if a per-client session was already started for the specified TSQLRestClientURI

- overridden constructors will set the parameters expected by the server

destructor Destroy; **override**;

This overridden method (called at aService.Free) will notify the server

property ClientID: **string** **read** fClientID;

The currently running instance ID on the server side

- only one instance is allowed per TSQLRestClientURI process

TSQLRestRoutingAbstract = **class**(TObject)

Class used to determine the protocol of interface-based services

- see TSQLRestRoutingREST and TSQLRestRoutingJSON_RPC for overridden methods - NEVER set this abstract TSQLRestRoutingAbstract class on TSQLRest.ServicesRouting property !

class procedure ClientSideInvoke(**var** uri: **string**; **const** method, params, clientDrivenID: **string**; **var** sent: **string**); **virtual**; **abstract**;

At Client Side, compute URI and BODY according to the routing scheme

- abstract implementation which is to be overridden

- as input, "method" should be the method name to be executed for "uri", "params" should contain the incoming parameters as JSON array (with []), and "clientDriven" ID should contain the optional Client ID value

- at output, should update the HTTP "uri" corresponding to the proper routing, and should return the corresponding HTTP body within "sent"

TSQLRestRoutingREST = **class**(TSQLRestRoutingAbstract)

Default simple REST protocol for interface-based services

- this is the default protocol used by TSQLRest

```
class procedure ClientSideInvoke(var uri: string; const method, params,  
clientDrivenID: string; var sent: string); override;
```

At Client Side, compute URI and BODY according to RESTful routing scheme

- e.g. on input uri='root/Calculator', method='Add', params='[1,2]' and clientDrivenID='1234' ->
on output uri='root/Calculator.Add/1234' and sent='[1,2]'

```
TSQLEstRoutingJSON_RPC = class(TSQLEstRoutingAbstract)
```

JSON/RPC protocol for interface-based services

- alternative to the TSQLEstRoutingREST default protocol set by TSQLEst

```
class procedure ClientSideInvoke(var uri: string; const method, params,  
clientDrivenID: string; var sent: string); override;
```

At Client Side, compute URI and BODY according to JSON/RPC routing scheme

- e.g. on input uri='root/Calculator', method='Add', params='[1,2]' and clientDrivenID='1234' ->
on output uri='root/Calculator' and sent={'method':"Add","params":[1,2],"id":1234}

```
TSQLEst = class(TObject)
```

Abstract REST access class

```
constructor Create(aModel: TSQLEstModel; aOwnModel: boolean=false); virtual;
```

Initialize the class, and associate it to a specified database Model

- if aOwnModel is TRUE, this class destructor will free aModel instance

```
destructor Destroy; override;
```

Will release the associated Model, if aOwnModel was TRUE at Create()

```
function Add(Value: TSQLEstRecord; SendData: boolean; ForceID: boolean=false;  
FieldNames: string=''): TID; virtual;
```

Create a new member, returning the newly created ID, or 0 on error

- if SendData is true, content of Value is sent to the server as JSON

- if ForceID is true, client sends the Value.ID field to use this ID for adding the record (instead of a database-generated ID)

- by default, only simple fields are pushed to the server, but you may specify a CSV list of field values to be transmitted - including blobs, which will be sent as base-64 encoded JSON

```
function BatchAdd(Value: TSQLEstRecord; SendData: boolean; ForceID: boolean=false;  
FieldNames: string=''): integer;
```

Create a new member in current BATCH sequence

- similar to Add(), but in BATCH mode: nothing is sent until BatchSend()

- returns the corresponding index in the current BATCH sequence, -1 on error

- you can set FieldNames="" to sent simple fields, '*' to add all fields (including BLOBs), or specify a CSV list of added fields

- this method will always compute and send TCreateTime/TModTime fields

```
function BatchCount: integer;
```

Retrieve the current number of pending transactions in the BATCH sequence

- every call to BatchAdd/Update/Delete methods increases this count

function BatchDelete(ID: TID): integer; overload;

Delete a member in current BATCH sequence

- similar to Delete(), but in BATCH mode: nothing is sent until BatchSend()
- returns the corresponding index in the current BATCH sequence, -1 on error
- deleted record class is the TSQLRecordClass used at BatchStart() call: it will fail if no class was specified for this BATCH sequence

function BatchDelete(Table: TSQLRecordClass; ID: TID): integer; overload;

Delete a member in current BATCH sequence

- similar to Delete(), but in BATCH mode: nothing is sent until BatchSend()
- returns the corresponding index in the current BATCH sequence, -1 on error
- with this overloaded method, the deleted record class is specified: no class shall have been set at BatchStart() call, or should be the same

function BatchDelete(Value: TSQLRecord): integer; overload;

Delete a member in current BATCH sequence

- similar to Delete(), but in BATCH mode: nothing is sent until BatchSend()
- returns the corresponding index in the current BATCH sequence, -1 on error

function BatchSend(var Results: TIDDynArray): integer;

Execute a BATCH sequence started by BatchStart() method

- send all pending BatchAdd/Update/Delete statements to the remote server
- will return the URI Status value, i.e. 200/HTTP_SUCCESS OK on success
- a dynamic array of 64 bit integers will be created in Results, containing all ROWDID created for each BatchAdd call, or 200 (=HTTP_SUCCESS) for all successful BatchUpdate/BatchDelete, or 0 on error
- any error during server-side process MUST be checked against Results[] (the main URI Status is 200 if about communication success, and won't imply that all statements in the BATCH sequence were successful)

function BatchStart(aTable: TSQLRecordClass; AutomaticTransactionPerRow: cardinal=10000; BatchOptions: TSQLRestBatchOptions=[]): boolean; **virtual**;

Begin a BATCH sequence to speed up huge database change

- then call BatchAdd(), BatchUpdate() or BatchDelete() methods with the proper class or instance of the
- at BatchSend call, all the sequence transactions will be sent at once
- at BatchAbort call, all operations will be aborted
- expect one TSQLRecordClass as parameter, which will be used for the whole sequence (in this case, you can't mix classes in the same BATCH sequence)
- if no TSQLRecordClass is supplied, the BATCH sequence will allow any kind of individual record in BatchAdd/BatchUpdate/BatchDelete
- return TRUE on success, FALSE if aTable is incorrect or a previous BATCH sequence was already initiated
- this method includes a AutomaticTransactionPerRow parameter, which will let all BATCH process be executed on the server side within a unique transaction grouped by the given number of rows

function BatchUpdate(Value: TSQLRecord; FieldNames: string=''): integer;

Update a member in current BATCH sequence

- similar to Update(), but in BATCH mode: nothing is sent until BatchSend()
- returns the corresponding index in the current BATCH sequence, -1 on error
- you can set FieldNames="" to sent simple fields, '*' to add all fields (including BLOBs), or specify a CSV list of added fields
- this method will always compute and send any TModTime fields

function Delete(Table: TSQLRecordClass; ID: TID): boolean; **virtual; abstract;**

Delete a member

function ExecuteList(const SQL: string): TSQLTableJSON; **virtual; abstract;**

Execute directly a SQL statement, returning a list of data rows or nil

function MultiFieldValues(Table: TSQLRecordClass; const FieldNames, SQLWhere: string): TSQLTableJSON; **overload;**

Execute directly a SQL statement, expecting a list of results

- return a result table on success, nil on failure
- FieldNames="" retrieve simple fields, '*' all fields, or as specified

function MultiFieldValues(Table: TSQLRecordClass; const FieldNames, SQLWhere: string; const BoundsSQLWhere: array of const; LimitFirstRow: Boolean=false): TSQLTableJSON; **overload;**

Execute directly a SQL statement, expecting a list of results

- return a result table on success, nil on failure
- you can bind parameters by using ? in the SQLWhere clause
- use DateTimeToSQL() for date/time database fields
- FieldNames="" retrieve simple fields, '*' all fields, or as specified

function Retrieve(const FieldNames, SQLWhere: string; const BoundsSQLWhere: array of const; Value: TSQLRecord): boolean; **overload;**

Get a member from a where clause

- you can bind parameters by using ? in the SQLWhere clause
- use DateTimeToSQL() for date/time database fields
- FieldNames="" retrieve simple fields, '*' all fields, or as specified

function Retrieve(aID: TID; Value: TSQLRecord; ForUpdate: boolean=false): boolean; **overload; virtual; abstract;**

Get a member from its ID

- return true on success, and fill all simple fields

function RetrieveBlob(Table: TSQLRecordClass; aID: TID; const BlobFieldName: string; out BlobData: TSQLRawBlob): boolean; **virtual; abstract;**

Get a blob field content from its record ID and supplied blob field name

- returns true on success, and the blob binary data

function RetrieveList(Table: TSQLRecordClass; const FieldNames, SQLWhere: string; const BoundsSQLWhere: array of const): TObjectList; **overload;**

Execute directly a SQL statement, returning a list of TSQLRecord

- you can bind parameters by using ? in the SQLWhere clause
- use DateTimeToSQL() for date/time database fields
- FieldNames="" retrieve simple fields, '*' all fields, or as specified

function Update(Value: TSQLRecord; FieldNames: string=''): boolean; virtual;

Update a member

- you can let default FieldNames="" to update simple fields, '*' to update all fields (including BLOBs), or specify a CSV list of updated fields

procedure BatchAbort;

Abort a BATCH sequence started by BatchStart() method

- in short, nothing is sent to the remote server, and sequence is voided

procedure Log(Level: TSynLogInfo; Instance: TObject); overload;

Call this method to add some information to the log at a specified level

- overloaded method which will log the corresponding class name and address
- the supplied log level will be checked against TSQLRest.LogLevel
- use LogToFile() or LogToRemoteServer() to set the OnLog callback

procedure Log(E: Exception); overload;

Call this method to add some information to the log for an Exception

- will log the Exception class name and message, if sllException is set

procedure Log(Level: TSynLogInfo; const Text: string; Instance: TObject=nil); overload;

Call this method to add some information to the log at a specified level

- the supplied log level will be checked against TSQLRest.LogLevel
- if Instance is set, it will log the corresponding class name and address
- will compute the text line in the very same format as TSynLog class
- use LogToFile() or LogToRemoteServer() to set the OnLog callback

procedure Log(Level: TSynLogInfo; const Fmt: string; const Args: array of const; Instance: TObject=nil); overload;

Call this method to add some information to the log at a specified level

- overloaded method which will call Format() to render the text
- here the Fmt layout is e.g. '%s %d %g', as standard Format(), and not the same as with SynCommons' FormatUTF8()
- the supplied log level will be checked against TSQLRest.LogLevel
- if Instance is set, it will log the corresponding class name and address
- use LogToFile() or LogToRemoteServer() to set the OnLog callback

procedure LogToFile(LogLevel: TSynLogInfos; const aFolderName: TFileName=''; const aFileName: TFileName='');

Start the logging process into a file

- if no directory is specified, will use the current one
- if no file name is supplied, will compute a new one with the current time stamp, in the specified directory

procedure LogToRemoteServer(LogLevel: TSynLogInfos; const aServer: string; aPort: integer=8091; const aRoot: string='LogService');

Start the logging process into a remote log server

- the server could be for instance a LogView tool running in server mode

property InternalState: cardinal read fInternalState;

Internal state counter of the mORMot server at last access time

- can be used to check if retrieved data may be out of date

property LogLevel: TSynLogInfos read fLogLevel write fLogLevel;

The set of log events which will be logged by Log() overloaded methods
- set to [] by default, meaning that log is disabled

property Model: TSQLModel read fModel;

The associated data model

property OnLog: TOnSQLRestLog read fOnLog write fOnLog;

The callback to be executed by Log() overloaded methods
- if none is set, the instance won't log anything

property ServerTimeStamp: TTimeLog read GetServerTimeStamp;

The current Date and Time, as retrieved from the server at connection

property ServicesRouting: TSQLRestRoutingAbstractClass read fServicesRouting;

The access protocol to be used for interface-based services
- is set to TSQLRestRoutingREST by default
- you can set TSQLRestRoutingJSON_RPC if the server expects this protocol

TSQLRestClientURI = class(TSQLRest)

REST client access class

constructor Create(aModel: TSQLModel; aOwnModel: boolean=false); **override;**

Initialize the class, and associate it to a specified database Model
- if aOwnModel is TRUE, this class destructor will free aModel instance

destructor Destroy; **override;**

Will call SessionClose

function CallBackGetResult(const aMethodName: string; const aNameValueParameters: array of const; aTable: TSQLRecordClass; aID: TID=0): string;

Decode "result":... content as returned by CallBackGet()
- if no Table is expected, set aTable=nil (we do not define nil as default parameter, since the SMS compiler is sometimes confused)

function Connect: boolean;

Connect to the REST server, and retrieve its time stamp offset
- under SMS, you should not use this blocking version, but the overloaded asynchronous method

function Delete(Table: TSQLRecordClass; ID: TID): boolean; **override;**

Delete a member

function ExecuteList(const SQL: string): TSQLTableJSON; **override;**

Execute directly a SQL statement, returning a list of rows or nil
- we expect reURLEncodedSQL to be defined in AllowRemoteExecute on server side, since we will encode the SQL at URL level, so that all HTTP client libraires will accept this layout (e.g. Indy or AJAX)

function Retrieve(aID: TID; Value: TSQLRecord; ForUpdate: boolean=false): boolean; **overload; override;**

Get a member from its ID using URI()

```
function RetrieveBlob(Table: TSQLRecordClass; aID: TID; const BlobFieldName:
string; out BlobData: TSQLRawBlob): boolean; override;
```

Get a blob field content from its record ID and supplied blob field name

- returns true on success, and the blob binary data, as directly retrieved from the server via a dedicated HTTP GET request

```
function SetUser(aAuthenticationClass: TSQLRestServerAuthenticationClass; const
aUserName, aPassword: string; aHashedPassword: Boolean=False): boolean;
```

Authenticate an User to the current connected Server

- using TSQLRestServerAuthenticationDefault or TSQLRestServerAuthenticationNone
- will set Authentication property on success

```
procedure CallbackGet(const aMethodName: string; const aNameValueParameters: array
of const; var Call: TSQLRestURIParams; aTable: TSQLRecordClass; aID: TID=0);
```

Wrapper to the protected URI method to call a method on the server

- perform a ModelRoot/[TableName/[ID/]]MethodName RESTful GET request
- if no Table is expected, set aTable=nil (we do not define nil as default parameter, since the SMS compiler is sometimes confused)

```
procedure CallRemoteService(aCaller: TServiceClientAbstract; const aMethodName:
string; aExpectedOutputParamsCount: integer; const aInputParams: array of variant;
out res: TVariantDynArray; aReturnsCustomAnswer: boolean=false);
```

Execute a specified interface-based service method on the server

- this blocking method would raise an EServiceException on error
- you should not call it, but directly TServiceClient* methods

```
procedure SessionClose;
```

Close the session initiated with SetUser()

- will reset Authentication property to nil

```
procedure URI(var Call: TSQLRestURIParams); virtual;
```

Method calling the remote Server via a RESTful command

- calls the InternalURI abstract method
- this method will sign the url, if authentication is enabled

```
property Authentication: TSQLRestServerAuthentication read fAuthentication;
```

If not nil, point to the current authentication session running

```
property OnlyJSONRequests: boolean read fOnlyJSONRequests write fOnlyJSONRequests;
```

Set this property to TRUE if the server expects only APPLICATION/JSON

- applies only for AJAX clients (i.e. SmartMobileStudio platform)
- true will let any remote call be identified as "preflighted requests", so will send an OPTIONS method prior to any request: may be twice slower
- the default is false, as in TSQLHttpServer.OnlyJSONRequests

```
TSQLRestLogClientThread = class(TThread)
```

Thread used to asynchronously log to a remote client

```
constructor Create(Owner: TSQLRest; const aServer: string; aPort: integer; const
aRoot: string);
```

Initialize the thread

destructor Destroy; **override**;

Finalize the thread

procedure LogToRemoteServerText(const Text: string);

Log one line of text

TSQLRestServerAuthentication = class(TObject)

Abstract class used for client authentication

constructor Create(const aUserName, aPassword: string; aHashedPassword: Boolean=false);

Initialize client authentication instance, i.e. the User associated instance

destructor Destroy; **override**;

Finalize the instance

property SessionID: cardinal **read** fSessionID;

Contains the session ID used for the authentication

property User: TSQLAuthUser **read** fUser;

Read-only access to the logged user information

- only LogonName and PasswordHashHexa are set here

TSQLRestServerAuthenticationDefault = class(TSQLRestServerAuthentication)

MORMot secure RESTful authentication scheme

TSQLRestServerAuthenticationNone = class(TSQLRestServerAuthentication)

MORMot weak RESTful authentication scheme

TSQLRestClientHTTP = class(TSQLRestClientURI)

REST client via HTTP

- note that this implementation is not thread-safe yet

constructor Create(const aServer: string; aPort: integer; aModel: TSQLModel; aOwnModel: boolean=false; aHttps: boolean=false; const aProxyName: string=''; const aProxyByPass: string=''; aSendTimeout: Cardinal=30000; aReceiveTimeout: Cardinal=30000; aConnectionTimeOut: cardinal=30000); **reintroduce**; **virtual**;

Access to a mORMot server via HTTP

destructor Destroy; **override**;

Finalize the connection

procedure SetHttpBasicAuthHeaders(const aUserName, aPasswordClear: RawUTF8);

Force the HTTP headers of any request to contain some HTTP BASIC authentication, without creating any remote session

- here the password should be given as clear content

- potential use case is to use a mORMot client through a HTTPS proxy

- then you can use SetUser(TSQLRestServerAuthenticationDefault,...) to define any another "mORMot only" authentication

property Connection: TAbstractHttpConnection **read** fConnection;

The associated connection, if active

property KeepAlive: Integer **read** fKeepAlive **write** fKeepAlive;

The keep-alive timeout, in ms (20000 by default)

property Parameters: TSQLRestConnectionParams **read** fParameters;

The connection parameters

Types implemented in the *SynCrossPlatformREST* unit

RawUTF8 = **string**;

Alias to share the same string type between client and server

TCreateTime = **type** TTimeLog;

Used to define a field which shall be set at record creation

TID = **type** Int64;

The TSQLRecord primary key is a 64 bit integer

TIDDynArray = **array of** TID;

A dynamic array of TSQLRecord primary keys

- used e.g. for BATCH process

TModTime = **type** TTimeLog;

Used to define a field which shall be set at each modification

TOnSQLRestLog = **procedure**(const Text: **string**) **of object**;

Callback event used to write some text to a logging system

- could be a local file (not for SMS apps), or a remote log server

- the Text is already in the same format than the one generated by TSynLog

TServiceClientAbstractClass = **class of** TServiceClientAbstract;

Class type used to identify an interface-based service

- we do not rely on interfaces here, but simply on abstract classes

TServiceInstanceImplementation = (sicSingle, sicShared, sicClientDriven,
sicPerSession, sicPerUser, sicPerGroup, sicPerThread);

The possible Server-side instance implementation patterns for interface-based services

- each interface-based service will be implemented by a corresponding class instance on the server:
this parameter is used to define how class instances are created and managed

- on the Client-side, each instance will be handled depending on the server side implementation (i.e.
with sicClientDriven behavior if necessary)

TSQLAuthGroupClass = **class of** TSQLAuthGroup;

Class of the table containing the available user access rights for authentication

TSQLFieldBit = 0..MAX_SQLFIELDS-1;

Used to identify the a field in a Table as in TSQLFieldBits

TSQLFieldBits = **set of** TSQLFieldBit;

Used to store bit set for all available fields in a Table

- in this unit, field at index [0] indicates TSQLRecord.ID

TSQLFieldKind = (sftUnspecified, sftDateTime, sftTimeLog, sftBlob, sftModTime,
sftCreateTime, sftRecord, sftVariant);

A published property kind

- does not match mORMot.pas TSQLFieldType: here we recognize only types which may expect a

special behavior in this unit

TSQLFieldKinds = set of TSQLFieldKind;

A set of published property Kind

TSQLModelInfoDynArray = array of TSQLModelInfo;

Store information of several TSQLRecord class

TSQLModelInfoPropInfoDynArray = array of TSQLModelInfoPropInfo;

Store information of all TSQLRecord published properties

TSQLRawBlob = TByteDynArray;

Alias to share the same blob type between client and server

TSQLRestBatchOption = (boInsertOrIgnore);

The available options for TSQLRest.BatchStart() process

- boInsertOrIgnore will create 'INSERT OR IGNORE' statements instead of plain 'INSERT' - by now, only direct SQLite3 engine supports it on server

TSQLRestBatchOptions = set of TSQLRestBatchOption;

A set of options for TSQLRest.BatchStart() process

TSQLRestRoutingAbstractClass = class of TSQLRestRoutingAbstract;

Used to define the protocol of interface-based services

TSQLRestServerAuthenticationClass = class of TSQLRestServerAuthentication;

Class used for client authentication

TSynLogInfo = (sllNone, sllInfo, sllDebug, sllTrace, sllWarning, sllError, sllEnter, sllLeave, sllLastError, sllException, sllExceptionOS, sllMemory, sllStackTrace, sllFail, sllSQL, sllCache, sllResult, sllDB, sllHTTP, sllClient, sllServer, sllServiceCall, sllServiceReturn, sllUserAuth, sllCustom1, sllCustom2, sllCustom3, sllCustom4, sllNewRun, sllDDDError, sllDDDInfo);

The available logging events, as handled by our Cross-Platform units

- defined with the same values in SynCommons.pas
- sllInfo will log general information events
- sllDebug will log detailed debugging information
- sllTrace will log low-level step by step debugging information
- sllWarning will log unexpected values (not an error)
- sllError will log errors
- sllEnter will log every method start
- sllLeave will log every method exit
- sllLastError will log the GetLastError OS message
- sllException will log all exception raised - available since Windows XP
- sllExceptionOS will log all OS low-level exceptions (EDivByZero, ERangeError, EAccessViolation...)
- sllMemory will log memory statistics
- sllStackTrace will log caller's stack trace (it's by default part of TSynLogFamily.LevelStackTrace like sllError, sllException, sllExceptionOS, sllLastError and sllFail)
- sllFail was defined for TSynTestsLogged.Failed method, and can be used to log some customer-side assertions (may be notifications, not errors)
- sllSQL is dedicated to trace the SQL statements
- sllCache should be used to trace the internal caching mechanism
- sllResult could trace the SQL results, JSON encoded
- sllDB is dedicated to trace low-level database engine features

- sllHTTP could be used to trace HTTP process
- sllClient/sllServer could be used to trace some Client or Server process
- sllServiceCall/sllServiceReturn to trace some remote service or library
- sllUserAuth to trace user authentication (e.g. for individual requests)
- sllCustom* items can be used for any purpose
- sllNewRun will be written when a process opens a rotated log
- sllDDDError will log any DDD-related low-level error information
- sllDDDInfo will log any DDD-related low-level debugging information

TSynLogInfos = set of TSynLogInfo;

Used to define a set of logging level abilities

- i.e. a combination of none or several logging event
- e.g. use LOG_VERBOSE constant to log all events, or LOG_STACKTRACE to log all errors and exceptions

TTimeLog = type Int64;

Fast bit-encoded date and time value

Constants implemented in the SynCrossPlatformREST unit

AS_UNIQUE = false;

Used as "stored AS_UNIQUE" published property definition in TSQLRecord

ID_SQLFIELD: TSQLFieldBit = TSQLFieldBit(0);

The first field in TSQLFieldBits is always ID/RowID

JSON_SQLDATE_MAGIC = #\$ef#\$bf#\$b1;

\uFFF1 special code to mark ISO-8601 SQLDATE in JSON

- e.g. ""\uFFF12012-05-04"" pattern
- Unicode special char U+FFF1 is UTF-8 encoded as EF BF B1 bytes
- as generated by DateTimeToSQL/TimeLogToSQL functions, and expected by our mORMot server
- should be used with BoundsSQLWhere parameters, e.g. with FormatBind()

MAX_SQLFIELDS = 256;

Maximum number of fields in a database Table

Functions or procedures implemented in the SynCrossPlatformREST unit

Functions or procedures	Description	Page
BlobToVariant	Convert a binary blob into its base-64 representation	1897
DateTimeToSQL	Convert a date/time to a ISO-8601 string format for SQL '?' inlined parameters	1897
DateTimeToTTimeLog	Compute a TTimeLog value from Delphi date/time type	1897
FormatBind	Can be used to create a statement with inlined parameters	1897
GetOutHeader	Retrieve one header from a low-level HTTP response	1898
GUIDToVariant	Convert a TGUID instance into a string value	1898
HttpBodyToVariant	Convert a THttpBody binary content into a variant value	1898

Functions or procedures	Description	Page
IsRowID	True if PropName is either 'ID' or 'RowID'	1898
ObjectToVariant	Convert any TSQLRecord class instance into a TJSONVariant type	1898
SHA256Compute	Hash the supplied text values after UTF-8 encoding	1898
TimeLogToSQL	Convert a TTimeLog value into a ISO-8601 string format for SQL '?' inlined parameters	1898
ToDigit2	Returns a string with 2 digits	1898
ToDigit4	Returns a string with 4 digits	1898
TTimeLogToDateTime	Convert a TTimeLog value into the Delphi date/time type	1898
TTimeLogToIso8601	Convert a TTimeLog value into an ISO-8601 encoded date/time text	1898
UrlDecode	Decode a text as defined by RFC 3986	1898
UrlEncode	Encode name=value pairs as defined by RFC 3986	1898
UrlEncode	Encode a text as defined by RFC 3986	1898
VariantToBlob	Convert a base-64 encoded blob into its binary representation	1898
VariantToEnum	Convert a text or integer enumeration representation into its ordinal value	1899
VariantToGUID	Convert a string value into a TGUID instance	1899
VariantToHttpBody	Convert a variant value into a THttpBody binary	1899

function BlobToVariant(const Blob: TSQLRawBlob): variant;

Convert a binary blob into its base-64 representation

function DateTimeToSQL(DT: TDateTime): string;

Convert a date/time to a ISO-8601 string format for SQL '?' inlined parameters

- if DT=0, returns ''
- if DT contains only a date, returns the date encoded as '\uFFFF1YYYY-MM-DD'
- if DT contains only a time, returns the time encoded as '\uFFFF1Thh:mm:ss'
- otherwise, returns the ISO-8601 date and time encoded as '\uFFFF1YYYY-MM-DDThh:mm:ss'
- to be used e.g. as in:
aRec.CreateAndFillPrepare(Client, 'Datum<=?', [DateTimeToSQL(Now)]);
- see TimeLogToSQL() if you are using TTimeLog/TModTime/TCreatTime values

function DateTimeToTTimeLog(Value: TDateTime): TTimeLog;

Compute a TTimeLog value from Delphi date/time type

function FormatBind(const SQLWhere: string; const BoundsSQLWhere: array of const): string;

- Can be used to create a statement with inlined parameters*
- use DateTimeToSQL() for date/time database fields

function GetOutHeader(const Call: TSQLRestURIParams; const Name: string): string;

Retrieve one header from a low-level HTTP response
- use e.g. location := GetOutHeader(Call,'location');

function GUIDToVariant(const GUID: TGUID): variant;

Convert a TGUID instance into a string value

function HttpBodyToVariant(const HttpBody: THttpBody): variant;

Convert a THttpBody binary content into a variant value
- will use a variant of type string as mean of proprietary raw binary storage: you need to use VariantToHttpBody() to get the value back from the variant

function IsRowID(const PropName: string): boolean;

True if PropName is either 'ID' or 'RowID'

function ObjectToVariant(value: TSQLRecord): variant;

Convert any TSQLRecord class instance into a TJSONVariant type

function SHA256Compute(const Values: array of string): string;

Hash the supplied text values after UTF-8 encoding
- as expected by the framework server

function TimeLogToSQL(const TimeStamp: TTimeLog): string;

Convert a TTimeLog value into a ISO-8601 string format for SQL '?' inlined parameters
- follows the same pattern as DateToSQL or DateTimeToSQL functions, i.e. will return the date or time encoded as '\uFFFF1YYYY-MM-DDThh:mm:ss'

function ToDigit2(value: integer): string;

Returns a string with 2 digits
- the supplied value should be in 0..99 range

function ToDigit4(value: integer): string;

Returns a string with 4 digits
- the supplied value should be in 0..9999 range

function TTimeLogToDateTime(Value: TTimeLog): TDateTime;

Convert a TTimeLog value into the Delphi date/time type

function TTimeLogToIso8601(Value: TTimeLog): string;

Convert a TTimeLog value into an ISO-8601 encoded date/time text

function UrlDecode(const aValue: string): string;

Decode a text as defined by RFC 3986

function UrlEncode(const aValue: string): string; overload;

Encode a text as defined by RFC 3986

function UrlEncode(const aNameValueParameters: array of const): string; overload;

Encode name=value pairs as defined by RFC 3986

function VariantToBlob(const Value: variant): TSQLRawBlob;

Convert a base-64 encoded blob into its binary representation

```
function VariantToEnum(const Value: variant; const TextValues: array of string):  
integer;
```

Convert a text or integer enumeration representation into its ordinal value

```
function VariantToGUID(const value: variant): TGUID;
```

Convert a string value into a TGUID instance

```
function VariantToHttpBody(const value: variant): THttpBody;
```

Convert a variant value into a THttpBody binary

- will use a variant of type string as mean of proprietary raw binary storage: format is limited to
 HttpBodyToVariant() conversion

Variables implemented in the *SynCrossPlatformREST* unit

```
LOG_LEVEL_TEXT: array[TSynLogInfo] of string = ( ' ', ' info ', ' debug ', ' trace '  
, ' warn ', ' ERROR ', ' + ', ' - ', ' OSERR ', ' EXC ', ' EXCOS ', ' mem ', ' stack '  
, ' fail ', ' SQL ', ' cache ', ' res ', ' DB ', ' http ', ' clnt ', ' srvr ', ' call '  
, ' ret ', ' auth ', ' cust1 ', ' cust2 ', ' cust3 ', ' cust4 ', ' rotat ', ' dddER '  
, ' dddIN ');
```

The text equivalency of each logging level, as written in the log content

- and expected by TSynLog and our LogView tool

```
LOG_STACKTRACE: TSynLogInfos;
```

Contains the logging levels for which stack trace should be dumped

- which are mainly exceptions or application errors

```
LOG_VERBOSE: TSynLogInfos;
```

Can be set to TSQLRest.LogLevel in order to log all available events

```
NO_SQLFIELDBITS: TSQLFieldBits;
```

Contains no field bit set

27.50. SynCrossPlatformSpecific.pas unit

Purpose: System-specific cross-platform units

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the *SynCrossPlatformSpecific* unit

Unit Name	Description	Page
<i>SynCrtSock</i>	Classes implementing TCP/UDP/HTTP client and server protocol - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1086

SynCrossPlatformSpecific class hierarchy

Objects implemented in the *SynCrossPlatformSpecific* unit

Objects	Description	Page
TAbstractHttpConnection	Abstract class for HTTP client connection	1901
TMutex	Cross-platform thread safe locking	1900
TSQLRestConnectionParams	The connection parameters, as stored and used by TAbstractHttpConnection	1901
TSQLRestURIParams	Used to store the request of a REST call	1900

TMutex = class(TObject)

Cross-platform thread safe locking

- will use TMonitor on the newest Delphi platforms

TSQLRestURIParams = object(TObject)

Used to store the request of a REST call

InBody: THttpBody;

Input parameter containing the caller message body

InHead: string;

Input parameter containing the caller message headers

OutBody: THttpBody;

Output parameter to be set to the response message body

OutHead: string;

Output parameter to be set to the response message header

OutStatus: cardinal;

Output parameter to be set to the HTTP status integer code

Url: string;

Input parameter containing the caller URI

UrlWithoutSignature: string;

Caller URI, without any appended signature

Verb: string;

Input parameter containing the caller method

function OutBodyUtf8: string;

Get the response message body as UTF-8

procedure Init(const aUrl,aVerb,aUTF8Body: string);

Set the caller content

TSQLRestConnectionParams = record

The connection parameters, as stored and used by TAbstractHttpConnection

ConnectionTimeOut: integer;

The connection timeout, in ms

Https: boolean;

If the connection should be HTTPS

Port: integer;

The server port

ProxyByPass: string;

The optional proxy password to be used

ProxyName: string;

The optional proxy name to be used

ReceiveTimeout: cardinal

The timeout when receiving data, in ms

SendTimeout: cardinal;

The timeout when sending data, in ms

Server: string;

The server name or IP address

TAbstractHttpConnection = class(TObject)

Abstract class for HTTP client connection

constructor Create(**const** aParameters: TSQLRestConnectionParams); **virtual**;

This is the main entry point for all HTTP clients

- connect to http://aServer:aPort or https://aServer:aPort
- optional aProxyName may contain the name of the proxy server to use, and aProxyByPass an optional semicolon delimited list of host names or IP addresses, or both, that should not be routed through the proxy

procedure URI(**var** Call: TSQLRestURIParams; **const** InDataType: **string**; KeepAlive: **integer**); **virtual**; **abstract**;

Perform the request

- this is the main entry point of this class
- inherited classes should override this abstract method

property ActualConnection: TObject **read** fOpaqueConnection;

Opaque access to the effective connection class instance

- which may be a TFPHttpClient, a TIdHTTP or a TWinHttpAPI

property Parameters: TSQLRestConnectionParams **read** fParameters;

The connection parameters

property Server: **string** **read** fURL;

The remote server full URI

- e.g. 'http://myserver:888/'

Types implemented in the *SynCrossPlatformSpecific* unit

TAbstractHttpConnectionClass = **class of** TAbstractHttpConnection;

Define the inherited class for HTTP client connection

THttpBody = **array of** **byte**;

Will store input and output HTTP body content

- HTTP body may not match the string type, and could be binary
- this kind of variable is compatible with NextGen version of the compiler

Constants implemented in the *SynCrossPlatformSpecific* unit

HTTP_ACCEPTED = 202;

HTTP Status Code for "Accepted"

HTTP_BADGATEWAY = 502;

HTTP Status Code for "Bad Gateway"

HTTP_BADREQUEST = 400;

HTTP Status Code for "Bad Request"

HTTP_CONTINUE = 100;

HTTP Status Code for "Continue"

HTTP_CREATED = 201;

HTTP Status Code for "Created"

HTTP_FORBIDDEN = 403;

HTTP Status Code for "Forbidden"

HTTP_FOUND = 302;

HTTP Status Code for "Found"

HTTP_GATEWAYTIMEOUT = 504;

HTTP Status Code for "Gateway Timeout"

HTTP_HTTPVERSIONNOTSUPPORTED = 505;

HTTP Status Code for "HTTP Version Not Supported"

HTTP_MOVEDPERMANENTLY = 301;

HTTP Status Code for "Moved Permanently"

HTTP_MULTIPLECHOICES = 300;

HTTP Status Code for "Multiple Choices"

HTTP_NOCONTENT = 204;

HTTP Status Code for "No Content"

HTTP_NONAUTHORIZEDINFO = 203;

HTTP Status Code for "Non-Authoritative Information"

HTTP_NOTACCEPTABLE = 406;

HTTP Status Code for "Not Acceptable"

HTTP_NOTALLOWED = 405;

HTTP Status Code for "Method Not Allowed"

HTTP_NOTFOUND = 404;

HTTP Status Code for "Not Found"

HTTP_NOTIMPLEMENTED = 501;

HTTP Status Code for "Not Implemented"

HTTP_NOTMODIFIED = 304;

HTTP Status Code for "Not Modified"

HTTP_PARTIALCONTENT = 206;

HTTP Status Code for "Partial Content"

HTTP_PROXYAUTHREQUIRED = 407;

HTTP Status Code for "Proxy Authentication Required"

HTTP_SEEOTHER = 303;

HTTP Status Code for "See Other"

HTTP_SERVERERROR = 500;

HTTP Status Code for "Internal Server Error"

HTTP_SUCCESS = 200;

HTTP Status Code for "Success"

HTTP_SWITCHINGPROTOCOLS = 101;

HTTP Status Code for "Switching Protocols"

HTTP_TEMPORARYREDIRECT = 307;

HTTP Status Code for "Temporary Redirect"

HTTP_TIMEOUT = 408;

HTTP Status Code for "Request Time-out"

HTTP_UNAUTHORIZED = 401;

HTTP Status Code for "Unauthorized"

HTTP_UNAVAILABLE = 503;

HTTP Status Code for "Service Unavailable"

HTTP_USEPROXY = 305;

HTTP Status Code for "Use Proxy"

JSON_CONTENT_TYPE = 'application/json; charset=UTF-8';

MIME content type used for JSON communication

Functions or procedures implemented in the *SynCrossPlatformSpecific* unit

Functions or procedures	Description	Page
GetNextCSV	Will return the next CSV value from the supplied text	1904
HttpBodyToText	Convert a UTF-8 binary buffer into texts	1904
HttpConnectionClass	Gives access to the class type to implement a HTTP connection	1904
TextToHttpBody	Convert a text into UTF-8 binary buffer	1904

function GetNextCSV(const str: string; var index: Integer; var res: string; Sep: char=','; resultTrim: boolean=false): boolean;

Will return the next CSV value from the supplied text

procedure HttpBodyToText(const Body: THttpBody; var Text: string);

Convert a UTF-8 binary buffer into texts

function HttpConnectionClass: TAbstractHttpConnectionClass;

Gives access to the class type to implement a HTTP connection

- will use WinHTTP API (from our SynCrtSock) under Windows
- will use Indy for Delphi on other platforms
- will use fcl-web (fphttpclient) with FreePascal

function TextToHttpBody(const Text: string): THttpBody;

Convert a text into UTF-8 binary buffer

27.51. SynCrossPlatformTests.pas unit

Purpose: Regression tests for mORMot's cross-platform units

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

Units used in the *SynCrossPlatformTests* unit

Unit Name	Description	Page
<i>SynCrossPlatformCrypto</i>	Cryptographic cross-platform units - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1867
<i>SynCrossPlatformJSON</i>	Minimum stand-alone cross-platform JSON process using variants - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1869
<i>SynCrossPlatformREST</i>	Minimum stand-alone cross-platform REST process for mORMot client - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1878
<i>SynCrossPlatformSpecific</i>	System-specific cross-platform units - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1900

SynCrossPlatformTests class hierarchy

Objects implemented in the *SynCrossPlatformTests* unit

Objects	Description	Page
TSynCrossPlatformClient	Regression tests of our CrossPlatform units	1906
TSynCrossPlatformTests	Regression tests of our CrossPlatform units	1906
TSynTest	Generic class for performing simple tests	1905

TSynTest = class(TObject)

Generic class for performing simple tests

- purpose of this ancestor is to have RTTI for its published methods, which will contain the tests

Failed: cardinal;

How many Check() call did failed

Ident: string;

The test case name

Passed: cardinal;

How many Check() call did pass

Tests: TPublishedMethodDynArray;

The registered tests, i.e. all published methods of this class

constructor Create(const aIdent: string='');

Create the test instance

- this constructor will add all published methods to the internal test list, accessible via the Count/TestName/TestMethod properties

procedure Check(test: Boolean; const Msg: string=''); overload;

Validate a test

procedure Run(LogToConsole: boolean);

Run all tests

TSynCrossPlatformTests = class(TSynTest)

Regression tests of our CrossPlatform units

TSynCrossPlatformClient = class(TSynTest)

Regression tests of our CrossPlatform units

Types implemented in the *SynCrossPlatformTests* unit

TSynTestEvent = procedure of object;

As generated by mORMotWrappers.pas ! the prototype of an individual test

- to be used with TSynTest descendants

27.52. mORMot.pas unit

Purpose: Common ORM and SOA classes for mORMot

- this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

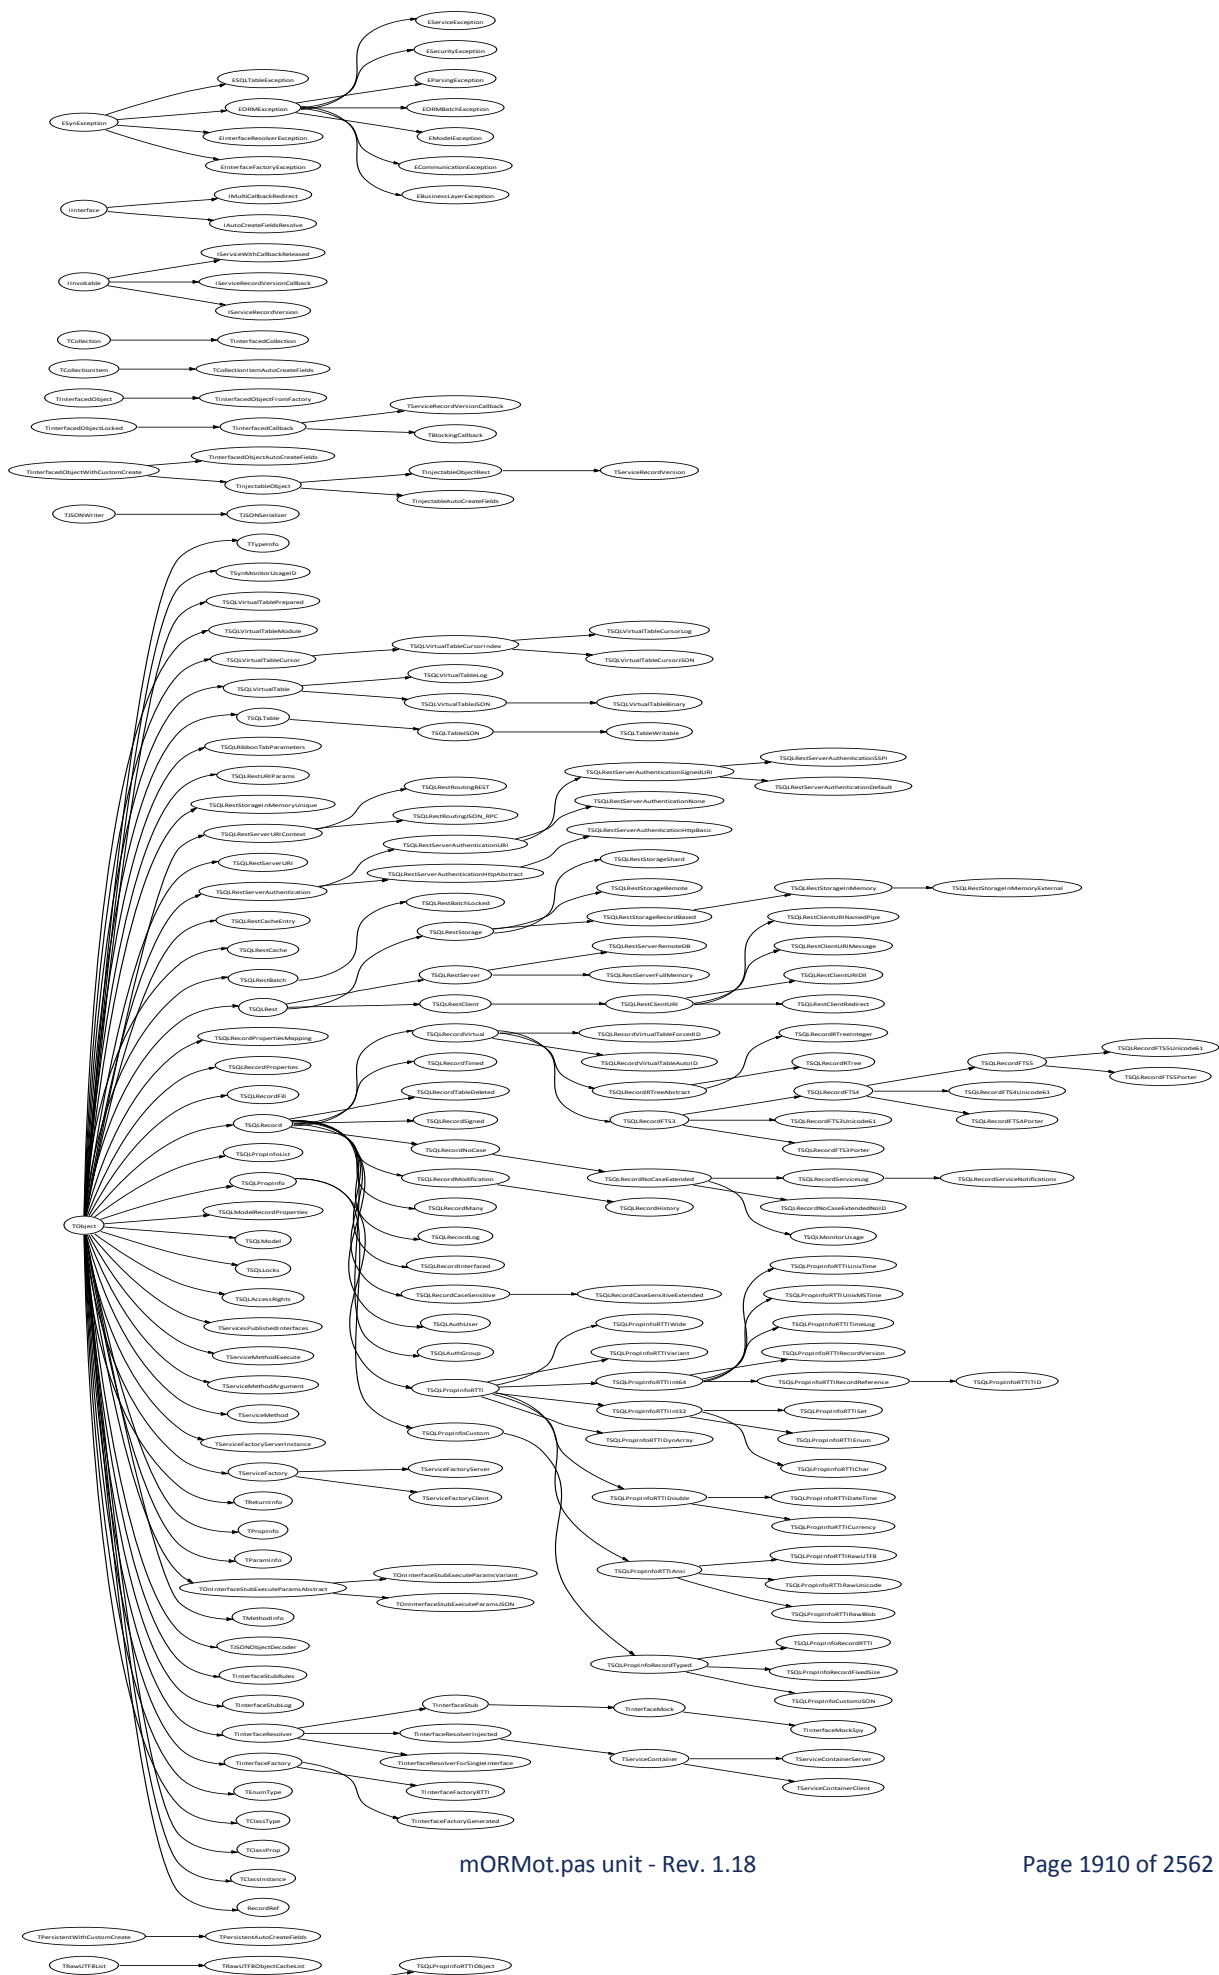

The *mORMot* unit is quoted in the following items

SWRS #	Description	Page
DI-2.1.1	Client-Server framework	2553
DI-2.1.1.1	RESTful framework	2553
DI-2.1.1.2.1	In-Process communication	2554
DI-2.1.1.2.2	Named Pipe protocol	2554
DI-2.1.1.2.3	Windows Messages protocol	2554
DI-2.1.1.2.4	HTTP/1.1 protocol	2555
DI-2.1.2	UTF-8 JSON format shall be used to communicate	2555
DI-2.1.3	The framework shall use an innovative ORM (Object-relational mapping) approach, based on classes RTTI (Runtime Type Information)	2556
DI-2.1.5	The framework shall offer a complete SOA process	2557
DI-2.2.1	The <i>SQLite3</i> engine shall be embedded to the framework	2558

Units used in the *mORMot* unit

Unit Name	Description	Page
<i>SynCommons</i>	Common functions used by most Synapse projects - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	718
<i>SynCrypto</i>	Fast cryptographic routines (hashing and cypher) - implements AES,XOR,ADLER32,MD5,RC4,SHA1,SHA256,SHA384,SHA512,SHA3 and JWT - optimized for speed (tuned assembler and SSE3/SSE4/AES-NI/PADLOCK support) - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1143
<i>SynLog</i>	Logging functions used by Synapse projects - this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1368
<i>SynSSPI</i>	Low level access to Windows SSPI/SChannel API for the Win32/Win64 platform - this unit is a part of the freeware Synapse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1721

Unit Name	Description	Page
<i>SynSSPIAuth</i>	Low level access to Windows Authentication for the Win32/Win64 platform - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1725
<i>SynTable</i>	Filter/database/cache/buffer/security/search/multithread/OS features - as a complement to SynCommons, which tended to increase too much - licensed under a MPL/GPL/LGPL tri-license; version 1.18	1728
<i>SynTests</i>	Unit test functions used by Synopse projects - this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1840
<i>SynZip</i>	Low-level access to ZLib compression (1.2.5 engine version) - this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18	1853

mORMot class hierarchy

Objects implemented in the *mORMot* unit

Objects	Description	Page
EBusinessLayerException	Exception raised in case of an error in project implementation logic	1956
ECommunicationException	Exception raised in case of a Client-Server communication error	1956
EInterfaceFactoryException	Exception dedicated to interface factory, e.g. services and mock/stubs	1956
EInterfaceResolverException	Exception raised in case of Dependency Injection (aka IoC) issue	1956
EModelException	Exception raised in case of wrong Model definition	1956
EORMBatchException	Exception raised in case of TSQLRestBatch problem	1956
EORMException	Generic parent class of all custom Exception types of this unit	1956
EParsingException	Exception raised in case of unexpected parsing error	1956
ESecurityException	Exception raised in case of any authentication error	1956
EServiceException	Exception dedicated to interface based service implementation	1956
ESQLTableException	Exception raised in case of incorrect TSQLTable.Step / Field*() use	1956
IAutoCreateFieldsResolver	Used to set the published properties of a TInjectableAutoCreateFields	2073
IMultiCallbackRedirect	Prototype of a class implementing redirection of a given interface	2110
IServiceRecordVersion	Service definition for master/slave replication notifications subscribe	2104
IServiceRecordVersionCallback	A callback interface used to notify a TSQLRecord modification in real time	2104
IServiceWithCallbackReleased	Service definition with a method which will be called when a callback interface instance is released on the client side	2105
PropWrap	Used to map a TPropInfo.GetProc/SetProc and retrieve its kind	1936
RecordRef	Useful object to type cast TRecordReference type value into explicit TSQLRecordClass and ID	2047
TAuthSession	Class used to maintain in-memory sessions	2149
TBlockingCallback	Asynchronous callback to emulate a synchronous/blocking process	2108
TClassInstance	Store information about a class, able to easily create new instances	1922
TClassProp	A wrapper to published properties of a class	1923
TClassType	A wrapper to class type information, as defined by the Delphi RTTI	1923

Objects	Description	Page
TCollectionItemAutoCreateFields	Abstract TCollectionItem class, which will instantiate all its nested class published properties, then release them (and any T*ObjArray) when freed	1950
TEnumType	A wrapper to enumeration type information, as defined by the Delphi RTTI	1924
TINIWriter	Simple writer to a Stream, specialized for writing an object as INI	1946
TInjectableAutoCreateFields	Abstract class which will auto-inject its dependencies (DI/IOC), and also manage the instances of its TPersistent/TSynPersistent published properties	2073
TInjectableObject	Any service implementation class could inherit from this class to allow dependency injection aka SOLID DI/IOC by the framework	2071
TInjectableObjectRest	Service implementation class, with direct access on the associated TServiceFactoryServer/TSQLRestServer instances	2072
TInterfacedCallback	TInterfacedObject class which will notify a REST server when it is released	2108
TInterfacedCollection	Any TCollection used between client and server shall inherit from this class	1949
TInterfacedObjectAutoCreateFields	Abstract TInterfacedObject class, which will instantiate all its nested TPersistent/TSynPersistent published properties, then release them when freed	1952
TInterfacedObjectFromFactory	Abstract class handling a generic interface implementation class	2076
TInterfaceFactory	Class handling interface RTTI and fake implementation class	2073
TInterfaceFactoryGenerated	Class handling interface implementation generated from source	2077
TInterfaceFactoryRTTI	Class handling interface RTTI and fake implementation class	2076
TInterfaceMock	Used to mock an interface implementation via expect-run-verify pattern	2088
TInterfaceMockSpy	Used to mock an interface implementation via run-verify pattern	2089
TInterfaceResolver	Abstract factory class allowing to call interface resolution in cascade	2068
TInterfaceResolverForSingleInterface	Abstract factory class targetting a single kind of interface	2068
TInterfaceResolverInjected	Abstract factory class targetting any kind of interface	2069
TInterfaceStub	Used to stub an interface implementation	2082
TInterfaceStubLog	Used to keep track of one stubbed method call	2081
TInterfaceStubRule	Define a mocking / stubbing rule used internally by TInterfaceStub	2080
TInterfaceStubRules	Define the rules for a given method as used internally by TInterfaceStub	2081

Objects	Description	Page
TInterfaceTypeData	A wrapper to interface type information, as defined by the Delphi RTTI	1926
TJSONObjectDecoder	JSON object decoding and SQL generation, in the context of ORM process	1920
TJSONSerializer	Simple writer to a Stream, specialized for writing an object as JSON	1946
TMethodInfo	A wrapper around a method definition	1936
TObjectVariant	A custom variant type used to have direct access to object published properties	2029
TOnInterfaceStubExecuteParamsAbstract	Abstract parameters used by TInterfaceStub.Executes() events callbacks	2077
TOnInterfaceStubExecuteParamsJSON	Parameters used by TInterfaceStub.Executes() events callbacks as JSON	2079
TOnInterfaceStubExecuteParamsVariant	Parameters used by TInterfaceStub.Executes() events callbacks as Variant	2078
TParamInfo	A wrapper around an individual method parameter definition	1935
TPersistentAutoCreateFields	Abstract TPersistent class, which will instantiate all its nested TPersistent class published properties, then release them (and any T*ObjArray) when freed	1950
TPropInfo	A wrapper containing a RTTI property definition	1928
TRawUTF8ObjectCache	Maintain information cache for a given key	1953
TRawUTF8ObjectCacheList	Manage a list of information cache, identified by a hashed key	1953
TRawUTF8ObjectCacheSettings	Used by TRawUTF8ObjectCacheList to manage a list of information cache	1952
TReturnInfo	A wrapper around method returned result definition	1935
TServiceContainer	A global services provider class	2102
TServiceContainerClient	A services provider class to be used on the client side	2107
TServiceContainerInterface	Used to lookup one service in a global list of interface-based services	2101
TServiceContainerInterfaceMethod	Used to lookup one method in a global list of interface-based services	2101
TServiceContainerServer	A services provider class to be used on the server side	2105
TServiceCustomAnswer	A record type to be used as result for a function method for custom content for interface-based services	2068
TServiceFactory	An abstract service provider, as registered in TServiceContainer	2091
TServiceFactoryClient	A service provider implemented on the client side	2099

Objects	Description	Page
TServiceFactoryExecution	Internal per-method list of execution context as hold in TServiceFactory	1970
TServiceFactoryServer	A service provider implemented on the server side	2093
TServiceFactoryServerInstance	Server-side service provider uses this to store one internal instance	2093
TServiceMethod	Describe an interface-based service provider method	2062
TServiceMethodArgument	Describe a service provider method argument	2059
TServiceMethodExecute	Execute a method of a TInterfacedObject instance, from/to JSON	2066
TServiceRecordVersion	This class implements a service, which may be called to push notifications for master/slave replication	2107
TServiceRecordVersionCallback	This class implements a callback interface, able to write all remote ORM notifications to the local DB	2109
TServiceRunningContext	Will identify the currently running service on the server side	1969
TServicesPublishedInterfaces	Used to publish all Services supported by a TSQLRestServer instance	2166
TServicesPublishedInterfacesList	Used e.g. by TSQLRestServer to store a list of TServicesPublishedInterfaces	2166
TSQLAccessRights	Set the User Access Rights, for each Table	1970
TSQLAuthGroup	Table containing the available user access rights for authentication	2147
TSQLAuthUser	Table containing the Users registered for authentication	2148
TSQLHttpServerDefinition	Parameters supplied to publish a TSQLRestServer via HTTP	2157
TSQLLocks	Used to store the locked record list, in a specified table	2031
TSQLModel	A Database Model (in a MVC-driven way), for storing some tables types as TSQLRecord classes	2041
TSQLModelRecordProperties	ORM properties associated to a TSQLRecord within a given model	2039
TSQLModelRecordPropertiesSQL	Pre-computed SQL statements for ORM operations for a given TSQLModelRecordProperties instance	2034
TSQLModelRecordReference	How a TSQLModel stores a foreign link to be cascaded	2040
TSQLMonitorUsage	ORM table used to store TSynMonitorUsage information in TSynMonitorUsageRest	2164
TSQLPropInfo	Abstract parent class to store information about a published property	1936
TSQLPropInfoCustom	Abstract information about a record-like property defined directly in code	1942

Objects	Description	Page
TSQLPropInfoCustomJSON	Information about a custom property defined directly in code	1944
TSQLPropInfoList	Handle a read-only list of fields information for published properties	1945
TSQLPropInfoRecordFixedSize	Information about a fixed-size record property defined directly in code	1943
TSQLPropInfoRecordRTTI	Information about a record property defined directly in code	1943
TSQLPropInfoRecordTyped	Information about a record property defined directly in code using RTTI	1942
TSQLPropInfoRTTI	Parent information about a published property retrieved from RTTI	1939
TSQLPropInfoRTTIAnsi	Information about a AnsiString published property	1941
TSQLPropInfoRTTIChar	Information about a character published property	1940
TSQLPropInfoRTTICurrency	Information about a fixed-decimal Currency published property	1941
TSQLPropInfoRTTIDateTime	Information about a TDateTime published property	1941
TSQLPropInfoRTTIDouble	Information about a floating-point Double published property	1941
TSQLPropInfoRTTIDynArray	Information about a dynamic array published property	1941
TSQLPropInfoRTTIEnum	Information about a enumeration published property	1940
TSQLPropInfoRTTIID	Information about a TSQLRecord class TSQLRecord property	1958
TSQLPropInfoRTTIInstance	Information about a TSQLRecord class property	1957
TSQLPropInfoRTTIInt32	Information about an ordinal Int32 published property	1940
TSQLPropInfoRTTIInt64	Information about an ordinal Int64 published property	1940
TSQLPropInfoRTTIMany	Information about a TSQLRecord class TSQLRecordMany property	1959
TSQLPropInfoRTTIObject	Information about a TSQLRecord class TStrings/TRawUTF8List/TCollection property	1958
TSQLPropInfoRTTIRawBlob	Information about a TSQLRawBlob published property	1941
TSQLPropInfoRTTIRawUnicode	Information about a RawUnicode published property	1941
TSQLPropInfoRTTIRawUTF8	Information about a RawUTF8 published property	1941
TSQLPropInfoRTTIRecordReference	Information about a TRecordReference/TRecordReferenceToBeDeleted published property	1957
TSQLPropInfoRTTIRecordVersion	Information about a TRecordVersion published property	1958

Objects	Description	Page
TSQLPropInfoRTTISet	Information about a set published property	1940
TSQLPropInfoRTTITID	Information about a TID published property	1957
TSQLPropInfoRTTITimeLog	Information about a TTimeLog published property	1941
TSQLPropInfoRTTIUnixMSTime	Information about a TUnixMSTime published property	1941
TSQLPropInfoRTTIUnixTime	Information about a TUnixTime published property	1941
TSQLPropInfoRTTIVariant	Information about a variant published property	1942
TSQLPropInfoRTTIWide	Information about a WideString published property	1941
TSQLQueryCustom	Store one custom query parameters	2032
TSQLRecord	Root class for defining and mapping database records	1990
TSQLRecordCaseSensitive	Root class for defining and mapping database records with case-sensitive BINARY collation	2012
TSQLRecordCaseSensitiveExtended	Database records with BINARY collation and JSON_OPTIONS_FAST_EXTENDED variants	2012
TSQLRecordFill	Internal data used by TSQLRecord.FillPrepare()/FillPrepareMany() methods	1984
TSQLRecordFTS3	A base record, corresponding to a FTS3 table, i.e. implementing full-text	2051
TSQLRecordFTS3Porter	This base class will create a FTS3 table using the Porter Stemming algorithm	2052
TSQLRecordFTS3Unicode61	This base class will create a FTS3 table using the Unicode61 Stemming algorithm	2052
TSQLRecordFTS4	A base record, corresponding to a FTS4 table, which is an enhancement to FTS3	2052
TSQLRecordFTS4Porter	This base class will create a FTS4 table using the Porter Stemming algorithm	2052
TSQLRecordFTS4Unicode61	This base class will create a FTS4 table using the Unicode61 Stemming algorithm	2052
TSQLRecordFTS5	A base record, corresponding to a FTS5 table, which is an enhancement to FTS4	2053
TSQLRecordFTS5Porter	This base class will create a FTS5 table using the Porter Stemming algorithm	2053
TSQLRecordFTS5Unicode61	This base class will create a FTS5 table using the Unicode61 Stemming algorithm	2053
TSQLRecordHistory	Common ancestor for tracking changes on TSQLRecord tables	2159

Objects	Description	Page
TSQLRecordInterfaced	Common ancestor for tables which should implement any interface	2059
TSQLRecordLog	A base record, with a JSON-logging capability	2057
TSQLRecordMany	Handle "has many" and "has many through" relationships	2054
TSQLRecordModification	Common ancestor for tracking TSQLRecord modifications	2158
TSQLRecordNoCase	Root class for defining and mapping database records with case-insensitive NOCASE collation	2012
TSQLRecordNoCaseExtended	Database records with NOCASE collation and JSON_OPTIONS_FAST_EXTENDED variants	2012
TSQLRecordNoCaseExtendedNoID	Database records with NOCASE collation and JSON_OPTIONS_FAST_EXTENDED variants, and itoNoIndex4TID option to avoid indexes on TID/T*ID properties	2013
TSQLRecordProperties	Some information about a given TSQLRecord class properties	1959
TSQLRecordPropertiesMapping	Allow custom field mapping of a TSQLRecord	2035
TSQLRecordRTree	A base record, corresponding to an R-Tree table of floating-point values	2049
TSQLRecordRTreeAbstract	An abstract base class, corresponding to an R-Tree table of values	2048
TSQLRecordRTreeInteger	A base record, corresponding to an R-Tree table of 32-bit integer values	2050
TSQLRecordServiceLog	Common ancestor for storing interface-based service execution statistics	2065
TSQLRecordServiceNotifications	Execution statistics used for DB-based asynchronous notifications	2065
TSQLRecordSigned	Common ancestor for tables with digitally signed RawUTF8 content	2058
TSQLRecordTableDeleted	ORM table used to store the deleted items of a versioned table	2161
TSQLRecordTimed	A base record, which will have creation and modification timestamp fields	2059
TSQLRecordVirtual	Parent of all virtual classes	2034
TSQLRecordVirtualTableAutoID	Record associated to Virtual Table implemented in Delphi, with ID generated automatically at INSERT	2230
TSQLRecordVirtualTableForcedID	Record associated to a Virtual Table implemented in Delphi, with ID forced at INSERT	2230
TSQLRest	A generic REpresentational State Transfer (REST) client/server class	2117
TSQLRestAcquireExecution	Used to store the execution parameters for a TSQLRest instance	2114

Objects	Description	Page
TSQLEstBackgroundTimer	TThread able to run one or several tasks at a periodic pace, or do asynchronous interface or batch execution, with proper TSQLEst integration	2114
TSQLEstBatch	Used to store a BATCH sequence of writing operations	1985
TSQLEstBatchLocked	Thread-safe class to store a BATCH sequence of writing operations	1989
TSQLEstCache	Implement a fast TSQLEstRecord cache, per ID, at the TSQLEst level	2112
TSQLEstCacheEntry	For TSQLEstCache, stores a table settings and values	2111
TSQLEstCacheEntryValue	For TSQLEstCache, stores a table values	2110
TSQLEstClient	A generic REpresentational State Transfer (REST) client	2202
TSQLEstClientCallbackItem	Store information about registered interface callbacks	2205
TSQLEstClientCallbacks	Store the references to active interface callbacks on a REST Client	2205
TSQLEstClientRedirect	Rest client with redirection to another TSQLEst instance	2217
TSQLEstClientURI	A generic REpresentational State Transfer (REST) client with URI	2206
TSQLEstClientURIDll	Rest client with remote access to a server through a dll	2217
TSQLEstClientURIMessage	Rest client with remote access to a server through Windows messages	2218
TSQLEstClientURINamedPipe	Rest client with remote access to a server through a Named Pipe	2219
TSQLEstRoutingJSON_RPC	Calling context for a TSQLEstServerCallback using JSON/RPC for interface-based services	1983
TSQLEstRoutingREST	Calling context for a TSQLEstServerCallback using simple REST for interface-based services	1983
TSQLEstServer	A generic REpresentational State Transfer (REST) server	2168
TSQLEstServerAuthentication	Abstract class used to implement server-side authentication in TSQLEstServer	2151
TSQLEstServerAuthenticationDefault	MORMot secure RESTful authentication scheme	2153
TSQLEstServerAuthenticationHttpAbstract	Abstract class for implementing HTTP authentication	2155
TSQLEstServerAuthenticationHttpBasic	Authentication using HTTP Basic scheme	2156
TSQLEstServerAuthenticationNone	MORMot weak RESTful authentication scheme	2154
TSQLEstServerAuthenticationSignedURI	Secure authentication scheme using URL-level digital signature	2152

Objects	Description	Page
TSQLEstServerAuthent icationSSPI	Authentication of the current logged user using Windows Security Support Provider Interface (SSPI) or GSSAPI library on Linux	2156
TSQLEstServerAuthent icationURI	Weak authentication scheme using URL-level parameter	2152
TSQLEstServerFullMem ory	A REST server using only in-memory tables	2200
TSQLEstServerMethod	Description of a method-based service	1984
TSQLEstServerMonitor	Used for high-level statistics in TSQLEstServer.URI()	2163
TSQLEstServerNamedPi pe	Server thread accepting connections from named pipes	2145
TSQLEstServerNamedPi peResponse	Server child thread dealing with a connection through a named pipe	2146
TSQLEstServerRemoted B	A REST server using another TSQLEst instance for all its ORM process	2202
TSQLEstServerURI	Used to access a TSQLEstServer from its TSQLEstServerURIString URI	2165
TSQLEstServerURICont ext	Abstract calling context for a TSQLEstServerCallBack event handler	1972
TSQLEstServerURIPagi ngParameters	Structure used to specify custom request paging parameters for TSQLEstServer	2146
TSQLEstStorage	REST class with direct access to an external database engine	2188
TSQLEstStorageInMemo ry	REST storage with direct access to a TObjectList memory-stored table	2192
TSQLEstStorageInMemo ryExternal	REST storage with direct access to a memory database, to be used as an external SQLite3 Virtual table	2197
TSQLEstStorageInMemo ryUnique	Class able to handle a O(1) hashed-based search of a property	2191
TSQLEstStorageRecord Based	Abstract REST storage exposing some internal TSQLEstRecord-based methods	2190
TSQLEstStorageRemote	REST storage with redirection to another REST instance	2198
TSQLEstStorageShard	Abstract REST storage with redirection to several REST instances, implementing range ID partitioning for horizontal scaling	2198
TSQLEstTempStorage	Abstract class used for temporary in-memory storage of TSQLEstRecord	2161
TSQLEstTempStorageIt em	Used to store an entry in the TSQLEstTempStorage class	2161
TSQLEstThread	A simple TThread for doing some process within the context of a REST instance	2144
TSQLEstURIParams	Store all parameters for a Client or Server method call	1968
TSQLEstRibbonTabParamete rs	Defines the settings for a Tab for User Interface generation	2033

Objects	Description	Page
TSQLTable	Wrapper to an ORM result table, statically stored as UTF-8 text	2013
TSQLTableFieldType	Store TSQLFieldType and RTTI for a given TSQLTable field	2013
TSQLTableJSON	Store a read-only ORM result table from a JSON message	2029
TSQLTableRowVariant	A custom variant type used to have direct access to TSQLTable content	2028
TSQLTableRowVariantData	Memory structure used for our TSQLTableRowVariant custom variant type used to have direct access to TSQLTable content	2028
TSQLTableSortParams	Contains the parameters used for sorting	1920
TSQLTableWritable	Store a writable ORM result table, optionally read from a JSON message	2031
TSQLVirtualTable	Abstract class able to access a Virtual Table content	2223
TSQLVirtualTableBinary	A TSQLRestStorageInMemory-based virtual table using Binary storage	2229
TSQLVirtualTableCursor	Abstract class able to define a Virtual Table cursor	2226
TSQLVirtualTableCursorIndex	A generic Virtual Table cursor associated to Current/Max index properties	2226
TSQLVirtualTableCursorJSON	A Virtual Table cursor for reading a TSQLRestStorageInMemory content	2227
TSQLVirtualTableCursorLog	A Virtual Table cursor for reading a TSynLogFile content	2229
TSQLVirtualTableJSON	A TSQLRestStorageInMemory-based virtual table using JSON storage	2227
TSQLVirtualTableLog	Implements a read/only virtual table able to access a .log file, as created by TSynLog	2229
TSQLVirtualTableModule	Parent class able to define a Virtual Table module	2222
TSQLVirtualTablePrepared	The WHERE and ORDER BY statements as set by TSQLVirtualTable.Prepare	2221
TSQLVirtualTablePreparedConstraint	A WHERE constraint as set by the TSQLVirtualTable.Prepare() method	2220
TSQLVirtualTablePreparedOrderBy	An ORDER BY clause as set by the TSQLVirtualTable.Prepare() method	2221
TSynAuthenticationRest	TSynAuthentication* class using TSQLAuthUser/TSQLAuthGroup for credentials	2158
TSynAutoCreateFields	Our own empowered TPersistentAutoCreateFields-like parent class	1951
TSynAutoCreateFieldsLocked	Adding locking methods to a TSynAutoCreateFields with virtual constructor	1951
TSynJsonFileSettings	Abstract parent class able to store settings as JSON file	1952

Objects	Description	Page
TSynMonitorUsage	Abstract class to track, compute and store TSynMonitor detailed statistics	1955
TSynMonitorUsageID	How the TSynMonitorUsage storage IDs are computed	1954
TSynMonitorUsageRest	Will store TSynMonitorUsage information in TSQLMonitorUsage ORM tables	2165
TSynValidateRest	Will define a validation to be applied to a TSQLRecord field, using if necessary an associated TSQLRest instance and a TSQLRecord class	2219
TSynValidateUniqueField	Will define a validation for a TSQLRecord Unique text field	2220
TSynValidateUniqueFields	Will define an unicity validation for a set of TSQLRecord text fields	2220
TTypeInfo	A wrapper containing type information definition	1927
TVirtualTableModuleProperties	Used to store and handle the main specifications of a TSQLVirtualTableModule	2222

TSQLTableSortParams = record

Contains the parameters used for sorting

- FieldCount is 0 if was never sorted
- used to sort data again after a successful data update with TSQLTableJSON.FillFrom()

TJSONObjectDecoder = object(TObject)

JSON object decoding and SQL generation, in the context of ORM process

- this is the main process for marshalling JSON into SQL statements
- used e.g. by GetJSONObjectAsSQL() function or ExecuteFromJSON and InternalBatchStop methods

DecodedFieldNames: PRawUTF8Array;

Internal pointer over field names to be used after Decode() call

- either FieldNames, either Fields[] array as defined in Decode(), or external names as set by TSQLRestStorageExternal.JSONDecodedPrepareToSQL

DecodedFieldTypesToUnnest: PSQLDBFieldTypeArray;

Internal pointer over field types to be used after Decode() call

- to create 'INSERT INTO ... SELECT UNNEST(...)' or 'UPDATE ... FROM SELECT UNNEST(...)' statements for very efficient bulk writes in a PostgreSQL database
- as set by TSQLRestStorageExternal.JSONDecodedPrepareToSQL when cPostgreBulkArray flag is detected (for SynDBPostgres)

DecodedRowID: TID;

The ID=.. value as sent within the JSON object supplied to Decode()

FieldCount: integer;

Number of fields decoded in FieldNames[] and FieldValues[]

FieldNames: array[0..MAX_SQLFIELDS-1] of RawUTF8;

Contains the decoded field names

FieldTypeApproximation: array[0..MAX_SQLFIELDS-1] of TJSONObjectDecoderFieldType;

Decode() will set each field type approximation

- will recognize also JSON_BASE64_MAGIC/JSON_SQLDATE_MAGIC prefix

FieldValues: array[0..MAX_SQLFIELDS-1] of RawUTF8;

Contains the decoded field values

InlinedParams: TJSONObjectDecoderParams;

Set to TRUE if parameters are to be :(...): inlined

function EncodeAsSQL(Update: boolean): RawUTF8;

Encode as a SQL-ready INSERT or UPDATE statement

- after a successful call to Decode()

- escape SQL strings, according to the official SQLite3 documentation (i.e. ' inside a string is stored as '')

- if InlinedParams was TRUE, it will create prepared parameters like 'COL1=(:"VAL1");',
COL2=(:VAL2):'

- called by GetJSONObjectAsSQL() function or TSQLRestStorageExternal

**function EncodeAsSQLPrepared(const TableName: RawUTF8; Occasion: TSQLOccasion;
const UpdateIDFieldName: RawUTF8; BatchOptions: TSQLRestBatchOptions): RawUTF8;**

Encode as a SQL-ready INSERT or UPDATE statement with ? as values

- after a successful call to Decode()

- FieldValues[] content will be ignored

- Occasion can be only solInsert or soUpdate

- for soUpdate, will create UPDATE ... SET ... where UpdateIDFieldName=?

- you can specify some options, e.g. bolInsertOrIgnore for solInsert

function FindFieldName(const FieldName: RawUTF8): integer;

Search for a field name in the current identified FieldNames[]

function SameFieldNames(const Fields: TRawUTF8DynArray): boolean;

Returns TRUE if the specified array match the decoded fields names

- after a successful call to Decode()

**procedure AddFieldValue(const FieldName,FieldValue: RawUTF8; FieldType:
TJSONObjectDecoderFieldType);**

Can be used after Decode() to add a new field in FieldNames/FieldValues

- so that EncodeAsSQL() will include this field in the generated SQL

- caller should ensure that the FieldName is not already defined in FieldNames[] (e.g. when the TRecordVersion field is forced)

- the caller should ensure that the supplied FieldValue will match the quoting/inlining expectations of Decode(TJSONObjectDecoderParams) - e.g. that string values are quoted if needed

procedure AssignFieldNamesTo(var Fields: TRawUTF8DynArray);

Set the specified array to the fields names

- after a successful call to Decode()

```
procedure Decode(const JSON: RawUTF8; const Fields: TRawUTF8DynArray; Params:
TJSONObjectDecoderParams; const RowID: TID=0; ReplaceRowIDWithID: Boolean=false);
overload;
```

Decode the JSON object fields into FieldNames[] and FieldValues[]

- overloaded method expecting a RawUTF8 buffer, making a private copy of the JSON content to avoid unexpected in-place modification, then calling Decode(P: PUTF8Char) to perform the process

```
procedure Decode(var P: PUTF8Char; const Fields: TRawUTF8DynArray; Params:
TJSONObjectDecoderParams; const RowID: TID=0; ReplaceRowIDWithID: Boolean=false);
overload;
```

Decode the JSON object fields into FieldNames[] and FieldValues[]

- if Fields=nil, P should be a true JSON object, i.e. defined as "COL1"="VAL1" pairs, stopping at '}' or ']' ; otherwise, Fields[] contains column names and expects a JSON array as "VAL1","VAL2".. in P

- P should be after the initial '{' or '[' character, i.e. at first field

- P returns the next object start or nil on unexpected end of input

- P^ buffer will let the JSON be decoded in-place, so consider using the overloaded Decode(JSON: RawUTF8; ...) method

- FieldValues[] strings will be quoted and/or inlined depending on Params

- if RowID is set, a RowID column will be added within the returned content

```
procedure EncodeAsJSON(out result: RawUTF8);
```

Encode the FieldNames/FieldValues[] as a JSON object

```
TClassInstance = object(TObject)
```

Store information about a class, able to easily create new instances

- using this temporary storage will speed up the creation process

- any virtual constructor will be used, including for TCollection types

```
CollectionItemClass: TCollectionItemClass;
```

For TCollection instances, the associated TCollectionItem class

```
ItemClass: TClass;
```

The class type itself

```
ItemCreate: TClassInstanceItemCreate;
```

How the class instance is expected to be created

```
function CreateNew: TObject;
```

Create a new instance of the registered class

```
procedure Init(C: TClass);
```

Fill the internal information fields for a given class type

```
procedure SetCustomComment(var CustomComment: RawUTF8);
```

Compute the custom JSON commentary corresponding to this class

TClassProp = object(TObject)

A wrapper to published properties of a class

- start enumeration by getting a PClassProp with ClassProp()
- use PropCount, P := @PropList to get the first PPropInfo, and then P^.Next
- this enumeration is very fast and doesn't require any temporary memory, as in the TypInfo.GetPropInfos() PPropList usage
- for TSQLRecord, you should better use the RecordProps.Fields[] array, which is faster and contains the properties published in parent classes

Used for DI-2.1.3 (page 2556).

PropCount: Word;

Number of published properties in this object

PropList: record

Point to a TPropInfo packed array

- layout is as such, with variable TPropInfo storage size:

PropList: array[1..PropCount] of TPropInfo

- use TPropInfo.Next to get the next one:

```
P := @PropList;  
for i := 1 to PropCount do begin  
  // ... do something with P  
  P := P^.Next;  
end;
```

function FieldProp(const PropName: shortstring): PPropInfo;

Retrieve a Field property RTTI information from a Property Name

TClassType = object(TObject)

A wrapper to class type information, as defined by the Delphi RTTI

Used for DI-2.1.3 (page 2556).

ClassType: TClass;

The class type

ParentInfo: PTypeInfo;

The parent class type information

PropCount: SmallInt;

The number of published properties

UnitName: string[255];

The name (without .pas extension) of the unit where the class was defined

- then the PClassProp follows: use the method ClassProp to retrieve its address

function ClassProp: PClassProp;

Get the information about the published properties of this class

- stored after UnitName memory

function InheritsFrom(AClass: TClass): boolean;

Fast and easy find if this class inherits from a specific class type
- you should rather consider using TTypeInfo.InheritsFrom directly

function RTTISize: integer;

Return the size (in bytes) of this class type information
- can be used to create class types at runtime

TEnumType = object(TObject)

A wrapper to enumeration type information, as defined by the Delphi RTTI
- we use this to store the enumeration values as integer, but easily provide a text equivalent, translated if necessary, from the enumeration type definition itself
Used for DI-2.1.3 (page 2556).

BaseType: PTypeInfo;

The base type of this enumeration
- always use PEnumType(typeinfo(TEnumType))^.BaseType or more useful method
PTypeInfo(typeinfo(TEnumType))^.EnumBaseType before calling any of the methods below

MaxValue: Longint;

Same as ord(high(type)): not the enumeration count, but the highest index

MinValue: Longint;

First value of enumeration type, typically 0

NameList: string[255];

A concatenation of shortstrings, containing the enumeration names
- those shortstrings are not aligned whatsoever (even if FPC_REQUIRES_PROPER_ALIGNMENT is set)

OrdType: TOrdType;

Specify ordinal storage size and sign
- is preferred to MaxValue to identify the number of stored bytes

function GetCaption(const Value): string;

Get the corresponding caption name, without the first lowercase chars (otDone -> 'Done')
- return "string" type, i.e. UnicodeString for Delphi 2009+
- internally call UnCamelCase() then System.LoadResStringTranslate() if available
- Value will be converted to the matching ordinal value (byte or word)

function GetCaptionStrings(UsedValuesBits: Pointer=nil): string;

Get all caption names, ready to be display, as lines separated by #13#10
- return "string" type, i.e. UnicodeString for Delphi 2009+
- if UsedValuesBits is not nil, only the corresponding bits set are added

function GetEnumName(const Value): PShortString;

Get the corresponding enumeration name
- return the first one if Value is invalid (>MaxValue)
- Value will be converted to the matching ordinal value (byte or word)

```
function GetEnumNameAllAsJSONArray(TrimLeftLowerCase: boolean; UnCamelCased: boolean=false): RawUTF8;
```

Get all enumeration names as a JSON array of strings

```
function GetEnumNameOrd(Value: Integer): PShortString;
```

Get the corresponding enumeration name

- return the first one if Value is invalid (>MaxValue)

```
function GetEnumNameTrimmed(const Value): RawUTF8;
```

Get the corresponding enumeration name, without the first lowercase chars (otDone -> 'Done')

- Value will be converted to the matching ordinal value (byte or word)

```
function GetEnumNameTrimmedValue(const EnumName: ShortString): Integer; overload;
```

Get the corresponding enumeration ordinal value, from its name without its first lowercase chars ('Done' will find otDone e.g.)

- return -1 if not found (don't use directly this value to avoid any GPF)

```
function GetEnumNameTrimmedValue(Value: PUTF8Char; ValueLen: integer=0): Integer; overload;
```

Get the corresponding enumeration ordinal value, from its name without its first lowercase chars ('Done' will find otDone e.g.)

- return -1 if not found (don't use directly this value to avoid any GPF)

```
function GetEnumNameValue(Value: PUTF8Char; ValueLen: integer; AlsoTrimLowerCase: boolean=true): Integer; overload;
```

Get the corresponding enumeration ordinal value, from its name

- if Value does start with lowercases 'a'..'z', they will be searched: e.g.

GetEnumNameValue('sllWarning') will find sllWarning item

- if AlsoTrimLowerCase is TRUE, and EnumName does not start with lowercases 'a'..'z', they will be ignored: e.g. GetEnumNameValue('Warning') will find sllWarning item

- return -1 if not found (don't use directly this value to avoid any GPF)

```
function GetEnumNameValue(const EnumName: ShortString): Integer; overload;
```

Get the corresponding enumeration ordinal value, from its name

- if EnumName does start with lowercases 'a'..'z', they will be searched: e.g.

GetEnumNameValue('sllWarning') will find sllWarning item

- if Value does not start with lowercases 'a'..'z', they will be ignored: e.g.

GetEnumNameValue('Warning') will find sllWarning item

- return -1 if not found (don't use directly this value to avoid any GPF)

```
function GetEnumNameValue(Value: PUTF8Char): Integer; overload;
```

Get the corresponding enumeration ordinal value, from its name

- if Value does start with lowercases 'a'..'z', they will be searched: e.g.

GetEnumNameValue('sllWarning') will find sllWarning item

- if Value does not start with lowercases 'a'..'z', they will be ignored: e.g.

GetEnumNameValue('Warning') will find sllWarning item

- return -1 if not found (don't use directly this value to avoid any GPF)

```
function GetSetNameAsDocVariant(Value: integer; FullSetsAsStar: boolean=false): variant;
```

Get the enumeration names corresponding to a set value, as a JSON array

function GetSetNameCSV(Value: integer; SepChar: AnsiChar=','; FullSetsAsStar: boolean=false): RawUTF8; overload;

Get the enumeration names corresponding to a set value

function SizeInStorageAsEnum: Integer;

Compute how many bytes this type will use to be stored as a enumerate

function SizeInStorageAsSet: Integer;

Compute how many bytes this type will use to be stored as a set

procedure AddCaptionStrings(Strings: TStrings; UsedValuesBits: Pointer=nil);

Add caption names, ready to be display, to a TStrings class

- add pointer(ord(element)) as Objects[] value
- if UsedValuesBits is not nil, only the corresponding bits set are added
- can be used e.g. to populate a combo box as such:
 PTypeInfo(TypeInfo(TMyEnum))^ .EnumBaseType^.AddCaptionStrings(ComboBox.Items);

procedure GetEnumNameAll(var result: TRawUTF8DynArray; TrimLeftLowerCase: boolean); overload;

Retrieve all element names as a dynamic array of RawUTF8

- names could be optionally trimmed left from their initial lower chars

procedure GetEnumNameAll(var result: RawUTF8; const Prefix: RawUTF8=''; quotedValues: boolean=false; const Suffix: RawUTF8=''; trimmedValues: boolean=false; unCamelCased: boolean=false); overload;

Retrieve all element names as CSV, with optional quotes

procedure GetEnumNameTrimmedAll(var result: RawUTF8; const Prefix: RawUTF8=''; quotedValues: boolean=false; const Suffix: RawUTF8='');

Retrieve all trimmed element names as CSV

procedure GetSetNameCSV(W: TTextWriter; Value: integer; SepChar: AnsiChar=','; FullSetsAsStar: boolean=false); overload;

Get the enumeration names corresponding to a set value

procedure SetEnumFromOrdinal(out Value; Ordinal: Integer);

Store an enumeration value from its ordinal representation

TInterfaceTypeData = record

A wrapper to interface type information, as defined by the Delphi RTTI

IntfFlags: TIntfFlags;

Ancestor

TTypeInfo = object(TObject)

A wrapper containing type information definition

- user types defined as an alias don't have this type information:
`type NewType = OldType;`
- user types defined as new types have this type information:
`type NewType = type OldType;`

Used for DI-2.1.3 (page 2556).

Kind: TTypeKind;

The value type family

Name: ShortString;

The declared name of the type ('String','Word','RawUnicode'...)

function AnsiStringCodePage: integer;

Recognize most used string types, returning their code page

- will recognize TSQLRawBlob as the fake CP_SQLRAWBLOB code page
- will return the exact code page since Delphi 2009, from RTTI
- for non Unicode versions of Delphi, will recognize WinAnsiString as CODEPAGE_US, RawUnicode as CP_UTF16, RawByteString as CP_RAWBYTESTRING, AnsiString as 0, and any other type as RawUTF8

function ClassCreate: TObject;

Create an instance of the corresponding class

- will call TObject.Create, or TSQLRecord.Create virtual constructor
- will raise EParsingException if class cannot be constructed on the fly, e.g. for a plain TCollectionItem class

function ClassFieldCount(onlyWithoutGetter: boolean): integer;

Get the number of published properties in this class

- you can count the plain fields without any getter function, if you do need only the published properties corresponding to some value actually stored, and ignore e.g. any textual conversion

function ClassSQLFieldType: TSQLFieldType;

Get the SQL type of this Delphi class type

- returns either sftObject, sftID, sftMany or sftUnknown

function ClassType: PClassType;

Get the class type information

function DynArrayItemSize: integer;

Get the dynamic array size (in bytes) of the stored item

function DynArrayItemType(aDataSize: PInteger=nil): PTypeInfo;

Get the dynamic array type information of the stored item

function DynArraySQLFieldType: TSQLFieldType;

Get the SQL type of the items of a dynamic array

function EnumBaseType: PEnumType;

Get the enumeration type information

function FloatType: TFloatType;

For floating point types, get the storage size and precision

function GetSQLFieldType: TSQLFieldType;

Get the SQL type of this Delphi type, as managed with the database driver

function InheritsFrom(AClass: TClass): boolean;

Fast and easy find if a class type inherits from a specific class type

function InterfaceAncestor: PTypeInfo;

Get the ancestor/parent of a given interface type information

- returns nil if this type has no parent

function InterfaceGUID: PGUID;

Get the TGUID of a given interface type information

- returns nil if this type is not an interface

function InterfaceType: PInterfaceTypeData;

Get the interface type information

function InterfaceUnitName: PShortString;

Get the unit name of a given interface type information

- returns '' if this type is not an interface

function IsQWord: boolean;

Return TRUE if the property is an unsigned 64-bit field

function OrdType: TOrdType;

For ordinal types, get the storage size and sign

function RecordType: PRecordType;

Get the record type information

function SetEnumType: PEnumType;

For set types, get the type information of the corresponding enumeration

procedure InterfaceAncestors(out Ancestors: PTypeInfoDynArray; OnlyImplementedBy: TInterfacedObjectClass; out AncestorsImplementedEntry: TPointerDynArray);

Get all ancestors/parents of a given interface type information

- only ancestors with an associated TGUID will be added

- if OnlyImplementedBy is not nil, only the interface explicitly implemented by this class will be added, and AncestorsImplementedEntry[] will contain the corresponding PInterfaceEntry values

TPropInfo = object(TObject)

A wrapper containing a RTTI property definition

- used for direct Delphi / UTF-8 SQL type mapping/conversion

- doesn't depend on RTL's TypInfo unit, to enhance cross-compiler support

Used for DI-2.1.3 (page 2556).

GetProc: PtrUInt;

Contains the offset of a field, or the getter method set by 'read' declaration

- if this field is 0 (no 'read' was specified), raw access methods will use SetProc to get the field memory address to read from
- call TPropInfo.Getter for cross-compiler access to this information

Index: Integer;

Contains the index value of an indexed class data property

- outside SQLite3, this can be used to define a VARCHAR() length value for the textual field definition (sftUTF8Text/sftAnsiText); e.g. the following will create a NAME VARCHAR(40) field:
`Name: RawUTF8 index 40 read fName write fName;`
- is used by a dynamic array property for fast usage of the TSQLRecord.DynArray(DynArrayFieldIndex) method

Name: ShortString;

The property definition Name

NameIndex: SmallInt;

Contains the default value (NO_DEFAULT=\$80000000 indicates none set) when an ordinal or set property is saved as TPersistent

- see TPropInfo.DefaultOr0/DefaultOrVoid for easy use index of the property in the current inherited class definition
- first name index at a given class level is 0
- index is reset to 0 at every inherited class level

PropType: PTypeInfo;

The type definition of this property

- call TPropInfo.TypeInfo for cross-compiler access to this information

SetProc: PtrUInt;

Contains the offset of a field, or the setter method set by 'write' declaration

- if this field is 0 (no 'write' was specified), raw access methods will use GetProc to get the field memory address to save into
- call TPropInfo.Setter for cross-compiler access to this information

StoredProc: PtrUInt;

Contains the 'stored' boolean value/method (used in TPersistent saving)

- either integer(True) - the default, integer(False), reference to a Boolean field, or reference to a parameterless method that returns a Boolean value
- if a property is marked as "stored AS_UNIQUE" (i.e. "stored false"), it is created as UNIQUE in the SQL database and its bit is set in Model.flsUnique[]
- call TPropInfo.IsStored for cross-compiler access to this information

function ClassFromJSON(Instance: TObject; From: PUTF8Char; var Valid: boolean; Options: TJSONToJSONObjectOptions=[]): PUTF8Char;

Read an TObject published property, as saved by ObjectToJSON() function
 - will use direct in-memory reference to the object, or call the corresponding setter method (if any), creating a temporary instance via TTypeInfo.ClassCreate
 - unserialize the JSON input buffer via a call to JSONToJSONObject()
 - by default, a temporary instance will be created if a published field has a setter, and the instance is expected to be released later by the owner class: you can set the j2oSetterExpectsToFreeTempInstance option to let this method release it when the setter returns

function CopyToNewObject(aFrom: TObject): TObject;

Create a new instance of a published property
 - copying its properties values from a given instance of another class
 - if the destination property is not of the aFrom class, it will first search for any exact match in the destination nested properties

function DefaultOr0: integer;

Return the Default RTTI value defined for this property, or 0 if not set

function DynArrayIsObjArray: boolean;

*Return TRUE if this dynamic array has been registered as a T*ObjArray*
 - the T*ObjArray dynamic array should have been previously registered via TJSONSerializer.RegisterObjArrayForJSON() overloaded methods

function DynArrayIsObjArrayInstance: PClassInstance;

*Return class instance creation information about a T*ObjArray*
 - the T*ObjArray dynamic array should have been previously registered via TJSONSerializer.RegisterObjArrayForJSON() overloaded methods
 - returns nil if the supplied type is not a registered T*ObjArray
 - you can create a new item instance just by calling result^.CreateNew

function GetCurrencyProp(Instance: TObject): currency;

Raw retrieval of tkFloat/currency
 - use instead GetCurrencyValue

function GetCurrencyValue(Instance: TObject): Currency;

Low-level getter of the currency property value of a given instance
 - this method will check if the corresponding property is exactly currency
 - return 0 on any error

function GetDoubleProp(Instance: TObject): double;

Raw retrieval of tkFloat/double

function GetDoubleValue(Instance: TObject): double;

Low-level getter of the floating-point property value of a given instance
 - this method will check if the corresponding property is floating-point
 - return 0 on any error

function GetDynArray(Instance: TObject): TDynArray; overload;

Low-level getter of a dynamic array wrapper
 - this method will NOT check if the property is a dynamic array: caller must have already checked that PropType^.Kind=tkDynArray

function GetFieldAddr(Instance: TObject): pointer;

Low-level getter of the field value memory pointer
- return NIL if both getter and setter are methods

function GetFloatProp(Instance: TObject): double;

Raw retrieval of tkFloat - with conversion to 64-bit double
- use instead GetDoubleValue

function GetGenericStringValue(Instance: TObject): string;

Low-level getter of the long string property value of a given instance
- uses the generic string type: to be used within the VCL
- this method will check if the corresponding property is a Long String, or an UnicodeString (for Delphi 2009+), and will return "" if it's not the case

function GetInt64Prop(Instance: TObject): Int64;

Raw retrieval of tkInt64, tkQWord
- rather call GetInt64Value

function GetInt64Value(Instance: TObject): Int64;

Low-level getter of the ordinal property value of a given instance
- this method will check if the corresponding property is ordinal
- ordinal properties smaller than tkInt64 will return an Int64-converted value (e.g. tkInteger)
- return 0 on any error

function GetObjProp(Instance: TObject): TObject;

Raw retrieval of tkClass

function GetOrdProp(Instance: TObject): PtrInt;

Raw retrieval of tkInteger, tkEnumeration, tkSet, tkChar, tkWChar, tkBool
- rather call GetOrdValue/GetInt64Value

function GetOrdValue(Instance: TObject): PtrInt;

Low-level getter of the ordinal property value of a given instance
- this method will check if the corresponding property is ordinal
- return -1 on any error

function Getter(Instance: TObject; Call: PMethod): TPropInfoCall;

Raw retrieval of the property read access definition
- note: 'var Call' generated incorrect code on Delphi XE4 -> use PMethod

function GetterAddr(Instance: pointer): pointer;

Returns the low-level field read address, if GetterIsField is TRUE

function GetterIsField: boolean;

Return TRUE if the property has no getter but direct field read

function IsBlob: boolean;

Return true if this property is a BLOB (TSQLRawBlob)

function IsDefaultOrVoid(Instance: TObject): boolean;

Return TRUE if the property has its Default RTTI value, or is 0/""/nil
- will call function IsObjectDefaultOrVoid() for class properties

function IsStored(Instance: TObject): boolean;

Return FALSE (AS_UNIQUE) if was marked as "stored AS_UNIQUE" (i.e. "stored false"), or TRUE by default

- if Instance=nil, will work only at RTTI level, not with field or method (and will return TRUE if nothing is defined in the RTTI)

function Next: PPropInfo;

Get the next property information

- no range check: use ClassProp().PropCount to determine the properties count

- get the first PPropInfo with ClassProp().PropList

function RetrieveFieldSize: integer;

Compute in how many bytes this property is stored

function SameValue(Source: TObject; DestInfo: PPropInfo; Dest: TObject): boolean;

Compare two published properties

function Setter(Instance: TObject; Call: PMethod): TPropInfoCall;

Raw retrieval of the property access definition

function SetterAddr(Instance: pointer): pointer;

Returns the low-level field write address, if SetterIsField is TRUE

function SetterIsField: boolean;

Return TRUE if the property has no setter but direct field write

function TypeInfo: PTypeInfo;

The type information of this property

- will de-reference the PropType pointer on Delphi and newer FPC compilers

function WriteIsDefined: boolean;

Return TRUE if the property has a write setter or direct field

procedure CopyLongStrProp(Source, Dest: TObject);

Raw copy of tkLString

procedure CopyValue(Source, Dest: TObject; DestInfo: PPropInfo=nil);

Copy a published property value from one instance to another

- this method use direct copy of the low-level binary content, and is therefore faster than a SetValue(Dest, GetValue(Source)) call

- if DestInfo is nil, it will assume DestInfo=@self

procedure GetDynArray(Instance: TObject; var result: TDynArray); overload;

Low-level getter of a dynamic array wrapper

- this method will NOT check if the property is a dynamic array: caller must have already checked that PropType^.Kind=tkDynArray

procedure GetLongStrProp(Instance: TObject; var Value: RawByteString);

Raw retrieval of tkLString

procedure GetLongStrValue(Instance: TObject; var result: RawUTF8);

Low-level getter of the long string property value of a given instance

- this method will check if the corresponding property is a Long String, and will return "" if it's not the case
- it will convert the property content into RawUTF8, for RawUnicode, WinAnsiString, TSQLRawBlob and generic Delphi 6-2007 string property
- WideString and UnicodeString properties will also be UTF-8 converted

procedure GetRawByteStringValue(Instance: TObject; var Value: RawByteString);

Low-level getter of the long string property content of a given instance

- just a wrapper around low-level GetLongStrProp() function
- call GetLongStrValue() method if you want a conversion into RawUTF8
- will work only for Kind=tkLString

procedure GetShortStrProp(Instance: TObject; var Value: RawByteString);

Raw retrieval of tkString into an Ansi7String

procedure GetToText(Instance: TObject; WR: TTextWriter; RawUTF8DynArrayAsCSV: boolean=false; Escape: TTextWriterKind=twNone);

Low-level appender of the property value to a text buffer

- write the published integer, Int64, floating point values, (wide)string, enumerates (e.g. boolean), variant properties of the object
- dynamic arrays will be serialized as JSON, unless RawUTF8DynArrayAsCSV is set, and a TRawUTF8DynArray property will be stored as CSV

procedure GetVariant(Instance: TObject; var Dest: variant);

Low-level getter of the property value into a variant value

- a tkDynArray property is expected to be a T*ObjArray and will be converted into a TDocVariant using a temporary JSON serialization

procedure GetVariantProp(Instance: TObject; var result: Variant);

Raw retrieval of tkVariant

procedure GetWideStrProp(Instance: TObject; var Value: WideString);

Raw retrieval of tkWString

procedure SetCurrencyProp(Instance: TObject; const Value: Currency);

Raw assignment of tkFloat/currency

procedure SetDefaultValue(Instance: TObject; FreeAndNilNestedObjects: boolean=true);

Low-level setter of the property value as its default

- this method will check the property type, e.g. setting "" for strings, and 0 for numbers, or running FreeAndNil() on any nested object (unless FreeAndNilNestedObjects is false so that ClearObject() is used)

procedure SetDoubleProp(Instance: TObject; Value: Double);

Raw assignment of tkFloat/double

procedure SetDoubleValue(Instance: TObject; const Value: double);

Low-level setter of the floating-point property value of a given instance

- this method will check if the corresponding property is floating-point

procedure SetFloatProp(Instance: TObject; Value: TSynExtended);

Raw assignment of tkFloat
- use instead SetDoubleValue

procedure SetFromText(Instance: TObject; **const** Text: RawUTF8; TryCustomVariants: PDocVariantOptions=nil; AllowDouble: boolean=false);

Low-level setter of the property value from its text representation
- handle published integer, Int64, floating point values, (wide)string, enumerates (e.g. boolean), variant properties of the object
- for variant properties, could unserialize the Text as JSON into a TDocVariantData if TryCustomVariants (and AllowDouble) are set
- dynamic arrays are unserialized from JSON [...], unless a TRawUTF8DynArray property has been stored as CSV

procedure SetFromVariant(Instance: TObject; **const** Value: **variant**);

Low-level setter of the property value from a supplied variant
- will optionally make some conversion if the property type doesn't match the variant type, e.g. a text variant could be converted to integer when setting a tkInteger kind of property
- a tkDynArray property is expected to be a T*ObjArray and will be converted from a TDocVariant using a newly allocated T*ObjArray

procedure SetGenericStringValue(Instance: TObject; **const** Value: **string**);

Low-level setter of the string property value of a given instance
- uses the generic string type: to be used within the VCL
- this method will check if the corresponding property is a Long String or an UnicodeString (for Delphi 2009+), and will call the corresponding SetLongStrValue() or SetUnicodeStrValue() method

procedure SetInt64Prop(Instance: TObject; **const** Value: Int64);

Raw assignment of tkInt64, tkQWord
- rather call SetInt64Value

procedure SetInt64Value(Instance: TObject; Value: Int64);

Low-level setter of the ordinal property value of a given instance
- this method will check if the corresponding property is ordinal

procedure SetLongStrProp(Instance: TObject; **const** Value: RawByteString);

Raw assignment of tkLString

procedure SetLongStrValue(Instance: TObject; **const** Value: RawUTF8);

Low-level setter of the long string property value of a given instance
- this method will check if the corresponding property is a Long String
- it will convert the property content into RawUTF8, for RawUnicode, WinAnsiString, TSQLRawBlob and generic Delphi 6-2007 string property
- will set WideString and UnicodeString properties from UTF-8 content

procedure SetOrdProp(Instance: TObject; Value: PtrInt);

Raw assignment of tkInteger, tkEnumeration, tkSet, tkChar, tkWChar, tkBool
- rather call SetOrdValue/SetInt64Value

procedure SetOrdValue(Instance: TObject; Value: PtrInt);

Low-level setter of the ordinal property value of a given instance
- this method will check if the corresponding property is ordinal

procedure SetVariantProp(Instance: TObject; **const** Value: Variant);

Raw assignment of tkVariant

procedure SetWideStrProp(Instance: TObject; **const** Value: WideString);

Raw assignment of tkWString

TReturnInfo = **object**(TObject)

A wrapper around method returned result definition

CallingConvention: TCallingConvention;

Expected calling convention (only relevant for x86 mode)

ParamCount: Byte;

Number of expected parameters

ParamSize: Word;

Total size of data needed for stack parameters + 8 (ret-addr + pushed EBP)

ReturnType: ^PTypeInfo;

The expected type of the returned function result

- is nil for procedure

Version: byte;

RTTI version

- 2 up to Delphi 2010, 3 for Delphi XE and up

function Param: PParamInfo;

Access to the first method parameter definition

TParamInfo = **object**(TObject)

A wrapper around an individual method parameter definition

Flags: TParamFlags;

The kind of parameter

Name: ShortString;

Parameter name

Offset: Word;

Parameter offset

- 0 for EAX, 1 for EDX, 2 for ECX

- any value >= 8 for stack-based parameter

ParamType: PTypeInfo;

The parameter type information

function Next: PParamInfo;

Get the next parameter information

- no range check: use TReturnInfo.ParamCount to determine the appropriate count

TMethodInfo = object(TObject)

A wrapper around a method definition

Addr: Pointer;

The associated method code address

Len: Word;

Size (in bytes) of this TMethodInfo block

Name: ShortString;

Method name

function MethodAddr: Pointer;

Wrapper returning nil and avoiding a GPF if @self=nil

function ReturnInfo: PReturnInfo;

Retrieve the associated parameters information

PropWrap = packed record

*Used to map a TPropInfo.GetProc/SetProc and retrieve its kind
 - defined here for proper Delphi inlining*

Kind: byte;

= \$ff for a ptField address, or = \$fe for a ptVirtual method

TSQLPropInfo = class(TObject)

*Abstract parent class to store information about a published property
 - property information could be retrieved from RTTI (TSQLPropInfoRTTI*), or be defined by code (TSQLPropInfoCustom derived classes) when RTTI is not available*

constructor Create(const aName: RawUTF8; aSQLFieldType: TSQLFieldType; aAttributes: TSQLPropInfoAttributes; aFieldWidth, aPropertyIndex: integer); reintroduce; virtual;

Initialize the internal fields

*- should not be called directly, but with dedicated class methods like class function
 TSQLPropInfoRTTI.CreateFrom() or overridden constructors*

function CompareValue(Item1, Item2: TObject; CaseInsensitive: boolean): PtrInt; virtual;

Compare the content of the property of two objects

*- not all kind of properties are handled: only main types (like GetHash)
 - if CaseInsensitive is TRUE, will apply NormToUpper[] 8 bits uppercase, handling RawUTF8 properties just like the SYSTEMNOCASE collation
 - this method should match the case-sensitivity of GetHash()
 - this default implementation will call GetValueVar() for slow comparison*

function GetFieldAddr(Instance: TObject): pointer; virtual; abstract;

Returns an untyped pointer to the field property memory in a given instance

function GetHashCode(Instance: TObject; CaseInsensitive: boolean): cardinal; **virtual**;

Retrieve an unsigned 32-bit hash of the corresponding property

- not all kind of properties are handled: only main types
- if CaseInsensitive is TRUE, will apply NormToUpper[] 8 bits uppercase, handling RawUTF8 properties just like the SYSTEMNOCASE collation
- note that this method can return a hash value of 0
- this method should match the case-sensitivity of CompareValue()
- this default implementation will call GetValueVar() for slow computation

function GetValue(Instance: TObject; ToSQL: boolean; wasSQLString: PBoolean=nil): RawUTF8;

Convert the property value into an UTF-8 encoded text

- if ToSQL is true, result is on SQL form (false->'0' e.g.)
- if ToSQL is false, result is on JSON form (false->'false' e.g.)
- BLOB field returns SQLite3 BLOB literals ("x'01234'" e.g.) if ToSQL is true, or base-64 encoded stream for JSON ("\"uFFF0base64encodedbinary")
- getter method (read Get*) is called if available
- handle Delphi values into UTF-8 SQL conversion
- sftBlobDynArray, sftBlobCustom or sftBlobRecord are returned as BLOB literals ("X'53514C697465'" e.g.) if ToSQL is true, or base-64 encoded stream for JSON ("\"uFFF0base64encodedbinary")
- handle TPersistent, TCollection, TRawUTF8List or TStringList with ObjectToJSON

function IsValueVoid(Instance: TObject): boolean;

Returns TRUE if value is 0 or ""

function SetBinary(Instance: TObject; P, PEnd: PAnsiChar): PAnsiChar; **virtual**;
abstract;

Read the property value from a binary buffer

- PEnd should point to the end of the P input buffer, to avoid any overflow
- returns next char in input buffer on success, or nil in case of invalid content supplied e.g.

function SetFieldSQLVar(Instance: TObject; const aValue: TSQLVar): boolean;
virtual;

Set a field value from a TSQLVar value

function SQLDBFieldTypeNames: PShortString;

The corresponding column type name, as managed for abstract database access

procedure CopyProp(Source: TObject; DestInfo: TSQLPropInfo; Dest: TObject);

Copy a value from one instance to another property instance

- if the property has been flattened (for a TSQLPropInfoRTTI), the real Source/Dest instance will be used for the copy

procedure CopyValue(Source, Dest: TObject); **virtual**;

Copy a property value from one instance to another

- both objects should have the same exact property

procedure GetBinary(Instance: TObject; W: TFileBufferWriter); **virtual**; **abstract**;

Append the property value into a binary buffer

```
procedure GetFieldSQLVar(Instance: TObject; var aValue: TSQLVar; var temp: RawByteString); virtual;
```

Retrieve a field value into a TSQLVar value

- the temp RawByteString is used as a temporary storage for TEXT or BLOB and should be available during all access to the TSQLVar fields

```
procedure GetJSONValues(Instance: TObject; W: TJSONSerializer); virtual;
```

Add the JSON content corresponding to the given property

- this default implementation will call safe but slow GetValueVar() method

```
procedure GetValueVar(Instance: TObject; ToSQL: boolean; var result: RawUTF8; wasSQLString: PBoolean); virtual; abstract;
```

Convert the property value into an UTF-8 encoded text

- this method is the same as GetValue(), but avoid assigning the result string variable (some speed up on multi-core CPUs, since avoid a CPU LOCK)
- this virtual method is the one to be overridden by the implementing classes

```
procedure GetVariant(Instance: TObject; var Dest: Variant); virtual;
```

Retrieve the property value into a Variant

- will set the Variant type to the best matching kind according to the SQLFieldType type
- BLOB field returns SQLite3 BLOB textual literals ("x'01234'" e.g.)
- dynamic array field is returned as a variant array

```
procedure NormalizeValue(var Value: RawUTF8); virtual; abstract;
```

Normalize the content of Value, so that GetValue(Object,true) should return the same content (true for ToSQL format)

```
procedure SetValue(Instance: TObject; Value: PUTF8Char; wasString: boolean); virtual; abstract;
```

Convert UTF-8 encoded text into the property value

- setter method (write Set*) is called if available
- if no setter exists (no write declaration), the getted field address is used
- handle UTF-8 SQL to Delphi values conversion
- expect BLOB fields encoded as SQLite3 BLOB literals ("x'01234'" e.g.) or base-64 encoded stream for JSON ("uFFF0base64encodedbinary") - i.e. both format supported by BlobToTSQLRawBlob() function
- handle TPersistent, TCollection, TRawUTF8List or TStringList with JSONToObject
- note that the supplied Value buffer won't be modified by this method: overridden implementation should create their own temporary copy

```
procedure SetValueVar(Instance: TObject; const Value: RawUTF8; wasString: boolean); virtual;
```

Convert UTF-8 encoded text into the property value

- just a wrapper around SetValue(...,pointer(Value),...) which may be optimized for overridden methods

```
procedure SetVariant(Instance: TObject; const Source: Variant); virtual;
```

Set the property value from a Variant value

- dynamic array field must be set from a variant array
- will set the Variant type to the best matching kind according to the SQLFieldType type
- expect BLOB fields encoded as SQLite3 BLOB literals ("x'01234'" e.g.)

property Attributes: TSQLPropInfoAttributes read fAttributes write fAttributes;

The ORM attributes of this property

- contains alsUnique e.g. for TSQLRecord published properties marked as

property MyProperty: RawUTF8 stored AS_UNIQUE;

(i.e. "stored false")

property FieldWidth: integer read fFieldWidth;

The optional width of this field, in external databases

- is set e.g. by index attribute of TSQLRecord published properties as

property MyProperty: RawUTF8 index 10;

property Name: RawUTF8 read fName;

The property definition Name

property NameDisplay: string read GetNameDisplay;

The property definition Name, after un-camelcase and translation

property NameUnflattened: RawUTF8 read fNameUnflattened;

The property definition Name, with full path name if has been flattened

- if the property has been flattened (for a TSQLPropInfoRTTI), the real full nested class will be returned, e.g. 'Address.Country.Iso' for the 'Address_Country' flattened property name

property PropertyIndex: integer read fPropertyIndex;

The property index in the RTTI

property SQLDBFieldType: TSQLDBFieldType read fSQLDBFieldType;

The corresponding column type, as managed for abstract database access

- TNullable* fields will report here the corresponding simple DB type, e.g. ftInt64 for TNullableInteger (following SQLFieldTypeStored value)

property SQLFieldRTTITypeName: RawUTF8 read GetSQLFieldRTTITypeName;

The type name, as defined in the RTTI

- returns e.g. 'RawUTF8'

- will return the TSQLPropInfo class name if it is not a TSQLPropInfoRTTI

property SQLFieldType: TSQLFieldType read fSQLFieldType;

The corresponding column type, as managed by the ORM layer

property SQLFieldName: PShortString read GetSQLFieldName;

The corresponding column type name, as managed by the ORM layer and retrieved by the RTTI

- returns e.g. 'sftTimeLog'

property SQLFieldTypeStored: TSQLFieldType read fSQLFieldTypeStored;

The corresponding column type, as stored by the ORM layer

- match SQLFieldType, unless for SQLFieldType=sftNullable, in which this field will contain the simple type eventually stored in the database

TSQLPropInfoRTTI = class(TSQLPropInfo)

Parent information about a published property retrieved from RTTI

constructor Create(aPropInfo: PPropInfo; aPropIndex: integer; aSQLFieldType: TSQLFieldType; aOptions: TSQLPropInfoListOptions); **reintroduce; virtual;**

Initialize the internal fields

- should not be called directly, but with dedicated class methods like class function CreateFrom()

class function CreateFrom(aPropInfo: PPropInfo; aPropIndex: integer; aOptions: TSQLPropInfoListOptions; **const** aFlattenedProps: PPropInfoDynArray): TSQLPropInfo;

This meta-constructor will create an instance of the exact descendant of the specified property RTTI

- it will raise an EORMException in case of an unhandled type

function Flattened(Instance: TObject): TObject;

For pilSubClassesFlattening properties, compute the actual instance containing the property value

- if the property was not flattened, return the instance

function GetFieldAddr(Instance: TObject): pointer; **override;**

Generic way of implementing it

procedure GetVariant(Instance: TObject; **var** Dest: Variant); **override;**

Retrieve the property value into a Variant

- will set the Variant type to the best matching kind according to the SQLFieldType type

- BLOB field returns SQLite3 BLOB textual literals ("x'01234'" e.g.)

- dynamic array field is returned as a variant array

class procedure RegisterTypeInfo(aTypeInfo: Pointer);

Register this class corresponding to the RTTI TypeInfo() pointer

- could be used e.g. to define custom serialization and process of any custom type

property FlattenedPropInfo: PPropInfoDynArray **read** fFlattenedProps;

For pilSubClassesFlattening properties, the parents RTTI

property PropInfo: PPropInfo **read** fPropInfo;

Corresponding RTTI information

property PropType: PTypeInfo **read** fPropType;

Corresponding type information, as retrieved from PropInfo RTTI

TSQLPropInfoRTTIInt32 = **class**(TSQLPropInfoRTTI)

Information about an ordinal Int32 published property

TSQLPropInfoRTTISet = **class**(TSQLPropInfoRTTIInt32)

Information about a set published property

TSQLPropInfoRTTIEnum = **class**(TSQLPropInfoRTTIInt32)

Information about a enumeration published property

- can be either sftBoolean or sftEnumerate kind of property

TSQLPropInfoRTTIChar = **class**(TSQLPropInfoRTTIInt32)

Information about a character published property

TSQLPropInfoRTTIInt64 = **class**(TSQLPropInfoRTTI)

Information about an ordinal Int64 published property

TSQLPropInfoRTTITimeLog = class(TSQLPropInfoRTTIInt64)

Information about a TTimeLog published property
 - stored as an Int64, but with a specific class

TSQLPropInfoRTTIUnixTime = class(TSQLPropInfoRTTIInt64)

Information about a TUnixTime published property
 - stored as an Int64, but with a specific class

TSQLPropInfoRTTIUnixMSTime = class(TSQLPropInfoRTTIInt64)

Information about a TUnixMSTime published property
 - stored as an Int64, but with a specific class

TSQLPropInfoRTTIDouble = class(TSQLPropInfoRTTI)

Information about a floating-point Double published property

TSQLPropInfoRTTICurrency = class(TSQLPropInfoRTTIDouble)

Information about a fixed-decimal Currency published property

TSQLPropInfoRTTIDateTime = class(TSQLPropInfoRTTIDouble)

Information about a TDateTime published property

TSQLPropInfoRTTIAnsi = class(TSQLPropInfoRTTI)

Information about a AnsiString published property

TSQLPropInfoRTTIRawUTF8 = class(TSQLPropInfoRTTIAnsi)

Information about a RawUTF8 published property
 - will also serialize a RawJSON property without JSON escape

TSQLPropInfoRTTIRawUnicode = class(TSQLPropInfoRTTIAnsi)

Information about a RawUnicode published property

TSQLPropInfoRTTIRawBlob = class(TSQLPropInfoRTTIAnsi)

Information about a TSQLRawBlob published property

TSQLPropInfoRTTIWide = class(TSQLPropInfoRTTI)

Information about a WideString published property

TSQLPropInfoRTTIDynArray = class(TSQLPropInfoRTTI)

Information about a dynamic array published property

constructor Create(aPropInfo: PPropInfo; aPropIndex: integer; aSQLFieldType: TSQLFieldType; aOptions: TSQLPropInfoListOptions); **override;**

Initialize the internal fields

- should not be called directly, but with dedicated class methods like class function CreateFrom()

property DynArrayElemType: PTypeInfo **read** GetDynArrayElemType;

Read-only access to the low-level type information the array item type

property DynArrayIndex: integer **read** fFieldWidth;

Optional index of the dynamic array published property

- used e.g. for fast lookup by TSQLRecord.DynArray(DynArrayFieldIndex)

property ObjArray: PClassInstance **read** fObjArray;

*Dynamic array item information for a T*ObjArray*

- equals nil if this dynamic array was not previously registered via TJSONSerializer.RegisterObjArrayForJSON()
- note that if the field is a T*ObjArray, you could create a new item by calling ObjArray^.CreateNew
- T*ObjArray database column will be stored as text

TSQLPropInfoRTTIVariant = class(TSQLPropInfoRTTI)

Information about a variant published property

- is also used for TNullable* properties

constructor Create(aPropInfo: PPropInfo; aPropIndex: integer; aSQLFieldType: TSQLFieldType; aOptions: TSQLPropInfoListOptions); **override**;

Initialize the internal fields

property DocVariantOptions: TDocVariantOptions **read** fDocVariantOptions **write** fDocVariantOptions;

How this property will deal with its instances (including TDocVariant)

- by default, contains JSON_OPTIONS_FAST for best performance - i.e. [dvoReturnNullForUnknownProperty,dvoValueCopiedByReference]
- set JSON_OPTIONS_FAST_EXTENDED (or include dvoSerializeAsExtendedJson) so that any TDocVariant nested field names will not be double-quoted, saving some chars in the stored TEXT column and in the JSON escaped transmitted data over REST, by writing '{name:"John",age:123}' instead of '{"name":"John","age":123}': be aware that this syntax is supported by the ORM, SOA, TDocVariant, TBSONVariant, and our SynCrossPlatformJSON unit, but not AJAX/JavaScript or most JSON libraries
- see also TSQLModel/TSQLRecordProperties.SetVariantFieldsDocVariantOptions

TSQLPropInfoCustom = class(TSQLPropInfo)

Abstract information about a record-like property defined directly in code

- do not use this class, but TSQLPropInfoRecordRTTI and TSQLPropInfoRecordFixedSize
- will store the content as BLOB by default, and SQLFieldType as sftBlobCustom
- if aData2Text/aText2Data are defined, use TEXT storage and sftUTF8Custom type

constructor Create(const aName: RawUTF8; aSQLFieldType: TSQLFieldType; aAttributes: TSQLPropInfoAttributes; aFieldWidth, aPropIndex: Integer; aProperty: pointer; aData2Text: TOnSQLPropInfoRecord2Text; aText2Data: TOnSQLPropInfoRecord2Data); **reintroduce**;

Define a custom property in code

- do not call this constructor directly, but one of its inherited classes, via a call to TSQLRecordProperties.RegisterCustom*()

TSQLPropInfoRecordTyped = class(TSQLPropInfoCustom)

Information about a record property defined directly in code using RTTI

TSQLPropInfoRecordRTTI = class(TSQLPropInfoRecordTyped)

Information about a record property defined directly in code

- Delphi does not publish RTTI for published record properties
- you can use this class to register a record property from its RTTI
- will store the content as BLOB by default, and SQLFieldType as sftBlobCustom
- if aData2Text/aText2Data are defined, use TEXT storage and sftUTF8Custom type
- this class will use only binary RecordLoad/RecordSave methods

constructor Create(aRecordInfo: PTypeInfo; **const** aName: RawUTF8; aPropertyIndex: integer; aPropertyPointer: pointer; aAttributes: TSQLPropInfoAttributes=[]; aFieldWidth: integer=0; aData2Text: TOnSQLPropInfoRecord2Text=nil; aText2Data: TOnSQLPropInfoRecord2Data=nil); **reintroduce**; overload;

Define a record property from its RTTI definition

- handle any kind of record with available generated TypeInfo()
- aPropertyPointer shall be filled with the offset to the private field within a nil object, e.g for

```
class TMainObject = class(TSQLRecord)
  (...)
  fFieldName: TMyRecord;
public
  (...)
  property FieldName: TMyRecord read fFieldName write fFieldName;
end;
```

you will have to register it via a call to

TSQLRecordProperties.RegisterCustomRTTIRecordProperty()

- optional alsNotUnique parameter can be defined
- implementation will use internally RecordLoad/RecordSave functions
- you can specify optional aData2Text/aText2Data callbacks to store the content as textual values, and not as BLOB

TSQLPropInfoRecordFixedSize = class(TSQLPropInfoRecordTyped)

Information about a fixed-size record property defined directly in code

- Delphi does not publish RTTI for published record properties
- you can use this class to register a record property with no RTTI (i.e. a record with no reference-counted types within)
- will store the content as BLOB by default, and SQLFieldType as sftBlobCustom
- if aData2Text/aText2Data are defined, use TEXT storage and sftUTF8Custom type

constructor Create(aRecordSize: cardinal; **const** aName: RawUTF8; aPropertyIndex: integer; aPropertyPointer: pointer; aAttributes: TSQLPropInfoAttributes=[]; aFieldWidth: integer=0; aData2Text: TOnSQLPropInfoRecord2Text=nil; aText2Data: TOnSQLPropInfoRecord2Data=nil); **reintroduce**; overload;

Define an unmanaged fixed-size record property

- simple kind of records (i.e. those not containing reference-counted members) do not have RTTI generated, at least in older versions of Delphi: use this constructor to define a direct property access
- main parameter is the record size, in bytes

TSQLPropInfoCustomJSON = class(TSQLPropInfoRecordTyped)

Information about a custom property defined directly in code

- you can define any kind of property, either a record or any type
- this class will use JSON serialization, by type name or TypeInfo() pointer
- will store the content as TEXT by default, and SQLFieldType as sftUTF8Custom

constructor Create(const aTypeName, aName: RawUTF8; aPropertyIndex: integer; aPropertyPointer: pointer; aAttributes: TSQLPropInfoAttributes=[]; aFieldWidth: integer=0); **reintroduce**; overload;

Define a custom property from its RTTI definition

- handle any kind of property, e.g. from enhanced RTTI or a custom record defined via TTextWriter.RegisterCustomJSONSerializer[FromText]()
- aPropertyPointer shall be filled with the offset to the private field within a nil object, e.g. for

```
class TMainObject = class(TSQLRecord)
  (...)
  fGUID: TGUID;
public
  (...)
  property GUID: TGUID read fGUID write fGUID;
end;
```

you will have to register it via a call to

TSQLRecordProperties.RegisterCustomPropertyFromTypeName()

- optional alsNotUnique parameter can be defined
- implementation will use internally RecordLoadJSON/RecordSave functions
- you can specify optional aData2Text/aText2Data callbacks to store the content as textual values, and not as BLOB

constructor Create(aTypeInfo: PTypeInfo; const aName: RawUTF8; aPropertyIndex: integer; aPropertyPointer: pointer; aAttributes: TSQLPropInfoAttributes=[]; aFieldWidth: integer=0); **reintroduce**; overload;

Define a custom property from its RTTI definition

- handle any kind of property, e.g. from enhanced RTTI or a custom record defined via TTextWriter.RegisterCustomJSONSerializer[FromText]()
- aPropertyPointer shall be filled with the offset to the private field within a nil object, e.g. for

```
class TMainObject = class(TSQLRecord)
  (...)
  fFieldName: TMyRecord;
public
  (...)
  property FieldName: TMyRecord read fFieldName write fFieldName;
end;
```

you will have to register it via a call to

TSQLRecordProperties.RegisterCustomPropertyFromRTTI()

- optional alsNotUnique parameter can be defined
- implementation will use internally RecordLoadJSON/RecordSave functions
- you can specify optional aData2Text/aText2Data callbacks to store the content as textual values, and not as BLOB

constructor Create(aPropInfo: PPropInfo; aPropIndex: integer); **reintroduce**; overload; **virtual**;

Initialize the internal fields

- should not be called directly

destructor Destroy; **override**;

Finalize the instance

property CustomParser: TJSONCustomParserRTTI **read** fCustomParser;

The corresponding custom JSON parser

TSQLPropInfoList = **class**(TObject)

Handle a read-only list of fields information for published properties

- is mainly used by our ORM for TSQLRecord RTTI, but may be used for any TPersistent

constructor Create(aTable: TClass; aOptions: TSQLPropInfoListOptions);

Initialize the list from a given class RTTI

destructor Destroy; **override**;

Release internal list items

function Add(aItem: TSQLPropInfo): integer;

Add a TSQLPropInfo to the list

function ByName(aName: PUTF8Char): TSQLPropInfo; **overload**;

Find an item in the list

- returns nil if not found

function ByRawUTF8Name(**const** aName: RawUTF8): TSQLPropInfo; **overload**;

Find an item in the list

- returns nil if not found

function IndexByName(aName: PUTF8Char): integer; **overload**;

Find an item in the list

- returns -1 if not found

function IndexByName(**const** aName: RawUTF8): integer; **overload**;

Find an item in the list

- returns -1 if not found

function IndexByNameOrExcept(**const** aName: RawUTF8): integer;

Find an item by name in the list, including RowID/ID

- will identify 'ID' / 'RowID' field name as -1

- raise an EORMException if not found in the internal list

function IndexByNameUnflattenedOrExcept(**const** aName: RawUTF8): integer;

Find an item in the list, searching by unflattened name

- for a flattened property, you may for instance call

IndexByNameUnflattenedOrExcept('Address.Country.Iso') instead of
 IndexByNameOrExcept('Address_Country')

- won't identify 'ID' / 'RowID' field names, just List[.].

- raise an EORMException if not found in the internal list

procedure IndexesByNamesOrExcept(**const** aNames: array of RawUTF8; **const** aIndexes: array of PInteger);

Find one or several items by name in the list, including RowID/ID

- will identify 'ID' / 'RowID' field name as -1

- raise an EORMException if not found in the internal list

procedure NamesToRawUTF8DynArray(**var** Names: TRawUTF8DynArray);

Fill a TRawUTF8DynArray instance from the field names
 - excluding ID

property Count: integer **read** fCount;

Returns the number of TSQLPropInfo in the list

property Items[aIndex: integer]: TSQLPropInfo **read** GetItem;

Read-only retrieval of a TSQLPropInfo item
 - will raise an exception if out of range

property List: TSQLPropInfoObjArray **read** fList;

Quick access to the TSQLPropInfo list
 - note that length(List) may not equal Count, since is its capacity

TINIWriter = class(TTextWriter)

Simple writer to a Stream, specialized for writing an object as INI
 - resulting content will be UTF-8 encoded
 - use an internal buffer, faster than string+string

procedure WriteObject(Value: TObject; **const** SubCompName: RawUTF8=''; WithSection: boolean=true; RawUTF8DynArrayAsCSV: boolean=false); **reintroduce**;

Write the published properties of the object in INI text format
 - i.e. append PropertyName=PropertyValue lines
 - add a new INI-like section with [Value.ClassName] if WithSection is true
 - use internally TPropInfo.GetToText for the conversion to text
 - Value object must have been compiled with the \$M+ define, i.e. must inherit from TPersistent, TSynPersistent or TSQLRecord
 - the enumerates properties are stored with their integer index value
 - dynamic arrays will be serialized as JSON, unless RawUTF8DynArrayAsCSV is set, and a TRawUTF8DynArray property will be stored as CSV
 - content can be read back using overloaded procedures ReadObject()

TJSONSerializer = class(TJSONWriter)

Simple writer to a Stream, specialized for writing an object as JSON
 - override WriteObject() to use class RTTI process of this unit, and allow custom JSON serialization
 - this is the full-feature JSON serialization class

class function RegisterObjArrayFindType(aDynArray: PTypeInfo): PClassInstance;

*Retrieve TClassInstance information for a T*ObjArray dynamic array type*
 - the T*ObjArray dynamic array should have been previously registered via TJSONSerializer.RegisterObjArrayForJSON() overloaded methods
 - returns nil if the supplied type is not a registered T*ObjArray

class function RegisterObjArrayFindTypeInfo(aClass: TClass): PTypeInfo;

*Retrieve the T*ObjArray dynamic array type RTTI for a given item class*
 - the T*ObjArray dynamic array should have been previously registered via TJSONSerializer.RegisterObjArrayForJSON() overloaded methods
 - returns nil if the supplied type is not a registered T*ObjArray

class procedure RegisterClassForJSON(const aItemClass: array of TClass); overload;

Let a given class be recognized by JSONToObject() from "ClassName": ".."

- TObjectList item instances will be created corresponding to the serialized class name field specified, and JSONToNewObject() can create a new instance using the "ClassName": ".." field to identify the class type
- by default, all referenced TSQLRecord classes will be globally registered when TSQLRecordProperties information is retrieved
- this method is thread-safe, but should be called before any serialization

class procedure RegisterClassForJSON(aItemClass: TClass); overload;

Let a given class be recognized by JSONToObject() from "ClassName": ".."

- TObjectList item instances will be created corresponding to the serialized class name field specified, and JSONToNewObject() can create a new instance using the "ClassName": ".." field to identify the class type
- by default, all referenced TSQLRecord classes will be globally registered when TSQLRecordProperties information is retrieved
- this method is thread-safe, but should be called before any serialization

class procedure RegisterCollectionForJSON(aCollection: TCollectionClass; aItem: TCollectionItemClass);

Let a given TCollection be recognized during JSON serialization

- due to how TCollection instances are created, you can not create a server-side instance of TCollection directly
- first workaround is to inherit from TInterfacedCollection
- this method allows to recognize the needed TCollectionItem class for a given TCollection class, so allow to (un)serialize any TCollection, without defining a new method and inherits from TInterfacedCollection
- note that both supplied classes will be registered for the internal "ClassName": ".." RegisterClassForJSON() process
- this method is thread-safe, but should be called before any serialization

class procedure RegisterCustomSerializer(aClass: TClass; aReader: TJSONSerializerCustomReader; aWriter: TJSONSerializerCustomWriter);

Define a custom serialization for a given class

- by default, TSQLRecord, TPersistent, TStrings, TCollection classes are processed: but you can specify here some callbacks to perform the serialization process for any class
- any previous registration is overridden
- setting both aReader=aWriter=nil will return back to the default class serialization (i.e. published properties serialization)
- note that any inherited classes will be serialized as the parent class
- this method is thread-safe, but should be called before any serialization

```
class procedure RegisterCustomSerializerFieldNames(aClass: TClass; const
aClassFields, aJsonFields: array of ShortString);
```

Define custom serialization of field names for a given class

- any aClassField[] property name will be serialized using aJsonFields[]
- if any aJsonFields[] equals "", this published property will be excluded from the serialization object
- aJsonFields[] is expected to be only plain pascal identifier, i.e. A-Z a-z 0-9 and _ characters, up to 63 in length
- setting both aClassField=aJsonFields=[] will return back to the default class serialization (i.e. serialization with published properties names)
- by design, this customization excludes RegisterCustomSerializer() with custom reader/writer callbacks
- note that any inherited classes will be serialized as the parent class
- this method is thread-safe, but should be called before any serialization

```
class procedure RegisterObjArrayForJSON(const aDynArrayClassPairs: array of const);
overload;
```

*Let T*ObjArray dynamic arrays be used for storage of class instances*

- will allow JSON serialization and unserialization of the registered dynamic array property defined in any TPersistent or TSQLRecord
- will call the overloaded RegisterObjArrayForJSON() class method by pair:
 TJSONSerializer.RegisterObjArrayForJSON([
 TypeInfo(TAddressObjArray), TAddress, TypeInfo(TUserObjArray), TUser]);

```
class procedure RegisterObjArrayForJSON(aDynArray: PTypeInfo; aItem: TClass;
aReader: TDynArrayJSONCustomReader=nil; aWriter: TDynArrayJSONCustomWriter=nil);
overload;
```

*Let a T*ObjArray dynamic array be used for storage of class instances*

- will allow JSON serialization and unserialization of the registered dynamic array property defined in any TPersistent or TSQLRecord
- could be used as such (note the T*ObjArray type naming convention):
 TUserObjArray = **array of** TUser;
 ...
 TJSONSerializer.RegisterObjArrayForJSON(TypeInfo(TUserObjArray), TUser);
- then you can use ObjArrayAdd/ObjArrayFind/ObjArrayDelete to manage the stored items, and never forget to call ObjArrayClear to release the memory
- will use the default published properties serializer, unless you specify your custom Reader/Write callbacks

procedure WriteObject(Value: TObject; Options: TTextWriterWriteObjectOptions=[woDontStoreDefault]); **override;**

Serialize as JSON the published integer, Int64, floating point values, TDateTime (stored as ISO 8601 text), string and enumerate (e.g. boolean) properties of the object

- won't handle shortstring properties
- the object must have been compiled with the \$M+ define, i.e. must inherit from TPersistent or TSQLRecord, or has been defined with a custom serializer via RegisterCustomSerializer()
- will write also the properties published in the parent classes
- the enumerates properties are stored with their integer index value by default, but will be written as text if woFullExpand option is set
- TList objects are not handled by default - they will be written only if FullExpand is set to true (and JSOToObj won't be able to read it)
- nested properties are serialized as nested JSON objects
- any TCollection property will also be serialized as JSON array
- any TString or TRawUTF8List property will also be serialized as JSON string array
- function ObjectToJSON() is just a wrapper over this method

property SQLRecordOptions: TJSONSerializerSQLRecordOptions **read** fSQLRecordOptions **write** SetSQLRecordOptions;

Customize TSQLRecord.GetJSONValues serialization process

- jwoAsJsonNotAsString will force TSQLRecord.GetJSONValues to serialize nested property instances as a JSON object/array, not a JSON string: i.e. root/table/id REST will be ready-to-be-consumed from AJAX clients (e.g. TSQLPropInfoRTTIObj.GetJSONValues as a JSON object, and TSQLPropInfoRTTIDynArray.GetJSONValues as a JSON array)
- jwoID_str will add an "ID_str": "12345" property to the default "ID": 12345 field to circumvent JavaScript's limitation of 53-bit for integer numbers, which is easily reached with our 64-bit TID values, e.g. if TSynUniqueIdentifier are used to generate the IDs: AJAX clients should better use this "ID_str" string value to identify each record, and ignore the "id" fields

TInterfacedCollection = class(TCollection)

Any TCollection used between client and server shall inherit from this class

- you should override the GetClass virtual method to provide the expected collection item class to be used on server side
- another possibility is to register a TCollection/TCollectionItem pair via a call to TJSONSerializer.RegisterCollectionForJSON()

constructor Create; **reintroduce;** **virtual;**

This constructor which will call GetClass to initialize the collection

TCollectionItemAutoCreateFields = class(TCollectionItem)

*Abstract TCollectionItem class, which will instantiate all its nested class published properties, then release them (and any T*ObjArray) when freed*

- could be used for gathering of TCollectionItem properties, e.g. for Domain objects in DDD, especially for list of value objects
- consider using T*ObjArray dynamic array published properties in your value types instead of TCollection storage: T*ObjArray have a lower overhead and are easier to work with, once TJSONSerializer.RegisterObjArrayForJSON is called to register the T*ObjArray type
- note that non published (e.g. public) properties won't be instantiated, serialized, nor released - but may contain weak references to other classes
- please take care that you will not create any endless recursion: you should ensure that at one level, nested published properties won't have any class instance referring to its owner (there is no weak reference - remember!)
- since the destructor will release all nested properties, you should never store a reference to any of those nested instances if this owner may be freed before

constructor Create(Collection: TCollection); override;

*This overridden constructor will instantiate all its nested
TPersistent/TSynPersistent/TSynAutoCreateFields published properties*

destructor Destroy; override;

Finalize the instance, and release its published properties

TPersistentAutoCreateFields = class(TPersistentWithCustomCreate)

*Abstract TPersistent class, which will instantiate all its nested TPersistent class published properties, then release them (and any T*ObjArray) when freed*

- TSynAutoCreateFields is to be preferred in most cases, thanks to its lower overhead
- note that non published (e.g. public) properties won't be instantiated, serialized, nor released - but may contain weak references to other classes
- please take care that you will not create any endless recursion: you should ensure that at one level, nested published properties won't have any class instance referring to its owner (there is no weak reference - remember!)
- since the destructor will release all nested properties, you should never store a reference to any of those nested instances if this owner may be freed before

constructor Create; override;

*This overridden constructor will instantiate all its nested
TPersistent/TSynPersistent/TSynAutoCreateFields published properties*

destructor Destroy; override;

Finalize the instance, and release its published properties

TSynAutoCreateFields = class(TSynPersistent)

Our own empowered TPersistentAutoCreateFields-like parent class

- this class is a perfect parent to store any data by value, e.g. DDD Value Objects, Entities or Aggregates
- is defined as an abstract class able with a virtual constructor, RTTI for published properties, and automatic memory management of all nested class published properties: any class defined as a published property will be owned by this instance - i.e. with strong reference
- will also release any T*ObjArray dynamic array storage of persistents, previously registered via TJSONSerializer.RegisterObjArrayForJSON()
- nested published classes (or T*ObjArray) don't need to inherit from TSynAutoCreateFields: they may be from any TPersistent/TSynPersistent type
- note that non published (e.g. public) properties won't be instantiated, serialized, nor released - but may contain weak references to other classes
- please take care that you will not create any endless recursion: you should ensure that at one level, nested published properties won't have any class instance referring to its owner (there is no weak reference - remember!)
- since the destructor will release all nested properties, you should never store a reference to any of those nested instances if this owner may be freed before
- TPersistent/TPersistentAutoCreateFields have an unexpected speed overhead due a giant lock introduced to manage property name fixup resolution (which we won't use outside the VCL) - this class is definitively faster

destructor Destroy; override;

Finalize the instance, and release its published properties

class function NewInstance: TObject; override;

This overridden constructor will instantiate all its nested TPersistent/TSynPersistent/TSynAutoCreateFields published properties

procedure AfterLoad; virtual;

Virtual method allowing instance customization after initialization

- called e.g. by JsonToObject, but may be executed after manual fields assignment
- do nothing by default
- may be overridden for string interning or content customization

TSynAutoCreateFieldsLocked = class(TSynAutoCreateFields)

Adding locking methods to a TSynAutoCreateFields with virtual constructor

constructor Create; override;

Initialize the object instance, and its associated lock

destructor Destroy; override;

Release the instance (including the locking resource)

procedure Lock;

Could be used as a short-cut to Safe.Lock

procedure Unlock;

Could be used as a short-cut to Safe.Unlock

property Safe: TSynLocker read fSafe;

Access to the locking methods of this instance

- use Safe.Lock/TryLock with a try ... finally Safe.Unlock block

TInterfacedObjectAutoCreateFields = class(TInterfacedObjectWithCustomCreate)

Abstract TInterfacedObject class, which will instantiate all its nested TPersistent/TSynPersistent published properties, then release them when freed

- will handle automatic memory management of all nested class and T*ObjArray published properties: any class or T*ObjArray defined as a published property will be owned by this instance
- i.e. with strong reference
- non published properties (e.g. public) won't be instantiated, so may store weak class references
- could be used for gathering of TCollectionItem properties, e.g. for Domain objects in DDD, especially for list of value objects, with some additional methods defined by an Interface
- since the destructor will release all nested properties, you should never store a reference to any of those nested instances if this owner may be freed before

constructor Create; **override**;

This overridden constructor will instantiate all its nested

*TPersistent/TSynPersistent/TSynAutoCreateFields class and T*ObjArray published properties*

destructor Destroy; **override**;

Finalize the instance, and release its published properties

TSynJsonFileSettings = class(TSynAutoCreateFields)

Abstract parent class able to store settings as JSON file

function LoadFromFile(const aFileName: TFileName): boolean; **virtual**;

Read existing settings from a JSON file

function LoadFromJson(var aJson: RawUTF8): boolean;

Read existing settings from a JSON content

procedure SaveIfNeeded; **virtual**;

Persist the settings as a JSON file, named from LoadFromFile() parameter

property FileName: TFileName read fFileName;

Optional persistence file name, as set by LoadFromFile()

TRawUTF8ObjectCacheSettings = class(TSynPersistent)

Used by TRawUTF8ObjectCacheList to manage a list of information cache

constructor Create; **override**;

Will set default values to settings

property PurgePeriodMS: integer read fPurgePeriodMS write fPurgePeriodMS;

Period after which TRawUTF8ObjectCacheList will search for expired entries

- use -1 to disable purge (not advised, since may break process)
- default is 1000, i.e. 1 second

property TimeoutMS: integer **read** fTimeoutMS **write** fTimeoutMS;

Period after which the cache information should be flushed

- use -1 to disable time out; any big value will be limited to 10 minutes
- default is 120000, i.e. 2 minutes

TRawUTF8ObjectCache = class(TSynAutoCreateFieldsLocked)

Maintain information cache for a given key

- after a given period of time, the entry is not deleted, but CacheClear virtual method is called to release the associated data or services
- inherit from this abstract class to store your own key-defined information or you own interface-based services

constructor Create(aOwner: TRawUTF8ObjectCacheList; **const** aKey: RawUTF8);
reintroduce; virtual;

Initialize the information cache entry

- should not be called directly, but by TRawUTF8ObjectCacheList.GetLocked

destructor Destroy; **override;**

Finalize the information cache entry

- will also call the virtual CacheClear method

function Resolve(**const** aInterface: TGUID; **out** Obj): boolean;

Dependency Injection using fOwner.OnKeyResolve, for the current Key

property Owner: TRawUTF8ObjectCacheList **read** fOwner;

Access to the associated storage list

TRawUTF8ObjectCacheList = class(TRawUTF8List)

Manage a list of information cache, identified by a hashed key

- you should better inherit from this class, to give a custom name and constructor, or alter the default behavior
- will maintain a list of TRawUTF8ObjectCache instances

constructor Create(aClass: TRawUTF8ObjectCacheClass; aSettings: TRawUTF8ObjectCacheSettings; aLog: TSynLogFamily; aLogEvent: TSynLogInfo; **const** aOnKeyResolve: TOnKeyResolve); **reintroduce;**

Initialize the cache-information for a given class

- inherited classes may reintroduce a new constructor, for ease of use

destructor Destroy; **override;**

Finalize the cache information

function GetLocked(**const** Key: RawUTF8; **out** cache: TRawUTF8ObjectCache; onlyexisting: boolean=false): boolean; **virtual;**

Fill TRawUTF8ObjectCache with the matching key information

- an unknown key, but with a successful NewObjectCache() call, will create and append a new fClass instance to the list (if onlyexisting is left to its default FALSE)
- global or key-specific purge will be performed, if needed
- on success (true), output cache instance will be locked

procedure AddToPurge(**const** Key: RawUTF8); **virtual**;

Register a key identifier so that next TryPurge will flush the entry

- a direct CacheClear may trigger a race condition in NewObjectCache: so you may use this function e.g. from a SOA callback

procedure ForceCacheClear;

This method will clear all associated information

- a regular Clear will destroy all TRawUTF8ObjectCache instances, whereas this method will call CacheClear on each entry, so will be more thread-safe and efficient in practice

procedure Log(**const** TextFmt: RawUTF8; **const** TextArgs: **array of const**; Level: TSynLogInfo = slNone);

Access to the associated logging instance

procedure TryPurge;

You may call this method regularly to check for a needed purge

- if Settings.PurgePeriodMS is reached, each TRawUTF8ObjectCache instance will check for its TimeOutMS and call CacheClear if information is outdated

property OnKeyResolve: TOnKeyResolve **read** fOnKeyResolve **write** fOnKeyResolve;

Optional service locator for by-key Dependency Injection

TSynMonitorUsageID = **object**(TObject)

How the TSynMonitorUsage storage IDs are computed

- stored e.g. in TSQLMonitorUsage.ID primary key (after a shift)
- it follows a 23 bit pattern of hour (5 bit), day (5 bit), month (4 bit), year (9 bit - starting at 2016) so that it is monotonic over time
- by default, will store the information using mugHour granularity (i.e. values for the 60 minutes in a record), and pseudo-hours of 29, 30 and 31 (see USAGE_ID_HOURLMARKER[]) will identify mugDay, mugMonth and mugYear consolidated statistics
- it will therefore store up to $24 \times 365 + 365 + 12 + 1 = 9138$ records per year in the associated storage engine (so there is no actual need to purge it)

Value: integer;

The TID, as computed from time and granularity

function GetTime(**gran**: TSynMonitorUsageGranularity; **monthdaystartat0**: **boolean**=false): integer;

Low-level read of a time field stored in this ID, per granularity

function Granularity: TSynMonitorUsageGranularity;

Retrieve the resolution of the stored information

- i.e. either mugHour, mugDay, mugMonth or mugYear, which will store a true 0..23 hour value (for mugHour), or 29/30/31 pseudo-hour (i.e. USAGE_ID_HOURLMARKER[mugDay/mugMonth/mugYear])

function Text(**Expanded**: **boolean**; **FirstTimeChar**: AnsiChar = 'T'): RawUTF8;

Convert to Iso-8601 encoded text

function ToTimeLog: TTimeLog;

Returns the date/time

- minutes and seconds will set to 0

procedure From(Y,M,D: integer); overload;

Computes an ID corresponding to mugDay granularity of a given time

- hours, minutes and seconds will be merged
- mugDay granularity will store 0..23 information about each hour
- a pseudo hour of 29 (i.e. USAGE_ID_HOURLMARKER[mugDay]) is used

procedure From(Y,M,D,H: integer); overload;

Computes an ID corresponding to mugHour granularity of a given time

- minutes and seconds will be ignored
- mugHour granularity will store 0..59 information about each minute

procedure From(Y: integer); overload;

Computes an ID corresponding to mugYear granularity of a given time

- months, days, hours, minutes and seconds will be merged
- mugYear granularity will store 0..11 information about each month
- a pseudo hour of 31 (i.e. USAGE_ID_HOURLMARKER[mugYear]) is used

procedure From(Y,M: integer); overload;

Computes an ID corresponding to mugMonth granularity of a given time

- days, hours, minutes and seconds will be merged
- mugMonth granularity will store 0..31 information about each day
- a pseudo hour of 30 (i.e. USAGE_ID_HOURLMARKER[mugMonth]) is used

procedure FromNowUTC;

Computes an ID corresponding to the current UTC date/time

- minutes and seconds will be ignored

procedure FromTimeLog(const TimeLog: TTimeLog);

Computes an ID corresponding to a given time

- will set the ID with mugHour granularity, i.e. the information about the given hour, stored as per minute 0..59 values
- minutes and seconds in supplied TimeLog value will therefore be ignored

procedure SetTime(gran: TSynMonitorUsageGranularity; aValue: integer);

Low-level modification of a time field stored in this ID, per granularity

procedure Truncate(gran: TSynMonitorUsageGranularity);

Change the resolution of the stored information

TSynMonitorUsage = class(TSynPersistentLock)

Abstract class to track, compute and store TSynMonitor detailed statistics

- you should inherit from this class to implement proper data persistence, e.g. using TSynMonitorUsageRest for ORM-based storage

destructor Destroy; **override**;

Finalize the statistics, saving any pending information

function Modified(Instance: TObject; const PropNames: array of RawUTF8;
ModificationTime: TTimeLog=0): integer; **overload**; **virtual**;

To be called when tracked properties changed on a tracked class instance

function Modified(Instance: TObject): integer; overload;

To be called when tracked properties changed on a tracked class instance

function Track(Instance: TObject; **const** Name: RawUTF8=''): integer; overload;
virtual;

Track the values of one named object instance

- will recognize the TSynMonitor* properties as TSynMonitorType from RTTI, using MonitorPropUsageValue(), within any (nested) object
- the instance will be stored in fTracked[].Instance: ensure it will stay available during the whole TSynMonitorUsage process

procedure Track(**const** Instances: **array of** TSynMonitor); overload;

Track the values of the given object instances

- will recognize the TSynMonitor* properties as TSynMonitorType from RTTI, using MonitorPropUsageValue(), within any (nested) object
- instances will be stored in fTracked[].Instance: ensure they will stay available during the whole TSynMonitorUsage process

property Comment: RawUTF8 **read** fComment **write** fComment;

Some custom text, associated with the current stored state

- will be persisted by Save() methods

ESQLTableException = **class**(ESynException)

Exception raised in case of incorrect TSQLTable.Step / Field() use*

EORMException = **class**(ESynException)

Generic parent class of all custom Exception types of this unit

EORMBatchException = **class**(EORMException)

Exception raised in case of TSQLRestBatch problem

EModelException = **class**(EORMException)

Exception raised in case of wrong Model definition

EParsingException = **class**(EORMException)

Exception raised in case of unexpected parsing error

ECommunicationException = **class**(EORMException)

Exception raised in case of a Client-Server communication error

EBusinessLayerException = **class**(EORMException)

Exception raised in case of an error in project implementation logic

ESecurityException = **class**(EORMException)

Exception raised in case of any authentication error

EInterfaceFactoryException = **class**(ESynException)

Exception dedicated to interface factory, e.g. services and mock/stubs

EInterfaceResolverException = **class**(ESynException)

Exception raised in case of Dependency Injection (aka IoC) issue

EServiceException = **class**(EORMException)

Exception dedicated to interface based service implementation

TSQLPropInfoRTTIInstance = class(TSQLPropInfoRTTIPtrInt)

Information about a TSQLRecord class property

- sftID for TSQLRecord properties, which are pointer(RecordID), not any true class instance
- sftMany for TSQLRecordMany properties, for which no data is stored in the table itself, but in a pivot table
- sftObject for e.g. TStringList TRawUTF8List TCollection instances

constructor Create(aPropInfo: PPropInfo; aPropIndex: integer; aSQLFieldType: TSQLFieldType; aOptions: TSQLPropInfoListOptions); **override**;

Will setup the corresponding ObjectClass property

function GetInstance(Instance: TObject): TObject;

Direct access to the property class instance

procedure SetInstance(Instance, Value: TObject);

Direct access to the property class instance

property ObjectClass: TClass **read** fObjectClass;

Direct access to the property class

- can be used e.g. for TSQLRecordMany properties

TSQLPropInfoRTTIRecordReference = class(TSQLPropInfoRTTIInt64)

Information about a TRecordReference/TRecordReferenceToBeDeleted published property

- identified as a sftRecord kind of property

constructor Create(aPropInfo: PPropInfo; aPropIndex: integer; aSQLFieldType: TSQLFieldType; aOptions: TSQLPropInfoListOptions); **override**;

Will identify TRecordReferenceToBeDeleted kind of field, and setup the corresponding CascadeDelete property

property CascadeDelete: boolean **read** fCascadeDelete;

TRUE if this sftRecord is a TRecordReferenceToBeDeleted

TSQLPropInfoRTTITID = class(TSQLPropInfoRTTIRecordReference)

Information about a TID published property

- identified as a sftTID kind of property, optionally tied to a TSQLRecord class, via its custom type name, e.g.

`TSQLRecordClientID = type TID; -> TSQLRecordClient class`

constructor Create(aPropInfo: PPropInfo; aPropIndex: integer; aSQLFieldType: TSQLFieldType; aOptions: TSQLPropInfoListOptions); **override**;

Will setup the corresponding RecordClass property from the TID type name

- the TSQLRecord type should have previously been registered to the TJSONSerializer.RegisterClassForJSON list, e.g. in TSQLModel.Create, so that e.g. 'TSQLRecordClientID' type name will match TSQLRecordClient
- in addition, the '...ToBeDeletedID' name pattern will set CascadeDelete

property CascadeDelete: boolean read fCascadeDelete;

TRUE if this sftTID type name follows the '...ToBeDeletedID' pattern

- e.g. 'TSQLRecordClientToBeDeletedID' type name will match TSQLRecordClient and set CascadeDelete

- is computed from its type name - for instance, if you define:

```
type
  TSQLRecordClientToBeDeletedID = type TID;
  TSQLOrder = class(TSQLRecord)
  ...
  published OrderedBy: TSQLRecordClientToBeDeletedID read fOrderedBy write fOrderedBy;
  ...
```

then this OrderedBy property will be tied to the TSQLRecordClient class of the corresponding model, and the whole record will be deleted when the targetting record is deleted (emulating a ON DELETE CASCADE)

property RecordClass: TSQLRecordClass read fRecordClass;

The TSQLRecord class associated to this TID

- is computed from its type name - for instance, if you define:

```
type
  TSQLRecordClientID = type TID;
  TSQLOrder = class(TSQLRecord)
  ...
  published OrderedBy: TSQLRecordClientID read fOrderedBy write fOrderedBy;
  ...
```

then this OrderedBy property will be tied to the TSQLRecordClient class of the corresponding model, and the field value will be reset to 0 when the targetting record is deleted (emulating a ON DELETE SET DEFAULT)

- equals TSQLRecord for plain TID field

- equals nil if T*ID type name doesn't match any registered class

TSQLPropInfoRTTIRecordVersion = class(TSQLPropInfoRTTIInt64)

Information about a TRecordVersion published property

- identified as a sftRecordVersion kind of property, to track changes

TSQLPropInfoRTTIID = class(TSQLPropInfoRTTIInstance)

Information about a TSQLRecord class TSQLRecord property

- kind sftID, which are pointer(RecordID), not any true class instance

- will store the content just as an integer value

- will recognize any instance pre-allocated via Create*Joined() constructor

procedure GetJSONValues(Instance: TObject; W: TJSONSerializer); override;

*This method will recognize if the TSQLRecord was allocated by a Create*Joined() constructor: in this case, it will write the ID of the nested property, and not the PtrInt() transtyped value*

procedure SetValue(Instance: TObject; Value: PUTF8Char; wasString: boolean); override;

*Raise an exception if was created by Create*Joined() constructor*

TSQLPropInfoRTTIObject = class(TSQLPropInfoRTTIInstance)

Information about a TSQLRecord class TString/TRawUTF8List/TCollection property

- kind sftObject e.g. for TString TRawUTF8List TCollection TObjectList instances

- binary serialization will store textual JSON serialization of the object, including custom serialization

TSQLPropInfoRTTMany = class(TSQLPropInfoRTTIInstance)

Information about a TSQLRecord class TSQLRecordMany property

- kind sftMany, for which no data is stored in the table itself, but in a separated pivot table

TSQLRecordProperties = class(TObject)

Some information about a given TSQLRecord class properties

- used internally by TSQLRecord, via a global cache handled by this unit: you can access to each record's properties via TSQLRecord.RecordProps class
 - such a global cache saves some memory for each TSQLRecord instance, and allows faster access to most wanted RTTI properties

Used for DI-2.1.3 (page 2556).

ComputeBeforeAddFieldsBits: TSQLFieldBits;

Bit set to 1 for indicating TModTime/TCreateTime/TSessionUserID fields of this TSQLRecord

- as applied before an INSERT
 - i.e. sftModTime, sftCreateTime and sftSessionUserID fields

ComputeBeforeUpdateFieldsBits: TSQLFieldBits;

Bit set to 1 for indicating TModTime/TSessionUserID fields of this TSQLRecord (leaving TCreateTime untouched)

- as applied before an UPDATE
 - i.e. sftModTime and sftSessionUserID fields

CopiableFieldsBits: TSQLFieldBits;

Bit set to 1 for the all fields storing some data

- match COPIABLE_FIELDS mask, i.e. all fields except sftMany

FieldBits: array[TSQLFieldType] of TSQLFieldBits;

Bit set to 1 for indicating each TSQLFieldType fields of this TSQLRecord

IsUniqueFieldsBits: TSQLFieldBits;

Bit set to 1 for an unique field

- an unique field is defined as "stored AS_UNIQUE" (i.e. "stored false") in its property definition

MainField: array[boolean] of integer;

Contains the main field index (e.g. mostly 'Name')

- the [boolean] is for [ReturnFirstIfNoUnique] version
 - contains -1 if no field matches

RTreeCoordBoundaryFields: integer;

Count of coordinate fields of a TSQLRecordRTree, before auxiliary columns

SimpleFieldsBits: array[TSQLOccasion] of TSQLFieldBits;

Bit set to 1 for indicating fields to export, i.e. "simple" fields

- this array will handle special cases, like the TCreateTime fields which shall not be included in soUpdate but soInsert and soSelect e.g.

SimpleFieldsCount: array[TSQLOccasion] of integer;

Number of fields to export, i.e. "simple" fields

- this array will handle special cases, like the TCreateTime fields which shall not be included in soUpdate but soInsert and soSelect e.g.

SmallFieldsBits: TSQLFieldBits;

Bit set to 1 for the smallest simple fields

- i.e. excluding non only sftBlob and sftMany, but also sftVariant, sftBlobDynArray, sftBlobCustom and sftUTF8Custom fields
- may be used to minimize the transmitted content, e.g. when serializing to JSON for the most

constructor Create(aTable: TSQLRecordClass);

Initialize the properties content

destructor Destroy; **override;**

Release associated used memory

function AddFilterOrValidate(aFieldIndex: integer; aFilter: TSynFilterOrValidate): boolean; **overload;**

Register a custom filter (transformation) or validation rule to the TSQMRecord class for a specified field

- this will be used by TSQLRecord.Filter and TSQLRecord.Validate methods (in default implementation)
- will return FALSE in case of an invalid field index

function AppendFieldName(FieldIndex: Integer; var Text: RawUTF8; ForceNoRowID: boolean): boolean;

Append a field name to a RawUTF8 Text buffer

- if FieldIndex=VIRTUAL_TABLE_ROWID_COLUMN (-1), appends 'RowID' or 'ID' (if ForceNoRowID=TRUE) to Text
- on error (i.e. if FieldIndex is out of range) will return TRUE
- otherwise, will return FALSE and append the field name to Text

function BlobFieldPropFromRawUTF8(const PropName: RawUTF8): PPropInfo;

Retrieve a Field property RTTI information from a Property Name

- this version returns nil if the property is not a BLOB field

function BlobFieldPropFromUTF8(PropName: PUTF8Char; PropNameLen: integer): PPropInfo;

Retrieve a Field property RTTI information from a Property Name

- this version returns nil if the property is not a BLOB field

function CheckBinaryHeader(var R: TFileBufferReader): boolean;

Ensure that the TSQLRecord RTTI matches the supplied binary header

- used e.g. by TSQLRestStorageInMemory.LoadFromBinary()

function CreateJSONWriter(JSON: TStream; Expand: boolean; const aFieldsCSV: RawUTF8; KnownRowCount: integer; aBufSize: integer=8192): TJSONSerializer; **overload;**

Create a TJSONWriter, ready to be filled with TSQLRecord.GetJSONValues(W)

- this overloaded method will call FieldBitsFromCSV(aFieldsCSV,bits,withID) to retrieve the bits just like a SELECT (i.e. '*' for simple fields)

function CreateJSONWriter(JSON: TStream; Expand, withID: boolean; const aFields: TSQLFieldBits; KnownRowCount: integer; aBufSize: integer=8192): TJSONSerializer; **overload;**

Create a TJSONWriter, ready to be filled with TSQLRecord.GetJSONValues

- you can use TSQLRecordProperties.FieldBitsFromCSV() or TSQLRecordProperties.FieldBitsFromRawUTF8() to compute aFields

function CreateJSONWriter(JSON: TStream; Expand, withID: boolean; **const** aFields: TSQLFieldIndexDynArray; KnownRowCount: integer; aBufSize: integer=8192): TJSONSerializer; overload;

Create a TJSONWriter, ready to be filled with TSQLRecord.GetJSONValues(W)
 - you can use TSQLRecordProperties.FieldBitsFromCSV() or
 TSQLRecordProperties.FieldBitsFromRawUTF8() to compute aFields

function CSVFromFieldBits(**const** Bits: TSQLFieldBits): RawUTF8;

Compute the CSV field names text from a set of bits

function FieldBitsFromBlobField(aBlobField: PPropInfo; **var** Bits: TSQLFieldBits): boolean;

Set all bits corresponding to the supplied BLOB field type information
 - returns TRUE on success, FALSE if blob field is not recognized

function FieldBitsFromCSV(**const** aFieldsCSV: RawUTF8; **var** Bits: TSQLFieldBits): boolean; overload;

Set all bits corresponding to the supplied CSV field names
 - returns TRUE on success, FALSE if any field name is not existing

function FieldBitsFromCSV(**const** aFieldsCSV: RawUTF8; **var** Bits: TSQLFieldBits; **out** withID: boolean): boolean; overload;

Set all bits corresponding to the supplied CSV field names, including ID
 - returns TRUE on success, FALSE if any field name is not existing
 - this overloaded method will identify ID/RowID field name, and set withID output parameter according to its presence
 - if aFieldsCSV='*', Bits will contain all simple fields, and withID=true

function FieldBitsFromCSV(**const** aFieldsCSV: RawUTF8): TSQLFieldBits; overload;

Set all bits corresponding to the supplied CSV field names
 - returns the matching fields set

function FieldBitsFromExcludingCSV(**const** aFieldsCSV: RawUTF8; aOccasion: TSQLOccasion=soSelect): TSQLFieldBits;

Set all simple bits corresponding to the simple fields, excluding some
 - could be a convenient alternative to FieldBitsFromCSV() if only some fields are to be excluded
 - returns the matching fields set

function FieldBitsFromRawUTF8(**const** aFields: **array of** RawUTF8; **var** Bits: TSQLFieldBits): boolean; overload;

Set all bits corresponding to the supplied field names
 - returns TRUE on success, FALSE if any field name is not existing

function FieldBitsFromRawUTF8(**const** aFields: **array of** RawUTF8): TSQLFieldBits; overload;

Set all bits corresponding to the supplied field names
 - returns the matching fields set

function FieldIndexDynArrayFromBlobField(aBlobField: PPropInfo; **var** Indexes: TSQLFieldIndexDynArray): boolean;

Set all field indexes corresponding to the supplied BLOB field type information
 - returns TRUE on success, FALSE if blob field is not recognized

function FieldIndexDynArrayFromCSV(**const** aFieldsCSV: RawUTF8; **var** Indexes: TSQLFieldIndexDynArray): boolean; overload;

Set all field indexes corresponding to the supplied CSV field names
 - returns TRUE on success, FALSE if any field name is not existing

function FieldIndexDynArrayFromCSV(**const** aFieldsCSV: RawUTF8): TSQLFieldIndexDynArray; overload;

Set all field indexes corresponding to the supplied CSV field names
 - returns the matching fields set

function FieldIndexDynArrayFromRawUTF8(**const** aFields: array of RawUTF8; **var** Indexes: TSQLFieldIndexDynArray): boolean; overload;

Set all field indexes corresponding to the supplied field names
 - returns TRUE on success, FALSE if any field name is not existing

function FieldIndexDynArrayFromRawUTF8(**const** aFields: array of RawUTF8): TSQLFieldIndexDynArray; overload;

Set all field indexes corresponding to the supplied field names
 - returns the matching fields set

function IsFieldName(**const** PropName: RawUTF8): boolean;

Return TRUE if the given name is either ID/RowID, either a property name

function IsFieldNameOrFunction(**const** PropName: RawUTF8): boolean;

Return TRUE if the given name is either ID/RowID, either a property name, or an aggregate function (MAX/MIN/AVG/SUM) on a valid property name

function MainFieldName(ReturnFirstIfNoUnique: boolean=false): RawUTF8;

Return the first unique property of kind RawUTF8
 - this property is mainly the "Name" property, i.e. the one with "stored AS_UNIQUE" (i.e. "stored false") definition on most TSQLRecord
 - if ReturnFirstIfNoUnique is TRUE and no unique property is found, the first RawUTF8 property is returned anyway
 - returns "" if no matching field was found

function SaveSimpleFieldsFromJsonArray(**var** P: PUTF8Char; **var** EndOfObject: AnsiChar; ExtendedJSON: boolean): RawUTF8;

Convert a JSON array of simple field values into a matching JSON object

function SetCustomCollation(**const** aFieldName, aCollationName: RawUTF8): boolean; overload;

Set a custom SQLite3 text column collation for a specified field
 - overloaded method which expects the field to be named

function SetCustomCollation(FieldIndex: integer; **const** aCollationName: RawUTF8): boolean; overload;

Set a custom SQLite3 text column collation for a specified field
 - can be used e.g. to override the default COLLATE SYSTEMNOCASE of RawUTF8
 - collations defined within our SynSQLite3 unit are named BINARY, NOCASE, RTRIM and our custom SYSTEMNOCASE, ISO8601, WIN32CASE, WIN32NOCASE
 - do nothing if FieldIndex is not valid, and returns false
 - could be set in overridden class procedure TSQLRecord.InternalDefineModel so that it will be common to all database models, for both client and server

function SQLAddField(FieldIndex: integer): RawUTF8;

Return the UTF-8 encoded SQL statement source to alter the table for adding the specified field

function SQLFieldTypeToSQL(FieldIndex: integer): RawUTF8;

Return the SQLite3 field datatype for each specified field

- set to '' for fields with no column created in the database (e.g. sftMany)
- returns e.g. 'INTEGER,' or 'TEXT COLLATE SYSTEMNOCASE,'

procedure AddFilterOrValidate(const aFieldName: RawUTF8; aFilter: TSynFilterOrValidate); overload;

Register a custom filter (transformation) or validation to the TSQLRecord class for a specified field

- this will be used by TSQLRecord.Filter and TSQLRecord.Validate methods (in default implementation)
- will raise an EModelException if the field name does not exist

procedure RegisterCustomFixedSizeRecordProperty(aTable: TClass; aRecordSize: cardinal; const aName: RawUTF8; aPropertyPointer: pointer; aAttributes: TSQLPropInfoAttributes; aFieldWidth: integer; aData2Text: TOnSQLPropInfoRecord2Text=nil; aText2Data: TOnSQLPropInfoRecord2Data=nil);

Add a custom unmanaged fixed-size record property

- simple kind of records (i.e. those not containing reference-counted members) do not have RTTI generated, at least in older versions of Delphi
- use this method within TSQLRecord.InternalRegisterCustomProperties overridden method to define a custom record property with no reference-counted types within (like strings) - typical use may be TGUID
- main parameters are the record size, in bytes, and the property pointer
- add an TSQLPropInfoRecordFixedSize instance to the internal list
- if aData2Text/aText2Data parameters are not defined, it will fallback to TSQLPropInfo.BinaryToText() simple text Base64 encoding
- can be used to override the default TSQLRecord corresponding method:

```
class procedure TSQLMyRecord.InternalRegisterCustomProperties(
  Props: TSQLRecordProperties);
begin
  Props.RegisterCustomFixedSizeRecordProperty(self, SizeOf(TMyRec), 'RecField',
    @TSQLMyRecord(nil).fRecField, [], SizeOf(TMyRec));
end;
```

```
procedure RegisterCustomPropertyFromRTTI(aTable: TClass; aTypeInfo: PTypeInfo;
const aName: RawUTF8; aPropertyPointer: pointer; aAttributes:
TSQLPropInfoAttributes=[]; aFieldWidth: integer=0);
```

Add a custom property from its RTTI definition stored as JSON

- handle any kind of record with TypeInfo() generated
- use this method within InternalRegisterCustomProperties overridden method to define a custom record property containing reference-counted types
- main parameters are the record RTTI information, and the property pointer
- add an TSQLPropInfoCustomJSON instance to the internal list
- can be used as such:

```
class procedure TSQLMyRecord.InternalRegisterCustomProperties(
  Props: TSQLRecordProperties);
begin
  Props.RegisterCustomPropertyFromRTTI(self, TypeInfo(TMyRec), 'RecField',
    @TSQLMyRecord(nil).fRecField);
end;
```

```
procedure RegisterCustomPropertyFromTypeName(aTable: TClass; const aTypeName,
aName: RawUTF8; aPropertyPointer: pointer; aAttributes: TSQLPropInfoAttributes=[];
aFieldWidth: integer=0);
```

Add a custom property from its type name, stored as JSON

- handle any kind of registered record, including TGUID
- use this method within InternalRegisterCustomProperties overridden method to define a custom record property containing reference-counted types
- main parameters are the record RTTI information, and the property pointer
- add an TSQLPropInfoCustomJSON instance to the internal list
- can be used as such:

```
class procedure TSQLMyRecord.InternalRegisterCustomProperties(
  Props: TSQLRecordProperties);
begin
  Props.RegisterCustomPropertyFromTypeName(self, 'TGUID', 'GUID',
    @TSQLMyRecord(nil).fGUID, [aIsUnique], 38);
end;
```

```
procedure RegisterCustomRTTIRecordProperty(aTable: TClass; aRecordInfo: PTypeInfo;
const aName: RawUTF8; aPropertyPointer: pointer; aAttributes:
TSQLPropInfoAttributes=[]; aFieldWidth: integer=0; aData2Text:
TOnSQLPropInfoRecord2Text=nil; aText2Data: TOnSQLPropInfoRecord2Data=nil);
```

Add a custom record property from its RTTI definition

- handle any kind of record with TypeInfo() generated
- use this method within InternalRegisterCustomProperties overridden method to define a custom record property containing reference-counted types
- main parameters are the record RTTI information, and the property pointer
- add an TSQLPropInfoRecordRTTI instance to the internal list
- can be used as such:

```
class procedure TSQLMyRecord.InternalRegisterCustomProperties(
  Props: TSQLRecordProperties);
begin
  Props.RegisterCustomRTTIRecordProperty(self, TypeInfo(TMyRec), 'RecField',
    @TSQLMyRecord(nil).fRecField);
end;
```

procedure SaveBinaryHeader(W: TFileBufferWriter);

Save the TSQLRecord RTTI into a binary header

- used e.g. by TSQLRestStorageInMemory.SaveToBinary()

procedure SetCustomCollationForAll(aFieldType: TSQLFieldType; const aCollationName: RawUTF8);

Set a custom SQLite3 text column collation for a given field type

- can be used e.g. to override ALL default COLLATE SYSTEMNOCASE of RawUTF8, or the default COLLATE ISO8601 of TDateTime, and let the generated SQLite3 file be available outside the scope of mORMot's SQLite3 engine

- collations defined within our SynSQLite3 unit are named BINARY, NOCASE, RTRIM and our custom SYSTEMNOCASE, ISO8601, WIN32CASE, WIN32NOCASE

- could be set in overridden class procedure TSQLRecord.InternalDefineModel so that it will be common to all database models, for both client and server

- note that you may inherit from TSQLRecordNoCase to use the NOCASE standard SQLite3 collation for all descendant ORM objects

procedure SetJSONWriterColumnNames(W: TJSONSerializer; KnownRowCount: integer);

Set the W.ColNames[] array content + W.AddColumns

procedure SetMaxLengthFilterForTextFields(IndexIsUTF8Length: boolean=false);

Allow to filter the length of all text published properties of this table

- the "index" attribute of the RawUTF8/string published properties could be used to specify a maximum length for external VARCHAR() columns

- SQLite3 will just ignore this "index" information, but it could be handy to be able to filter the value length before sending to the DB

- this method will create TSynFilterTruncate corresponding to the maximum field size specified by the "index" attribute, to filter before write

- will expect the "index" value to be in UTF-16 codepoints, unless IndexIsUTF8Length is set to TRUE, indicating UTF-8 length in "index"

procedure SetMaxLengthValidatorForTextFields(IndexIsUTF8Length: boolean=false);

Allow to validate length of all text published properties of this table

- the "index" attribute of the RawUTF8/string published properties could be used to specify a maximum length for external VARCHAR() columns

- SQLite3 will just ignore this "index" information, but it could be handy to be able to validate the value length before sending to the DB

- this method will create TSynValidateText corresponding to the maximum field size specified by the "index" attribute, to validate before write

- will expect the "index" value to be in UTF-16 codepoints, unless IndexIsUTF8Length is set to TRUE, indicating UTF-8 length in "index"

procedure SetVariantFieldsDocVariantOptions(const Options: TDocVariantOptions);

Customize the TDocVariant options for all variant published properties

- will change the TSQLPropInfoRTTIVariant.DocVariantOptions value

- use e.g. as SetVariantFieldDocVariantOptions(JSON_OPTIONS_FAST_EXTENDED)

- see also TSQLRecordNoCaseExtended root class

property BlobCustomFields: TSQLPropInfoObjArray read fBlobCustomFields;

List of all sftBlobCustom fields of this TSQLRecord

- have been defined e.g. as TSQLPropInfoCustom custom definition

property BlobFields: TSQLPropInfoRTTIObjArray read fBlobFields;

List all BLOB fields of this TSQLRecord

- i.e. generic sftBlob fields (not sftBlobDynArray, sftBlobCustom nor sftBlobRecord)

property CopiableFields: TSQLPropInfoObjArray read fCopiableFields;

List all fields which can be copied from one TSQLRecord instance to another

- match COPIABLE_FIELDS mask, i.e. all fields except sftMany

property DynArrayFields: TSQLPropInfoRTTIDynArrayObjArray read fDynArrayFields;

List of all sftBlobDynArray fields of this TSQLRecord

property DynArrayFieldsHasObjArray: boolean read fDynArrayFieldsHasObjArray;

*TRUE if any of the sftBlobDynArray fields of this TSQLRecord is a T*ObjArray*

- used e.g. by TSQLRecord.Destroy to release all owned nested instances

property Fields: TSQLPropInfoList read fFields;

List all fields, as retrieved from RTTI

property Filters: TSynFilterOrValidateObjArrayArray read fFilters;

All TSynFilter or TSynValidate instances registered per each field

- since validation and filtering are used within some CPU-consuming part of the framework (like UI edition), both filters and validation rules are grouped in the same list - for TSynTableFieldProperties there are separated Filters[] and Validates[] arrays, for better performance

property HasNotSimpleFields: boolean read fHasNotSimpleFields;

If this class has any BLOB or TSQLRecordMany fields

- i.e. some fields to be ignored

property HasTypeFields: TSQLFieldTypes read fHasTypeFields;

Set of field types appearing in this record

property JoinedFields: TSQLPropInfoRTTIIDObjArray read fJoinedFields;

List all TSQLRecord fields of this TSQLRecord

- ready to be used by TSQLTableJSON.CreateFromTables()

- i.e. the class itself then, all fields of type sftID (excluding sftMany)

property JoinedFieldsTable: TSQLRecordClassDynArray read fJoinedFieldsTable;

Wrapper of all nested TSQLRecord class of this TSQLRecord

- ready to be used by TSQLTableJSON.CreateFromTables()

- i.e. the class itself as JoinedFieldsTable[0], then, all nested TSQLRecord published properties (of type sftID, ergo excluding sftMany)

- equals nil if there is no nested TSQLRecord property (i.e. JoinedFields=nil)

property ManyFields: TSQLPropInfoRTTIManyObjArray read fManyFields;

List all TSQLRecordMany fields of this TSQLRecord

property RecordManyDestProp: TSQLPropInfoRTTIInstance read fRecordManyDestProp;

For a TSQLRecordMany class, points to the Dest property RTTI

property RecordManySourceProp: TSQLPropInfoRTTIInstance read fRecordManySourceProp;

For a TSQLRecordMany class, points to the Source property RTTI

property RecordVersionField: TSQLPropInfoRTTIRecordVersion read fRecordVersionField;

Points to any TRecordVersion field

- contains nil if no such sftRecordVersion field do exist
- will be used by low-level storage engine to compute and store the monotonic version number during any write operation

property SimpleFields: TSQLPropInfoObjArray read fSimpleFields;

List all "simple" fields of this TSQLRecord

- by default, the TSQLRawBlob and TSQLRecordMany fields are not included into this set: they must be read specifically (in order to spare bandwidth for BLOBs)
- dynamic arrays belong to simple fields: they are sent with other properties content
- match inverted NOT_SIMPLE_FIELDS mask

property SQLTableName: RawUTF8 read fSQLTableName;

The Table name in the database, associated with this TSQLRecord class

- 'TSQL' or 'TSQLRecord' chars are trimmed at the beginning of the ClassName
- or the ClassName is returned as is, if no 'TSQL' or 'TSQLRecord' at first

property SQLTableNameUpperWithDot: RawUTF8 read fSQLTableNameUpperWithDot;

The Table name in the database in uppercase with a final '.'

- e.g. 'TEST.' for TSQLRecordTest class
- can be used with IdempChar() for fast check of a table name

property SQLTableRetrieveAllFields: RawUTF8 read fSQLTableRetrieveAllFields;

Returns 'COL1,COL2' with all COL set to all field names, including RowID, TRecordVersion and BLOBs*

- this won't change depending on the ORM settings: so it can be safely computed here and not in TSQLModelRecordProperties
- used e.g. by TSQLRest.InternalListJSON()

property SQLTableRetrieveBlobFields: RawUTF8 read fSQLTableRetrieveBlobFields;

Returns 'COL1,COL2' with all BLOB columns names

- used e.g. by TSQLRestServerDB.RetrieveBlobFields()

property SQLTableSimpleFieldsNoRowID: RawUTF8 read fSQLTableSimpleFieldsNoRowID;

Returns 'COL1,COL2' with all COL set to simple field names*

- same value as SQLTableSimpleFields[false,false]
- this won't change depending on the ORM settings: so it can be safely computed here and not in TSQLModelRecordProperties
- used e.g. by TSQLRecord.GetSQLValues

property SQLTableUpdateBlobFields: RawUTF8 read fSQLTableUpdateBlobFields;

Returns 'COL1=?,COL2=?' with all BLOB columns names

- used e.g. by TSQLRestServerDB.UpdateBlobFields()

property Table: TSQLRecordClass read fTable;

The TSQLRecord class

property TableClassProp: PClassProp read fClassProp;

Fast access to the RTTI properties attribute

property TableClassType: PClassType **read** fClassType;

Fast access to the RTTI properties attribute

TSQLRestURIParams = object(TObject)

Store all parameters for a Client or Server method call

- as used by TSQLRestServer.URI or TSQLRestClientURI.InternalURI

InBody: RawUTF8;

Input parameter containing the caller message body

- e.g. some GET/POST/PUT JSON data can be specified here

InHead: RawUTF8;

Input parameter containing the caller message headers

- you can use e.g. to retrieve the remote IP:

Call.Header(HEADER_REMOTEIP_UPPER)

or FindNameValue(Call.InHead, HEADER_REMOTEIP_UPPER)

but consider rather using TSQLRestServerURIContext.RemoteIP

LowLevelConnectionID: Int64;

Opaque reference to the protocol context which made this request

- may point e.g. to a THttpServerResp, a TWebSocketServerResp, a THttpApiServer, a TSQLRestClientURI, a TFastCGIServer or a TSQLRestServerNamedPipeResponse instance

- stores SynCrtSock's THttpServerConnectionID, i.e. a Int64 as expected by http.sys, or an incremental rolling sequence of 31-bit integers for THttpServer/TWebSocketServer, or maybe a raw PtrInt(self/THandle)

LowLevelFlags: TSQLRestURIParamsLowLevelFlags;

Low-level properties of the current protocol context

Method: RawUTF8;

Input parameter containing the caller method

- handle enhanced REST codes: LOCK/UNLOCK/BEGIN/END/ABORT

OutBody: RawUTF8;

Output parameter to be set to the response message body

OutHead: RawUTF8;

Output parameter to be set to the response message header

- it is the right place to set the returned message body content type, e.g.

TEXT_CONTENT_TYPE_HEADER or HTTP_CONTENT_TYPE_HEADER: if not set, the default

JSON_CONTENT_TYPE_HEADER will be returned to the client, meaning that the message is JSON

- you can use OutBodyType() function to retrieve the stored content-type

OutInternalState: cardinal;

Output parameter to be set to the database internal state

OutStatus: cardinal;

Output parameter to be set to the HTTP status integer code

- HTTP_NOTFOUND=404 e.g. if the url doesn't start with Model.Root (caller can try another TSQLRestServer)

RestAccessRights: PSQLAccessRights;

Associated RESTful access rights

- AccessRights must be handled by the TSQLRestServer child, according to the Application Security Policy (user logging, authentication and rights management) - making access rights a parameter allows this method to be handled as pure stateless, thread-safe and session-free

Url: RawUTF8;

Input parameter containing the caller URI

function Header(UpperName: PAnsiChar): RawUTF8;

Just a wrapper around FindNameValue(InHead,UpperName)

- use e.g. as

Call.Header(HEADER_REMOTEIP_UPPER) or Call.Header(HEADER_BEARER_UPPER)

- consider rather using TSQLRestServerURIContext.InHeader[] or even dedicated TSQLRestServerURIContext.RemoteIP/AuthenticationBearerToken

function HeaderOnce(var Store: RawUTF8; UpperName: PAnsiChar): RawUTF8;

Wrap FindNameValue(InHead,UpperName) with a cache store

function InBodyType(GuessJSONIfNoneSet: boolean=True): RawUTF8;

Retrieve the "Content-Type" value from InHead

- if GuessJSONIfNoneSet is TRUE, returns JSON if none was set in headers

function InBodyTypeIsJson(GuessJSONIfNoneSet: boolean=True): boolean;

Check if the "Content-Type" value from InHead is JSON

- if GuessJSONIfNoneSet is TRUE, assume JSON is used

function OutBodyType(GuessJSONIfNoneSet: boolean=True): RawUTF8;

Retrieve the "Content-Type" value from OutHead

- if GuessJSONIfNoneSet is TRUE, returns JSON if none was set in headers

function OutBodyTypeIsJson(GuessJSONIfNoneSet: boolean=True): boolean;

Check if the "Content-Type" value from OutHead is JSON

- if GuessJSONIfNoneSet is TRUE, assume JSON is used

procedure Init; overload;

Initialize the non RawUTF8 values

procedure Init(const aURI,aMethod,aInHead,aInBody: RawUTF8); overload;

Initialize the input values

TServiceRunningContext = record

Will identify the currently running service on the server side

- is the type of the global ServiceContext threadvar

- to access the current TSQLRestServer instance (and e.g. its ORM/CRUD or SOA methods), use Request.Server and not Factory.Server, which may not be available e.g. if you run the service from the server side (so no factory is involved)

- note that the safest (and slightly faster) access to the TSQLRestServer instance associated with a service is to inherit your implementation class from TInjectableObjectRest

Factory: TServiceFactoryServer;

The currently running service factory

- it can be used within server-side implementation to retrieve the associated TSQLRestServer instance
- note that TServiceFactoryServer.Get() won't override this value, when called within another service (i.e. if Factory is not nil)

Request: TSQLRestServerURIContext;

The currently running context which launched the method

- low-level RESTful context is also available in its Call member
- Request.Server is the safe access point to the underlying TSQLRestServer, unless the service is implemented via TInjectableObjectRest, so the TInjectableObjectRest.Server property is preferred
- make available e.g. current session or authentication parameters (including e.g. user details via Request.Server.SessionGetUser)

RunningThread: TThread;

The thread which launched the request

- is set by TSQLRestServer.BeginCurrentThread from multi-thread server handlers - e.g. TSQLite3HttpServer or TSQLRestServerNamedPipeResponse

TServiceFactoryExecution = record

Internal per-method list of execution context as hold in TServiceFactory

Denied: set of 0..255;

The list of denied TSQLAuthGroup ID(s)

- used on server side within TSQLRestServerURIContext.ExecuteSOABByInterface
- bit 0 for client TSQLAuthGroup.ID=1 and so on...
- is therefore able to store IDs up to 256
- void by default, i.e. no denial = all groups allowed for this method

LogClass: TSQLRecordServiceLogClass;

The TSQLRecordServiceLog class to use, as defined in LogRest.Model

LogRest: TSQLRest;

Where execution information should be written as TSQLRecordServiceLog

Options: TServiceMethodOptions;

Execution options for this method (about thread safety or logging)

TSQLAccessRights = object(TObject)

Set the User Access Rights, for each Table

- one property for every and each URI method (GET/POST/PUT/DELETE)
- one bit for every and each Table in Model.Tables[]

AllowRemoteExecute: TSQLAllowRemoteExecute;

Set of allowed actions on the server side

DELETE: TSQLFieldTables;

DELETE method (delete record) table access bits

GET: TSQLFieldTables;

GET method (retrieve record) table access bits

- note that a GET request with a SQL statement without a table (i.e. on 'ModelRoot' URI with a SQL statement as SentData, as used in TSQLRestClientURI.UpdateFromServer) will be checked for simple cases (i.e. the first table in the FROM clause), otherwise will follow , whatever the bits here are: since TSQLRestClientURI.UpdateFromServer() is called only for refreshing a direct statement, it will be OK; you can improve this by overriding the TSQLRestServer.URI() method
- if the REST request is LOCK, the PUT access bits will be read instead of the GET bits value

POST: TSQLFieldTables;

POST method (create record) table access bits

PUT: TSQLFieldTables;

PUT method (update record) table access bits

- if the REST request is LOCK, the PUT access bits will be read instead of the GET bits value

function CanExecuteORMWrite(Method: TSQLURIMethod; Table: TSQLRecordClass; TableIndex: integer; **const** TableID: TID; Context: TSQLRestServerURIContext): boolean;

Validate mPost/mPut/mDelete action against those access rights

- used by TSQLRestServerURIContext.ExecuteORMWrite and TSQLRestServer.EngineBatchSend methods for proper security checks

function ToString: RawUTF8;

Serialize the content as TEXT

- use the TSQLAuthGroup.AccessRights CSV format

procedure Edit(aModel: TSQLModel; aTable: TSQLRecordClass; aRights: TSQLOccasions); overload;

Wrapper method which can be used to set the CRUD abilities over a table

- will raise an EModelException if the supplied table is incorrect
- use TSQLOccasion set as parameter

procedure Edit(aTableIndex: integer; C, R, U, D: Boolean); overload;

Wrapper method which can be used to set the CRUD abilities over a table

- C=Create, R=Read, U=Update, D=Delete rights

procedure Edit(aTableIndex: integer; aRights: TSQLOccasions); overload;

Wrapper method which can be used to set the CRUD abilities over a table

- use TSQLOccasion set as parameter

procedure Edit(aModel: TSQLModel; aTable: TSQLRecordClass; C, R, U, D: Boolean); overload;

Wrapper method which can be used to set the CRUD abilities over a table

- will raise an EModelException if the supplied table is incorrect
- C=Create, R=Read, U=Update, D=Delete rights

procedure FromString(P: PUTF8Char);

Unserialize the content from TEXT

- use the TSQLAuthGroup.AccessRights CSV format

TSQLRestServerURIContext = class(TObject)

Abstract calling context for a TSQLRestServerCallBack event handler

- having a dedicated class avoid changing the implementation methods signature if the framework add some parameters or behavior to it
- see TSQLRestServerCallBack for general code use
- most of the internal methods are declared as virtual, so it allows any kind of custom routing or execution scheme
- instantiated by the TSQLRestServer.URI() method using its ServicesRouting property
- see TSQLRestRoutingREST and TSQLRestRoutingJSON_RPC for working inherited classes - NEVER set this abstract TSQLRestServerURIContext class to TSQLRest.ServicesRouting property !

Call: PSQLRestURIParams;

Access to all input/output parameters at TSQLRestServer.URI() level

- process should better call Results() or Success() methods to set the appropriate answer or Error() method in case of an error
- low-level access to the call parameters can be made via this pointer

Command: TSQLRestServerURIContextCommand;

The current execution command

CustomErrorMsg: RawUTF8;

Optional error message which will be transmitted as JSON error (if set)

- contains e.g. TNotifyAuthenticationFailedReason text during TSQLRestServer.OnAuthenticationFailed event call, or the reason of a TSQLRestServer.RecordCanBeUpdated failure

ForceServiceResultAsJSONObject: boolean;

Force the interface-based service methods to return a JSON object

- default behavior is to follow Service.ResultAsJSONObject property value (which own default is to return a more convenient JSON array)
- if set to TRUE, this execution context will FORCE the method to return a JSON object, even if Service.ResultAsJSONObject=false: this may be handy when the method is executed from a JavaScript content

ForceServiceResultAsJSONObjectWithoutResult: boolean;

Force the interface-based service methods to return a plain JSON object

- i.e. '{...}' instead of '{"result":{...}}'
- only set if ForceServiceResultAsJSONObject=TRUE and if no ID is about to be returned
- could be used e.g. for stateless interaction with a (non mORMot) stateless JSON REST Server

ForceServiceResultAsXMLObject: boolean;

Force the interface-based service methods to return a XML object

- default behavior is to follow Service.ResultAsJSONObject property value (which own default is to return a more convenient JSON array)
- if set to TRUE, this execution context will FORCE the method to return a XML object, by setting ForceServiceResultAsJSONObject then converting the resulting JSON object into the corresponding XML via JSONBufferToXML()
- TSQLRestServerURIContext.InternalExecuteSOABByInterface will inspect the Accept HTTP header to check if the answer should be XML rather than JSON

ForceServiceResultAsXMLObjectNamespace: RawUTF8;

Specify a custom name space content when returning a XML object

- default behavior is to follow Service.ResultAsXMLObjectNamespace property (which is void by default)
- service may set e.g. XMLUTF8_NAMESPACE, which will append <content ...> </content> around the generated XML data, to avoid validation problems or set a particular XML name space, depending on the application

JWTContent: TJWTContent;

JWT validation information, as filled by AuthenticationCheck()

Log: TSynLog;

Associated logging instance for the current thread on the server

- you can use it to log some process on the server side

Method: TSQLURIMethod;

The used Client-Server method (matching the corresponding HTTP Verb)

- this property will be set from incoming URI, even if RESTful authentication is not enabled

MethodIndex: integer;

The index of the callback published method within the internal class list

MicroSecondsElapsed: QWord;

High-resolution timing of the execution command, in micro-seconds

- only set when TSQLRestServer.URI finished

Parameters: PUTF8Char;

URI inlined parameters

- use UriDecodeValue*() functions to retrieve the values
- for mPOST requests, will also be filled for following content types:
application/x-www-form-urlencoded or multipart/form-data

ParametersPos: integer;

URI inlined parameters position in Call^.url string

- use Parameters field to retrieve the values

SafeProtocolID: integer;

The internal ID used to identify modelroot/_safe_ custom encryption

Server: TSQLRestServer;

The associated TSQLRestServer instance which executes its URI method

Service: TServiceFactoryServer;

The service identified by an interface-based URI

ServiceExecution: PServiceFactoryExecution;

The current execution context of an interface-based service

- maps to Service.fExecution[ServiceMethodIndex-SERVICE_PSEUDO_METHOD_COUNT]

ServiceExecutionOptions: TServiceMethodOptions;

The current execution options of an interface-based service

- contain ServiceExecution.Options including optNoLogInput/optNoLogOutput in case of TInterfaceFactory.RegisterUnsafeSPIType

ServiceInstanceID: PtrUInt;

The instance ID for interface-based services instance

- can be e.g. the client session ID for sicPerSession or the thread ID for sicPerThread

ServiceMethod: pointer;

Access to the raw PServiceMethod information of an interface-based URI

- equals nil if ServiceMethodIndex in 0..2 (pseudo-methods)

ServiceMethodIndex: integer;

The method index for an interface-based service

- Service member has already be retrieved from URI (so is not nil)

- 0..2 are the internal _free/_contract/_signature_ pseudo-methods

ServiceParameters: PUTF8Char;

The JSON array of parameters for an the interface-based service

- Service member has already be retrieved from URI (so is not nil)

Session: cardinal;

The corresponding session TAuthSession.IDCardinal value

- equals 0 (CONST_AUTHENTICATION_SESSION_NOT_STARTED) if the session is not started yet - i.e. if still in handshaking phase

- equals 1 (CONST_AUTHENTICATION_NOT_USED) if authentication mode is not enabled - i.e. if TSQLRestServer.HandleAuthentication = FALSE

SessionGroup: integer;

The corresponding TAuthSession.User.GroupRights.ID value

- is undefined if Session is 0 or 1 (no authentication running)

SessionUser: TID;

The corresponding TAuthSession.User.ID value

- is undefined if Session is 0 or 1 (no authentication running)

SessionUserName: RawUTF8;

The corresponding TAuthSession.User.LogonName value

- is undefined if Session is 0 or 1 (no authentication running)

Static: TSQLRest;

The static instance corresponding to the associated Table (if any)

StaticKind: TSQLRestServerKind;

The kind of static instance corresponding to the associated Table (if any)

Table: TSQLRecordClass;

The Table as specified at the URI level (if any)

TableEngine: TSQLRest;

The RESTful instance implementing the Table specified at the URI level (if any)

- equals TSQLRestServer most of the time, but may be an TSQLRestStorage for any in-memory/MongoDB/virtual instance

TableID: TID;

The associated TSQLRecord.ID, as decoded from URI scheme

- this property will be set from incoming URI, even if RESTful authentication is not enabled

TableIndex: integer;

The index in the Model of the Table specified at the URI level (if any)

TableRecordProps: TSQLModelRecordProperties;

The RTTI properties of the Table specified at the URI level (if any)

URI: RawUTF8;

The URI address, excluding trailing /info and ?par1=.... parameters
- can be either the table name (in RESTful protocol), or a service name

URIAfterRoot: PUTF8Char;

Points inside Call^.URI, after the 'root/' prefix

URIBlobFieldName: RawUTF8;

The optional Blob field name as specified in URI
- e.g. retrieved from "ModelRoot/TableName/TableID/BlobFieldName"

URISessionSignaturePos: integer;

Position of the &session_signature=... text in Call^.url string

URIUnderscoreAsSlash: RawUTF8;

Decoded URI for rsoMethodUnderscoreAsSlashURI in Server.Options
- e.g. 'Method_Name' from 'ModelRoot/Method/Name' URI

URIWithoutSignature: RawUTF8;

Same as Call^.URI, but without the &session_signature=... ending

constructor Create(aServer: TSQLRestServer; **const** aCall: TSQLRestURIParams);
virtual;

Initialize the execution context
- this method could have been declared as protected, since it should never be called outside the TSQLRestServer.URI() method workflow
- should set Call, and Method members

destructor Destroy; **override;**

Finalize the execution context

function AuthenticationBearerToken: RawUTF8;

Retrieve the "Authorization: Bearer <token>" value from incoming HTTP headers
- typically returns a JWT for stateless self-contained authentication, as expected by TJWTAbstract.Verify method
- as an alternative, a non-standard and slightly less safe way of token transmission may be to encode its value as ?authenticationbearer=.... URI parameter (may be convenient when embedding resources in HTML DOM)

function AuthenticationCheck(jwt: TJWTAbstract): boolean; **virtual**;

Validate "Authorization: Bearer <JWT>" content from incoming HTTP headers

- returns true on success, storing the payload in the JWTContent field
- set JWTContent.result = jwtNoToken if jwt is nil
- on failure (i.e. returns false), will set the error context as 403 HTTP_FORBIDDEN so that you may directly write:

```

procedure TMyDaemon.Files(Ctxt: TSQLRestServerURIContext);
begin
  if Ctxt.AuthenticationCheck(fJWT) then
    Ctxt.ReturnFileFromFolder('c:\datafolder');
end;
```

function ClientKind: TSQLRestServerURIContextClientKind;

Identify which kind of client is actually connected

- the "User-Agent" HTTP will be checked for 'mORMot' substring, and set ckFramework on match
- either ckAjax for a classic (AJAX) browser, or any other kind of HTTP client
- will be used e.g. by ClientSQLRecordOptions to check if the current remote client expects standard JSON in all cases

function ClientSQLRecordOptions: TJSONSerializerSQLRecordOptions;

Identify if the request is about a Table containing nested objects or arrays, which could be serialized as JSON objects or arrays, instead of plain JSON string (as stored in the database)

- will identify ClientKind=ckAjax, or check for rsoGetAsJsonNotAsString in TSQLRestServer.Options

function GetInputAsTDocVariant(const Options: TDocVariantOptions; ServiceMethod: pointer): **variant**;

Retrieve all input parameters from URI as a variant JSON object

- returns Unassigned if no parameter was defined
- returns a JSON object with input parameters encoded as
`{"name1":value1,"name2":value2...}`
- optionally with a PServiceMethod information about the actual values types
- if the parameters were encoded as multipart, the JSON object will be encoded with its textual values, or with nested objects, if the data was supplied as binary:
`{"name1":{"data":...,"filename":...,"contenttype":...},"name2":...}`

since name1.data will be Base64 encoded, so you should better use the InputAsMultiPart() method instead when working with binary

function InputAsMultiPart(var MultiPart: TMultiPartDynArray): Boolean;

Decode any multipart/form-data POST request input

- returns TRUE and set MultiPart array as expected, on success

```
function InputEnum(const ParamName: RawUTF8; EnumType: PTypeInfo; out ValueEnum;  
DefaultEnumOrd: integer=0): boolean;
```

Retrieve one input parameter from its URI name as an enumeration

- will expect the value to be specified as integer, or as the textual representation of the enumerate, ignoring any optional lowercase prefix as featured by TEnumType.GetEnumNameValue()
- returns TRUE and set ValueEnum if the parameter is found and correct
- returns FALSE and set ValueEnum to first item (i.e. DefaultEnumOrd) if the parameter is not found, or not containing a correct value

```
function InputOrError(const ParamName: RawUTF8; out Value: variant; const  
ErrorMessageForMissingParameter: string): boolean;
```

Retrieve one input parameter from its URI name as variant

- returns FALSE and call Error(ErrorMessageForMissingParameter) - which may be a resourcestring - if the parameter is not found
- returns TRUE and set Value if the parameter is found
- if the parameter value is text, it is stored in the variant as a RawUTF8: so before Delphi 2009, you won't lose any Unicode character, but you should convert its value to AnsiString using UTF8ToString()

```
function InputUTF8OrDefault(const ParamName, DefaultValue: RawUTF8): RawUTF8;
```

Retrieve one input parameter from its URI name as RawUTF8

- returns supplied DefaultValue if the parameter is not found

```
function InputUTF8OrError(const ParamName: RawUTF8; out Value: RawUTF8; const  
ErrorMessageForMissingParameter: string): boolean;
```

Retrieve one input parameter from its URI name as RawUTF8

- returns FALSE and call Error(ErrorMessageForMissingParameter) - which may be a resourcestring - if the parameter is not found
- returns TRUE and set Value if the parameter is found

```
function IsRemoteAdministrationExecute: boolean;
```

True if called from TSQLRestServer.AdministrationExecute

```
class procedure ClientSideInvoke(var uri: RawUTF8; ctxt:  
TSQLRestServerURIContextClientInvoke; const method, params, clientDrivenID:  
RawUTF8; out sent, head: RawUTF8); virtual; abstract;
```

At Client Side, compute URI and BODY according to the routing scheme

- abstract implementation which is to be overridden
- as input, method should be the method name to be executed, params should contain the incoming parameters as JSON CSV (without []), and clientDriven ID should contain the optional Client ID value
- at output, should update the HTTP uri corresponding to the proper routing, and should return the corresponding HTTP body within sent

procedure ConfigurationRestMethod(SettingsStorage: TObject);

Implements a method-based service for live update of some settings

- should be called from a method-based service, e.g. Configuration()
- the settings are expected to be stored e.g. in a TSynAutoCreateFields instance, potentially with nested objects

- accept the following REST methods to read and write the settings:

GET <http://server:888/root/configuration>

GET <http://server:888/root/configuration/propname>

GET <http://server:888/root/configuration/propname?value=propvalue>

- could be used e.g. as such:

```
procedure TMyRestServerMethods.Configuration(Ctxt: TSQLRestServerURIContext);
```

```
begin // http://server:888/myrestserver/configuration/name?value=newValue
```

```
  Ctxt.ConfigurationRestMethod(fSettings);
```

```
end;
```

procedure Error(const Format: RawUTF8; const Args: array of const; Status: integer=HTTP_BADREQUEST; CacheControlMaxAge: integer=0); overload;

Use this method to send back an error to the caller

- implementation is just a wrapper over Error(FormatUTF8(Format,Args))

procedure Error(const ErrorMessage: RawUTF8=''; Status: integer=HTTP_BADREQUEST; CacheControlMaxAge: integer=0); overload; **virtual**;

Use this method to send back an error to the caller

- expects Status to not be HTTP_SUCCESS neither HTTP_CREATED, and will send back a JSON error message to the caller, with the supplied error text
- set CacheControlMaxAge<>0 to include a Cache-Control: max-age=xxx header
- if no ErrorMessage is specified, will return a default text corresponding to the Status code

procedure Error(E: Exception; const Format: RawUTF8; const Args: array of const; Status: integer=HTTP_BADREQUEST); overload;

Use this method to send back an error to the caller

- will serialize the supplied exception, with an optional error message

procedure FillInput(const LogInputIdent: RawUTF8='');

Extract the input parameters from its URI

- you should not have to call this method directly, but rather all the InputInt/InputDouble/InputUTF8/InputExists/... properties
- may be useful if you want to access directly to InputPairs[] with no prior knowledge of the input parameter names
- you can specify a title text to optionally log the input array

procedure Redirect(const NewLocation: RawUTF8; PermanentChange: boolean=false);

Use this method notify the caller that the resource URI has changed

- returns a HTTP_TEMPORARYREDIRECT status with the specified location, or HTTP_MOVEDPERMANENTLY if PermanentChange is TRUE

```
procedure Results(const Values: array of const; Status: integer=HTTP_SUCCESS;  
Handle304NotModified: boolean=false; CacheControlMaxAge: integer=0);
```

Use this method to send back a JSON object with a "result" field

- this method will encode the supplied values as a {"result": "..."} JSON object, as such for one value:

```
 {"result": "OneValue"}
```

(with one value, you can just call TSQLRestClientURI.CallBackGetResult method to call and decode this value) or as a JSON object containing an array of values:

```
 {"result": ["One", "two"]}
```

- expects Status to be either HTTP_SUCCESS or HTTP_CREATED

- caller can set Handle304NotModified=TRUE for Status=HTTP_SUCCESS and/or set CacheControlMaxAge<>0 to include a Cache-Control: max-age=xxx header

```
procedure ReturnBlob(const Blob: RawByteString; Status: integer=HTTP_SUCCESS;  
Handle304NotModified: boolean=true; const FileName: TFileName='';  
CacheControlMaxAge: integer=0);
```

Uses this method to send back directly any binary content to the caller

- the exact MIME type will be retrieved using GetMimeContentTypeHeader(), from the supplied Blob binary buffer, and optional a file name

- by default, the HTTP_NOTMODIFIED process will take place, to minimize bandwidth between the server and the client

- set CacheControlMaxAge<>0 to include a Cache-Control: max-age=xxx header

```
procedure ReturnFile(const FileName: TFileName; Handle304NotModified:  
boolean=false; const ContentType: RawUTF8=''; const AttachmentFileName: RawUTF8='';  
const Error404Redirect: RawUTF8=''; CacheControlMaxAge: integer=0);
```

Use this method to send back a file to the caller

- this method will let the HTTP server return the file content

- if Handle304NotModified is TRUE, will check the file age to ensure that the file content will be sent back to the server only if it changed; set CacheControlMaxAge<>0 to include a Cache-Control: max-age=xxx header

- if ContentType is left to default "", method will guess the expected mime-type from the file name extension

- if the file name does not exist, a generic 404 error page will be returned, unless an explicit redirection is defined in Error404Redirect

- you can also specify the resulting file name, as downloaded and written by the client browser, in the optional AttachmentFileName parameter, if the URI does not match the expected file name

```
procedure ReturnFileFromFolder(const FolderName: TFileName; Handle304NotModified:  
boolean=true; const DefaultFileName: TFileName='index.html'; const  
Error404Redirect: RawUTF8=''; CacheControlMaxAge: integer=0);
```

Use this method to send back a file from a local folder to the caller

- URIBlobFieldName value, as parsed from the URI, will contain the expected file name in the local folder, using DefaultFileName if the URI is void, and redirecting to Error404Redirect if the file is not found

- this method will let the HTTP server return the file content

- if Handle304NotModified is TRUE, will check the file age to ensure that the file content will be sent back to the server only if it changed set CacheControlMaxAge<>0 to include a Cache-Control: max-age=xxx header

```
procedure Returns(const NameValuePairs: array of const; Status: integer=HTTP_SUCCESS; Handle304NotModified: boolean=false; HandleErrorAsRegularResult: boolean=false; const CustomHeader: RawUTF8=''); overload;
```

Use this method to send back a JSON object to the caller

- this method will encode the supplied values e.g. as
`JSONEncode(['name', 'John', 'year', 1972]) = '{"name": "John", "year": 1972}'`
- implementation is just a wrapper around `Returns(JSONEncode([]))`
- note that cardinal values should be type-casted to `Int64()` (otherwise the integer mapped value will be transmitted, therefore wrongly)
- expects Status to be either `HTTP_SUCCESS` or `HTTP_CREATED`
- caller can set `Handle304NotModified=TRUE` for `Status=HTTP_SUCCESS`

```
procedure Returns(const Result: RawUTF8; Status: integer=HTTP_SUCCESS; const CustomHeader: RawUTF8=''; Handle304NotModified: boolean=false; HandleErrorAsRegularResult: boolean=false; CacheControlMaxAge: integer=0; ServerHash: RawUTF8=''); overload;
```

Use this method to send back directly a result value to the caller

- expects Status to be either `HTTP_SUCCESS`, `HTTP_NOTMODIFIED`, `HTTP_CREATED`, or `HTTP_TEMPORARYREDIRECT`, and will return as answer the supplied Result content with no transformation
- if Status is an error code, it will call `Error()` method
- CustomHeader optional parameter can be set e.g. to `TEXT_CONTENT_TYPE_HEADER` if the default `JSON_CONTENT_TYPE` is not OK, or calling `GetMimeContentTypeHeader()` on the returned binary buffer
- if `Handle304NotModified` is `TRUE` and Status is `HTTP_SUCCESS`, the Result content will be hashed (using `crc32c`) and in case of no modification will return `HTTP_NOTMODIFIED` to the browser, without the actual result content (to save bandwidth)
- set `CacheControlMaxAge<>0` to include a `Cache-Control: max-age=xxx` header

```
procedure Returns(Value: TObject; Status: integer=HTTP_SUCCESS; Handle304NotModified: boolean=false; SQLRecordOptions: TJSONSerializerSQLRecordOptions=[]; const CustomHeader: RawUTF8=''); overload;
```

Use this method to send back any object as JSON document to the caller

- this method will call `ObjectToJson()` to compute the returned content
- you can customize `SQLRecordOptions`, to force the returned JSON object to have its `TSQLRecord` nested fields serialized as true JSON arrays or objects, or add an `"ID_str"` string field for JavaScript

```
procedure ReturnsJson(const Value: variant; Status: integer=HTTP_SUCCESS; Handle304NotModified: boolean=false; Escape: TTextWriterKind=twJSONEscape; MakeHumanReadable: boolean=false; const CustomHeader: RawUTF8='');
```

Use this method to send back any variant as JSON to the caller

- this method will call `VariantSaveJSON()` to compute the returned content

```
procedure Success(Status: integer=HTTP_SUCCESS); virtual;
```

Use this method if the caller expect no data, just a status

- just wrap the overloaded `Returns()` method with no result value
- if Status is an error code, it will call `Error()` method
- by default, calling this method will mark process as successful

property InCookie[CookieName: RawUTF8]: RawUTF8 **read** GetInCookie **write** SetInCookie;

Retrieve an incoming HTTP cookie value
- cookie name are case-sensitive

property InHeader[**const** HeaderName: RawUTF8]: RawUTF8 **read** GetInHeader;

Retrieve an incoming HTTP header
- the supplied header name is case-insensitive
- but rather call RemoteIP or UserAgent properties instead of InHeader['remoteip'] or InHeader['User-Agent']

property Input[**const** ParamName: RawUTF8]: **variant** **read** GetInput;

Retrieve one input parameter from its URI name as variant
- if the parameter value is text, it is stored in the variant as a generic VCL string content: so before Delphi 2009, you may loose some characters at decoding from UTF-8 input buffer
- raise an EParsingException if the parameter is not found

property InputDouble[**const** ParamName: RawUTF8]: double **read** GetInputDouble;

Retrieve one input parameter from its URI name as double
- raise an EParsingException if the parameter is not found

property InputDoubleOrVoid[**const** ParamName: RawUTF8]: double **read** GetInputDoubleOrVoid;

Retrieve one input parameter from its URI name as double
- returns 0 if the parameter is not found

property InputExists[**const** ParamName: RawUTF8]: Boolean **read** GetInputExists;

Return TRUE if the input parameter is available at URI
- even if InputUTF8['param']=" ", there may be '...?param=&another=2'

property InputHexaOrVoid[**const** ParamName: RawUTF8]: cardinal **read** GetInputHexaOrVoid;

Retrieve one hexadecimal input parameter from its URI name as cardinal
- returns 0 if the parameter is not found

property InputInt[**const** ParamName: RawUTF8]: Int64 **read** GetInputInt;

Retrieve one input parameter from its URI name as Int64
- raise an EParsingException if the parameter is not found

property InputIntOrVoid[**const** ParamName: RawUTF8]: Int64 **read** GetInputIntOrVoid;

Retrieve one input parameter from its URI name as Int64
- returns 0 if the parameter is not found

property InputOrVoid[**const** ParamName: RawUTF8]: **variant** **read** GetInputOrVoid;

Retrieve one input parameter from its URI name as variant
- if the parameter value is text, it is stored in the variant as a RawUTF8: so before Delphi 2009, you won't loose any Unicode character, but you should convert its value to AnsiString using UTF8ToString()
- returns Unassigned if the parameter is not found

property InputPairs: TRawUTF8DynArray read FInput;

Low-level access to the input parameters, stored as pairs of UTF-8

- even items are parameter names, odd are values
- Input*[] properties should have been called previously to fill the internal array, or by calling FillInput if you do not know the input parameters which may appear

property InputString[const ParamName: RawUTF8]: string read GetInputString;

Retrieve one input parameter from its URI name as a VCL string

- raise an EParsingException if the parameter is not found
- prior to Delphi 2009, some Unicode characters may be missing in the returned AnsiString value

property InputStringOrVoid[const ParamName: RawUTF8]: string read
GetInputStringOrVoid;

Retrieve one input parameter from its URI name as a VCL string

- returns '' if the parameter is not found
- prior to Delphi 2009, some Unicode characters may be missing in the returned AnsiString value

property InputUTF8[const ParamName: RawUTF8]: RawUTF8 read GetInputUTF8;

Retrieve one input parameter from its URI name as RawUTF8

- raise an EParsingException if the parameter is not found

property InputUTF8OrVoid[const ParamName: RawUTF8]: RawUTF8 read
GetInputUTF8OrVoid;

Retrieve one input parameter from its URI name as RawUTF8

- returns '' if the parameter is not found

property OutSetCookie: RawUTF8 read fOutSetCookie write SetOutSetCookie;

Define a new 'name=value' cookie to be returned to the client

- if not void, TSQLRestServer.URI() will define a new 'set-cookie: ...' header in Call^.OutHead
- you can use COOKIE_EXPIRED as value to delete a cookie in the browser
- if no Path=/. is included, it will append
'; Path=/' + Server.Model.Root + '; HttpOnly'

property RemoteIP: RawUTF8 read GetRemoteIP;

Retrieve the "RemoteIP" value from the incoming HTTP headers

property RemoteIPIsLocalHost: boolean read GetRemoteIPIsLocalHost;

True if the "RemoteIP" value from the incoming HTTP headers is '127.0.0.1'

property RemoteIPNotLocal: RawUTF8 read GetRemoteIPNotLocal;

"RemoteIP" value from the incoming HTTP headers but '' for '127.0.0.1'

property ResourceFileName: TFileName read GetResourceFileName;

Compute the file name corresponding to the URI

- e.g. '/root/methodname/toto/index.html' will return 'toto\index.html'

property UserAgent: RawUTF8 read GetUserAgent;

Retrieve the "User-Agent" value from the incoming HTTP headers

TSQLEstRoutingREST = class(TSQLEstServerURIContext)

Calling context for a TSQLEstServerCallBack using simple REST for interface-based services
 - this class will use RESTful routing for interface-based services: method name will be identified within the URI, as
 /Model/Interface.Method[/ClientDrivenID]

e.g. for ICalculator.Add:

```
POST /root/Calculator.Add
(...)
[1,2]
```

or, for a sicClientDriven mode service:

```
POST /root/ComplexNumber.Add/1234
(...)
[20,30]
```

in this case, the sent content will be a JSON array of [parameters...]

- as an alternative, input parameters may be encoded at URI level (with a size limit depending on the HTTP routers, whereas there is no such limitation when they are transmitted as message body)

- one benefit of having .../ClientDrivenID encoded at URI is that it will be more secured in our RESTful authentication scheme: each method and even client driven session will be signed individually

```
class procedure ClientSideInvoke(var uri: RawUTF8; ctxt:
TSQLEstServerURIContextClientInvoke; const method, params, clientDrivenID:
RawUTF8; out sent, head: RawUTF8); override;
```

At Client Side, compute URI and BODY according to RESTful routing scheme

- e.g. on input uri='root/Calculator', method='Add', params='1,2' and clientDrivenID='1234' -> on output uri='root/Calculator.Add/1234' and sent='[1,2]'

TSQLEstRoutingJSON_RPC = class(TSQLEstServerURIContext)

Calling context for a TSQLEstServerCallBack using JSON/RPC for interface-based services
 - in this routing scheme, the URI will define the interface, then the method name will be inlined with parameters, e.g.

```
POST /root/Calculator
(...)
{"method": "Add", "params": [1,2]}
```

or, for a sicClientDriven mode service:

```
POST /root/ComplexNumber
(...)
{"method": "Add", "params": [20,30], "id": 1234}
```

```
class procedure ClientSideInvoke(var uri: RawUTF8; ctxt:
TSQLEstServerURIContextClientInvoke; const method, params, clientDrivenID:
RawUTF8; out sent, head: RawUTF8); override;
```

At Client Side, compute URI and BODY according to JSON/RPC routing scheme

- e.g. on input uri='root/Calculator', method='Add', params='1,2' and clientDrivenID='1234' -> on output uri='root/Calculator' and sent='{"method": "Add", "params": [1,2], "id": 1234}'

TSQLRestServerMethod = record

Description of a method-based service

ByPassAuthentication: boolean;

Set to TRUE disable Authentication check for this method

- use TSQLRestServer.ServiceMethodByPassAuthentication() method

CallBack: TSQLRestServerCallBack;

The event which will be executed for this method

Name: RawUTF8;

The method name

Stats: TSynMonitorInputOutput;

Detailed statistics associated with this method

TSQLRecordFill = class(TObject)

Internal data used by TSQLRecord.FillPrepare()/FillPrepareMany() methods

- using a dedicated class will reduce memory usage for each TSQLRecord instance (which won't need these properties most of the time)

destructor Destroy; **override;**

Finalize the mapping

function Fill(aRow: integer; aDest: TSQLRecord): Boolean; **overload;**

Fill a TSQLRecord published properties from a TSQLTable row

- overloaded method using a specified destination record to be filled

- won't work with cross-reference mapping (FillPrepareMany)

- use the mapping prepared with Map() method

function Fill(aRow: integer): Boolean; **overload;**

Fill a TSQLRecord published properties from a TSQLTable row

- use the mapping prepared with Map() method

function TableMapFields: TSQLFieldBits;

Return all mapped fields, or [] if nil

procedure ComputeSetUpdatedFieldBits(Props: TSQLRecordProperties; **out** Bits: TSQLFieldBits);

Used to compute the updated field bits during a fill

- will return Props.SimpleFieldsBits[soUpdate] if no fill is in process

procedure Fill(aTableRow: PPUtf8CharArray; aDest: TSQLRecord); **overload;**

Fill a TSQLRecord published properties from a TSQLTable row

- overloaded method using a specified destination record to be filled

- won't work with cross-reference mapping (FillPrepareMany)

- use the mapping prepared with Map() method

- aTableRow will point to the first column of the matching row

procedure Fill(aTableRow: PPUtf8CharArray); overload;

Fill a TSQLRecord published properties from a TSQLTable row

- use the mapping prepared with Map() method
- aTableRow will point to the first column of the matching row

procedure Map(aRecord: TSQLRecord; aTable: TSQLTable; aCheckTableName: TSQLCheckTableName);

Map all columns of a TSQLTable to a record mapping

procedure UnMap;

Reset the mapping

- is called e.g. by TSQLRecord.FillClose
- will free any previous Table if necessary
- will release TSQLRecordMany.Dest instances as set by TSQLRecord.FillPrepareMany()

property FillCurrentRow: integer **read** fFillCurrentRow;

The current Row during a Loop

property JoinedFields: boolean **read** GetJoinedFields;

Equals TRUE if the instance was initialized via TSQLRecord.CreateJoined()

TSQLRecord.CreateAndFillPrepareJoined()

- it means that all nested TSQLRecord are pre-allocated instances, not trans-typed pointer(IDs)

property Table: TSQLTable **read** fTable;

The TSQLTable stated as FillPrepare() parameter

- the internal temporary table is stored here for TSQLRecordMany
- this instance is freed by TSQLRecord.Destroy if fTable.OwnerMustFree=true

TSQLRestBatch = class(TObject)

Used to store a BATCH sequence of writing operations

- is used by TSQLRest to process BATCH requests using BatchSend() method, or TSQLRestClientURI for its Batch*() methods
- but you can create your own stand-alone BATCH process, so that it will be able to make some transactional process - aka the "Unit Of Work" pattern

```
constructor Create(aRest: TSQLRest; aTable: TSQLRecordClass;  
AutomaticTransactionPerRow: cardinal=0; Options: TSQLRestBatchOptions=[];  
InternalBufferSize: cardinal=65536); virtual;
```

Begin a BATCH sequence to speed up huge database changes

- each call to normal Add/Update/Delete methods will create a Server request, therefore can be slow (e.g. if the remote server has bad ping timing)
- start a BATCH sequence using this method, then call BatchAdd() BatchUpdate() or BatchDelete() methods to make some changes to the database
- when BatchSend will be called, all the sequence transactions will be sent as one to the remote server, i.e. in one URI request
- if BatchAbort is called instead, all pending BatchAdd/Update/Delete transactions will be aborted, i.e. ignored
- expect one TSQLRecordClass as parameter, which will be used for the whole sequence (in this case, you can't mix classes in the same BATCH sequence)
- if no TSQLRecordClass is supplied, the BATCH sequence will allow any kind of individual record in BatchAdd/BatchUpdate/BatchDelete
- return TRUE on success, FALSE if aTable is incorrect or a previous BATCH sequence was already initiated
- should normally be used inside a Transaction block: there is no automated TransactionBegin..Commit/RollBack generated in the BATCH sequence if you leave the default AutomaticTransactionPerRow=0 parameter - but this may be a concern with a lot of concurrent clients
- you should better set AutomaticTransactionPerRow > 0 to execute all BATCH processes within an unique transaction grouped by a given number of rows, on the server side - set AutomaticTransactionPerRow=maxInt if you want one huge transaction, or set a convenient value (e.g. 10000) depending on the back-end database engine abilities, if you want to retain the transaction log file small enough for the database engine
- BatchOptions could be set to tune the SQL execution, e.g. force INSERT OR IGNORE on internal SQLite3 engine
- InternalBufferSize could be set to some high value (e.g. 10 shl 20), if you expect a very high number of rows in this BATCH

```
destructor Destroy; override;
```

Finalize the BATCH instance

```
function Add(Value: TSQLRecord; SendData: boolean; ForceID: boolean=false; const CustomFields: TSQLFieldBits=[]; DoNotAutoComputeFields: boolean=false): integer;
```

Create a new member in current BATCH sequence

- work in BATCH mode: nothing is sent to the server until BatchSend call
- returns the corresponding index in the current BATCH sequence, -1 on error
- if SendData is true, content of Value is sent to the server as JSON
- if ForceID is true, client sends the Value.ID field to use this ID for adding the record (instead of a database-generated ID)
- if Value is TSQLRecordFTS3/4/5, Value.ID is stored to the virtual table
- Value class MUST match the TSQLRecordClass used at BatchStart, or may be of any kind if no class was specified
- BLOB fields are NEVER transmitted here, even if ForceBlobTransfert=TRUE
- if CustomFields is left void, the simple fields will be used; otherwise, you can specify your own set of fields to be transmitted when SendData=TRUE (including BLOBs, even if they will be Base64-encoded within JSON content) - CustomFields could be computed by TSQLRecordProperties.FieldBitsFromCSV() or TSQLRecordProperties.FieldBitsFromRawUTF8(), or by setting ALL_FIELDS
- this method will always compute and send TCreateTime/TModTime fields

```
function Delete(ID: TID): integer; overload;
```

Delete a member in current BATCH sequence

- work in BATCH mode: nothing is sent to the server until BatchSend call
- returns the corresponding index in the current BATCH sequence, -1 on error
- deleted record class is the TSQLRecordClass used at BatchStart() call: it will fail if no class was specified for this BATCH sequence

```
function Delete(Table: TSQLRecordClass; ID: TID): integer; overload;
```

Delete a member in current BATCH sequence

- work in BATCH mode: nothing is sent to the server until BatchSend call
- returns the corresponding index in the current BATCH sequence, -1 on error
- with this overloaded method, the deleted record class is specified: no TSQLRecordClass shall have been set at BatchStart() call

```
function PrepareForSending(out Data: RawUTF8): boolean; virtual;
```

Close a BATCH sequence started by Start method

- Data is ready to be supplied to TSQLRest.BatchSend() overloaded method
- will also notify the TSQLRest.Cache for all deleted IDs
- you should not have to call it in normal use cases

```
function RawAdd(const SentData: RawUTF8): integer;
```

Allow to append some JSON content to the internal raw buffer for a POST

- could be used to emulate Add() with an already pre-computed JSON object
- returns the corresponding index in the current BATCH sequence, -1 on error

```
function RawAppend(FullRow: boolean=true): TTextWriter;
```

Allow to append some JSON content to the internal raw buffer

- could be used to emulate Add/Update/Delete
- FullRow=TRUE will increment the global Count

function RawUpdate(const SentData: RawUTF8; ID: TID): integer;

Allow to append some JSON content to the internal raw buffer for a PUT

- could be used to emulate Update() with an already pre-computed JSON object
- returns the corresponding index in the current BATCH sequence, -1 on error

function Update(Value: TSQLRecord; const CustomFields: TSQLFieldBits=[];
 DoNotAutoComputeFields: boolean=false; ForceCacheUpdate: boolean=false): integer;
 overload; **virtual**;

Update a member in current BATCH sequence

- work in BATCH mode: nothing is sent to the server until BatchSend call
- returns the corresponding index in the current BATCH sequence, -1 on error
- Value class MUST match the TSQLRecordClass used at BatchStart, or may be of any kind if no class was specified
- BLOB fields are NEVER transmitted here, even if ForceBlobTransfert=TRUE
- if Value has an opened FillPrepare() mapping, only the mapped fields will be updated (and also ID and TModTime fields) - FillPrepareMany() is not handled yet (all simple fields will be updated)
- if CustomFields is left void, the simple fields will be used, or the fields retrieved via a previous FillPrepare() call; otherwise, you can specify your own set of fields to be transmitted (including BLOBs, even if they will be Base64-encoded within the JSON content) - CustomFields could be computed by TSQLRecordProperties.FieldBitsFromCSV() or TSQLRecordProperties.FieldBitsFromRawUTF8()
- this method will always compute and send any TModTime fields, unless DoNotAutoComputeFields is set to true
- if not all fields are specified, will reset the cache entry associated with this value, unless ForceCacheUpdate is TRUE

function Update(Value: TSQLRecord; const CustomCSVFields: RawUTF8;
 DoNotAutoComputeFields: boolean=false; ForceCacheUpdate: boolean=false): integer;
 overload;

Update a member in current BATCH sequence

- work in BATCH mode: nothing is sent to the server until BatchSend call
- is an overloaded method to Update(Value,FieldBitsFromCSV())

procedure Reset(aTable: TSQLRecordClass; AutomaticTransactionPerRow: cardinal=0;
 Options: TSQLRestBatchOptions=[]); overload; **virtual**;

Reset the BATCH sequence so that you can re-use the same TSQLRestBatch

procedure Reset; overload;

Reset the BATCH sequence to its previous state

- could be used to prepare a next chunk of values, after a call to TSQLRest.BatchSend

property AddCount: integer **read** fAddCount;

How many times Add() has been called for this BATCH process

property Count: integer **read** GetCount;

Retrieve the current number of pending transactions in the BATCH sequence

property DeleteCount: integer **read** fDeleteCount;

How many times Delete() has been called for this BATCH process

property OnWrite: TOnBatchWrite **read** fOnWrite **write** fOnWrite;

This event handler will be triggered by each Add/Update/Delete method

property Rest: TSQLRest **read** fRest;

Read only access to the associated TSQLRest instance

property SizeBytes: cardinal **read** GetSizeBytes;

Retrieve the current JSON size of pending transaction in the BATCH sequence

property Table: TSQLRecordClass **read** fTable;

Read only access to the main associated TSQLRecord class (if any)

property UpdateCount: integer **read** fUpdateCount;

How many times Update() has been called for this BATCH process

TSQLRestBatchLocked = **class**(TSQLRestBatch)

Thread-safe class to store a BATCH sequence of writing operations

constructor Create(aRest: TSQLRest; aTable: TSQLRecordClass;
AutomaticTransactionPerRow: cardinal=0; Options: TSQLRestBatchOptions=[];
InternalBufferSize: cardinal=65536); **override**;

Initialize the BATCH instance

destructor Destroy; **override**;

Finalize the BATCH instance

procedure Reset(aTable: TSQLRecordClass; AutomaticTransactionPerRow: cardinal=0;
Options: TSQLRestBatchOptions=[]); **override**;

Reset the BATCH sequence so that you can re-use the same TSQLRestBatch

property ResetTix: Int64 **read** fTix **write** fTix;

Property set to the current GetTickCount64 value when Reset is called

property Safe: TSynLocker **read** fSafe;

Access to the locking methods of this instance

- use Safe.Lock/TryLock with a try ... finally Safe.Unlock block

property Threshold: integer **read** fThreshold **write** fThreshold;

May be used to store a number of rows to flush the content

TSQLRecord = class(TObject)

Root class for defining and mapping database records

- inherits a class from TSQLRecord, and add published properties to describe the table columns (see TPropInfo for SQL and Delphi type mapping/conversion)
- this published properties can be auto-filled from TSQLTable answer with FillPrepare() and FillRow(), or FillFrom() with TSQLTable or JSON data
- these published properties can be converted back into UTF-8 encoded SQL source with GetSQLValues or GetSQLSet or into JSON format with GetJSONValues
- BLOB fields are decoded to auto-freeing TSQLRawBlob properties
- any published property defined as a T*ObjArray dynamic array storage of persistents (via TJSONSerializer.RegisterObjArrayForJSON) will be freed
- consider inherit from TSQLRecordNoCase and TSQLRecordNoCaseExtended if you expect regular NOCASE collation and smaller (but not standard JSON) variant fields persistence
- is called TOrm in mORMot 2

Used for DI-2.1.1 (page 2553), DI-2.1.2 (page 2555), DI-2.1.3 (page 2556).

constructor Create(aClient: TSQLRest; aID: TID; ForUpdate: boolean=false); overload;

This constructor initializes the object as above, and fills its content from a client or server connection

- if ForUpdate is true, the REST method is LOCK and not GET: it tries to lock the corresponding record, then retrieve its content; caller has to call UnLock() method after Value usage, to release the record

constructor Create(const aSimpleFields: array of const; aID: TID); overload;

This constructor initializes the record and set the simple fields with the supplied values

- the aSimpleFields parameters must follow explicitly the order of published properties of the aTable class, excepting the TSQLRawBlob and TSQLRecordMany kind (i.e. only so called "simple fields") - in particular, parent properties must appear first in the list
- the aSimpleFields must have exactly the same count of parameters as there are "simple fields" in the published properties
- will raise an EORMException in case of wrong supplied values

constructor Create; overload; virtual;

This constructor initializes the record

- auto-instantiate any TSQLRecordMany instance defined in published properties
- override this method if you want to use some internal objects (e.g. TStringList or TCollection as published property)

constructor Create(aClient: TSQLRest; const FormatSQLWhere: RawUTF8; const ParamsSQLWhere, BoundsSQLWhere: array of const); overload;

This constructor initializes the object as above, and fills its content from a client or server connection, using a specified WHERE clause with parameters

- the FormatSQLWhere clause will replace all '%' chars with the supplied ParamsSQLWhere[] values, and all '?' chars with BoundsSQLWhere[] values, as :(...): inlined parameters - you should either call:

```
Rec := TSQLMyRecord.Create(aClient, 'Count=(:):' [aCount], []);
```

or (letting the inlined parameters being computed by FormatUTF8)

```
Rec := TSQLMyRecord.Create(aClient, 'Count=?', [], [aCount]);
```

or even better, using the other Create overloaded constructor:

```
Rec := TSQLMyRecord.Create(aClient, 'Count=?', [aCount]);
```

- using '?' and BoundsSQLWhere[] is perhaps more readable in your code, and will in all case create a request with :(..): inline parameters, with automatic RawUTF8 quoting if necessary

constructor Create(aClient: TSQLRest; aPublishedRecord: TSQLRecord; ForUpdate: boolean=false); overload;

This constructor initializes the object and fills its content from a client or server connection, from a TSQLRecord published property content

- is just a wrapper around Create(aClient, PtrInt(aPublishedRecord)) or Create(aClient, aPublishedRecord.ID)

- a published TSQLRecord property is not a class instance, but a typecast to TObject(RecordID) - you can also use its ID property

- if ForUpdate is true, the REST method is LOCK and not GET: it tries to lock the corresponding record, then retrieve its content; caller has to call UnLock() method after Value usage, to release the record

constructor Create(aClient: TSQLRest; const aSQLWhere: RawUTF8); overload;

This constructor initializes the object as above, and fills its content from a client or server connection, using a specified WHERE clause

- the WHERE clause should use inlined parameters (like 'Name=(:Arnaud):') for better server speed - note that you can use FormatUTF8() as such:

```
aRec := TSQLMyRec.Create(Client, FormatUTF8('Salary>? AND Salary<?', [], [1000, 2000]));
```

or call the overloaded constructor with BoundsSQLWhere array of parameters

constructor Create(aClient: TSQLRest; const FormatSQLWhere: RawUTF8; const BoundsSQLWhere: array of const); overload;

This constructor initializes the object as above, and fills its content from a client or server connection, using a specified WHERE clause with parameters

- for better server speed, the WHERE clause should use bound parameters identified as '?' in the FormatSQLWhere statement, which is expected to follow the order of values supplied in BoundsSQLWhere open array - use DateToSQL/DateTimeToSQL for TDateTime, or directly any integer / double / currency / RawUTF8 values to be bound to the request as parameters - note that this method prototype changed with revision 1.17 of the framework: array of const used to be ParamsSQLWhere and '%' in the FormatSQLWhere statement, whereas it now expects bound parameters as '?'

constructor CreateAndFillPrepare(aClient: TSQLRest; **const** aSQLWhere: RawUTF8; **const** aCustomFieldsCSV: RawUTF8=''); overload;

This constructor initializes the object as above, and prepares itself to loop through a statement using a specified WHERE clause

- this method creates a TSQLTableJSON, retrieves all records corresponding to the WHERE clause, then call FillPrepare - previous Create(aClient) methods retrieve only one record, this one more multiple rows
- you should then loop for all rows using 'while Rec.FillOne do ...'
- the TSQLTableJSON will be freed by TSQLRecord.Destroy
- the WHERE clause should use inlined parameters (like 'Name=:(\'Arnaud\')) for better server speed - note that you can use FormatUTF8() as such:

```
aRec := TSQLMyRec.CreateAndFillPrepare(Client, FormatUTF8('Salary>? AND Salary<?', [], [1000, 2000]));
```

or call the overloaded CreateAndFillPrepare() constructor directly with BoundsSQLWhere array of parameters

- aCustomFieldsCSV can be used to specify which fields must be retrieved
- default aCustomFieldsCSV="" will retrieve all simple table fields
- if aCustomFieldsCSV='*', it will retrieve all fields, including BLOBs
- aCustomFieldsCSV can also be set to a CSV field list to retrieve only the needed fields, and save remote bandwidth - note that any later Update() will update all simple fields, so potentially with wrong values; but BatchUpdate() can be safely used since it will

constructor CreateAndFillPrepare(**const** aJSON: RawUTF8); overload;

This constructor initializes the object, and prepares itself to loop through a specified JSON table, which will use a private copy

- this method creates a TSQLTableJSON, fill it with the supplied JSON buffer, then call FillPrepare
- previous Create(aClient) methods retrieve only one record, this one more multiple rows
- you should then loop for all rows using 'while Rec.FillOne do ...'
- the TSQLTableJSON will be freed by TSQLRecord.Destroy

constructor CreateAndFillPrepare(aJSON: PUTF8Char; aJSONLen: integer); overload;

This constructor initializes the object, and prepares itself to loop through a specified JSON table buffer, which will be modified in-place

- this method creates a TSQLTableJSON, fill it with the supplied JSON buffer, then call FillPrepare
- previous Create(aClient) methods retrieve only one record, this one more multiple rows
- you should then loop for all rows using 'while Rec.FillOne do ...'
- the TSQLTableJSON will be freed by TSQLRecord.Destroy

constructor CreateAndFillPrepare(aClient: TSQLRest; **const** aIDs: array of Int64; **const** aCustomFieldsCSV: RawUTF8=''); overload;

This constructor initializes the object as above, and prepares itself to loop through a given list of IDs

- this method creates a TSQLTableJSON, retrieves all records corresponding to the specified IDs, then call FillPrepare - previous Create(aClient) methods retrieve only one record, this one more multiple rows
- you should then loop for all rows using 'while Rec.FillOne do ...'
- the TSQLTableJSON will be freed by TSQLRecord.Destroy
- aCustomFieldsCSV can be used to specify which fields must be retrieved
- default aCustomFieldsCSV="" will retrieve all simple table fields, but you may need to access only one or several fields, and will save remote bandwidth by specifying the needed fields
- if aCustomFieldsCSV='*', it will retrieve all fields, including BLOBs
- note that you should not use this aCustomFieldsCSV optional parameter if you want to Update the retrieved record content later, since any missing fields will be left with previous values - but BatchUpdate() can be safely used after FillPrepare (will set only ID, TModTime and mapped fields)

constructor CreateAndFillPrepare(aClient: TSQLRest; **const** FormatSQLWhere: RawUTF8; **const** BoundsSQLWhere: array of **const**; **const** aCustomFieldsCSV: RawUTF8=''); overload;

This constructor initializes the object as above, and prepares itself to loop through a statement using a specified WHERE clause

- this method creates a TSQLTableJSON, retrieves all records corresponding to the WHERE clause, then call FillPrepare - previous Create(aClient) methods retrieve only one record, this one more multiple rows
- you should then loop for all rows using 'while Rec.FillOne do ...'
- the TSQLTableJSON will be freed by TSQLRecord.Destroy
- for better server speed, the WHERE clause should use bound parameters identified as '?' in the FormatSQLWhere statement, which is expected to follow the order of values supplied in BoundsSQLWhere open array - use DateToSQL/DateTimeToSQL for TDateTime, or directly any integer / double / currency / RawUTF8 values to be bound to the request as parameters
- note that this method prototype changed with revision 1.17 of the framework: array of **const** used to be ParamsSQLWhere and '%' in the FormatSQLWhere statement, whereas it now expects bound parameters as '?'
- aCustomFieldsCSV can be used to specify which fields must be retrieved
- default aCustomFieldsCSV="" will retrieve all simple table fields, but you may need to access only one or several fields, and will save remote bandwidth by specifying the needed fields
- if aCustomFieldsCSV='*', it will retrieve all fields, including BLOBs
- note that you should not use this aCustomFieldsCSV optional parameter if you want to Update the retrieved record content later, since any missing fields will be left with previous values - but BatchUpdate() can be safely used after FillPrepare (will set only ID, TModTime and mapped fields)

```
constructor CreateAndFillPrepare(aClient: TSQLRest; const FormatSQLWhere: RawUTF8;  
const ParamsSQLWhere, BoundsSQLWhere: array of const; const aCustomFieldsCSV:  
RawUTF8=''); overload;
```

This constructor initializes the object as above, and prepares itself to loop through a statement using a specified WHERE clause

- this method creates a TSQLTableJSON, retrieves all records corresponding to the WHERE clause, then call FillPrepare - previous Create(aClient) methods retrieve only one record, this one more multiple rows
- you should then loop for all rows using 'while Rec.FillOne do ...'
- the TSQLTableJSON will be freed by TSQLRecord.Destroy
- the FormatSQLWhere clause will replace all '%' chars with the supplied ParamsSQLWhere[] supplied values, and bind all '?' chars as parameters with BoundsSQLWhere[] values
- aCustomFieldsCSV can be used to specify which fields must be retrieved
- default aCustomFieldsCSV='' will retrieve all simple table fields, but you may need to access only one or several fields, and will save remote bandwidth by specifying the needed fields
- if aCustomFieldsCSV='*', it will retrieve all fields, including BLOBs
- note that you should not use this aCustomFieldsCSV optional parameter if you want to Update the retrieved record content later, since any missing fields will be left with previous values - but BatchUpdate() can be safely used after FillPrepare (will set only ID, TModTime and mapped fields)

```
constructor CreateAndFillPrepareJoined(aClient: TSQLRest; const aFormatSQLJoin:  
RawUTF8; const aParamsSQLJoin, aBoundsSQLJoin: array of const);
```

This constructor initializes the object, and prepares itself to loop nested TSQLRecord properties, through a JOINed statement and a WHERE clause

- by default, CreateAndFillPrepare() will return only the one-to-one nested TSQLRecord published properties IDs trans-typed as pointer - this constructor allow to retrieve the nested values in one statement
- this method creates a TSQLTableJSON, fill it with the supplied JSON buffer, then call FillPrepare
- previous CreateJoined() method retrieve only one record, this one more multiple rows
- you should then loop for all rows using 'while Rec.FillOne do ...'
- use this constructor if you want all TSQLRecord published properties to be allocated, and loaded with the corresponding values
- Free/Destroy will release these instances
- warning: if you call Update() after it, only the main object will be updated, not the nested TSQLRecord properties

constructor CreateAndFillPrepareMany(aClient: TSQLRest; const aFormatSQLJoin: RawUTF8; const aParamsSQLJoin, aBoundsSQLJoin: array of const);

This constructor initializes the object including all TSQLRecordMany properties, and prepares itself to loop through a JOINed statement

- the created instance will have all its TSQLRecordMany Dest property allocated with proper instance (and not only pointer(DestID) e.g.), ready to be consumed during a while FillOne do... loop (those instances will be freed by TSQLRecord.FillClose or Destroy) - and the Source property won't contain pointer(SourceID) but the main TSQLRecord instance
- the aFormatSQLJoin clause will define a WHERE clause for an automated JOINed statement, including TSQLRecordMany published properties (and their nested properties)
- a typical use could be the following:

```
aProd := TSQLProduct.CreateAndFillPrepareMany(Database,
  'Owner=? and Categories.Dest.Name=? and (Sizes.Dest.Name=? or Sizes.Dest.Name=?)', [],
  ['mark', 'for boy', 'small', 'medium']);
if aProd <> nil then
try
  while aProd.FillOne do
    // here e.g. aProd.Categories.Dest are instantiated (and Categories.Source=aProd)
    writeln(aProd.Name, ' ', aProd.Owner, ' ', aProd.Categories.Dest.Name, '
', aProd.Sizes.Dest.Name);
    // you may also use aProd.FillTable to fill a grid, e.g.
    // (do not forget to set aProd.FillTable.OwnerMustFree := false)
  finally
    aProd.Free; // will also free aProd.Categories/Sizes instances
end;
```

this will execute a JOINed SELECT statement similar to the following:

```
select p.*, c.*, s.*
from Product p, Category c, Categories cc, Size s, Sizes ss
where c.id=cc.dest and cc.source=p.id and
      s.id=ss.dest and ss.source=p.id and
      p.Owner='mark' and c.Name='for boy' and (s.Name='small' or s.Name='medium')
```

- you SHALL call explicetely the FillClose method before using any methods of nested TSQLRecordMany instances which may override the Dest instance content (e.g. ManySelect) to avoid any GPF
- the aFormatSQLJoin clause will replace all '%' chars with the supplied aParamsSQLJoin[] supplied values, and bind all '?' chars as bound parameters with aBoundsSQLJoin[] values

constructor CreateFrom(const aDocVariant: variant); overload;

This constructor initializes the object as above, and fills its content from a supplied TDocVariant object document

- is a wrapper around Create + FillFrom() methods

constructor CreateFrom(P: PUTF8Char); overload;

This constructor initializes the object as above, and fills its content from a supplied JSON buffer

- is a wrapper around Create + FillFrom() methods
- use JSON data, as exported by GetJSONValues(), expanded or not
- the data inside P^ is modified (unescaped and transformed in-place): don't call CreateFrom(pointer(JSONRecord)) but CreateFrom(JSONRecord) which makes a temporary copy of the JSONRecord text variable before parsing

constructor CreateFrom(const JSONRecord: RawUTF8); overload;

This constructor initializes the object as above, and fills its content from a supplied JSON content

- is a wrapper around Create + FillFrom() methods
- use JSON data, as exported by GetJSONValues(), expanded or not
- make an internal copy of the JSONTTable RawUTF8 before calling FillFrom() below

constructor `CreateJoined(aClient: TSQLRest; aID: TID);`

This constructor initializes the object from its ID, including all nested TSQLRecord properties, through a JOINed statement

- by default, `Create(aClient,aID)` will return only the one-to-one nested TSQLRecord published properties IDs trans-typed as pointer - this constructor allow to retrieve the nested values in one statement
- use this constructor if you want all TSQLRecord published properties to be allocated, and loaded with the corresponding values
- Free/Destroy will release these instances
- warning: if you call `Update()` after it, only the main object will be updated, not the nested TSQLRecord properties

destructor `Destroy; override;`

Release the associated memory

- in particular, release all TSQLRecordMany instance created by the constructor of this TSQLRecord

class function `AutoFree(var localVariable; Rest: TSQLRest; const FormatSQLWhere: RawUTF8; const BoundsSQLWhere: array of const; const aCustomFieldsCSV: RawUTF8=''): IAutoFree; overload;`

FillPrepare and protect one TSQLRecord local variable instance

- is a wrapper around `TAutoFree.Create(localVariable,CreateAndFillPrepare(Rest,...))`
- be aware that it won't implement a full ARC memory model, but may be just used to avoid writing some try ... finally blocks on local variables
- use with caution, only on well defined local scope
- warning: under FPC, you should assign the result of this method to a local IAutoFree variable, or use a with `TSQLRecord.AutoFree()` do statement - see <http://bugs.freepascal.org/view.php?id=26602>

class function `AutoFree(var localVariable; Rest: TSQLRest; const FormatSQLWhere: RawUTF8; const ParamsSQLWhere, BoundsSQLWhere: array of const; const aCustomFieldsCSV: RawUTF8=''): IAutoFree; overload;`

FillPrepare and protect one TSQLRecord local variable instance

- is a wrapper around `TAutoFree.Create(localVariable,CreateAndFillPrepare(Rest,...))`
- be aware that it won't implement a full ARC memory model, but may be just used to avoid writing some try ... finally blocks on local variables
- use with caution, only on well defined local scope
- warning: under FPC, you should assign the result of this method to a local IAutoFree variable, or use a with `TSQLRecord.AutoFree()` do statement - see <http://bugs.freepascal.org/view.php?id=26602>

class function `AutoFree(var localVariable; Rest: TSQLRest; ID: TID): IAutoFree; overload;`

Read and protect one TSQLRecord local variable instance

- is a wrapper around `TAutoFree.Create(localVariable,Create(Rest,ID))`
- be aware that it won't implement a full ARC memory model, but may be just used to avoid writing some try ... finally blocks on local variables
- use with caution, only on well defined local scope
- warning: under FPC, you should assign the result of this method to a local IAutoFree variable, or use a with `TSQLRecord.AutoFree()` do statement - see <http://bugs.freepascal.org/view.php?id=26602>

class function AutoFree(varClassPairs: array of pointer): IAutoFree; overload;

Protect several TSQLRecord local variable instances

- specified as localVariable/recordClass pairs
- is a wrapper around TAutoFree.Several(...) constructor
- be aware that it won't implement a full ARC memory model, but may be just used to avoid writing some try ... finally blocks on local variables
- use with caution, only on well defined local scope
- you may write for instance:

```
var info: TSQLBlogInfo;
    article: TSQLArticle;
    comment: TSQLComment;
begin
  TSQLRecord.AutoFree([ // avoid several try..finally
    @info,TSQLBlogInfo, @article,TSQLArticle, @comment,TSQLComment]);
  .... now you can use info, article or comment
end; // will call info.Free article.Free and comment.Free
```

- warning: under FPC, you should assign the result of this method to a local IAutoFree variable, or use a with TSQLRecord.AutoFree() do statement - see <http://bugs.freepascal.org/view.php?id=26602>

class function AutoFree(var localVariable): IAutoFree; overload;

Protect one TSQLRecord local variable instance

- be aware that it won't implement a full ARC memory model, but may be just used to avoid writing some try ... finally blocks on local variables
- use with caution, only on well defined local scope
- you may write for instance:

```
var info: TSQLBlogInfo;
begin
  TSQLBlogInfo.AutoFree(info);
  .... now you can use info
end; // will call info.Free
```

- warning: under FPC, you should assign the result of this method to a local IAutoFree variable, or use a with TSQLRecord.AutoFree() do statement - see <http://bugs.freepascal.org/view.php?id=26602>

class function CaptionName(Action: PRawUTF8=nil; ForHint: boolean=false): string; virtual;

Get the captions to be used for this class

- if Action is nil, return the caption of the table name
- if Action is not nil, return the caption of this Action (lowercase left-trimmed)
- return "string" type, i.e. UnicodeString for Delphi 2009+
- internally call UnCamelCase() then System.LoadResStringTranslate() if available
- ForHint is set to TRUE when the record caption name is to be displayed inside the popup hint of a button (i.e. the name must be fully qualified, not the default short version)
- is not part of TSQLRecordProperties because has been declared as virtual

class function CaptionNameFromRTTI(Action: PShortString): string;

Get the captions to be used for this class

- just a wrapper calling CaptionName() virtual method, from a ShortString pointer

function ClassProp: PClassProp;

Return the RTTI property information for this record

Used for DI-2.1.3 (page 2556).

function CreateCopy: TSQLRecord; overload; **virtual**;

This method create a clone of the current record, with same ID and properties

- copy all COPIABLE_FIELDS, i.e. all fields excluding tftMany (because those fields don't contain any data, but a TSQLRecordMany instance which allow to access to the pivot table data)
- you can override this method to allow custom copy of the object, including (or not) published properties copy

function CreateCopy(**const** CustomFields: TSQLFieldBits): TSQLRecord; overload;

This method create a clone of the current record, with same ID and properties

- overloaded method to copy the specified properties

function DynArray(**const** DynArrayFieldName: RawUTF8): TDynArray; overload;

Initialize a TDynArray wrapper to map dynamic array property values

- if the field name is not existing or not a dynamic array, result.IsVoid will be TRUE

function DynArray(DynArrayFieldIndex: integer): TDynArray; overload;

Initialize a TDynArray wrapper to map dynamic array property values

- this overloaded version expect the dynamic array to have been defined with a not null index attribute, e.g.

published

property Ints: TIntegerDynArray **index** 1 **read** fInts **write** fInts;

property Currency: TCurrencyDynArray **index** 2 **read** fCurrency **write** fCurrency;

- if the field index is not existing or not a dynamic array, result.IsVoid will be TRUE

function EnginePrepareMany(aClient: TSQLRest; **const** aFormatSQLJoin: RawUTF8; **const** aParamsSQLJoin, aBoundsSQLJoin: **array of const**; **out** ObjectsClass: TSQLRecordClassDynArray; **out** SQL: RawUTF8): RawUTF8;

Compute a JOINed statement including TSQLRecordMany fields

- is called by FillPrepareMany() to retrieve the JSON of the corresponding request: so you could use this method to retrieve directly the same information, ready to be transmitted (e.g. as RawJSON) to a client

function FillOne(aDest: TSQLRecord=**nil**): **boolean**;

Fill all published properties of this object from the next available TSQLTable prepared row

- FillPrepare() must have been called before
- the Row number is taken from property FillCurrentRow
- return true on success, false if no more Row data is available
- internally call FillRow() to update published properties values

```
function FillPrepare(aClient: TSQLRest; const aSQLWhere: RawUTF8=''; const
aCustomFieldsCSV: RawUTF8=''; aCheckTableName: TSQLCheckTableName=ctnNoCheck):
boolean; overload;
```

Prepare to get values from a SQL where statement

- returns true in case of success, false in case of an error during SQL request
- then call FillRow(1..Table.RowCount) to get any row value
- or you can also loop through all rows with

```
while Rec.FillOne do
  dosomethingwith(Rec);
```
- a temporary TSQLTable is created then stored in an internal fTable protected field
- if aSQLWhere is left to '', all rows are retrieved as fast as possible (e.g. by-passing SQLite3 virtual table modules for external databases)
- the WHERE clause should use inlined parameters (like 'Name=:(\'Arnaud\')') for better server speed - note that you can use FormatUTF8() as such:

```
aRec.FillPrepare(Client,FormatUTF8('Salary>? AND Salary<?',[],[1000,2000]));
```

or call the overloaded FillPrepare() method directly with BoundsSQLWhere array of parameters

- aCustomFieldsCSV can be used to specify which fields must be retrieved
- default aCustomFieldsCSV='' will retrieve all simple table fields, but you may need to access only one or several fields, and will save remote bandwidth by specifying the needed fields
- if aCustomFieldsCSV='*', it will retrieve all fields, including BLOBs
- note that you should not use this aCustomFieldsCSV optional parameter if you want to Update the retrieved record content later, since any missing fields will be left with previous values - but BatchUpdate() can be safely used after FillPrepare (will set only ID, TModTime and mapped fields)

```
function FillPrepare(aClient: TSQLRest; const FormatSQLWhere: RawUTF8; const
BoundsSQLWhere: array of const; const aCustomFieldsCSV: RawUTF8=''): boolean;
overload;
```

Prepare to get values using a specified WHERE clause with '%' parameters

- returns true in case of success, false in case of an error during SQL request
- then call FillRow(1..Table.RowCount) to get any row value
- or you can also loop through all rows with

```
while Rec.FillOne do
  dosomethingwith(Rec);
```
- a temporary TSQLTable is created then stored in an internal fTable protected field
- for better server speed, the WHERE clause should use bound parameters identified as '?' in the FormatSQLWhere statement, which is expected to follow the order of values supplied in BoundsSQLWhere open array - use DateToSQL/DateTimeToSQL for TDateTime, or directly any integer / double / currency / RawUTF8 values to be bound to the request as parameters
- note that this method prototype changed with revision 1.17 of the framework: array of const used to be ParamsSQLWhere and '%' in the FormatSQLWhere statement, whereas it now expects bound parameters as '?'
- aCustomFieldsCSV can be used to specify which fields must be retrieved
- default aCustomFieldsCSV='' will retrieve all simple table fields, but you may need to access only one or several fields, and will save remote bandwidth by specifying the needed fields
- if aCustomFieldsCSV='*', it will retrieve all fields, including BLOBs
- note that you should not use this aCustomFieldsCSV optional parameter if you want to Update the retrieved record content later, since any missing fields will be left with previous values - but BatchUpdate() can be safely used after FillPrepare (will set only ID, TModTime and mapped fields)

```
function FillPrepare(aClient: TSQLRest; const FormatSQLWhere: RawUTF8; const ParamsSQLWhere, BoundsSQLWhere: array of const; const aCustomFieldsCSV: RawUTF8=''): boolean; overload;
```

Prepare to get values using a specified WHERE clause with '%' and '?' parameters

- returns true in case of success, false in case of an error during SQL request
- then call FillRow(1..Table.RowCount) to get any row value
- or you can also loop through all rows with

```
while Rec.FillOne do  
  dosomethingwith(Rec);
```
- a temporary TSQLTable is created then stored in an internal fTable protected field
- the FormatSQLWhere clause will replace all '%' chars with the supplied ParamsSQLWhere[] supplied values, and bind all '?' chars as bound parameters with BoundsSQLWhere[] values
- aCustomFieldsCSV can be used to specify which fields must be retrieved
- default aCustomFieldsCSV="" will retrieve all simple table fields, but you may need to access only one or several fields, and will save remote bandwidth by specifying the needed fields
- if aCustomFieldsCSV='*', it will retrieve all fields, including BLOBs
- note that you should not use this aCustomFieldsCSV optional parameter if you want to Update the retrieved record content later, since any missing fields will be left with previous values - but BatchUpdate() can be safely used after FillPrepare (will set only ID, TModTime and mapped fields)

```
function FillPrepare(aClient: TSQLRest; const aIDs: array of Int64; const aCustomFieldsCSV: RawUTF8=''): boolean; overload;
```

Prepare to get values from a list of IDs

- returns true in case of success, false in case of an error during SQL request
- then call FillRow(1..Table.RowCount) to get any row value
- or you can also loop through all rows with

```
while Rec.FillOne do  
  dosomethingwith(Rec);
```
- a temporary TSQLTable is created then stored in an internal fTable protected field
- aCustomFieldsCSV can be used to specify which fields must be retrieved
- default aCustomFieldsCSV="" will retrieve all simple table fields, but you may need to access only one or several fields, and will save remote bandwidth by specifying the needed fields
- if aCustomFieldsCSV='*', it will retrieve all fields, including BLOBs
- note that you should not use this aCustomFieldsCSV optional parameter if you want to Update the retrieved record content later, since any missing fields will be left with previous values - but BatchUpdate() can be safely used after FillPrepare (will set only ID, TModTime and mapped fields)

```
function FillPrepareMany(aClient: TSQLRest; const aFormatSQLJoin: RawUTF8; const
aParamsSQLJoin, aBoundsSQLJoin: array of const): boolean;
```

/ prepare to loop through a JOINed statement including TSQLRecordMany fields

- all TSQLRecordMany.Dest published fields will now contain a true TSQLRecord instance, ready to be filled with the JOINed statement results (these instances will be released at FillClose) - the same for Source which will point to the self instance
- the aFormatSQLJoin clause will define a WHERE clause for an automated JOINed statement, including TSQLRecordMany published properties (and their nested properties)
- returns true in case of success, false in case of an error during SQL request
- a typical use could be the following:

```
if aProd.FillPrepareMany(Database,
  'Owner=? and Categories.Dest.Name=? and (Sizes.Dest.Name=? or Sizes.Dest.Name=?)',[],
  ['mark','for boy','small','medium']) then
  while aProd.FillOne do
    // here e.g. aProd.Categories.Dest are instantiated (and Categories.Source=aProd)
    writeln(aProd.Name, ' ',aProd.Owner, ' ',aProd.Categories.Dest.Name, '
',aProd.Sizes.Dest.Name);
    // you may also use aProd.FillTable to fill a grid, e.g.
    // (do not forget to set aProd.FillTable.OwnerMustFree := false)
```

this will execute a JOINed SELECT statement similar to the following:

```
select p.*, c.*, s.*
from Product p, Category c, Categories cc, Size s, Sizes ss
where c.id=cc.dest and cc.source=p.id and
s.id=ss.dest and ss.source=p.id and
p.Owner='mark' and c.Name='for boy' and (s.Name='small' or s.Name='medium')
```

- the FormatSQLWhere clause will replace all '%' chars with the supplied ParamsSQLWhere[] supplied values, and bind all '?' chars as parameters with BoundsSQLWhere[] values
- you SHALL call explicite the FillClose method before using any methods of nested TSQLRecordMany instances which may override the Dest instance content (e.g. ManySelect) to avoid any GPF
- is used by TSQLRecord.CreateAndFillPrepareMany constructor

```
function FillRewind: boolean;
```

Go to the first prepared row, ready to loop through all rows with FillOne()

- the Row number (property FillCurrentRow) is reset to 1
- return true on success, false if no Row data is available
- you can use it e.g. as:

```
while Rec.FillOne do
  dosomethingwith(Rec);
if Rec.FillRewind then
  while Rec.FillOne do
    dosomeotherthingwith(Rec);
```

function FillRow(aRow: integer; aDest: TSQLRecord=nil): boolean; virtual;

Fill all published properties of an object from a TSQLTable prepared row

- FillPrepare() must have been called before
- if Dest is nil, this object values are filled
- if Dest is not nil, this object values will be filled, but it won't work with TSQLRecordMany properties (i.e. after FillPrepareMany call)
- ID field is updated if first Field Name is 'ID'
- Row number is from 1 to Table.RowCount
- setter method (write Set*) is called if available
- handle UTF-8 SQL to Delphi values conversion (see TPropInfo mapping)
- this method has been made virtual e.g. so that a calculated value can be used in a custom field

function Filter(const aFields: TSQLFieldBits=[0..MAX_SQLFIELDS-1]): boolean; overload; virtual;

Filter/transform the specified fields values of the TSQLRecord instance

- by default, this will perform all TSynFilter as registered by [RecordProps.]AddFilterOrValidate()
- inherited classes may add some custom filtering/transformation here, if it's not needed nor mandatory to create a new TSynFilter class type: in this case, the function has to return TRUE if the filtering took place, and FALSE if any default registered TSynFilter must be processed
- the default aFields parameter will process all fields

function Filter(const aFields: array of RawUTF8): boolean; overload;

Filter/transform the specified fields values of the TSQLRecord instance

- this version will call the overloaded Filter() method above
- return TRUE if all field names were correct and processed, FALSE otherwise

function FilterAndValidate(aRest: TSQLRest; const aFields: TSQLFieldBits=[0..MAX_SQLFIELDS-1]; aValidator: PSynValidate=nil): RawUTF8; overload;

Filter (transform) then validate the specified fields values of the TSQLRecord

- this version will call the overloaded Filter() and Validate() methods and return "" on validation success, or an error message with the faulty field names at the beginning

function FilterAndValidate(aRest: TSQLRest; out aErrorMessage: string; const aFields: TSQLFieldBits=[0..MAX_SQLFIELDS-1]; aValidator: PSynValidate=nil): boolean; overload;

Filter (transform) then validate the specified fields values of the TSQLRecord

- this version will call the overloaded Filter() and Validate() methods and display the faulty field name at the beginning of the error message
- returns true if all field names were correct and processed, or false and an explicit error message (translated in the current language) on error

function GetAsDocVariant(withID: boolean; const withFields: TSQLFieldBits; options: PDocVariantOptions=nil; replaceRowIDWithID: boolean=false): variant; overload;

Retrieve the record content as a TDocVariant custom variant object

function GetBinary: RawByteString;

Write the record fields into RawByteString a binary buffer

- same as GetBinaryValues(), but also writing the ID field first

function GetFieldValue(const PropName: RawUTF8): RawUTF8;

Retrieve a field value from a given property name, as encoded UTF-8 text

- you should use strong typing and direct property access, following the ORM approach of the framework; but in some cases (a custom Grid display, for instance), it could be useful to have this method available
- will return "" in case of wrong property name
- BLOB and dynamic array fields are returned as '\uFFFF0base64encodedbinary'

function GetFieldVariant(const PropName: string): Variant;

Retrieve the published property value into a Variant

- will set the Variant type to the best matching kind according to the property type
- will return a null variant in case of wrong property name
- BLOB fields are returned as SQLite3 BLOB literals ('x'01234' e.g.)
- dynamic array fields are returned as a Variant array

function GetJSONValues(Expand, withID: boolean; Occasion: TSQLOccasion;
UsingStream: TCustomMemoryStream=nil; SQLRecordOptions:
TJSONSerializerSQLRecordOptions=[]): RawUTF8; overload;

Same as overloaded GetJSONValues(), but returning result into a RawUTF8

- if UsingStream is not set, it will use a temporary THeapMemoryStream instance

Used for DI-2.1.2 (page 2555), DI-2.1.3 (page 2556).

function GetJSONValues(Expand, withID: boolean; const Fields: TSQLFieldBits;
SQLRecordOptions: TJSONSerializerSQLRecordOptions=[]): RawUTF8; overload;

Same as overloaded GetJSONValues(), but allowing to set the fields to be retrieved, and returning result into a RawUTF8

Used for DI-2.1.2 (page 2555), DI-2.1.3 (page 2556).

function GetJSONValues(Expand, withID: boolean; const FieldsCSV: RawUTF8;
SQLRecordOptions: TJSONSerializerSQLRecordOptions=[]): RawUTF8; overload;

Same as overloaded GetJSONValues(), but allowing to set the fields to be retrieved, and returning result into a RawUTF8

Used for DI-2.1.2 (page 2555), DI-2.1.3 (page 2556).

function GetNonVoidFields: TSQLFieldBits;

Set the bits corresponding to non-void (0,") copiable fields

function GetSimpleFieldsAsDocVariant(withID: boolean=true; options:
PDocVariantOptions=nil): variant;

Retrieve the simple record content as a TDocVariant custom variant object

class function GetSQLCreate(aModel: TSQLModel): RawUTF8; **virtual;**

Return the UTF-8 encoded SQL source to create the table containing the published fields of a TSQLRecord child

- a 'ID INTEGER PRIMARY KEY' field is always created first (mapping SQLite3 RowID)
- AnsiString are created as TEXT COLLATE NOCASE (fast SQLite3 7bits compare)
- RawUnicode and RawUTF8 are created as TEXT COLLATE SYSTEMNOCASE (i.e. use our fast UTF8Comp() for comparison)
- TDateTime are created as TEXT COLLATE ISO8601 (which calls our very fast ISO TEXT to Int64 conversion routine)
- an individual bit set in UniqueField forces the corresponding field to be marked as UNIQUE (an unique index is automatically created on the specified column); use TSQLModel flsUnique[] array, which set the bits values to 1 if a property field was published with "stored AS_UNIQUE" (i.e. "stored false")
- this method will handle TSQLRecordFTS* classes like FTS* virtual tables, TSQLRecordRTree as RTREE virtual table, and TSQLRecordVirtualTable*ID classes as corresponding Delphi designed virtual tables
- is not part of TSQLRecordProperties because has been declared as virtual so that you could specify a custom SQL statement, per TSQLRecord type
- anyway, don't call this method directly, but use TSQLModel.GetSQLCreate()
- the aModel parameter is used to retrieve the Virtual Table module name, and can be ignored for regular (not virtual) tables

function GetSQLSet: RawUTF8;

Return the UTF-8 encoded SQL source to UPDATE the values contained in the current published fields of a TSQLRecord child

- only simple fields name (i.e. not TSQLRawBlob/TSQLRecordMany) are retrieved: BLOB fields are ignored (use direct access via dedicated methods instead)
- format is 'COL1='VAL1', COL2='VAL2'
- is not used by the ORM (do not use prepared statements) - only here for convenience

function GetSQLValues: RawUTF8;

Return the UTF-8 encoded SQL source to INSERT the values contained in the current published fields of a TSQLRecord child

- only simple fields name (i.e. not TSQLRawBlob/TSQLRecordMany) are updated: BLOB fields are ignored (use direct update via dedicated methods instead)
- format is '(COL1, COL2) VALUES ('VAL1', 'VAL2')' if some column was ignored (BLOB e.g.)
- format is 'VALUES ('VAL1', 'VAL2')' if all columns values are available
- is not used by the ORM (do not use prepared statements) - only here for convenience

function RecordClass: TSQLRecordClass;

Return the Class Type of the current TSQLRecord

class function RecordProps: TSQLRecordProperties;

Direct access to the TSQLRecord properties from RTTI

- TSQLRecordProperties is faster than e.g. the class function FieldProp()
- use internal the unused vmtAutoTable VMT entry to fast retrieve of a class variable which is unique for each class ("class var" is unique only for the class within it is defined, and we need a var for each class: so even Delphi XE syntax is not powerful enough for our purpose, and the vmtAutoTable trick is very fast, and works with all versions of Delphi - including 64-bit target)

function RecordReference(Model: TSQLModel): TRecordReference;

Return the TRecordReference Int64 value pointing to this record

function SameRecord(Reference: TSQLRecord): boolean;

Return true if all published properties values in Other are identical to the published properties of this object

- instances must be of the same class type
- only simple fields (i.e. not TSQLRawBlob/TSQLRecordMany) are compared
- comparison is much faster than SameValues() below

function SameValues(Reference: TSQLRecord): boolean;

Return true if all published properties values in Other are identical to the published properties of this object

- work with different classes: Reference properties name must just be present in the calling object
- only simple fields (i.e. not TSQLRawBlob/TSQLRecordMany) are compared
- compare the text representation of the values: fields may be of different type, encoding or precision, but still have same values

function SetBinary(P, PEnd: PAnsiChar): Boolean; overload;

Set the record fields from a binary buffer saved by GetBinary()

- same as SetBinaryValues(), but also reading the ID field first
- PEnd should point to the end of the P input buffer, to avoid any overflow

function SetBinary(const binary: RawByteString): Boolean; overload;

Set the record fields from a binary buffer saved by GetBinary()

- same as SetBinaryValues(), but also reading the ID field first

function SetBinaryValues(var P: PAnsiChar; PEnd: PAnsiChar): Boolean;

Set the field values from a binary buffer

- won't read the ID field (should be read before, with the Count e.g.)
- PEnd should point just after the P input buffer, to avoid buffer overflow
- returns true on success, or false in case of invalid content in P^ e.g.
- P is updated to the next pending content after the read values

function SetBinaryValuesSimpleFields(var P: PAnsiChar; PEnd: PAnsiChar): Boolean;

Set the simple field values from a binary buffer

- won't read the ID field (should be read before, with the Count e.g.)
- PEnd should point just after the P input buffer, to avoid buffer overflow
- returns true on success, or false in case of invalid content in P^ e.g.
- P is updated to the next pending content after the read values,

function SetFieldSQLVars(const Values: TSQLVarDynArray): boolean;

Set all field values from a supplied array of TSQLVar values

- Values[] array must match the RecordProps.Field[] order: will return false if the Values[].VType does not match RecordProps.FieldType[]

function SimplePropertiesFill(const aSimpleFields: array of const): boolean;

Set the simple fields with the supplied values

- the aSimpleFields parameters must follow explicitly the order of published properties of the supplied aTable class, excepting the TSQLRawBlob and TSQLRecordMany kind (i.e. only so called "simple fields") - in particular, parent properties must appear first in the list
- the aSimpleFields must have exactly the same count of parameters as there are "simple fields" in the published properties
- return true on success, but be aware that the field list must match the field layout, otherwise it may return true but will corrupt data

class function SQLTableName: RawUTF8;

The Table name in the database, associated with this TSQLRecord class

- 'TSQL' or 'TSQLRecord' chars are trimmed at the beginning of the ClassName
- or the ClassName is returned as is, if no 'TSQL' or 'TSQLRecord' at first
- is just a wrapper around RecordProps.SQLTableName

function Validate(aRest: TSQLRest; const aFields: array of RawUTF8;
 aInvalidFieldIndex: PInteger=nil; aValidator: PSynValidate=nil): string; overload;

Validate the specified fields values of the current TSQLRecord instance

- this version will call the overloaded Validate() method above
- returns "" if all field names were correct and processed, or an explicit error message (translated in the current language) on error
- if aInvalidFieldIndex is set, it will contain the first invalid field index

function Validate(aRest: TSQLRest; const aFields:
 TSQLFieldBits=[0..MAX_SQLFIELDS-1]; aInvalidFieldIndex: PInteger=nil; aValidator:
 PSynValidate=nil): string; overload; virtual;

Validate the specified fields values of the current TSQLRecord instance

- by default, this will perform all TSynValidate as registered by [RecordProps.]AddFilterOrValidate()
- it will also check if any UNIQUE field value won't be duplicated
- inherited classes may add some custom validation here, if it's not needed nor mandatory to create a new TSynValidate class type: in this case, the function has to return an explicit error message (as a generic VCL string) if the custom validation failed, or "" if the validation was successful: in this later case, all default registered TSynValidate are processed
- the default aFields parameter will process all fields
- if aInvalidFieldIndex is set, it will contain the first invalid field index found
- caller SHOULD always call the Filter() method before calling Validate()

class procedure AddFilterNotVoidAllTextFields;

Register a TSynFilterTrim and a TSynValidateText filters so that all text fields, after space trimming, won't be void

- will only affect RAWTEXT_FIELDS

class procedure AddFilterNotVoidText(const aFieldNames: array of RawUTF8);

Register a TSynFilterTrim and a TSynValidateText filters so that the specified fields, after space trimming, won't be void

```
class procedure AddFilterOrValidate(const aFieldName: RawUTF8; aFilter: TSynFilterOrValidate);
```

- Register a custom filter (transformation) or validate to the TSQLRecord class for a specified field*
- this will be used by TSQLRecord.Filter and TSQLRecord.Validate methods (in default implementation)
- will raise an EModelException on failure
- this function is just a wrapper around RecordProps.AddFilterOrValidate

```
procedure AppendAsJsonObject(W: TJSONSerializer; Fields: TSQLFieldBits=[]);
```

- Will append the record fields as an expanded JSON object*
- GetJsonValues() will expect a dedicated TJSONSerializer, whereas this method will add the JSON object directly to any TJSONSerializer
- by default, will append the simple fields, unless the Fields optional parameter is customized to a non void value

```
procedure AppendFillAsJsonArray(const FieldName: RawUTF8; W: TJSONSerializer; Fields: TSQLFieldBits=[]);
```

- Will append all the FillPrepare() records as an expanded JSON array*
- generates '[{rec1},{rec2},...]' using a loop similar to:

```
while FillOne do .. AppendJsonObject() ..
```
- if FieldName is set, the JSON array will be written as a JSON property, i.e. surrounded as '"FieldName":[...],' - note the ',' at the end
- by default, will append the simple fields, unless the Fields optional parameter is customized to a non void value
- see also TSQLRest.AppendListAsJsonArray for a high-level wrapper method

```
procedure AppendFillAsJsonValues(W: TJSONSerializer);
```

- Will iterate over all FillPrepare items, appending them as a JSON array*
- creates a JSON array of all record rows, using

```
while FillOne do GetJSONValues(W)...
```

```
procedure ClearProperties(const aFieldsCSV: RawUTF8); overload;
```

- Clear the values of specified published properties*
- '' will leave the content untouched, '*' will clear all simple fields

```
procedure ClearProperties; overload;
```

- Clear the values of all published properties, and also the ID property*

```
procedure ComputeFieldsBeforeWrite(aRest: TSQLRest; aOccasion: TSQLEvent);  
virtual;
```

- Should modify the record content before writing to the Server*
- this default implementation will update any sftModTime / TModTime, sftCreateTime / TCreateTime and sftSessionUserID / TSessionUserID properties content with the exact server time stamp
- you may override this method e.g. for custom calculated fields
- note that this is computed only on the Client side, before sending back the content to the remote Server: therefore, TModTime / TCreateTime fields are a pure client ORM feature - it won't work directly at REST level

procedure FillClose;

Close any previous FillPrepare..FillOne loop

- is called implicitly by FillPrepare() call to release any previous loop
- release the internal hidden TSQLTable instance if necessary
- is not mandatory if the TSQLRecord is released just after, since TSQLRecord.Destroy will call it
- used e.g. by FillFrom methods below to avoid any GPF/memory confusion

procedure FillFrom(Table: TSQLTable; Row: integer); overload;

Fill all published properties of this object from a TSQLTable result row

- call FillPrepare() then FillRow(Row)

procedure FillFrom(const JSONRecord: RawUTF8; FieldBits: PSQLFieldBits=nil); overload;

Fill all published properties of this object from a JSON object result

- use JSON data, as exported by GetJSONValues()
- JSON data may be expanded or not
- make an internal copy of the JSONTable RawUTF8 before calling FillFrom() below
- if FieldBits is defined, it will store the identified field index

procedure FillFrom(const JSONTable: RawUTF8; Row: integer); overload;

Fill all published properties of this object from a JSON result row

- create a TSQLTable from the JSON data
- call FillPrepare() then FillRow(Row)

procedure FillFrom(aRecord: TSQLRecord; const aRecordFieldBits: TSQLFieldBits); overload;

Fill the specified properties of this object from another object

- source object must be a parent or of the same class as the current record
- copy the fields, as specified by their bit index in the source record; you may use aRecord.GetNonVoidFields if you want to update some fields

procedure FillFrom(aRecord: TSQLRecord); overload;

Fill all published properties of this object from another object

- source object must be a parent or of the same class as the current record
- copy all COPIABLE_FIELDS, i.e. all fields excluding tftMany (because those fields don't contain any data, but a TSQLRecordMany instance which allow to access to the pivot table data)

procedure FillFrom(const aDocVariant: variant); overload;

Fill all published properties of this object from a supplied TDocVariant object document

- is a wrapper around VariantSaveJSON() + FillFrom() methods

procedure FillFrom(P: PUTF8Char; FieldBits: PSQLFieldBits=nil); overload;

Fill all published properties of this object from a JSON result

- the data inside P^ is modified (unescaped and transformed): don't call FillFrom(pointer(JSONRecordUTF8)) but FillFrom(JSONRecordUTF8) which makes a temporary copy of the JSONRecordUTF8 text
- use JSON data, as exported by GetJSONValues()
- JSON data may be expanded or not
- if FieldBits is defined, it will store the identified field index

```
procedure FillPrepare(Table: TSQLTable; aCheckTableName:
TSQLCheckTableName=ctnNoCheck); overload;
```

Prepare to get values from a TSQLTable result

- then call FillRow(1..Table.RowCount) to get any row value
- or you can also loop through all rows with

```
while Rec.FillOne do
  dosomethingwith(Rec);
```
- the specified TSQLTable is stored in an internal fTable protected field
- set aCheckTableName if you want e.g. the Field Names from the Table any pending 'TableName.' trimmed before matching to the current record

```
procedure FillValue(PropName, Value: PUTF8Char; wasString: boolean; FieldBits:
PSQLFieldBits=nil);
```

Fill a published property value of this object from a UTF-8 encoded value

- see TPropInfo about proper Delphi / UTF-8 type mapping/conversion
- use this method to fill a BLOB property, i.e. a property defined with type TSQLRawBlob, since by default all BLOB properties are not set by the standard Retrieve() method (to save bandwidth)
- if FieldBits is defined, it will store the identified field index

```
procedure ForceVariantFieldsOptions(aOptions:
TDocVariantOptions=JSON_OPTIONS_FAST);
```

Change TDocVariantData.Options for all variant published fields

- may be used to replace e.g. JSON_OPTIONS_FAST_EXTENDED by JSON_OPTIONS_FAST

```
procedure GetAsDocVariant(withID: boolean; const withFields: TSQLFieldBits; var
result: variant; options: PDocVariantOptions=nil; ReplaceRowIDWithID:
boolean=false); overload;
```

Retrieve the record content as a TDocVariant custom variant object

```
procedure GetBinaryValues(W: TFileBufferWriter); overload;
```

Write the field values into the binary buffer

- won't write the ID field (should be stored before, with the Count e.g.)

```
procedure GetBinaryValues(W: TFileBufferWriter; const aFields: TSQLFieldBits);
overload;
```

Write the field values into the binary buffer

- won't write the ID field (should be stored before, with the Count e.g.)

```
procedure GetBinaryValuesSimpleFields(W: TFileBufferWriter);
```

Write the simple field values (excluding ID) into the binary buffer

```
procedure GetJSONValues(W : TJSONSerializer); overload;
```

Return the UTF-8 encoded JSON objects for the values of this TSQLRecord

- layout and fields should have been set at TJSONSerializer construction: to append some content to an existing TJsonSerializer, call the AppendAsJsonObject() method

Used for DI-2.1.2 (page 2555), DI-2.1.3 (page 2556).

procedure GetJSONValues(JSON: TStream; Expand, withID: boolean; Occasion: TSQLOccasion; SQLRecordOptions: TJJSONSerializerSQLRecordOptions=[]); overload;

Return the UTF-8 encoded JSON objects for the values contained in the current published fields of a TSQLRecord child

- only simple fields (i.e. not TSQLRawBlob/TSQLRecordMany) are retrieved: BLOB fields are ignored (use direct access via dedicated methods instead)
- if Expand is true, JSON data is an object, for direct use with any Ajax or .NET client:

```
{ "col1":val11, "col2": "val12" }
```
- if Expand is false, JSON data is serialized (as used in TSQLTableJSON)

```
{ "fieldCount":1, "values":["col1", "col2", val11, "val12", val21, .. ] }
```
- if withID is true, then the first ID field value is included
- you can customize SQLRecordOptions, e.g. if sftObject/sftBlobDynArray property instance will be serialized as a JSON object or array, not a JSON string (which is the default, as expected by the database storage), or if an "ID_str" string field should be added for JavaScript

Used for DI-2.1.2 (page 2555), DI-2.1.3 (page 2556).

procedure GetJSONValuesAndFree(JSON : TJJSONSerializer); overload;

Return the UTF-8 encoded JSON objects for the values of this TSQLRecord

- the JSON buffer will be finalized if needed (e.g. non expanded mode), and the supplied TJJSONSerializer instance will be freed by this method
- layout and fields should have been set at TJJSONSerializer construction: to append some content to an existing TJsonSerializer, call the AppendAsJsonObject() method

class procedure InitializeTable(Server: TSQLRestServer; const FieldName: RawUTF8; Options: TSQLInitializeTableOptions); virtual;

Virtual method called when the associated table is created in the database

- if FieldName is "", initialization regarding all fields must be made; if FieldName is specified, initialization regarding this field must be processed
- override this method in order to initialize indexes or create default records
- by default, create indexes for all TRecordReference properties, and for all TSQLRecord inherited properties (i.e. of sftID type, that is an INTEGER field containing the ID of the pointing record)
- the options specified at CreateMissingTables() are passed to this method, within the context of an opened DB transaction, in which missing tables and fields have already been added
- is not part of TSQLRecordProperties because has been declared as virtual

procedure SetFieldValue(const PropName: RawUTF8; Value: PUTF8Char);

Set a field value of a given property name, from some encoded UTF-8 text

- you should use strong typing and direct property access, following the ORM approach of the framework; but in some cases (a custom Grid display, for instance), it could be useful to have this method available
- won't do anything in case of wrong property name
- expect BLOB and dynamic array fields encoded as SQLite3 BLOB literals ("x'01234'" e.g.) or '\uFFFF0base64encodedbinary'

procedure SetFieldVariant(const PropName: string; const Source: Variant);

Set the published property value from a Variant value

- will convert from the variant type into UTF-8 text before setting the value (so will work with any kind of Variant)
- won't do anything in case of wrong property name
- expect BLOB fields encoded as SQLite3 BLOB literals ("x'01234'" e.g.)

property AsTSQLRecord: pointer read GetIDAsPointer;

This read-only property can be used to retrieve the ID as a TSQLRecord object

- published properties of type TSQLRecord (one-to-many relationship) do not store real class instances (only exception is if they inherit from TSQLRecordMany) - you can use this value to assign a TSQLRecord instance to a published property, as such:

```
Main := TSQLRecordMain.Create;
Client.Add(Main);
Detail := TSQLRecordDetail.Create;
Detail.Main := Main.AsTSQLRecord; // will store Main.ID in MAIN column
Client.Add(Detail);
```

- is especially useful on 64-bit platform, since on 32-bit:

```
Detail.Main := pointer(Main.ID)
```

compiles (whereas it won't on 64-bit) and is the same than platform-independent

```
Detail.Main := Main.AsTSQLRecord;
```

- using Main.AsTSQLRecord will ensure that the ID is retrieved, even if Main itself is not a true instance

- if the stored ID is bigger than 32-bit, then it will raise an EORMException: in this case, you should use a TID / T*ID kind of published property, and not a TSQLRecord, which is limited to the pointer size

- on FPC, if you get an Error: Incompatible types: got "Pointer" expected "T...", then you are missing a {\$mode Delphi} conditional in your unit: the easiest is to include {\$I Synopse.inc} at the top of your unit

property FillContext: TSQLRecordFill read fFill;

Used internally by FillPrepare() and corresponding Fill() methods*

property FillCurrentRow: integer read GetFillCurrentRow;

This property contains the current row number (beginning with 1), initialized to 1 by FillPrepare(), which will be read by FillOne

property FillReachedEnd: boolean read GetFillReachedEnd;

This property is set to true, if all rows have been browsed after FillPrepare / while FillOne do ...

property FillTable: TSQLTable read GetTable;

This property contains the TSQLTable after a call to FillPrepare()

property HasBlob: boolean read GetHasBlob;

This property is set to true, if any published property is a BLOB (TSQLRawBlob)

property ID: TID read GetID;

This property stores the record's integer ID

- if this TSQLRecord is not a instance, but a field value in a published property of type sftID (i.e. TSQLRecord(aID)), this method will try to retrieve it; but preferred method is to typecast it via PtrInt(aProperty), because GetID() relies on some low-level Windows memory mapping trick, and will recognize an ID value up to 1,048,576 (i.e. \$100000)

- notice: the Setter should not be used usually; you should not have to write aRecord.ID := someID in your code, since the ID is set during Retrieve or Add of the record

- use IDValue property for direct read/write access to the record's ID field, if you know that this TSQLRecord is a true allocated class instance

property IDValue: TID read fID write fID;

This property gives direct access to the record's integer ID

- using IDValue expects this TSQLRecord to be a true instance, not a transtyped sftID (i.e. TSQLRecord(aID))

property InternalState: cardinal read fInternalState;

This property contains the internal state counter of the server database when the data was retrieved from it

- can be used to check if retrieved data may be out of date

property SimpleFieldCount: integer read GetSimpleFieldCount;

This property returns the published property count with any valid database field except TSQLRawBlob/TSQLRecordMany

- by default, the TSQLRawBlob (BLOB) fields are not included into this set: they must be read specifically (in order to spare bandwidth)
- TSQLRecordMany fields are not accessible directly, but as instances created by TSQLRecord.Create

TSQLRecordNoCase = class(TSQLRecord)

Root class for defining and mapping database records with case-insensitive NOCASE collation

- abstract ancestor, from which you may inherit your own ORM classes
- by default, any sftUTF8Text field (RawUTF8, UnicodeString, WideString properties) will use our Unicode SYSTEMNOCASE SQLite3 collation, which calls UTF8ILComp() to handle most western languages, but is not standard
- you may inherit from this class to ensure any text field will use the faster and SQLite3 built-in NOCASE collation, handling only 7-bit A-Z chars
- inherit from TSQLRecordNoCase or TSQLRecordCaseSensitive if you expect your text fields to contain only basic (un)accentuated ASCII characters, and to be opened by any standard/ SQLite3 library or tool (outside of SynSQLite3.pas/SynDBExplorer)

TSQLRecordCaseSensitive = class(TSQLRecord)

Root class for defining and mapping database records with case-sensitive BINARY collation

- abstract ancestor, from which you may inherit your own ORM classes
- by default, any sftUTF8Text field (RawUTF8, UnicodeString, WideString properties) will use our Unicode SYSTEMNOCASE SQLite3 collation, which calls UTF8ILComp() to handle most western languages, but is not standard
- you may inherit from this class to ensure any text field will use the faster and SQLite3 built-in BINARY collation, which is case-sensitive
- inherit from TSQLRecordNoCase or TSQLRecordCaseSensitive if you expect your text fields to contain only basic (un)accentuated ASCII characters, and to be opened by any standard/ SQLite3 library or tool (outside of SynSQLite3.pas/SynDBExplorer)

TSQLRecordNoCaseExtended = class(TSQLRecordNoCase)

Database records with NOCASE collation and JSON_OPTIONS_FAST_EXTENDED variants

- abstract ancestor, from which you may inherit your own ORM classes

TSQLRecordCaseSensitiveExtended = class(TSQLRecordCaseSensitive)

Database records with BINARY collation and JSON_OPTIONS_FAST_EXTENDED variants

- abstract ancestor, from which you may inherit your own ORM classes

TSQLRecordNoCaseExtendedNoID = class(TSQLRecordNoCaseExtended)

*Database records with NOCASE collation and JSON_OPTIONS_FAST_EXTENDED variants, and itoNoIndex4TID option to avoid indexes on TID/T*ID properties*

- abstract ancestor, from which you may inherit your own ORM classes

class procedure InitializeTable(Server: TSQLRestServer; **const** FieldName: RawUTF8; Options: TSQLInitializeTableOptions); **override**;

*Overriden method forcing no index creation on TID/T*ID properties*

TSQLTableFieldType = record

Store TSQLFieldType and RTTI for a given TSQLTable field

ContentDB: TSQLDBFieldType;

How this field could be stored in a database

- equals ftUnknown if InitFields guessed the field type, or for sftVariant

ContentSize: integer;

The field size in bytes; -1 means not computed yet

ContentType: TSQLFieldType;

The field kind, as in JSON (match TSQLPropInfo.SQLFieldTypeStored)

ContentTypeInfo: pointer;

Used for sftEnumerate, sftSet and sftBlobDynArray fields

TableIndex: integer;

The corresponding index in fQueryTables[]

TSQLTable = class(TObject)

Wrapper to an ORM result table, statically stored as UTF-8 text

- contain all result in memory, until destroyed

- first row contains the field names

- following rows contains the data itself

- GetString() can be used in a TDrawString

- will be implemented as TSQLTableJSON for remote access through optimized JSON content

Used for DI-2.1.2 (page 2555).

constructor Create(**const** aSQL: RawUTF8);

Initialize the result table

- you can optionally associate the corresponding TSQLRecordClass types, by which the results were computed (it will use RTTI for column typing)

constructor CreateFromTables(**const** Tables: array of TSQLRecordClass; **const** aSQL: RawUTF8);

Initialize the result table

- you can associate the corresponding TSQLRecordClass types, by which the results were computed (it will use RTTI for column typing)

constructor CreateWithColumnTypes(const ColumnTypes: array of TSQLFieldType; const aSQL: RawUTF8);

Initialize the result table

- you can set the expected column types matching the results column layout

destructor Destroy; **override**;

Free associated memory and owned records

function CalculateFieldLengthMean(var aResult: TIntegerDynArray; FromDisplay: boolean=false): integer;

Get the mean of characters length of all fields

- the character length is for the first line of text only (stop counting at every newline character, i.e. #10 or #13 char)
 - return the sum of all mean of character lengths

function DeleteColumnValues(Field: integer): boolean;

Delete the specified Column text from the Table

- don't delete the Column: only delete UTF-8 text in all rows for this field

function DeleteRow(Row: integer): boolean;

Delete the specified data Row from the Table

- only overwrite the internal fResults[] pointers, don't free any memory, nor modify the internal DataSet

function ExpandAsString(Row,Field: integer; Client: TObject; out Text: string; const CustomFormat: string=''): TSQLFieldType;

Read-only access to a particular field value, as VCL text

- Client is one TSQLClient instance (used to display TRecordReference via the associated TSQLModel)
 - returns the Field Type
 - return generic string Text, i.e. UnicodeString for Delphi 2009+, ready to be displayed to the VCL, for sftEnumerate, sftTimeLog, sftUnixTime/sftUnixMSTime and sftRecord/sftRecordVersion/sftID/sftTID
 - returns '' as string Text, if text can be displayed directly with Get*() methods above
 - returns '' for other properties kind, if UTF8ToString is nil, or the ready to be displayed value if UTF8ToString event is set (to be used mostly with Language.UTF8ToString)
 - CustomFormat can optionally set a custom format string, e.g. '%f' or '%n' or complex FormatFloat()/FormatCurr() syntax (as '#,##0.00') for sftFloat and sftCurrency columns (instead of plain JSON float value), or date/time format as expected by FormatDateTime() for all date time kind of fields (as sftDateTime, sftDateTimeMS, sftTimeLog, sftModTime, sftCreateTime, sftUnixTime, sftUnixMSTime)

function ExpandAsSynUnicode(Row,Field: integer; Client: TObject; out Text: SynUnicode): TSQLFieldType;

Read-only access to a particular field value, as VCL text

- this method is just a wrapper around ExpandAsString method, returning the content as a SynUnicode string type (i.e. UnicodeString since Delphi 2009, and WideString for non Unicode versions of Delphi)
 - it is used by the reporting layers of the framework (e.g. TSQLRibbon.AddToReport)

function Field(const FieldName: RawUTF8): variant; overload;

Read-only access to a particular field value, as a variant

- raise an ESQLTableException if called outside valid Step() sequence
- will call GetVariant() method for appropriate data conversion

function Field(FieldIndex: integer): variant; overload;

Read-only access to a particular field value, as a variant

- raise an ESQLTableException if called outside valid Step() sequence
- will call GetVariant() method for appropriate data conversion

function FieldAsFloat(FieldIndex: Integer): TSynExtended; overload;

Read-only access to a particular field value, as floating-point value

- raise an ESQLTableException if called outside valid Step() sequence
- similar to GetAsFloat() method, but for the current Step

function FieldAsFloat(const FieldName: RawUTF8): TSynExtended; overload;

Read-only access to a particular field value, as floating-point value

- raise an ESQLTableException if called outside valid Step() sequence
- similar to GetAsFloat() method, but for the current Step

function FieldAsInteger(FieldIndex: Integer): Int64; overload;

Read-only access to a particular field value, as Integer

- raise an ESQLTableException if called outside valid Step() sequence
- similar to GetAsInteger() method, but for the current Step

function FieldAsInteger(const FieldName: RawUTF8): Int64; overload;

Read-only access to a particular field value, as Integer

- raise an ESQLTableException if called outside valid Step() sequence
- similar to GetAsInteger() method, but for the current Step

function FieldAsRawUTF8(FieldIndex: Integer): RawUTF8; overload;

Read-only access to a particular field value, as RawUTF8

- raise an ESQLTableException if called outside valid Step() sequence
- similar to GetU() method, but for the current Step

function FieldAsRawUTF8(const FieldName: RawUTF8): RawUTF8; overload;

Read-only access to a particular field value, as RawUTF8

- raise an ESQLTableException if called outside valid Step() sequence
- similar to GetU() method, but for the current Step

function FieldAsString(const FieldName: RawUTF8): String; overload;

Read-only access to a particular field value, as VCL String

- raise an ESQLTableException if called outside valid Step() sequence
- similar to GetString() method, but for the current Step

function FieldAsString(FieldIndex: Integer): String; overload;

Read-only access to a particular field value, as VCL String

- raise an ESQLTableException if called outside valid Step() sequence
- similar to GetString() method, but for the current Step

function FieldBuffer(FieldIndex: Integer): PUTF8Char; overload;

Read-only access to a particular field value, as UTF-8 encoded buffer
- raise an ESQLTableException if called outside valid Step() sequence
- similar to Get() method, but for the current Step

function FieldBuffer(const FieldName: RawUTF8): PUTF8Char; overload;

Read-only access to a particular field value, as UTF-8 encoded buffer
- raise an ESQLTableException if called outside valid Step() sequence
- similar to Get() method, but for the current Step

function FieldIndex(FieldName: PUTF8Char): integer; overload;

Get the Field index of a FieldName
- return -1 if not found, index (0..FieldCount-1) if found

function FieldIndex(const FieldNames: array of RawUTF8; const FieldIndexes: array of PInteger): integer; overload;

Get the Field indexes of several Field names
- could be used to speed-up field access in a TSQLTable loop, avoiding a FieldIndex(aFieldName) lookup for each value
- returns the number of matching Field names
- set -1 in FieldIndexes[] if not found, index (0..FieldCount-1) if found

function FieldIndex(const FieldName: RawUTF8): integer; overload;

Get the Field index of a FieldName
- return -1 if not found, index (0..FieldCount-1) if found

function FieldIndexExisting(const FieldName: RawUTF8): integer; overload;

Get the Field index of a FieldName
- raise an ESQLTableException if not found, index (0..FieldCount-1) if found

function FieldLengthMax(Field: integer; NeverReturnsZero: boolean=false): cardinal;

Get the maximum number of characters of this field

function FieldLengthMean(Field: integer): cardinal;

Get the mean of characters length of this field
- the character length is for the first line of text only (stop counting at every newline character, i.e. #10 or #13 char)
- very fast: calculated only once for all fields

function FieldLengthMeanSum: cardinal;

Get the sum of all mean of characters length of all fields
- very fast: calculated only once for all fields

function FieldNames: TRawUTF8DynArray;

Retrieve all field names as a RawUTF8 dynamic array

function FieldTable(Field: integer): TSQLRecordClass;

Get the record class (i.e. the table) associated to a field
- is nil if this table has no QueryTables property
- very fast: calculated only once for all fields

function FieldType(Field: integer): TSQLFieldType; overload;

Guess the field type from first non null data row

- if QueryTables[] are set, exact field type and enumerate TypeInfo() is retrieved from the Delphi RTTI; otherwise, get from the cells content
- return sftUnknown is all data fields are null
- sftBlob is returned if the field is encoded as SQLite3 BLOB literals (X'53514C697465' e.g.)
- since TSQLTable data is PUTF8Char, string type is sftUTF8Text only

function FieldType(Field: integer; out FieldTypeInfo: PSQLTableFieldType): TSQLFieldType; overload;

Guess the field type from first non null data row

- if QueryTables[] are set, exact field type and (enumerate) TypeInfo() is retrieved from the Delphi RTTI; otherwise, get from the cells content
- return sftUnknown is all data fields are null
- sftBlob is returned if the field is encoded as SQLite3 BLOB literals (X'53514C697465' e.g.)
- since TSQLTable data is PUTF8Char, string type is sftUTF8Text only

function FieldValue(const FieldName: RawUTF8; Row: integer): PUTF8Char;

Get the Field content (encoded as UTF-8 text) from a property name

- return nil if not found

function Get(Row: integer; const FieldName: RawUTF8): PUTF8Char; overload;

Read-only access to a particular field value, as UTF-8 encoded buffer

- points to memory buffer allocated by Init()

function Get(Row,Field: integer): PUTF8Char; overload;

Read-only access to a particular field value, as UTF-8 encoded buffer

- if Row and Fields are correct, returns a pointer to the UTF-8 buffer, or nil if the corresponding JSON was null or ""
- if Row and Fields are not correct, returns nil

function GetA(Row,Field: integer): WinAnsiString;

Read-only access to a particular field value, as Win Ansi text

function GetAsCurrency(Row,Field: integer): currency; overload;

Read-only access to a particular field value, as currency value

function GetAsCurrency(Row: integer; const FieldName: RawUTF8): currency; overload;

Read-only access to a particular field value, as currency value

function GetAsDateTime(Row: integer; const FieldName: RawUTF8): TDateTime;
overload;

Read-only access to a particular field value, as TDateTime value

function GetAsDateTime(Row,Field: integer): TDateTime; overload;

Read-only access to a particular field value, as TDateTime value

- sftDateTime/sftDateTimeMS will be converted from ISO-8601 text
- sftTimeLog, sftModTime, sftCreateTime will expect the content to be encoded as a TTimeLog Int64 value - as sftInteger may have been identified by TSQLTable.InitFieldTypes
- sftUnixTime/sftUnixMSTime field will call UnixTimeToDateTime/UnixMSTimeToDateTime
- for sftTimeLog, sftModTime, sftCreateTime or sftUnixTime fields, you may have to force the column type, since it may be identified as sftInteger or sftCurrency by default from its JSON number content, e.g. via:
 aTable.SetFieldType('FieldName',sftModTime);
- sftCurrency,sftFloat will return the corresponding double value
- any other types will try to convert ISO-8601 text }

function GetAsFloat(Row,Field: integer): TSynExtended; overload;

Read-only access to a particular field value, as extended value

function GetAsFloat(Row: integer; **const** FieldName: RawUTF8): TSynExtended; overload;

Read-only access to a particular field value, as extended value

function GetAsInt64(Row: integer; **const** FieldName: RawUTF8): Int64; overload;

Read-only access to a particular field value, as Int64 value

function GetAsInt64(Row,Field: integer): Int64; overload;

Read-only access to a particular field value, as Int64 value

function GetAsInteger(Row: integer; **const** FieldName: RawUTF8): integer; overload;

Read-only access to a particular field value, as integer value

function GetAsInteger(Row,Field: integer): integer; overload;

Read-only access to a particular field value, as integer value

function GetBlob(Row,Field: integer): TSQLRawBlob;

Read-only access to a particular Blob value

- a new TSQLRawBlob is created
- Blob data is converted from SQLite3 BLOB literals (X'53514C697465' e.g.) or Base-64 encoded content ('\uFFFF0base64encodedbinary')
- preferred manner is to directly use REST protocol to retrieve a blob field

function GetBytes(Row,Field: integer): TBytes;

Read-only access to a particular Blob value

- a new TBytes is created
- Blob data is converted from SQLite3 BLOB literals (X'53514C697465' e.g.) or Base-64 encoded content ('\uFFFF0base64encodedbinary')
- preferred manner is to directly use REST protocol to retrieve a blob field

function GetCaption(Row,Field: integer): **string**;

Read-only access to a particular field value, ready to be displayed

- mostly used with Row=0, i.e. to get a display value from a field name
- use "string" type, i.e. UnicodeString for Delphi 2009+
- value is first un-camel-cased: 'OnLine' value will return 'On line' e.g.
- then System.LoadResStringTranslate() is called if available

```
function GetCSVValues(Tab: boolean; CommaSep: AnsiChar=','; AddBOM: boolean=false;  
RowFirst: integer=0; RowLast: integer=0): RawUTF8; overload;
```

Save the table as CSV format, into a string variable

- if Tab=TRUE, will use TAB instead of ',' between columns
- you can customize the ',' separator - use e.g. the global ListSeparator variable (from SysUtils) to reflect the current system definition (some country use ',' as decimal separator, for instance our "douce France")
- AddBOM will add a UTF-8 Byte Order Mark at the beginning of the content

```
function GetDateTime(Row,Field: integer): TDateTime;
```

Read-only access to a particular DateTime field value

- expect SQLite3 TEXT field in ISO 8601 'YYYYMMDD hhmmss' or 'YYYY-MM-DD hh:mm:ss' format

```
function GetHtmlTable(const Header: RawUTF8='<head><style>table,th,td'+ '{border:  
1px solid black;border-collapse: collapse;}th,td{padding: 5px;'+ 'font-family:  
sans-serif;}'</style></head>'#10): RawUTF8; overload;
```

Save the table as a <html><body><table> </table></body></html> content

```
function GetJSONValues(Expand: boolean; IDBinarySize: integer=0; BufferSize:  
integer=0): RawUTF8; overload;
```

Same as the overloaded method, but returning result into a RawUTF8

Used for DI-2.1.2 (page 2555).

```
function GetMSRowSetValues: RawUTF8; overload;
```

Save the table in 'schemas-microsoft-com:rowset' XML format

- this format is used by ADODB.recordset, easily consumed by MS apps
- see @<https://synopse.info/forum/viewtopic.php?pid=11691#p11691>

```
function GetODSDocument(withColumnTypes: boolean=false): RawByteString;
```

Save the table in Open Document Spreadsheet compressed format

- this is a set of XML files compressed in a zip container
- this method will return the raw binary buffer of the file
- see @<https://synopse.info/forum/viewtopic.php?id=2133>

```
function GetRowLengths(Field: integer; var LenStore: TSynTempBuffer): integer;
```

Get all values lengths for a specified field into a PIntegerArray

- returns the total length as result, and fill LenStore with all rows individual lengths using StrLen()
- caller should eventually call LenStore.Done to release any temp memory
- returns 0 if Field is invalid or no data is stored in this TSQLTable - don't call LenStore.Done in this case

```
function GetRowValues(Field: integer; const Sep: RawUTF8=','; const Head:  
RawUTF8=''; const Trail: RawUTF8=''): RawUTF8; overload;
```

Get all values for a specified field as CSV

- don't perform any conversion, but create a CSV from raw PUTF8Char data

```
function GetRowValues(Field: integer; out Values: TRawUTF8DynArray): integer;  
overload;
```

Get all values for a specified field into a dynamic RawUTF8 array

- don't perform any conversion, but just create an array of raw PUTF8Char data
- returns the number of rows in Values[]

function GetRowValues(Field: integer; out Values: TInt64DynArray): integer;
overload;

Get all values for a specified field into a dynamic Integer array
- returns the number of rows in Values[]

function GetS(Row,Field: integer): shortstring;

Read-only access to a particular field value, as Win Ansi text shortstring

function GetStream(Row,Field: integer): TStream;

Read-only access to a particular Blob value
- a new TCustomMemoryStream is created - caller shall free its instance
- Blob data is converted from SQLite3 BLOB literals (X'53514C697465' e.g.) or Base-64 encoded content ('\uFFFF0base64encodedbinary')
- preferred manner is to directly use REST protocol to retrieve a blob field

function GetString(Row,Field: integer): string;

Read-only access to a particular field value, as VCL string text
- the global UTF8ToString() function will be used for the conversion: for proper i18n handling before Delphi 2009, you should use the overloaded method with aUTF8ToString=Language.UTF8ToString

function GetSynUnicode(Row,Field: integer): SynUnicode;

Read-only access to a particular field value, as fast Unicode string text
- SynUnicode is either WideString, either UnicodeString, depending on the Delphi compiler revision, to ensure fastest native Unicode process available

function GetTimeLog(Row,Field: integer; Expanded: boolean; FirstTimeChar: AnsiChar = 'T'): RawUTF8;

Read-only access to a particular TTimeLog field value
- return the result as TTimeLogBits.Text() Iso-8601 encoded text

function GetU(Row,Field: integer): RawUTF8; overload;

Read-only access to a particular field value, as RawUTF8 text

function GetU(Row: integer; const FieldName: RawUTF8): RawUTF8; overload;

Read-only access to a particular field value, as RawUTF8 text

function GetValue(const aLookupFieldName,aLookupValue,aValueFieldName: RawUTF8): variant;

Read-only access to a particular field, via a lookup field name
- will call GetVariant() on the corresponding field
- returns null if the lookup did not have any match

function GetVariant(Row,Field: integer): variant; overload;

Read-only access to a particular field value, as a Variant
- text will be stored as RawUTF8 (as varString type)
- will try to use the most appropriate Variant type for conversion (will use e.g. TDateTime for sftDateTime, or a TDocVariant for JSON objects in a sftVariant column) - so you should better set the exact field types (e.g. from ORM) before calling this method

function GetW(Row,Field: integer): RawUnicode;

Read-only access to a particular field value, as UTF-16 Unicode text
- Raw Unicode is WideChar(zero) terminated
- its content is allocated to contain all WideChars (not trimmed to 255, like GetWP() above)

function GetWP(Row,Field: integer; Dest: PWideChar; MaxDestChars: cardinal): integer;

Fill a unicode buffer with a particular field value
- return number of wide characters written in Dest^

function IDColumnHiddenValue(Row: integer): TID;

Return the (previously hidden) ID value, 0 on error

function IDColumnHide: boolean;

If the ID column is available, hides it from fResults[]
- useful for simpler UI, with a hidden ID field
- use IDColumnHiddenValue() to get the ID of a specific row
- return true is ID was succesfully hidden, false if not possible

function LengthW(Row,Field: integer): integer;

Widechar length (UTF-8 decoded as UTF-16) of a particular field value
- could be used with VCL's UnicodeString, or for Windows API

function NewRecord(RecordType: TSQLRecordClass=nil): TSQLRecord;

Create a new TSQLRecord instance for a specific Table
- a void TSQLRecord instance is created, ready to be filled
- use the specified TSQLRecord class or create one instance of the first associated record class (from internal QueryTables[])
- the returned records will be managed by this TSQLTable: they will be freed when the TSQLTable is destroyed: you don't need to make a try..finally..Free..end block with them

function QueryRecordType: TSQLRecordClass;

Retrieve QueryTables[0], if existing

function RowFromID(aID: TID; aNotFoundMinusOne: boolean=false): integer;

Get the Row index corresponding to a specified ID
- return the Row number, from 1 to RowCount
- return RowCount (last row index) if this ID was not found or no ID field is available, unless aNotFoundMinusOne is set, and then -1 is returned

function SearchFieldEquals(const Value: RawUTF8; FieldIndex: integer; StartRow: integer=1; CaseSensitive: boolean=false): integer; overload;

Search for a value inside the raw table data, using UTF8IComp/StrComp()
- returns 0 if not found, or the matching Row number otherwise

function SearchFieldEquals(Value: PUTF8Char; FieldIndex: integer; StartRow: integer=1; CaseSensitive: boolean=false): integer; overload;

Search for a value inside the raw table data, using UTF8IComp/StrComp()
- returns 0 if not found, or the matching Row number otherwise

function SearchFieldIdemPChar(const Value: RawUTF8; FieldIndex: integer; StartRow: integer=1): integer;

Search for a value inside the raw table data, using IdemPChar()
- returns 0 if not found, or the matching Row number otherwise

```
function SearchFieldSorted(const Value: RawUTF8; FieldIndex: integer;  
CustomCompare: TUTF8Compare=nil): integer; overload;
```

Search for a value using $O(\log(n))$ binary search of a sorted field

- here the content should have been previously sorted via Sort(), or CustomCompare should be defined, otherwise the SearchFieldEquals() slower $O(n)$ method is called
- returns 0 if not found, or the matching Row number otherwise

```
function SearchFieldSorted(Value: PUTF8Char; FieldIndex: integer; CustomCompare:  
TUTF8Compare=nil): integer; overload;
```

Search for a value using $O(\log(n))$ binary search of a sorted field

- here the content should have been previously sorted via Sort(), or CustomCompare should be defined, otherwise the SearchFieldEquals() slower $O(n)$ method is called
- returns 0 if not found, or the matching Row number otherwise

```
function SearchValue(const UpperValue: RawUTF8; StartRow, FieldIndex: integer;  
Client: TObject; Lang: TSynSoundExPronunciation=sndxNone; UnicodeComparison:  
boolean=false): integer; overload;
```

Search a text value inside the table data in a specified field

- the text value must already be uppercased 7-bits ANSI encoded
- return the Row on success, 0 on error
- search only in the content of FieldIndex data
- you can specify a Soundex pronunciation to use, or leave as sndxNone for standard case insensitive character match; aUpperValue can optional indicate a Soundex search, by preceding the searched text with % for English, %% for French or %%% for Spanish (only works with WinAnsi char set - i.e. code page 1252)
- if UnicodeComparison is set to TRUE, search will use low-level Windows API for Unicode-level conversion - it will be much slower, but accurate for the whole range of UTF-8 encoding
- if UnicodeComparison is left to FALSE, UTF-8 decoding will be done only if necessary: it will work only with standard western-occidental alphabet (i.e. WinAnsi - code page 1252), but it will be very fast

```
function SearchValue(const UpperValue: RawUTF8; StartRow: integer; FieldIndex:  
PInteger; Client: TObject; Lang: TSynSoundExPronunciation=sndxNone;  
UnicodeComparison: boolean=false): integer; overload;
```

Search a text value inside the table data in all fields

- the text value must already be uppercased 7-bits ANSI encoded
- return the Row on success, 0 on error
- search on all fields, returning field found in FieldIndex (if not nil)
- you can specify a Soundex pronunciation to use, or leave as sndxNone for standard case insensitive character match; aUpperValue can optional indicate a Soundex search, by preceding the searched text with % for English, %% for French or %%% for Spanish (only works with WinAnsi char set - i.e. code page 1252)
- if UnicodeComparison is set to TRUE, search will use low-level Windows API for Unicode-level conversion - it will be much slower, but accurate for the whole range of UTF-8 encoding
- if UnicodeComparison is left to FALSE, UTF-8 decoding will be done only if necessary: it will work only with standard western-occidental alphabet (i.e. WinAnsi - code page 1252), but it will be very fast

```
function SortCompare(Field: integer): TUTF8Compare;
```

Get the appropriate Sort comparison function for a field, nil if not available (bad field index or field is blob)

- field type is guessed from first data row

function Step(SeekFirst: boolean=false; RowVariant: PVariant=nil): boolean;

After a TSQLTable has been initialized, this method can be called one or more times to iterate through all data rows

- you shall call this method before calling FieldBuffer()/Field() methods
- return TRUE on success, with data ready to be retrieved by Field*()
- return FALSE if no more row is available (i.e. exceeded RowCount)
- if SeekFirst is TRUE, will put the cursor on the first row of results, otherwise, it will fetch one row of data, to be called within a loop
- you can specify a variant instance (e.g. allocated on the stack) in optional RowVariant parameter, to access field values using late binding
- typical use may be:

```
while TableCustomers.Step do
  writeln(Field('name'));
```

- or, when using a variant and late-binding:

```
var customer: variant;
...
while TableCustomers.Step(false,@customer) do
  writeln(customer.Name);
```

function ToObjArray(var ObjArray; RecordType: TSQLRecordClass=nil): boolean;

*Fill an existing T*ObjArray variable with TSQLRecord instances corresponding to this TSQLTable result set*

- use the specified TSQLRecord class or create instances of the first associated record class (from internal QueryTables[])
- returns TRUE on success (even if ObjArray=[]), FALSE on error

function ToObjectList(RecordType: TSQLRecordClass=nil): TObjectList; overload;

Create a TObjectList with TSQLRecord instances corresponding to this TSQLTable result set

- use the specified TSQLRecord class or create instances of the first associated record class (from internal QueryTables[])
- always returns an instance, even if the TSQLTable is nil or void

procedure Assign(source: TSQLTable);

Copy the parameters of a TSQLTable into this instance

- the fResults remain in the source TSQLTable: source TSQLTable has not to be destroyed before this TSQLTable

procedure FieldIndexExisting(const FieldNames: array of RawUTF8; const FieldIndexes: array of PInteger); overload;

Get the Field indexes of several Field names

- raise an ESQLTableException if not found
- set FieldIndexes[]^ to the index (0..FieldCount-1) if found
- could be used to speed-up field access in a TSQLTable loop, avoiding a FieldIndex(aFieldName) lookup for each value, as such:

```
list := TSQLTableJSON.Create('',pointer(json),length(json));
list.FieldIndexExisting(
  ['FirstName','LastName','YearOfBirth','YearOfDeath','RowID','Data'],
  [@FirstName,@LastName,@YearOfBirth,@YearOfDeath,@RowID,@Data]);
for i := 1 to list.RowCount do begin
  Check(list.Get(i,FirstName)<>nil);
  Check(list.Get(i,LastName)<>nil);
  Check(list.GetAsInteger(i,YearOfBirth)<10000);
```

procedure FieldLengthMeanIncrease(aField, aIncrease: integer);

Increase a particular Field Length Mean value

- to be used to customize the field appearance (e.g. for adding of left checkbox for Marked[] fields)

procedure GetAsVariant(row, field: integer; out value: variant;
expandTimeLogAsText, expandEnumsAsText, expandHugeIDsAsUniqueIdentifier: boolean;
options: TDocVariantOptions=JSON_OPTIONS_FAST);

Retrieve a field value in a variant

- returns null if the row/field is incorrect
- expand* methods will allow to return human-friendly representations

procedure GetCSVValues(Dest: TStream; Tab: boolean; CommaSep: AnsiChar=','; AddBOM:
boolean=false; RowFirst: integer=0; RowLast: integer=0); overload;

Save the table as CSV format, into a stream

- if Tab=TRUE, will use TAB instead of ',' between columns
- you can customize the ',' separator - use e.g. the global ListSeparator variable (from SysUtils) to reflect the current system definition (some country use ',' as decimal separator, for instance our "douce France")
- AddBOM will add a UTF-8 Byte Order Mark at the beginning of the content

procedure GetHTMLTable(Dest: TTextWriter); overload;

Append the table content as a HTML <table> ... </table>

procedure GetJSONValues(JSON: TStream; Expand: boolean; RowFirst: integer=0;
RowLast: integer=0; IDBinarySize: integer=0); overload;

Same as the overloaded method, but appending an array to a TStream

Used for DI-2.1.2 (page 2555).

procedure GetJSONValues(W: TJSONWriter; RowFirst: integer=0; RowLast: integer=0;
IDBinarySize: integer=0); overload;

{ \$ifdef HASINLINE } inline; { \$endif } won't reset docarray as required save the table values in JSON format

- JSON data is added to TJSONWriter, with UTF-8 encoding, and not flushed
- if Expand is true, JSON data is an array of objects, for direct use with any Ajax or .NET client:
[{ "col1": val11, "col2": "val12" }, { "col1": val21, ... }]
- if W.Expand is false, JSON data is serialized (used in TSQLTableJSON)
{ "fieldCount": 1, "values": ["col1", "col2", val11, "val12", val21, ...] }

- RowFirst and RowLast can be used to ask for a specified row extent of the returned data (by default, all rows are retrieved)

- IDBinarySize will force the ID field to be stored as hexadecimal text

Used for DI-2.1.2 (page 2555).

procedure GetMSRowSetValues(Dest: TStream; RowFirst, RowLast: integer); overload;

Save the table in 'schemas-microsoft-com:rowset' XML format

- this format is used by ADODB.recordset, easily consumed by MS apps
- see @<https://synopse.info/forum/viewtopic.php?pid=11691#p11691>

procedure GetVariant(Row,Field: integer; var result: variant); overload;

Read-only access to a particular field value, as a Variant

- text will be stored as RawUTF8 (as varString type)
- will try to use the most appropriate Variant type for conversion (will use e.g. TDateTime for sftDateTime, or a TDocVariant for JSON objects in a sftVariant column) - so you should better set the exact field types (e.g. from ORM) before calling this method

procedure IDArrayFromBits(const Bits; var IDs: TIDDynArray);

Get all IDs where individual bit in Bits are set

procedure IDArrayToBits(var Bits; var IDs: TIDDynArray);

Get all individual bit in Bits corresponding to the supplied IDs

- warning: IDs integer array will be sorted within this method call

procedure IDColumnHiddenValues(var IDs: TIDDynArray);

Return all (previously hidden) ID values

procedure SetFieldLengthMean(const Lengths: array of cardinal);

Force the mean of characters length for every field

- expect as many parameters as fields in this table
- override internal fFieldLengthMean[] and fFieldLengthMeanSum values

procedure SetFieldType(const FieldName: RawUTF8; FieldType: TSQLFieldType; FieldTypeInfo: pointer=nil; FieldSize: integer=-1); overload;

Set the exact type of a given field

- by default, column types and sizes will be retrieved from JSON content from first row, or all rows if FieldTypeIntegerDetectionOnAllRows is set
- you can define a specific type for a given column, and optionally a maximum column size
- FieldTypeInfo can be specified for sets or enumerations, as such:
 aTable.SetFieldType('Sample',sftEnumerate,TypeInfo(TEnumSample));
 aTable.SetFieldType('Samples',sftSet,TypeInfo(TSetSamples));

procedure SetFieldType(Field: integer; FieldType: TSQLFieldType; FieldTypeInfo: pointer=nil; FieldSize: integer=-1; FieldTableIndex: integer=-1); overload;

Set the exact type of a given field

- by default, column types and sizes will be retrieved from JSON content from first row, or all rows if FieldTypeIntegerDetectionOnAllRows is set
- you can define a specific type for a given column, and optionally a maximum column size
- FieldTypeInfo can be specified for sets or enumerations, as such:
 aTable.SetFieldType(0,sftEnumerate,TypeInfo(TEnumSample));
 aTable.SetFieldType(1,sftSet,TypeInfo(TSetSamples));

or for dynamic arrays

procedure SetFieldTypes(const DBTypes: TSQLDBFieldTypeDynArray);

Set the exact type of all fields, from the DB-like information

procedure SortBitsFirst(var Bits);

Sort result Rows, according to the Bits set to 1 first

procedure SortFields(const Fields: array of integer; const Asc: array of boolean;
 const CustomCompare: array of TUTF8Compare); overload;

Sort result Rows, according to some specific fields

- is able to make multi-field sort
- both Fields[] and Asc[] arrays should have the same count, otherwise default Asc[]=true value will be assumed
- set any Fields[]=-1 to identify the ID column (even if is hidden)
- if CustomCompare=[], which use the default comparison function for the field type, unless you set as many custom comparison function items as in the Fields[] and Asc[] parameters

procedure SortFields(const FieldName: RawUTF8; Asc: boolean=true; PCurrentRow:
 PInteger=nil; FieldType: TSQLFieldType=sftUnknown; CustomCompare:
 TUTF8Compare=nil); overload;

Sort result Rows, according to a specific field

- overloaded method allowing to specify the field by its name

procedure SortFields(Field: integer; Asc: boolean=true; PCurrentRow: PInteger=nil;
 FieldType: TSQLFieldType=sftUnknown; CustomCompare: TUTF8Compare=nil); overload;

Sort result Rows, according to a specific field

- default is sorting by ascending order (Asc=true)
- you can specify a Row index to be updated during the sort in PCurrentRow
- sort is very fast, even for huge tables (more faster than any indexed SQL query): 500,000 rows are sorted instantly
- this optimized sort implementation does the comparison first by the designed field, and, if the field value is identical, the ID value is used (it will therefore sort by time all identical values)

procedure ToDocVariant(Row: integer; out doc: variant; options:
 TDocVariantOptions=JSON_OPTIONS_FAST; expandTimeLogAsText: boolean=false;
 expandEnumsAsText: boolean=false; expandHugeIDAsUniqueIdentifier: boolean=false);
 overload;

Retrieve a row value as a variant, ready to be accessed via late-binding

- Row parameter numbering starts from 1 to RowCount
- this method will return a TDocVariant containing a copy of all field values of this row, uncoupled to the TSQLTable instance life time
- expand* methods will allow to return human-friendly representations

procedure ToDocVariant(out docs: TVariantDynArray; readonly: boolean); overload;

Retrieve all row values as a dynamic array of variants, ready to be accessed via late-binding

- if readonly is TRUE, will contain an array of TSQLTableRowVariant, which will point directly to the TSQLTable, which should remain allocated
- if readonly is FALSE, will contain an array of TDocVariant, containing a copy of all field values of this row, uncoupled to the TSQLTable instance
- readonly=TRUE is faster to allocate (around 4 times for 10,000 rows), but may be slightly slower to access than readonly=FALSE, if all values are likely be accessed later in the process

procedure ToDocVariant(out docarray: variant; readonly: boolean); overload;

Retrieve all row values as a TDocVariant of kind dvArray, ready to be accessed via late-binding

- if readonly is TRUE, will contain an array of TSQLTableRowVariant, which will point directly to the TSQLTable, which should remain allocated
- if readonly is FALSE, will contain an array of TDocVariant, containing a copy of all field values of this row, uncoupled to the TSQLTable instance
- readonly=TRUE is faster to allocate (around 4 times for 10,000 rows), but may be slightly slower to access than readonly=FALSE, if all values are likely be accessed later in the process

procedure ToObjectList(DestList: TObjectList; RecordType: TSQLRecordClass=nil); overload;

Fill an existing TObjectList with TSQLRecord instances corresponding to this TSQLTable result set

- use the specified TSQLRecord class or create instances of the first associated record class (from internal QueryTables[])

property FieldCount: integer read fFieldCount;

Read-only access to the number of fields for each Row in this table

property FieldIndexID: integer read fFieldIndexID;

Read-only access to the ID/RowID field index

- do not use this property if the ID column has been hidden, but use IDColumnHiddenValue() method instead

property FieldTypeIntegerDetectionOnAllRows: boolean read fFieldTypeAllRows write fFieldTypeAllRows;

By default, if field types are not set, only the content of the first row will be checked, to make a difference between a sftInteger and sftFloat

- you can set this property to TRUE so that all non string rows will be checked for the exact number precision
- note that the safest is to provide the column type, either by supplying the TSQLRecord class, or by calling SetFieldType() overloaded methods

property InternalState: cardinal read fInternalState write fInternalState;

This property contains the internal state counter of the server database when the data was retrieved from it

- can be used to check if retrieved data may be out of date

property OnExportValue: TOnSQLTableGetValue read fOnExportValue write fOnExportValue;

Used by GetJsonValues, GetHtmlTable and GetCSVValues methods to export custom JSON content

property OwnerMustFree: Boolean read fOwnerMustFree write fOwnerMustFree;

If the TSQLRecord is the owner of this table, i.e. if it must free it

property QuerySQL: RawUTF8 read fQuerySQL;

Contains the associated SQL statement on Query

property QueryTableNameFromSQL: RawUTF8 read GetQueryTableNameFromSQL;

Returns the SQL Table name, guessed from the associated QuerySQL statement

property QueryTables: TSQLRecordClassDynArray read fQueryTables;

Contains the associated record class on Query

property RowCount: integer **read** GetRowCount;

Read-only access to the number of data Rows in this table

- first row contains field name
- then 1..RowCount rows contain the data itself
- safely returns 0 if the TSQLTable instance is nil

property StepRow: integer **read** fStepRow;

Read-only access to the current Row number, after a Step() call

- contains 0 if accessed outside valid Step() sequence call
- contains 1..RowCount after a valid Step() iteration

TSQLTableRowVariantData = packed record

Memory structure used for our TSQLTableRowVariant custom variant type used to have direct access to TSQLTable content

- the associated TSQLTable must stay allocated as long as this variant is used, otherwise random GPF issues may occur

VRow: integer;

The row number corresponding to this value

- equals -1 if should follow StepRow property value

VTable: TSQLTable;

Reference to the associated TSQLTable

VType: TVarType;

The custom variant type registered number

TSQLTableRowVariant = class(TSynInvokeableVariantType)

A custom variant type used to have direct access to TSQLTable content

- use TSQLTable.Step(..,@Data) method to initialize such a Variant
- the variant members/fields are read-only by design
- the associated TSQLTable must stay allocated as long as this variant is used, otherwise random GPF issues may occur

procedure Cast(**var** Dest: TVarData; **const** Source: TVarData); **override;**

Handle type conversion to string

procedure CastTo(**var** Dest: TVarData; **const** Source: TVarData; **const** AVarType: TVarType); **override;**

Handle type conversion to string

procedure ToJSON(W: TTextWriter; **const** Value: **variant**; Escape: TTextWriterKind); **override;**

Customization of variant into JSON serialization

TObjectVariant = class(TSynInvokeableVariantType)

A custom variant type used to have direct access to object published properties

- TObjectVariant provides lazy-loading to object properties from a Variant variable - which may be used with SynMustache or with late-binding
- warning: this custom variant is just a wrapper around an existing TObject instance, which should remain available as long as the variant is used
- if you want a per-representation stateless variant, use ObjectToVariant() which convert all properties into a TDocVariant, so may use more resource

class procedure New(**var** V: **Variant**; Obj: TObject);

Initialize a new custom variant instance, wrapping the specified object

- warning: this custom variant is just a wrapper around an existing TObject instance, which should remain available as long as the variant is used

procedure ToJSON(W: TTextWriter; **const** Value: **variant**; Escape: TTextWriterKind);
override;

Will perform proper JSON serialization calling W.WriteObject()

TSQLTableJSON = class(TSQLTable)

Store a read-only ORM result table from a JSON message

- the JSON data is parsed and unescaped in-place, to enhanced performance and reduce resource consumption (mainly memory/heap fragmentation)
- is used by the ORM for TSQLRecord.FillPrepare/FillOne methods for fast access to individual object values

Used for DI-2.1.1 (page 2553), DI-2.1.2 (page 2555).

constructor Create(**const** aSQL, aJSON: RawUTF8); **reintroduce**; **overload**;

Create the result table from a JSON-formated Data message

- the JSON data is parsed and formatted in-place, after having been copied in the protected fPrivateCopy variable

Used for DI-2.1.2 (page 2555).

constructor Create(**const** aSQL: RawUTF8; JSONBuffer: PUTF8Char; JSONBufferLen: integer); **reintroduce**; **overload**;

Create the result table from a JSON-formated Data message

- the JSON data is parsed and formatted in-place
- please note that the supplied JSON buffer content will be changed: if you want to reuse this JSON content, you shall make a private copy before calling this constructor and you shall NOT release the corresponding variable (fResults/JSONResults[] will point inside this memory buffer): use instead the overloaded Create constructor expecting a **const** aJSON: RawUTF8 parameter to allocate and hold a private copy of the data

Used for DI-2.1.2 (page 2555).

constructor CreateFromTables(const Tables: array of TSQLRecordClass; const aSQL, aJSON: RawUTF8); reintroduce; overload;

Create the result table from a JSON-formated Data message

- you can specify a set of TSQLRecord classes which will be used to retrieve the column exact type information
- the JSON data is parsed and formatted in-place, after having been copied in the protected fPrivateCopy variable

constructor CreateFromTables(const Tables: array of TSQLRecordClass; const aSQL: RawUTF8; JSONBuffer: PUTF8Char; JSONBufferLen: integer); reintroduce; overload;

Create the result table from a JSON-formated Data message

- the JSON data is parsed and formatted in-place
- you can specify a set of TSQLRecord classes which will be used to retrieve the column exact type information
- please note that the supplied JSON buffer content will be changed

constructor CreateWithColumnTypes(const ColumnTypes: array of TSQLFieldType; const aSQL, aJSON: RawUTF8); reintroduce; overload;

Initialize the result table from a JSON-formated Data message

- you can set the expected column types matching the results column layout
- the JSON data is parsed and formatted in-place, after having been copied in the protected fPrivateCopy variable

constructor CreateWithColumnTypes(const ColumnTypes: array of TSQLFieldType; const aSQL: RawUTF8; JSONBuffer: PUTF8Char; JSONBufferLen: integer); reintroduce; overload;

Initialize the result table from a JSON-formated Data message

- you can set the expected column types matching the results column layout
- the JSON data is parsed and formatted in-place

function UpdateFrom(const aJSON: RawUTF8; var Refreshed: boolean; PCurrentRow: PInteger): boolean;

Update the result table content from a JSON-formated Data message

- return true on parsing success, false if no valid JSON data was found
- set Refreshed to true if the content changed
- update all content fields (fResults[], fRowCount, fFieldCount, etc...)
- call SortFields() or IDCColumnHide if was already done for this TSQLTable
- the conversion into PPUTF8CharArray is made inplace and is very fast (only one memory buffer is allocated for the whole data)

Used for DI-2.1.2 (page 2555).

property PrivateInternalCopy: RawUTF8 read fPrivateCopy;

The private copy of the processed data buffer

- available e.g. for Create constructor using aJSON parameter, or after the UpdateFrom() process
- 16 more bytes will be allocated, to allow e.g. proper SSE4.2 process
- this buffer is not to be access directly: this won't be a valid JSON content, but a processed buffer, on which fResults[] elements point to - it will contain unescaped text and numerical values, ending with #0

TSQLTableWritable = class(TSQLTableJSON)

Store a writable ORM result table, optionally read from a JSON message

- in respect to TSQLTableJSON, this class allows to modify field values, and add some new fields on the fly, even joined from another TSQLTable

function AddField(**const** FieldName: RawUTF8; FieldType: TSQLFieldType;
 FieldTypeInfo: pointer=nil; FieldSize: integer=-1): integer; overload;

Define a new field to be stored in this table

- returns the internal index of the newly created field

function AddField(**const** FieldName: RawUTF8): integer; overload;

Define a new field to be stored in this table

- returns the internal index of the newly created field

function AddField(**const** FieldName: RawUTF8; FieldTable: TSQLRecordClass; **const**
 FieldTableName: RawUTF8=''): integer; overload;

Define a new field to be stored in this table

- returns the internal index of the newly created field

procedure Join(From: TSQLTable; **const** FromKeyField, KeyField: RawUTF8);

Append/merge data from a secondary TSQLTable

- you should specify the primary keys on which the data rows are merged

- merged data will point to From.fResults[] content: so the From instance should remain available as long as you use this TSQLTableWritable

- warning: will call From.SortFields(FromKeyField) for faster process

procedure Update(Row: integer; **const** FieldName, Value: RawUTF8); overload;

Modify a field value in-place, using a RawUTF8 text value

procedure Update(Row,Field: integer; **const** Value: RawUTF8); overload;

Modify a field value in-place, using a RawUTF8 text value

procedure Update(Row: integer; **const** FieldName: RawUTF8; **const** Value: variant);
 overload;

Modify a field value in-place, using a variant value

procedure Update(Row,Field: integer; **const** Value: variant); overload;

Modify a field value in-place, using a variant value

property NewValuesCount: integer **read** fNewValuesCount;

How many values have been written via Update() overloaded methods

- is not used if NewValuesInterning was defined

property NewValuesInterning: TRawUTF8Interning **read** fNewValuesInterning **write**
 fNewValuesInterning;

Optionally de-duplicate Update() values

TSQLLocks = object(TObject)

Used to store the locked record list, in a specified table

- the maximum count of the locked list is fixed to 512 by default, which seems correct for common usage

Count: integer;

The number of locked records stored in this object

IDs: TIDDynArray;

Contains the locked record ID

- an empty position is marked with 0 after UnLock()

Ticks64s: TInt64DynArray;

Contains the time and date of the lock

- filled internally by the fast GetTickCount64() function (faster than TDateTime or TSystemTime/GetLocalTime)

- used to purge to old entries - see PurgeOlderThan() method below

function IsLocked(aID: TID): boolean;

Return true if a record, specified by its ID, is locked

function Lock(aID: TID): boolean;

Lock a record, specified by its ID

- returns true on success, false if was already locked

function UnLock(aID: TID): boolean;

Unlock a record, specified by its ID

- returns true on success, false if was not already locked

procedure PurgeOlderThan(MinutesFromNow: cardinal=30);

Delete all the locked IDs entries, after a specified time

- to be used to release locked records if the client crashed

- default value is 30 minutes, which seems correct for common database usage

TSQLQueryCustom = record

Store one custom query parameters

- add custom query by using the TSQLRest.QueryAddCustom() method

- use EnumType^.GetCaption(EnumIndex) to retrieve the caption associated to this custom query

EnumIndex: integer;

The associated enumeration index in EnumType

- will be used to fill the Operator parameter for the Event call

EnumType: PEnumType;

The associated enumeration type

Event: TSQLQueryEvent;

The associated evaluation Event handler

- the Operator parameter will be filled with the EnumIndex value

Operators: TSQLQueryOperators;

User Interface Query action operators

TSQLRibbonTabParameters = object(TObject)

Defines the settings for a Tab for User Interface generation

- used in mORMotToolBar.pas unit and TSQLModel.Create() overloaded method
- is defined as an object and not a record to allow easy inheritance for proper per-application customization - see e.g. FileTables.pas in main demo

AutoRefresh: boolean;

By default, the screens are not refreshed automatically

- but you can enable the auto-refresh feature by setting this property to TRUE, and creating a WM_TIMER message handler for the form, which will handle both WM_TIMER_REFRESH_SCREEN and WM_TIMER_REFRESH_REPORT timers:

```
procedure TMainForm.WMRefreshTimer(var Msg: TWMTimer);
begin
  Ribbon.WMRefreshTimer(Msg);
end;
```

CustomCaption: PResStringRec;

The caption of the Tab, to be translated on the screen

- by default, Tab name is taken from TSQLRecord.Caption(nil) method
- but you can override this value by setting a pointer to a resourcestrings

CustomHint: PResStringRec;

The hint type of the Tab, to be translated on the screen

- by default, hint will replace all %s instance by the Tab name, as taken from TSQLRecord.Caption(nil) method
- but you can override this value by setting a pointer to a resourcestrings

EditExpandFieldHints: boolean;

Write hints above field during the edition of this table

- if EditExpandFieldHints is TRUE, the hints are written as text on the dialog, just above the field content; by default, hints are displayed as standard delayed popup when the mouse hover the field editor

EditFieldHints: PResStringRec;

The associated hints to be displayed during the edition of this table

- every field hint must be separated by a '|' character (e.g. 'The First Name|Its Company Name')
- all fields need to be listed in this text resource, even if it won't be displayed on screen (enter a void item like |)
- you can define some value by setting a pointer to a resourcestrings

EditFieldHintsToReport: boolean;

If the default report must contain the edit field hints

- i.e. if the resourcestrings pointed by EditFieldHints must be used to display some text above every property value on the reports

EditFieldNameToHideCSV: RawUTF8;

A CSV list of field names to be hidden in both editor and default report

- handy to hide fields containing JSON data or the name of another sftRecord/sftID/sftTID (i.e. TRecordReference/TSQLRecord props) fields
- list is to be separated by commas (e.g. "RunLogJSON,OrdersJSON" or "ConnectionName")

EditFieldNameWidth: integer;

The associated field name width (in pixels) to be used for creating the edition dialog for this table

FieldWidth: RawUTF8;

*Displayed field length mean, one char per field (A=1,Z=26)
- put lowercase character in order to center the field data*

Group: integer;

Tab Group number (index starting at 0)

Layout: TSQLListLayout;

Layout of the List, below the ribbon

ListWidth: integer;

*Width of the List, in percent of the client area
- default value (as stated in TSQLRibbonTab.Create) is 30%*

NoReport: boolean;

*By default, the detail are displayed as a report (TGDIPages component)
- set this property to true to customize the details display
- this property is ignored if Layout is IIClient (i.e. details hidden)*

OrderFieldIndex: integer;

Index of field used for displaying order

ReverseOrder: boolean;

If set, the list is displayed in reverse order (i.e. decreasing)

Select: RawUTF8;

SQL fields to be displayed on the data lists 'ID,' is always added at the beginning

ShowID: boolean;

If set, the ID column is shown

Table: TSQLRecordClass;

The Table associated to this Tab

TSQLRecordVirtual = class(TSQLRecord)

Parent of all virtual classes

- you can define a plain TSQLRecord class as virtual if needed - e.g. inheriting from TSQLRecordMany then calling VirtualTableExternalRegister() - but using this class will seal its state to be virtual

TSQLModelRecordPropertiesSQL = record

Pre-computed SQL statements for ORM operations for a given TSQLModelRecordProperties instance

InsertSet: RawUTF8;

*All fields, excluding the ID field, exposed as 'COL1,COL2'
- to be used e.g. in TSQLVirtualTableExternal.Insert()*

SelectAllJoined: RawUTF8;

The JOINed SQL statement for reading all fields with ID, including nested TSQLRecord pre-allocated instances
 - is " if there is no nested TSQLRecord

SelectAllWithID: RawUTF8;

The SQL statement for reading all simple fields with ID
 - to be checked if we may safely call EngineList()

SelectAllWithRowID: RawUTF8;

The SQL statement for reading all simple fields and RowID
 - to be checked if we may safely call EngineList()

TableSimpleFields: array[boolean,boolean] of RawUTF8;

The simple field names in a SQL SELECT compatible format: 'COL1,COL2' e.g.

- format is

SQL.TableSimpleFields[withID: boolean; withTableName: boolean]

- returns '*' if no field is of TSQLRawBlob/TSQLRecordMany kind
- returns 'COL1,COL2' with all COL* set to simple field names if withID is false
- returns 'ID,COL1,COL2' with all COL* set to simple field names if withID is true
- returns 'Table.ID,Table.COL1,Table.COL2' if withTableName and withID are true

UpdateSetAll: RawUTF8;

All updated fields exposed as 'COL1=?,COL2=?'
 - excluding ID (but including TCreateTime fields - as used in TSQLVirtualTableExternal.Update method)
 - to be used e.g. for UPDATE statements

UpdateSetSimple: RawUTF8;

The updated simple fields exposed as 'COL1=?,COL2=?'
 - excluding ID (but including TCreateTime fields - as used in TSQLVirtualTableExternal.Update method)
 - to be used e.g. for UPDATE statements

TSQLRecordPropertiesMapping = object(TObject)

Allow custom field mapping of a TSQLRecord

- used e.g. for external database process, including SQL generation, as implemented in the mORMotDB.pas unit
- in end user code, mostly MapField/MapFields/Options methods should be used, if needed as a fluent chained interface - other lower level methods will be used by the framework internals

function AppendFieldName(FieldIndex: Integer; var Text: RawUTF8): boolean;

Append a field name to a RawUTF8 Text buffer

- if FieldIndex=VIRTUAL_TABLE_ROWID_COLUMN (-1), appends RowIDFieldName
- on error (i.e. if FieldIndex is out of range) will return TRUE
- otherwise, will return FALSE and append the external field name to Text

function ExternalToInternalIndex(**const** ExtFieldName: RawUTF8): integer;

Map an external field name into its internal field index

- returns the index ≥ 0 in FieldNames[] for a matching external field
- returns -1 if the field name is RowIDFieldName
- returns -2 if the field name is not mapped

function ExternalToInternalOrNull(**const** ExtFieldName: RawUTF8): RawUTF8;

Map an external field name into its internal field name

- return '' if the external field name is not RowIDFieldName nor in FieldNames[]

function FieldNameByIndex(FieldIndex: Integer): RawUTF8;

Return the field name as RawUTF8 value

- if FieldIndex=VIRTUAL_TABLE_ROWID_COLUMN (-1), appends RowIDFieldName
- otherwise, will return the external field name

function InternalCSVToExternalCSV(**const** CSVFieldNames: RawUTF8; **const** Sep: RawUTF8=','; **const** SepEnd: RawUTF8='') : RawUTF8;

Map a CSV list of field names from its internals to its externals values

- raise an EORMException if any of the supplied field name is not defined in the TSQLRecord as ID or as property (RowIDFieldName or FieldNames[])
- to be used for a simple CSV (e.g. for INSERT/SELECT statements):
 ExtCSV := InternalCSVToExternalCSV('ID,Name');
- or for a more complex CSV (e.g. for UPDATE statements):
 ExtCSV := InternalCSVToExternalCSV('ID=?,Name=?','=?','=?');

function InternalToExternal(**const** FieldName: RawUTF8): RawUTF8;

Map a field name from its internal name to its external name

- raise an EORMException if the supplied field name is not defined in the TSQLRecord as ID or a published property

function MapAutoKeywordFields: PSQLRecordPropertiesMapping;

Call this method to ensure that all fields won't conflict with a SQL keyword for the given database

- by default, no check is performed: you can use this method to ensure that all field names won't conflict with a SQL reserved keyword: such fields will be identified and automatically mapped as fieldname_
- can be used e.g. as

```
aModel.Props[TSQMyExternal].ExternalDB.  
  MapField('IntField','ExtField').  
  MapAutoKeywordFields;
```
- will in fact include the rpmAutoMapKeywordFields flag in Options
- since it returns a PSQLRecordPropertiesMapping instance, you can chain
 MapField().MapAutoKeywordFields.MapField(); calls to map several fields

```
function MapField(const InternalName, ExternalName: RawUTF8):  
PSQLRecordPropertiesMapping;
```

Add a custom field mapping

- will re-compute all needed SQL statements as needed, and initialize fSortedFieldsName[] and fSortedFieldsIndex[] internal sorted arrays
- can be used e.g. as
aModel.Props[TSQMyExternal].ExternalDB.MapField('IntField', 'ExtField');
- since it returns a PSQLRecordPropertiesMapping instance, you can chain MapField().MapField().MapField(); calls to map several fields

```
function MapFields(const InternalExternalPairs: array of RawUTF8):  
PSQLRecordPropertiesMapping;
```

Add several custom field mappings

- can be used e.g. as
aModel.Props[TSQMyExternal].ExternalDB.
MapFields(['IntField1', 'ExtField1', 'IntField2', 'ExtField2']);
- will re-compute all needed SQL statements as needed, and initialize fSortedFieldsName[] and fSortedFieldsIndex[] internal sorted arrays
- is slightly faster than several chained MapField() calls, since SQL will be computed only once

```
function SetOptions(aOptions: TSQLRecordPropertiesMappingOptions):  
PSQLRecordPropertiesMapping;
```

Specify some advanced options for the field mapping

- see TSQLRecordPropertiesMappingOptions for all possibilities
- can be used e.g. as
aModel.Props[TSQMyExternal].ExternalDB.
MapField('IntField', 'ExtField').
SetOptions([rpmNoCreateMissingTable, rpmNoCreateMissingField]);
- since it returns a PSQLRecordPropertiesMapping instance, you can chain MapField().SetOptions().MapField(); calls to map several fields

```
procedure Init(Table: TSQLRecordClass; const MappedTableName: RawUTF8;  
MappedConnection: TObject; AutoComputeSQL: boolean; MappingOptions:  
TSQLRecordPropertiesMappingOptions);
```

Initialize the field mapping for a given TSQLRecord

- if AutoComputeSQL is true, will pre-compute all needed SQL from the supplied information
- will left void fSortedFieldsName[] and fSortedFieldsIndex[], to disable custom field mapping

```
procedure InternalToExternalDynArray(const IntFieldNames: array of RawUTF8; out  
result: TRawUTF8DynArray; IntFieldIndex: PIntegerDynArray=nil);
```

Create a list of external field names, from the internal field names

- raise an EORMException if any of the supplied field name is not defined in the TSQLRecord as ID or a published property
- if IntFieldIndex is set, it will store an array of internal field indexes, i.e. -1 for ID or index in in FieldNames[] for other fields

property ConnectionProperties: TObject read fConnectionProperties;

Opaque object used on the Server side to specify e.g. the DB connection

- will define such a generic TObject, to avoid any unnecessary type dependency to other units, e.g. the SynDB unit in mORMot.pas
- in practice, will be assigned by VirtualTableExternalRegister() to a TSQLDBConnectionProperties instance in mORMotDB.pas, or by StaticMongoDBRegister() to a TMongoCollection instance, or by TDDDRepositoryRestObjectMapping.Create to its associated TSQLRest

- in ORM context, equals nil if the table is internal to SQLite3:

```
if Server.Model.Props[TSQLArticle].ExternalDB.ConnectionProperties=nil then
  // this is not an external table, since Init() was not called
```

property ExtFieldNames: TRawUTF8DynArray read fExtFieldNames;

The external field names, following fProps.Props.Field[] order

- excluding ID/RowID field, which is stored in RowIDFieldName

property ExtFieldNamesUnQuotedSQL: TRawUTF8DynArray read fExtFieldNamesUnQuotedSQL;

The unquoted external field names, following fProps.Props.Field[] order

- excluding ID/RowID field, which is stored in RowIDFieldName
- in respect to ExtFieldNames[], this array will never quote the field name

property FieldNamesMatchInternal: TSQLFieldBits read fFieldNamesMatchInternal;

Each bit set, following fProps.Props.Field[]+1 order (i.e. 0=ID, 1=Field[0], ...), indicates that this external field name has not been mapped

property MappingVersion: cardinal read fMappingVersion;

Each time MapField/MapFields is called, this number will increase

- can be used to track mapping changes in real time

property Options: TSQLRecordPropertiesMappingOptions read fOptions;

How the mapping process will take place

property Properties: TSQLRecordProperties read fProps;

The associated TSQLRecordProperties

property RowIDFieldName: RawUTF8 read fRowIDFieldName;

The ID/RowID customized external field name, if any

- is 'ID' by default, since 'RowID' is a reserved column name for some database engines (e.g. Oracle)

- can be customized e.g. via

```
aModel.Props[TSQLMyExternal].ExternalDB.MapField('ID', 'ExternalID');
```

property SQL: TSQLModelRecordPropertiesSQL read fSQL;

Pre-computed SQL statements for this external TSQLRecord in this model

- you can use those SQL statements directly with the external engine
- filled if AutoComputeSQL was set to true in Init() method

property TableName: RawUTF8 read fTableName;

Used on the Server side to specify the external DB table name

- e.g. for including a schema name or an existing table name, with an OleDB/MSSQL/Oracle/MySQL/PostgreSQL/Jet/SQLite3 backend
- equals SQLTableName by default (may be overridden e.g. by mORMotDB's VirtualTableExternalRegister procedure)

TSQLModelRecordProperties = class(TObject)

ORM properties associated to a TSQLRecord within a given model

- "stable" / common properties derived from RTTI are shared in the TSQLRecordProperties instance
- since the same TSQLRecord can be defined in several models, with diverse implementation patterns (e.g. internal in one, external in another), this class is used to regroup all model-specific settings, like SQL pre-generated patterns or external DB properties

ExternalDB: TSQLRecordPropertiesMapping;

Allow SQL process for one external TSQLRecord in this model

NoCreateMissingTable: boolean;

Will by-pass automated table and field creation for this TSQLRecord

- may be used e.g. when the TSQLRecord is in fact mapped into a View, or is attached as external table and not a real local table

SQL: TSQLModelRecordPropertiesSQL;

Pre-computed SQL statements for this TSQLRecord in this model

- those statements will work for internal tables, not for external tables with mapped table or fields names

constructor Create(aModel: TSQLModel; aTable: TSQLRecordClass; aKind: TSQLRecordVirtualKind);

Initialize the ORM properties from the TSQLRecord RTTI and the supplied TSQLModel

constructor CreateFrom(aModel: TSQLModel; aSource: TSQLModelRecordProperties);

Clone ORM properties from an existing TSQLModelRecordProperties to another model

function SQLFromSelectWhere(const SelectFields, Where: RawUTF8): RawUTF8;

Compute the SQL statement to be executed for a specific SELECT

- non simple fields (e.g. BLOBs) will be excluded if SelectFields='*'
- by default, will return the SELECT statement to be used for internal virtual SQLite3 table - but if ExternalTable is TRUE, then it will compute a SELECT matching ExternalDB settings

procedure FTS4WithoutContent(ContentTable: TSQLRecordClass);

Define if a FTS4 virtual table will not store its content, but will be defined as an "external content" FTS4 table

- see https://www.sqlite.org/fts3.html#section_6_2_2
- the virtual table will be created with content="ContentTableName", and all fields of the FTS4 table
- by design, all fields of the FTS4 table should exist in the source ContentTable - otherwise an exception is raised
- the indexed text will be assigned to the FTS4 table, using triggers generated by TSQLRecordFTS4.InitializeTable at table creation
- note that FTS3 does not support this feature

property Kind: TSQLRecordVirtualKind **read** fKind **write** SetKind **default** rSQLite3;

*Define if is a normal table (rSQLite3), an FTS/R-Tree virtual table or a custom TSQLVirtualTable*ID (rCustomForcedID/rCustomAutoID)*

- when set, all internal SQL statements will be (re)created, depending of the expected ID/RowID column name expected (i.e. SQLTableSimpleFields[] and SQLSelectAll[] - SQLUpdateSet and SQLInsertSet do not include ID)

property Prop[const PropName: RawUTF8]: TSQLPropInfo **read** GetProp;

Direct access to a property RTTI information, by name

property Props: TSQLRecordProperties **read** fProps;

The shared TSQLRecordProperties information of this TSQLRecord
 - as retrieved from RTTI

property TableIndex: Integer **read** fTableIndex;

The table index of this TSQLRecord in the associated Model

TSQLModelRecordReference = record

How a TSQLModel stores a foreign link to be cascaded

CascadeDelete: boolean;

TRUE if this field is a TRecordReferenceToBeDeleted

FieldTable: TSQLRecordClass;

The target TSQLRecordClass of the field

FieldTableIndex: integer;

The target TSQLRecordClass of the field, from its Tables[] index

FieldType: TSQLPropInfo;

The property

TableIndex: integer;

Refers to the source TSQLRecordClass as model Tables[] index

TSQLModel = class(TObject)

A Database Model (in a MVC-driven way), for storing some tables types as TSQLRecord classes

- share this Model between TSQLRest Client and Server
- use this class to access the table properties: do not rely on the low-level database methods (e.g. TSQLDataBase.GetTableNames), since the tables may not exist in the main SQLite3 database, but in-memory or external
- don't modify the order of Tables inside this Model, if you publish some TRecordReference property in any of your tables

constructor Create(CloneFrom: TSQLModel); reintroduce; overload;

Clone an existing Database Model

- all supplied classes won't be redefined as non-virtual: VirtualTableExternalRegister explicit calls are not mandatory here

constructor Create(Owner: TSQLRest; TabParameters: PSQLRibbonTabParameters; TabParametersCount, TabParametersSize: integer; const NonVisibleTables: array of TSQLRecordClass; Actions: PTypeInfo=nil; Events: PTypeInfo=nil; const aRoot: RawUTF8='root'); reintroduce; overload;

Initialize the Database Model from an User Interface parameter structure

- this constructor will reset all supplied classes to be defined as non-virtual (i.e. Kind=rSQLite3): VirtualTableExternalRegister explicit calls are to be made if tables should be managed as external

constructor Create(const Tables: array of TSQLRecordClass; const aRoot: RawUTF8='root'); reintroduce; overload;

Initialize the Database Model

- set the Tables to be associated with this Model, as TSQLRecord classes
- set the optional Root URI path of this Model
- initialize the flsUnique[] array from "stored AS_UNIQUE" (i.e. "stored false") published properties of every TSQLRecordClass

constructor Create; reintroduce; overload;

You should not use this constructor, but one of the overloaded versions, specifying the associated TSQLRecordClass

destructor Destroy; override;

Release associated memory

function ActionName(const Action): string;

Get the text conversion of a given Action, ready to be displayed

function AddTable(aTable: TSQLRecordClass; aTableIndexCreated: PInteger=nil): boolean;

Add the class if it doesn't exist yet

- return index in Tables[] if not existing yet and successfully added (in this case, aTableIndexCreated^ is set to the newly created index in Tables[])
- supplied class will be redefined as non-virtual: VirtualTableExternalRegister explicit call is to be made if table should be managed as external
- return FALSE if already present, or TRUE if was added to the internal list

function AddTableInherited(aTable: TSQLRecordClass): pointer;

Add the class if it doesn't exist yet as itself or as inherited class

- similar to AddTable(), but any class inheriting from the supplied type will be considered as sufficient

- return the class which has been added, or was already there as inherited, so that could be used for further instance creation:

```
fSQLAuthUserClass := Model.AddTableInherited(TSQLAuthUser);
```

function EventName(const Event): string;

Get the text conversion of a given Event, ready to be displayed

function GetIDGenerator(aTable: TSQLRecordClass): TSynUniqueIdentifierGenerator;

Returns the TSynUniqueIdentifierGenerator associated to a table, if any

function GetIsUnique(aTable: TSQLRecordClass; aFieldIndex: integer): boolean;

Return TRUE if the specified field of this class was marked as unique

- an unique field is defined as "stored AS_UNIQUE" (i.e. "stored false") in its property definition
- reflects the internal private flsUnique property

function GetSQLAddField(aTableIndex, aFieldIndex: integer): RawUTF8;

Return the UTF-8 encoded SQL source to add the corresponding field via a "ALTER TABLE" statement

function GetSQLCreate(aTableIndex: integer): RawUTF8;

Return the UTF-8 encoded SQL source to create the table

function GetTableIndex(const SQLTableName: RawUTF8): integer; overload;

Get the index of a table in Tables[]

- expects SQLTableName to be SQL-like formatted (i.e. without TSQL[Record])

function GetTableIndex(aTable: TSQLRecordClass): integer; overload;

Get the index of aTable in Tables[]

- returns -1 if the table is not in the model

function GetTableIndexesFromSQLSelect(const SQL: RawUTF8): TIntegerDynArray;

Try to retrieve one or several table index from a SQL statement

- naive search of '... FROM Table1,Table2' pattern in the supplied SQL, using
GetTableNamesFromSQLSelect() function

function GetTableIndexExisting(aTable: TSQLRecordClass): integer;

Get the index of aTable in Tables[]

- raise an EModelException if the table is not in the model

function GetTableIndexFromSQLSelect(const SQL: RawUTF8; EnsureUniqueTableInFrom: boolean): integer;

Try to retrieve a table index from a SQL statement

- naive search of '... FROM TableName' pattern in the supplied SQL, using
GetTableNameFromSQLSelect() function

- if EnsureUniqueTableInFrom is TRUE, it will check that only one Table is in the FROM clause, otherwise it will return the first Table specified

function GetTableIndexInheritsFrom(aTable: TSQLRecordClass): integer;

Get the index of any class inheriting from aTable in Tables[]
- returns -1 if no table is matching in the model

function GetTableIndexPtr(SQLTableName: PUTF8Char): integer;

Get the index of a table in Tables[]
- expects SQLTableName to be SQL-like formatted (i.e. without TSQL[Record])

function GetTableInherited(aTable: TSQLRecordClass): TSQLRecordClass;

Return any class inheriting from the given table in the model
- if the model does not contain such table, supplied aTable is returned

function GetTablesFromSQLSelect(const SQL: RawUTF8): TSQLRecordClassDynArray;

Try to retrieve one or several TSQLRecordClass from a SQL statement
- naive search of '... FROM Table1,Table2' pattern in the supplied SQL, using
GetTableNamesFromSQLSelect() function

function isLocked(aRec: TSQLRecord): boolean; overload;

Return true if a specified record is locked

function isLocked(aTable: TSQLRecordClass; aID: TID): boolean; overload;

Return true if a specified record is locked

function Lock(aTable: TSQLRecordClass; aID: TID): boolean; overload;

Lock a record
- returns true on success, false if was already locked

function Lock(aRec: TSQLRecord): boolean; overload;

Lock a record
- returns true on success, false if was already locked

function Lock(aTableIndex: integer; aID: TID): boolean; overload;

Lock a record
- returns true on success, false if was already locked

function NewRecord(const SQLTableName: RawUTF8): TSQLRecord;

Create a New TSQLRecord instance for a specific Table
- expects SQLTableName to be SQL-like formatted (i.e. without TSQL[Record])
- use this to create a working copy of a table's record, e.g.
- don't forget to Free it when not used any more (use a try...finally block)
- it's preferred in practice to directly call TSQLRecord*.Create() in your code

function RecordReference(Table: TSQLRecordClass; ID: TID): TRecordReference;

Return the TRecordReference pointing to the specified record

function RecordReferenceTable(const Ref: TRecordReference): TSQLRecordClass;

Return the table class correspondig to a TRecordReference

function SafeRoot: RawUTF8;

Returns the Root property, or "" if the instance is nil

```
function SetIDGenerator(aTable: TSQLRecordClass; aIdentifier:
TSynUniqueIdentifierProcess; const aSharedObfuscationKey: RawUTF8=''):
TSynUniqueIdentifierGenerator;
```

Force a given table to use a TSynUniqueIdentifierGenerator for its IDs

- will initialize a generator for the supplied table, using the given 16-bit process identifier
- you can supply an obfuscation key, which should be shared for the whole system, so that you may use FromObfuscated/ToObfuscated methods

```
function SQLFromSelectWhere(const Tables: array of TSQLRecordClass; const
SQLSelect, SQLWhere: RawUTF8): RawUTF8;
```

Compute the SQL statement to be executed for a specific SELECT on Tables

- you can set multiple Table class in Tables: the statement will contain the table name ('SELECT T1.F1,T1.F2,T1.F3,T2.F1,T2.F2 FROM T1,T2 WHERE ..' e.g.)

```
function UnLock(aTableIndex: integer; aID: TID): boolean; overload;
```

Unlock a specified record

- returns true on success, false if was not already locked

```
function UnLock(aTable: TSQLRecordClass; aID: TID): boolean; overload;
```

Unlock a specified record

- returns true on success, false if was not already locked

```
function UnLock(aRec: TSQLRecord): boolean; overload;
```

Unlock a specified record

- returns true on success, false if was not already locked

```
function URIMatch(const URI: RawUTF8): TSQLRestModelMatch;
```

Check if the supplied URI matches the model's Root property

- allows sub-domains, e.g. if Root='root/sub1', then '/root/sub1/toto' and '/root/sub1?n=1' will match, whereas '/root/sub1nope/toto' won't
- the returned enumerates allow to check if the match was exact (e.g. 'root/sub' matches exactly Root='root'), or with character case approximation (e.g. 'Root/sub' approximates Root='root')

```
function VirtualTableModule(aClass: TSQLRecordClass): TSQLVirtualTableClass;
```

Retrieve a Virtual Table module associated to a class

```
function VirtualTableRegister(aClass: TSQLRecordClass; aModule:
TSQLVirtualTableClass; const aExternalTableName: RawUTF8=''; aExternalDataBase:
TObject=nil; aMappingOptions: TSQLRecordPropertiesMappingOptions=[]): boolean;
```

Register a Virtual Table module for a specified class

- to be called server-side only (Client don't need to know the virtual table implementation details, and it will increase the code size)
- aClass parameter could be either a TSQLRecordVirtual class, either a TSQLRecord class which has its kind set to rCustomForcedID or rCustomAutoID (e.g. TSQLRecordMany calling VirtualTableExternalRegister)
- optional aExternalTableName, aExternalDataBase and aMappingOptions can be used to specify e.g. connection parameters as expected by mORMotDB
- call it before TSQLRestServer.Create()

```
procedure PurgeOlderThan(MinutesFromNow: cardinal=30);
```

Delete all the locked IDs entries, after a specified time

- to be used to release locked records if the client crashed
- default value is 30 minutes, which seems correct for common usage

procedure SetActions(aActions: PTypeInfo);

Assign an enumeration type to the possible actions to be performed with this model

- call with the TypeInfo() pointer result of an enumeration type
- actions are handled by TSQLRecordForList in the mORMotToolBar.pas unit

procedure SetCustomCollationForAll(aFieldType: TSQLFieldType; const aCollationName: RawUTF8);

Set a custom SQLite3 text column collation for all fields of a given type for all TSQLRecord of this model

- can be used e.g. to override ALL default COLLATE SYSTEMNOCASE of RawUTF8, or COLLATE ISO8601 for TDateTime, and let the generated SQLite3 file be available outside the scope of mORMot's SQLite3 engine
- collations defined within our SynSQLite3 unit are named BINARY, NOCASE, RTRIM and our custom SYSTEMNOCASE, ISO8601, WIN32CASE, WIN32NOCASE: if you want to use the slow but Unicode ready Windows API, set for each model:
SetCustomCollationForAll(sftUTF8Text, 'WIN32CASE');

- shall be set on both Client and Server sides, otherwise some issues may occur

procedure SetEvents(aEvents: PTypeInfo);

Assign an enumeration type to the possible events to be triggered with this class model

- call with the TypeInfo() pointer result of an enumeration type

procedure SetMaxLengthFilterForAllTextFields(IndexIsUTF8Length: boolean=false);

Allow to filter the length of all text published properties of all tables of this model

- the "index" attribute of the RawUTF8/string published properties could be used to specify a maximum length for external VARCHAR() columns
- SQLite3 will just ignore this "index" information, but it could be handy to be able to filter the value length before sending to the DB
- this method will create TSynFilterTruncate corresponding to the maximum field size specified by the "index" attribute, to validate before write
- will expect the "index" value to be in UTF-16 codepoints, unless IndexIsUTF8Length is set to TRUE, indicating UTF-8 length

procedure SetMaxLengthValidatorForAllTextFields(IndexIsUTF8Length: boolean=false);

Allow to validate length of all text published properties of all tables of this model

- the "index" attribute of the RawUTF8/string published properties could be used to specify a maximum length for external VARCHAR() columns
- SQLite3 will just ignore this "index" information, but it could be handy to be able to validate the value length before sending to the DB
- this method will create TSynValidateText corresponding to the maximum field size specified by the "index" attribute, to validate before write
- will expect the "index" value to be in UTF-16 codepoints, unless IndexIsUTF8Length is set to TRUE, indicating UTF-8 length

procedure SetVariantFieldsDocVariantOptions(const Options: TDocVariantOptions);

Customize the TDocVariant options for all variant published properties

- will change the TSQLPropInfoRTTIVariant.DocVariantOptions value
- use e.g. as SetVariantFieldDocVariantOptions(JSON_OPTIONS_FAST_EXTENDED)
- see also TSQLRecordNoCaseExtended root class

procedure UnLockAll;

Unlock all previously locked records

property Actions: PEnumType **read** fActions;

Performed with this model

- Actions are e.g. linked to some buttons in the User Interface

property Events: PEnumType **read** fEvents;

Get the enumerate type information about the possible Events to be performed with this model

- Events can be linked to actions and custom status, to provide a centralized handling of logging (e.g. in an Audit Trail table)

property Locks: TSQLLocksDynArray **read** fLocks;

For every table, contains a locked record list

- very fast, thanks to the use one TSQLLocks entry by table

property OnClientIdle: TOnIdleSynBackgroundThread **read** fOnClientIdle **write** fOnClientIdle;

Set a callback event to be executed in loop during client remote blocking process, e.g. to refresh the UI during a somewhat long request

- will be passed to TSQLRestClientURI.OnIdle property by

TSQLRestClientURI.RegisteredClassCreateFrom() method, if applying

property Owner: TSQLRest **read** fRestOwner **write** fRestOwner;

This property value is used to auto free the database Model class

- set this property after Owner.Create() in order to have Owner.Destroy autofreeing it

property Props[aClass: TSQLRecordClass]: TSQLModelRecordProperties **read** GetTableProps;

The associated ORM information for a given TSQLRecord class

- raise an EModelException if aClass is not declared within this model

- returns the corresponding TableProps[] item if the class is known

property RecordReferences: TSQLModelRecordReferenceDynArray **read** fRecordReferences;

This array contain all TRecordReference and TSQLRecord properties existing in the database model

- used in TSQLRestServer.Delete() to enforce relational database coherency after deletion of a record: all other records pointing to it will be reset to 0 or deleted (if CascadeDelete is true)

property Root: RawUTF8 **read** fRoot **write** SetRoot;

The Root URI path of this Database Model

- this textual value will be used directly to compute the URI for REST routing, so it should contain only URI-friendly characters, i.e. only alphanumerical characters, excluding e.g. space or '+', otherwise an EModelException is raised

property Table[const SQLTableName: RawUTF8]: TSQLRecordClass **read** GetTable;

Get a class from a table name

- expects SQLTableName to be SQL-like formatted (i.e. without TSQL[Record])

property TableExact[const TableName: RawUTF8]: TSQLRecordClass **read** GetTableExactClass;

Get a class from a table TableName (don't truncate TSQLRecord if necessary)*

property TableProps: TSQLModelRecordPropertiesObjArray read fTableProps;

The associated ORM information about all handled TSQLRecord class properties
 - this TableProps[] array will map the Tables[] array, and will allow fast direct access to the Tables[].RecordProps values

property Tables: TSQLRecordClassDynArray read fTables;

Get the classes list (TSQLRecord descendent) of all available tables

property TablesMax: integer read fTablesMax;

The maximum index of TableProps[] class properties array

property URI[aClass: TSQLRecordClass]: RawUTF8 read getURI;

Get the URI for a class in this Model, as 'ModelRoot/SQLTableName'

RecordRef = object(TObject)

Useful object to type cast TRecordReference type value into explicit TSQLRecordClass and ID
 - use RecordRef(Reference).TableIndex/Table/ID/Text methods to retrieve the details of a TRecordReference encoded value
 - use TSQLRest.Retrieve(Reference) to get a record content from DB
 - instead of From(Reference).From(), you could use the more explicit TSQLRecord.RecordReference(Model) or TSQLModel.RecordReference() methods or RecordReference() function to encode the value
 - don't change associated TSQLModel tables order, since TRecordReference depends on it to store the Table type
 - since 6 bits are used for the table index, the corresponding table MUST appear in the first 64 items of the associated TSQLModel.Tables[]

Value: TID;

The value itself

- (value and 63) is the TableIndex in the current database Model
 - (value shr 6) is the ID of the record in this table
 - value=0 means no reference stored
 - we use this coding and not the opposite (Table in MSB) to minimize integer values; but special UTF8CompareRecord() function has to be used for sorting
 - type definition matches TRecordReference (i.e. Int64/TID) to allow typecast as such:
 aClass := PRecordRef(@Reference)^.Table(Model);

function ID: TID;

Return the ID of the content

function Table(Model: TSQLModel): TSQLRecordClass;

Return the class of the content in a specified TSQLModel

function TableIndex: integer;

Return the index of the content Table in the TSQLModel

function Text(Model: TSQLModel): RawUTF8; overload;

Get a ready to be displayed text from the stored Table and ID
 - display 'Record 2301' e.g.

function Text(Rest: TSQLRest): RawUTF8; overload;

Get a ready to be displayed text from the stored Table and ID
- display 'Record "RecordName"' e.g.

procedure From(Model: TSQLModel; aTable: TSQLRecordClass; aID: TID);

Fill Value with the corresponding parameters
- since 6 bits are used for the table index, aTable MUST appear in the first 64 items of the associated TSQLModel.Tables[] array

TSQLRecordRTreeAbstract = class(TSQLRecordVirtual)

An abstract base class, corresponding to an R-Tree table of values

- do not use this class, but either TSQLRecordRTree or TSQLRecordRTreeInteger
- an R-Tree is a special index that is designed for doing range queries. R-Trees are most commonly used in geospatial systems where each entry is a rectangle with minimum and maximum X and Y coordinates. Given a query rectangle, an R-Tree is able to quickly find all entries that are contained within the query rectangle or which overlap the query rectangle. This idea is easily extended to three dimensions for use in CAD systems. R-Trees also find use in time-domain range look-ups. For example, suppose a database records the starting and ending times for a large number of events. A R-Tree is able to quickly find all events, for example, that were active at any time during a given time interval, or all events that started during a particular time interval, or all events that both started and ended within a given time interval. And so forth. See <http://www.sqlite.org/rtree.html>
- any record which inherits from this class as TSQLRecordRTree must have only sftFloat (double) fields (or integer fields for TSQLRecordRTreeInteger) grouped by pairs, each as minimum- and maximum-value, up to 5 dimensions (i.e. 11 columns, including the ID property)
- since SQLite version 3.24.0 (2018-06-04), R-Tree tables can have auxiliary columns that store arbitrary data: such fields should appear after the boundary columns, and have their property name starting with '_' in the class definition; in both SQL and Where clause, the '_' will be trimmed
- note that you should better use the SynSQLite3Static unit, since an external SQLite3.dll/.so library as supplied by the system may be outdated
- internally, the SQLite3 R-Tree extension will be implemented as a virtual table, storing coordinates/values as 32-bit floating point (single - as TSQLRecordRTree kind of ORM classes) or 32-bit integers (as TSQLRecordRTreeInteger), but will make all R-Tree computation using 64-bit floating point (double)
- as with any virtual table, the ID: TID property must be set before adding a TSQLRecordRTree to the database, e.g. to link a R-Tree representation to a regular TSQLRecord table
- queries against the ID or the coordinate ranges are almost immediate: so you can e.g. extract some coordinates box from the regular TSQLRecord table, then use a TSQLRecordRTree joined query to make the process faster; this is exactly what the TSQLRestClient.RTreeMatch method offers - of course Auxiliary Columns could avoid to make the JOIN and call RTreeMatch

class function ContainedIn(const BlobA,BlobB): boolean; **virtual; abstract;**

*Override this class function to implement a custom SQL *_in() function*

- in practice, an R-Tree index does not normally provide the exact answer but merely reduces the set of potential answers from millions to dozens: this method will be called from the *_in() SQL function to actually return exact matches
- by default, the BLOB array will be decoded via the BlobToCoord class procedure, and will create a SQL function from the class name
- used e.g. by the TSQLRestClient.RTreeMatch method

```
class function RTreeSQLFunctionName: RawUTF8; virtual;
```

Will return 'MapBox_in' e.g. for TSQLRecordMapBox

```
TSQLRecordRTree = class(TSQLRecordRTreeAbstract)
```

A base record, corresponding to an R-Tree table of floating-point values

- for instance, the following class will define a 2 dimensional RTree of floating point coordinates, and an associated MapBox_in() function:

```
TSQLRecordMapBox = class(TSQLRecordRTree)
protected
  fMinX, fMaxX, fMinY, fMaxY: double;
published
  property MinX: double read fMinX write fMinX;
  property MaxX: double read fMaxX write fMaxX;
  property MinY: double read fMinY write fMinY;
  property MaxY: double read fMaxY write fMaxY;
end;
```

- since SQLite version 3.24.0, TSQLRecordRTree can have auxiliary columns that store arbitrary data, having their property name starting with '_' (only in this class definition: SQL and Where clauses will trim it)

```
class function ContainedIn(const BlobA,BlobB): boolean; override;
```

*Override this class function to implement a custom SQL *_in() function*

- by default, the BLOB array will be decoded via the BlobToCoord() class procedure, and will create a SQL function from the class name
 - used e.g. by the TSQLRestClient.RTreeMatch method

```
class procedure BlobToCoord(const InBlob; var OutCoord: TSQLRecordTreeCoords);  
virtual;
```

Override this class function to implement a custom box coordinates from a given BLOB content

- by default, the BLOB array will contain a simple array of double
 - but you can override this method to handle a custom BLOB field content, intended to hold some kind of binary representation of the precise boundaries of the object, and convert it into box coordinates as understood by the ContainedIn() class function
 - the number of pairs in OutCoord will be taken from the current number of published double properties
 - used e.g. by the TSQLRest.RTreeMatch method

TSQLRecordRTreeInteger = class(TSQLRecordRTreeAbstract)

A base record, corresponding to an R-Tree table of 32-bit integer values

- for instance, the following class will define a 2 dimensional RTree of 32-bit integer coordinates, and an associated MapBox_in() function:

```
TSQLRecordMapBox = class(TSQLRecordRTree)
protected
  fMinX, fMaxX, fMinY, fMaxY: integer;
published
  property MinX: integer read fMinX write fMinX;
  property MaxX: integer read fMaxX write fMaxX;
  property MinY: integer read fMinY write fMinY;
  property MaxY: integer read fMaxY write fMaxY;
end;
```

- since SQLite version 3.24.0, TSQLRecordRTreeInteger can have auxiliary columns that store arbitrary data, having their property name starting with '_' (only in this class definition: SQL and Where clauses will trim it)

class function ContainedIn(const BlobA,BlobB): boolean; override;

*Override this class function to implement a custom SQL *_in() function*

- by default, the BLOB array will be decoded via the BlobToCoord() class procedure, and will create a SQL function from the class name
 - used e.g. by the TSQLRest.RTreeMatch method

class procedure BlobToCoord(const InBlob; var OutCoord: TSQLRecordTreeCoordsInteger); virtual;

Override this class function to implement a custom box coordinates from a given BLOB content

- by default, the BLOB array will contain a simple array of integer
 - but you can override this method to handle a custom BLOB field content, intended to hold some kind of binary representation of the precise boundaries of the object, and convert it into box coordinates as understood by the ContainedIn() class function
 - the number of pairs in OutCoord will be taken from the current number of published integer properties
 - used e.g. by the TSQLRest.RTreeMatch method

TSQLRecordFTS3 = class(TSQLRecordVirtual)

A base record, corresponding to a FTS3 table, i.e. implementing full-text

- FTS3/FTS4/FTS5 tables are SQLite virtual tables allowing users to perform full-text searches on a set of documents. The most common (and effective) way to describe full-text searches is "what Google, Yahoo and Altavista do with documents placed on the World Wide Web". Users input a term, or series of terms, perhaps connected by a binary operator or grouped together into a phrase, and the full-text query system finds the set of documents that best matches those terms considering the operators and groupings the user has specified. See <http://sqlite.org/fts3.html>
- any record which inherits from this class must have only sftUTF8Text (RawUTF8) fields - with Delphi 2009+, you can have string fields
- this record has its FID: TID property which may be published as DocID, to be consistent with SQLite3 praxis, and reflect that it points to an ID of another associated TSQLRecord
- a good approach is to store your data in a regular TSQLRecord table, then store your text content in a separated FTS3 table, associated to this TSQLRecordFTS3 table via its ID/DocID
- the ID/DocID property can be set when the record is added, to retrieve any associated TSQLRecord (note that for a TSQLRecord record, the ID property can't be set at adding, but is calculated by the engine)
- static tables don't handle TSQLRecordFTS3 classes
- by default, the FTS3 engine ignore all characters >= #80, but handle low-level case insensitivity (i.e. 'A'..'Z') so you must keep your request with the same range for upper case
- by default, the "simple" tokenizer is used, but you can inherits from TSQLRecordFTS3Porter class if you want a better English matching, using the Porter Stemming algorithm, or TSQLRecordFTS3Unicode61 for Unicode support - see <http://sqlite.org/fts3.html#tokenizer>
- you can select either the FTS3 engine, or the more efficient (and new) FTS4 engine (available since version 3.7.4), by using the TSQLRecordFTS4 type, or TSQLRecordFTS5 for the latest (and preferred) FTS5 engine
- in order to make FTS queries, use the dedicated TSQLRest.FTSMATCH method, with the MATCH operator (you can use regular queries, but you must specify 'RowID' instead of 'DocID' or 'ID' because of FTS3 Virtual table specificity):

```
var IDs: TIDDynArray;  
if FTSMATCH(TSQLMyFTS3Table, 'text MATCH "linu*"', IDs) then  
  // you have all matching IDs in IDs[]
```

- by convention, inherited class name could specify a custom stemming algorithm by starting with "TSQLRecordFTS3", and adding the algorithm name as suffix, e.g. TSQLRecordFTS3Porter will create a "tokenize=porter" virtual table

class function OptimizeFTS3Index(Server: TSQLRestServer): boolean;

Optimize the FTS3 virtual table

- this causes FTS3 to merge all existing index b-trees into a single large b-tree containing the entire index. This can be an expensive operation, but may speed up future queries. See http://sqlite.org/fts3.html#section_1_2
- this method must be called server-side
- returns TRUE on success

property DocID: TID **read** GetID **write** fID;

This DocID property map the internal Row_ID property

- but you can set a value to this property before calling the Add() method, to associate this TSQLRecordFTS3 to another TSQLRecord
- ID property is read-only, but this DocID property can be written/set
- internally, we use RowID in the SQL statements, which is compatible with both TSQLRecord and TSQLRecordFTS3 kind of table

TSQLRecordFTS3Porter = class(TSQLRecordFTS3)

This base class will create a FTS3 table using the Porter Stemming algorithm

- see <http://sqlite.org/fts3.html#tokenizer>
- will generate tokenize=porter by convention from the class name

TSQLRecordFTS3Unicode61 = class(TSQLRecordFTS3)

This base class will create a FTS3 table using the Unicode61 Stemming algorithm

- see <http://sqlite.org/fts3.html#tokenizer>
- will generate tokenize=unicode61 by convention from the class name

TSQLRecordFTS4 = class(TSQLRecordFTS3)

A base record, corresponding to a FTS4 table, which is an enhancement to FTS3

- FTS3 and FTS4 are nearly identical. They share most of their code in common, and their interfaces are the same. The only difference is that FTS4 stores some additional information about the document collection in two of new FTS shadow tables. This additional information allows FTS4 to use certain query performance optimizations that FTS3 cannot use. And the added information permits some additional useful output options in the matchinfo() function.
- for newer applications, TSQLRecordFTS5 is recommended; though if minimal disk usage or compatibility with older versions of SQLite are important, then TSQLRecordFTS3 will usually serve just as well
- see http://sqlite.org/fts3.html#section_1_1
- by convention, inherited class name could specify a custom stemming algorithm by starting with "TSQLRecordFTS4", and adding the algorithm name as suffix, e.g. TSQLRecordFTS4Porter will create a "tokenize=porter" virtual table

class procedure InitializeTable(Server: TSQLRestServer; **const** FieldName: RawUTF8; Options: TSQLInitializeTableOptions); **override**;

This overridden method will create TRIGGERS for FTSEnabledContent()

TSQLRecordFTS4Porter = class(TSQLRecordFTS4)

This base class will create a FTS4 table using the Porter Stemming algorithm

- see <http://sqlite.org/fts3.html#tokenizer>
- will generate tokenize=porter by convention from the class name

TSQLRecordFTS4Unicode61 = class(TSQLRecordFTS4)

This base class will create a FTS4 table using the Unicode61 Stemming algorithm

- see <http://sqlite.org/fts3.html#tokenizer>
- will generate tokenize=unicode61 by convention from the class name

TSQLRecordFTS5 = class(TSQLRecordFTS4)

A base record, corresponding to a FTS5 table, which is an enhancement to FTS4

- FTS5 is a new version of FTS4 that includes various fixes and solutions for problems that could not be fixed in FTS4 without sacrificing backwards compatibility
- for newer applications, TSQLRecordFTS5 is recommended; though if minimal disk usage or compatibility with older versions of SQLite are important, then TSQLRecordFTS3/TSQlRecordFTS4 will usually serve just as well
- see https://sqlite.org/fts5.html#appendix_a
- by convention, inherited class name could specify a custom stemming algorithm by starting with "TSQlRecordFTS5", and adding the algorithm name as suffix, e.g. TSQLRecordFTS5Porter will create a "tokenize=porter" virtual table

TSQlRecordFTS5Porter = class(TSQLRecordFTS5)

This base class will create a FTS5 table using the Porter Stemming algorithm

- see <https://sqlite.org/fts5.html#tokenizers>
- will generate tokenize=porter by convention from the class name

TSQlRecordFTS5Unicode61 = class(TSQLRecordFTS5)

This base class will create a FTS5 table using the Unicode61 Stemming algorithm

- see <https://sqlite.org/fts5.html#tokenizers>
- will generate tokenize=unicode61 by convention from the class name

TSQLRecordMany = class(TSQLRecord)

Handle "has many" and "has many through" relationships

- many-to-many relationship is tracked using a table specifically for that relationship, turning the relationship into two one-to-many relationships pointing in opposite directions
- by default, only two TSQLRecord (i.e. INTEGER) fields must be created, named "Source" and "Dest", the first pointing to the source record (the one with a TSQLRecordMany published property) and the second to the destination record - note that by design, those source/dest tables are stored as pointers, so are limited to 32-bit ID values on 32-bit systems
- you should first create a type inheriting from TSQLRecordMany, which will define the pivot table, providing optional "through" parameters if needed

```
TSQLDest = class(TSQLRecord);
TSQLSource = class;
TSQLDestPivot = class(TSQLRecordMany)
private
  fSource: TSQLSource;
  fDest: TSQLDest;
  fTime: TDateTime;
published
  property Source: TSQLSource read fSource; // map Source column
  property Dest: TSQLDest read fDest; // map Dest column
  property AssociationTime: TDateTime read fTime write fTime;
end;
TSQLSource = class(TSQLRecord)
private
  fDestList: TSQLDestPivot;
published
  DestList: TSQLDestPivot read fDestList;
end;
```

- in all cases, at least two 'Source' and 'Dest' published properties must be declared as TSQLRecord children in any TSQLRecordMany descendant because they will always be needed for the 'many to many' relationship
- when a TSQLRecordMany published property exists in a TSQLRecord, it is initialized automatically by TSQLRecord.Create
- to add some associations to the pivot table, use the ManyAdd() method
- to retrieve an association, use the ManySelect() method
- to delete an association, use the ManyDelete() method
- to read all Dest records IDs, use the DestGet() method
- to read the Dest records and the associated "through" fields content, use FillMany then FillRow, FillOne and FillRewind methods to loop through records
- to read all Source records and the associated "through" fields content, FillManyFromDest then FillRow, FillOne and FillRewind methods
- to read all Dest IDs after a join to the pivot table, use DestGetJoined

constructor Create; **override;**

Initialize this instance, and needed internal fields

- will set protected fSourceID/fDestID fields

function DestGet(aClient: TSQLRest; aSourceID: TID; **out** DestIDs: TIDDynArray): boolean; **overload;**

Retrieve all Dest items IDs associated to the specified Source

function DestGet(aClient: TSQLRest; **out** DestIDs: TIDDynArray): boolean; overload;

Retrieve all Dest items IDs associated to the current Source ID

- source ID is taken from the fSourceID field (set by TSQLRecord.Create)
- note that if the Source record has just been added, fSourceID is not set, so this method will fail: please call the other overloaded method

function DestGetJoined(aClient: TSQLRest; **const** aDestWhereSQL: RawUTF8; aSourceID: TID): TSQLRecord; overload;

Create a Dest record, then FillPrepare() it to retrieve all Dest items associated to the current or specified Source ID, adding a WHERE condition against the Dest rows

- if aSourceID is 0, the value is taken from current fSourceID field (set by TSQLRecord.Create)
- aDestWhereSQL can specify the Dest table name in the statement, e.g. 'Salary>:(1000): AND Salary<:(2000):' according to TSQLRecordMany properties - note that you should better use such inlined parameters as
FormatUTF8('Salary>? AND Salary<?', [], [1000, 2000])

function DestGetJoined(aClient: TSQLRest; **const** aDestWhereSQL: RawUTF8; aSourceID: TID; **out** DestIDs: TIDDynArray): boolean; overload;

Retrieve all Dest items IDs associated to the current or specified Source ID, adding a WHERE condition against the Dest rows

- if aSourceID is 0, the value is taken from current fSourceID field (set by TSQLRecord.Create)
- aDestWhereSQL can specify the Dest table name in the statement, e.g. 'Salary>:(1000): AND Salary<:(2000):' - note that you should better use inlined parameters for faster processing on server, so you may use the more convenient function
FormatUTF8('Salary>? AND Salary<?', [], [1000, 2000])
- this is faster than a manual FillMany() then loading each Dest, because the condition is executed in the SQL statement by the server

function DestGetJoinedTable(aClient: TSQLRest; **const** aDestWhereSQL: RawUTF8; aSourceID: TID; JoinKind: TSQLRecordManyJoinKind; **const** aCustomFieldsCSV: RawUTF8=''): TSQLTable;

Create a TSQLTable, containing all specified Fields, after a JOIN associated to the current or specified Source ID

- the Table will have the fields specified by the JoinKind parameter
- aCustomFieldsCSV can be used to specify which fields must be retrieved (for jkDestFields, jkPivotFields, jkPivotAndDestFields) - default is all
- if aSourceID is 0, the value is taken from current fSourceID field (set by TSQLRecord.Create)
- aDestWhereSQL can specify the Dest table name in the statement, e.g. 'Salary>:(1000): AND Salary<:(2000):' according to TSQLRecordMany properties - note that you should better use such inlined parameters as
FormatUTF8('Salary>? AND Salary<?', [], [1000, 2000])

```
function FillMany(aClient: TSQLRest; aSourceID: TID=0; const aAndWhereSQL: RawUTF8=''): integer;
```

Retrieve all records associated to a particular source record, which has a TSQLRecordMany property

- returns the Count of records corresponding to this aSource record
- the records are stored in an internal TSQLTable, referred in the private fTable field, and initialized via a FillPrepare call: all Dest items are therefore accessible with standard FillRow, FillOne and FillRewind methods
- use a "for .." loop or a "while FillOne do ..." loop to iterate through all Dest items, getting also any additional 'through' columns
- if source ID parameter is 0, the ID is taken from the fSourceID field (set by TSQLRecord.Create)
- note that if the Source record has just been added, fSourceID is not set, so this method will fail: please specify aSourceID parameter with the one just added/created
- the optional aAndWhereSQL parameter can be used to add any additional condition to the WHERE statement (e.g. 'Salary>:(1000): AND Salary<:(2000):') according to TSQLRecordMany properties - note that you should better use inlined parameters for faster processing on server, so you may call e.g.
aRec.FillMany(Client,0,FormatUTF8('Salary>? AND Salary<?',[],[1000,2000]));

```
function FillManyFromDest(aClient: TSQLRest; aDestID: TID; const aAndWhereSQL: RawUTF8=''): integer;
```

Retrieve all records associated to a particular Dest record, which has a TSQLRecordMany property

- returns the Count of records corresponding to this aSource record
- use a "for .." loop or a "while FillOne do ..." loop to iterate through all Dest items, getting also any additional 'through' columns
- the optional aAndWhereSQL parameter can be used to add any additional condition to the WHERE statement (e.g. 'Salary>:(1000): AND Salary<:(2000):') according to TSQLRecordMany properties - note that you should better use inlined parameters for faster processing on server, so you may call e.g.
aRec.FillManyFromDest(Client, DestID, FormatUTF8('Salary>? AND Salary<?',[],[1000,2000]));

```
function IDWhereSQL(aClient: TSQLRest; aID: TID; isDest: boolean; const aAndWhereSQL: RawUTF8=''): RawUTF8;
```

Get the SQL WHERE statement to be used to retrieve the associated records according to a specified ID

- search for aID as Source ID if isDest is FALSE
- search for aID as Dest ID if isDest is TRUE
- the optional aAndWhereSQL parameter can be used to add any additional condition to the WHERE statement (e.g. 'Salary>:(1000): AND Salary<:(2000):') according to TSQLRecordMany properties - note that you should better use such inlined parameters e.g. calling
FormatUTF8('Salary>? AND Salary<?',[],[1000,2000])

function ManyAdd(aClient: TSQLRest; aDestID: TID; NoDuplicates: boolean=false): boolean; overload;

Add a Dest record to the current Source record list

- source ID is taken from the fSourceID field (set by TSQLRecord.Create)
- note that if the Source record has just been added, fSourceID is not set, so this method will fail: please call the other overloaded method

function ManyAdd(aClient: TSQLRest; aSourceID, aDestID: TID; NoDuplicates: boolean=false; aUseBatch: TSQLRestBatch=nil): boolean; overload;

Add a Dest record to the Source record list

- returns TRUE on success, FALSE on error
- if NoDuplicates is TRUE, the existence of this Source/Dest ID pair is first checked
- current Source and Dest properties are filled with the corresponding TRecordReference values corresponding to the supplied IDs
- any current value of the additional fields are used to populate the newly created content (i.e. all published properties of this record)
- if aUseBatch is set, it will use this TSQLRestBatch.Add() instead of the slower aClient.Add() method

function ManyDelete(aClient: TSQLRest; aDestID: TID): boolean; overload;

Will delete the record associated with the current source and a specified Dest

- source ID is taken from the fSourceID field (set by TSQLRecord.Create)
- note that if the Source record has just been added, fSourceID is not set, so this method will fail: please call the other overloaded method

function ManyDelete(aClient: TSQLRest; aSourceID, aDestID: TID; aUseBatch: TSQLRestBatch=nil): boolean; overload;

Will delete the record associated with a particular Source/Dest pair

- will return TRUE if the pair was found and successfully deleted
- if aUseBatch is set, it will use this TSQLRestBatch.Delete() instead of the slower aClient.Delete() method

function ManySelect(aClient: TSQLRest; aDestID: TID): boolean; overload;

Will retrieve the record associated with the current source and a specified Dest

- source ID is taken from the fSourceID field (set by TSQLRecord.Create)
- note that if the Source record has just been added, fSourceID is not set, so this method will fail: please call the other overloaded method

function ManySelect(aClient: TSQLRest; aSourceID, aDestID: TID): boolean; overload;

Will retrieve the record associated with a particular Source/Dest pair

- will return TRUE if the pair was found
- in this case, all "through" columns are available in the TSQLRecordMany field instance

function SourceGet(aClient: TSQLRest; aDestID: TID; out SourceIDs: TIDDynArray): boolean;

Retrieve all Source items IDs associated to the specified Dest ID

TSQLRecordLog = class(TSQLRecord)

A base record, with a JSON-logging capability

- used to store a log of events into a JSON text, easy to be displayed with a TSQLTableToGrid
- this log can then be stored as a RawUTF8 field property into a result record, for instance

constructor CreateFrom(OneLog: TSQLRecord; const aJSON: RawUTF8);

Initialize the internal storage with a supplied JSON content

- this JSON content must follow the format retrieved by LogTableJSON and LogTableJSONFrom methods

destructor Destroy; **override**;

Release the private fLogTableWriter and fLogTableStorage objects

function LogCurrentPosition: integer;

Returns the internal position of the Log content

- use this value to later retrieve a log range with LogTableJSONFrom()

function LogTableJSON: RawUTF8;

Returns the JSON data as added by previous call to Log()

- JSON data is in not-expanded format
- this function can be called multiple times

function LogTableJSONFrom(StartPosition: integer): RawUTF8;

Returns the log JSON data from a given start position

- StartPosition was retrieved previously with LogCurrentPosition
- if StartPosition=0, the whole Log content is returned
- multiple instances of LogCurrentPosition/LogTableJSONFrom() can be used at once

procedure Log(OneLog: TSQLRecord);

Add the value of OneLog to the Log Table JSON content

- the ID property of the supplied OneLog record is incremented before adding

property LogTableRowCount: integer **read** fLogTableRowCount;

The current associated Log Table rows count value

- is incremented every time Log() method is called
- will be never higher than MaxLogTableRowCount below (if set)

property MaxLogTableRowCount: integer **read** fMaxLogTableRowCount;

If the associated Log Table rows count reaches this value, the first data row will be trimmed

- do nothing is value is left to 0 (which is the default)
- total rows count won't never be higher than this value
- used to spare memory usage

TSQLRecordSigned = class(TSQLRecord)

Common ancestor for tables with digitally signed RawUTF8 content

- content is signed according to a specific User Name and the digital signature date and time
- internally uses the very secure SHA-256 hashing algorithm for performing the digital signature

function CheckSignature(const Content: RawByteString): boolean;

Returns true if this record content is correct according to the stored digital Signature

function SetAndSignContent(const UserName: RawUTF8; const Content: RawByteString; ForcedSignatureTime: Int64=0): boolean;

Use this procedure to sign the supplied Content of this record for a specified UserName, with the current Date and Time

- SHA-256 hashing is used internally
- returns true if signed successfully (not already signed)

function SignedBy: RawUTF8;

Retrieve the UserName who digitally signed this record
- returns '' if was not digitally signed

procedure UnSign;

Reset the stored digital signature
- SetAndSignContent() can be called after this method

property Signature: RawUTF8 **read** fSignature **write** fSignature;

As the Content of this record is added to the database, its value is hashed and stored as 'UserName/03A35C92...' into this property
- secured SHA-256 hashing is used internally
- digital signature is allowed only once: this property is written only once
- this property is defined here to allow inherited to just declared the name in its published section:
property Signature;

property SignatureTime: TTimeLog **read** fSignatureTime **write** fSignatureTime;

Time and date of signature
- if the signature is invalid, this field will contain numerical 1 value
- this property is defined here to allow inherited to just declared the name in its published section:
property SignatureTime;

TSQLRecordTimed = class(TSQLRecord)

A base record, which will have creation and modification timestamp fields

property Created: TCreateTime **read** fCreated **write** fCreated;

Will be filled by the ORM when this item will be created in the database

property Modified: TModTime **read** fModified **write** fModified;

Will be filled by the ORM each time this item will be written in the database

TSQLRecordInterfaced = class(TSQLRecord)

Common ancestor for tables which should implement any interface
- by default, TSQLRecord does not implement any interface: this does make sense for performance and resource use reasons
- inherit from this class if you want your class to implement the needed IInterface methods (QueryInterface/AddRef/Release)

TServiceMethodArgument = object(TObject)

Describe a service provider method argument

ArgTypeInfo: PTypeInfo;

The low-level RTTI information of this argument

ArgTypeName: PShortString;

The type name, as declared in Delphi

DynArrayWrapper: TDynArray;

A TDynArray wrapper initialized properly for this smvDynArray

FPRegisterIdent: integer;

Used to specify if a floating-point argument is passed as register

- contains always 0 for x86/x87
- contains 1 for XMM0, 2 for XMM1, ..., 4 for XMM3 for x64
- contains 1 for D0, 2 for D1, ..., 8 for D7 for armhf
- contains 1 for V0, 2 for V1, ..., 8 for V7 for aarch64

IndexVar: integer;

Index of the associated variable in the local array[ArgsUsedCount[]]

- for smdConst argument, contains -1 (no need to a local var: the value will be on the stack only)

InStackOffset: integer;

Byte offset in the CPU stack of this argument

- may be -1 if pure register parameter with no backup on stack (x86)

ParamName: PShortString;

The argument name, as declared in Delphi

RegisterIdent: integer;

Used to specify if the argument is passed as register

- contains 0 if parameter is not a register
- contains 1 for EAX, 2 for EDX and 3 for ECX registers for x86
- contains 1 for RCX, 2 for RDX, 3 for R8, and 4 for R9, with a backing store on the stack for x64
- contains 1 for R0, 2 R1 ... 4 for R3, with a backing store on the stack for arm
- contains 1 for X0, 2 X1 ... 8 for X7, with a backing store on the stack for aarch64

SizeInBinary: integer;

Hexadecimal binary size (in bytes) of this smvv64 ordinal value

- set only if ValueType=smvBinary

SizeInStack: integer;

Size (in bytes) of this argument on the stack

SizeInStorage: integer;

Size (in bytes) of this smvv64 ordinal value

- e.g. depending of the associated kind of enumeration

ValueDirection: TServiceMethodValueDirection;

The variable direction as defined at code level

ValueKindAsm: TServiceMethodValueAsm;

How the variable is to be passed at asm level

ValueType: TServiceMethodValueType;

We do not handle all kind of Delphi variables

ValueVar: TServiceMethodValueVar;

How the variable may be stored

function FromJSON(**const** MethodName: RawUTF8; **var** R: PUTF8Char; V: pointer; Error: PShortString; DVO: TDocVariantOptions): boolean;

Unserialize a JSON value into this argument

function IsDefault(V: pointer): boolean;

Check if the supplied argument value is the default (e.g. 0, "" or null)

procedure AddAsVariant(**var** Dest: TDocVariantData; V: pointer);

Add a value into a TDocVariant object or array

- Dest should already have set its Kind to either dvObject or dvArray

procedure AddDefaultJSON(WR: TTextWriter);

Append the default JSON value corresponding to this argument

- includes a pending ','

procedure AddJSON(WR: TTextWriter; V: pointer; ObjectOptions: TTextWriterWriteObjectOptions=[woDontStoreDefault]);

Append the JSON value corresponding to this argument

- includes a pending ','

procedure AddJSONEscaped(WR: TTextWriter; V: pointer);

Append the value corresponding to this argument as within a JSON string

- will escape any JSON string character, and include a pending ','

procedure AddValueJSON(WR: TTextWriter; **const** Value: RawUTF8);

Append the JSON value corresponding to this argument, from its text value

- includes a pending ','

procedure AsJson(**var** DestValue: RawUTF8; V: pointer);

Convert a value into its JSON representation

procedure AsVariant(**var** DestValue: **variant**; V: pointer; Options: TDocVariantOptions);

Convert a value into its variant representation

- complex objects will be converted into a TDocVariant, after JSON serialization: variant conversion options may e.g. be retrieve from TInterfaceFactory.DocVariantOptions

procedure FixValue(**var** Value: **variant**);

Normalize a value containing one input or output argument

- sets and enumerates will be translated to strings (also in embedded objects and T*ObjArray)

procedure FixValueAndAddToObject(**const** Value: **variant**; **var** DestDoc: TDocVariantData);

Normalize a value containing one input or output argument, and add it to a destination variant Document

- sets and enumerates will be translated to strings (also in embedded objects and T*ObjArray)

procedure SerializeToContract(WR: TTextWriter);

Serialize the argument into the TServiceContainer.Contract JSON format

- non standard types (e.g. clas, enumerate, dynamic array or record) are identified by their type identifier - so contract does not extend up to the content of such high-level structures

procedure SetFromRTTI(**var** P: PByte);

Set ArgTypeName and ArgTypeInfo values from RTTI

TServiceMethod = object(TObject)

Describe an interface-based service provider method

Args: TServiceMethodArgumentDynArray;

Describe expected method arguments

- Args[0] always is smvSelf
- if method is a function, an additional smdResult argument is appended

ArgsInFirst: shortint;

The index of the first const / var argument in Args[]

ArgsInLast: shortint;

The index of the last const / var argument in Args[]

ArgsInputIsOctetStream: boolean;

True if there is a single input parameter as RawByteString/TSQLRawBlob

- TSQLRestRoutingREST.ExecuteSOABByInterface will identify binary input with mime-type 'application/octet-stream' as expected

ArgsInputValuesCount: byte;

The number of const / var parameters in Args[]

- i.e. the number of elements in the input JSON array

ArgsManagedFirst: shortint;

The index of the first argument expecting manual stack initialization

- set if there is any smvObject, smvDynArray, smvRecord, smvInterface or smvVariant

ArgsManagedLast: shortint;

The index of the last argument expecting manual stack initialization

- set if there is any smvObject, smvDynArray, smvRecord, smvInterface or smvVariant

ArgsNotResultLast: shortint;

The index of the last argument in Args[], excepting result

ArgsOutFirst: shortint;

The index of the first var / out / result argument in Args[]

ArgsOutLast: shortint;

The index of the last var / out / result argument in Args[]

ArgsOutNotResultLast: shortint;

The index of the last var / out argument in Args[]

ArgsOutputValuesCount: byte;

The number of var / out parameters + in Args[]

- i.e. the number of elements in the output JSON array or object

ArgsResultIndex: shortint;

The index of the result pseudo-argument in Args[]

- is -1 if the method is defined as a (not a function)

ArgsResultIsServiceCustomAnswer: boolean;

True if the result is a TServiceCustomAnswer record

- that is, a custom Header+Content BLOB transfert, not a JSON object

ArgsSizeInStack: cardinal;

Needed CPU stack size (in bytes) for all arguments

- under x64, does not include the backup space for the four registers

ArgsUsed: TServiceMethodValueTypes;

Contains all used kind of arguments

ArgsUsedCount: array[TServiceMethodValueVar] of byte;

Contains the count of variables for all used kind of arguments

DefaultResult: RawUTF8;

The method default result, formatted as a JSON array

- example of content may be '[]' for a procedure or '[0]' for a function

- any var/out and potential function result will be set as a JSON array of values, with 0 for numerical values, "" for textual values, false for booleans, [] for dynamic arrays, a void record serialized as expected (including customized serialization) and null for objects

ExecutionMethodIndex: byte;

Method index in the original (non emulated) interface

- our custom methods start at index 3 (RESERVED_VTABLE_SLOTS), since QueryInterface, _AddRef, and _Release are always defined by default
- so it maps TServiceFactory.Interface.Methods[ExecutionMethodIndex-3]

HasSPIParams: TServiceMethodValueDirections;

The directions of arguments with vlsSPI defined in Args[].ValueKindAsm

HierarchyLevel: byte;

Is 0 for the root interface, 1..n for all inherited interfaces

InterfaceDotMethodName: RawUTF8;

The fully qualified dotted method name, including the interface name

- as used by TServiceContainerInterfaceMethod.InterfaceDotMethodName
- match the URI fullpath name, e.g. 'Calculator.Add'

IsInherited: boolean;

TRUE if the method is inherited from another parent interface

URI: RawUTF8;

The method URI, i.e. the method name

- as declared in Delphi code, e.g. 'Add' for ICalculator.Add
- this property value is hashed internally for faster access

function ArgIndex(ArgName: PUTF8Char; ArgNameLen: integer; Input: boolean): integer;

Retrieve an argument index in Args[] from its name

- search is case insensitive

- if Input is TRUE, will search within const / var arguments

- if Input is FALSE, will search within var / out / result arguments

- returns -1 if not found

function ArgNext(**var** arg: integer; Input: boolean): boolean;

Find the next argument index in Args[]

- if Input is TRUE, will search within const / var arguments
- if Input is FALSE, will search within var / out / result arguments
- returns true if arg is the new value, false otherwise

function ArgsArrayToObject(P: PUTF8Char; Input: boolean): RawUTF8;

Convert parameters encoded as a JSON array into a JSON object

- if Input is TRUE, will handle const / var arguments
- if Input is FALSE, will handle var / out / result arguments

function ArgsCommandLineToObject(P: PUTF8Char; Input: boolean;
RaiseExceptionOnUnknownParam: boolean=false): RawUTF8;

Convert parameters encoded as name=value or name="value" or name='{somejson}' into a JSON object

- on Windows, use double-quotes (") anywhere you expect single-quotes (')
- as expected e.g. from a command line tool
- if Input is TRUE, will handle const / var arguments
- if Input is FALSE, will handle var / out / result arguments

function ArgsNames(Input: Boolean): TRawUTF8DynArray;

Returns a dynamic array list of all parameter names

- if Input is TRUE, will handle const / var arguments
- if Input is FALSE, will handle var / out / result arguments

procedure ArgsAsDocVariantFix(**var** ArgsObject: TDocVariantData; Input: boolean);

Normalize a TDocVariant containing the input or output arguments values

- "normalization" will ensure sets and enums are serialized as text
- if Input is TRUE, will handle const / var arguments
- if Input is FALSE, will handle var / out / result arguments

procedure ArgsAsDocVariantObject(**const** ArgsParams: TDocVariantData; **var** ArgsObject: TDocVariantData; Input: boolean);

Convert a TDocVariant array containing the input or output arguments values in order, into an object with named parameters

- here sets and enums will keep their current values, mainly numerical
- if Input is TRUE, will handle const / var arguments
- if Input is FALSE, will handle var / out / result arguments

procedure ArgsStackAsDocVariant(**const** Values: TTPointerDynArray; **out** Dest: TDocVariantData; Input: Boolean);

Computes a TDocVariant containing the input or output arguments values

- Values[] should point to the input/output raw binary values, as stored in TServiceMethodExecute.Values during execution

procedure ArgsValuesAsDocVariant(Kind: TServiceMethodParamsDocVariantKind; **out** Dest: TDocVariantData; **const** Values: TVariantDynArray; Input: boolean; Options: TDocVariantOptions=[dvoReturnNullForUnknownProperty, dvoValueCopiedByReference]);

Computes a TDocVariant containing the input or output arguments values

- Values[] should contain the input/output raw values as variant
- Kind will specify the expected returned document layout

TSQLRecordServiceLog = class(TSQLRecordNoCaseExtended)

Common ancestor for storing interface-based service execution statistics

- each call could be logged and monitored in the database
- TServiceMethodExecute could store all its calls in such a table
- enabled on server side via either TServiceFactoryServer.SetServiceLog or TServiceContainerServer.SetServiceLog method

class procedure InitializeTable(Server: TSQLRestServer; **const** FieldName: RawUTF8; Options: TSQLInitializeTableOptions); **override**;

Overriden method creating an index on the Method/MicroSec columns

property Input: **variant read fInput write fInput**;

The input parameters, as a JSON document

- will be stored in JSON_OPTIONS_FAST_EXTENDED format, i.e. with shortened field names, for smaller TEXT storage
- content may be searched using JsonGet/JsonHas SQL functions on a SQLite3 storage, or with direct document query under MongoDB/PostgreSQL

property IP: RawUTF8 **read fIP write fIP**;

If not localhost/127.0.0.1, the remote IP address

property Method: RawUTF8 **read fMethod write fMethod**;

The 'interface.method' identifier of this call

- this column will be indexed, for fast SQL queries, with the MicroSec column (for performance tuning)

property MicroSec: integer **read fMicroSec write fMicroSec**;

Execution time of this method, in micro seconds

property Output: **variant read fOutput write fOutput**;

The output parameters, as a JSON document, including result: for a function

- will be stored in JSON_OPTIONS_FAST_EXTENDED format, i.e. with shortened field names, for smaller TEXT storage
- content may be searched using JsonGet/JsonHas SQL functions on a SQLite3 storage, or with direct document query under MongoDB/PostgreSQL

property Session: integer **read fSession write fSession**;

The Session ID, if there is any

property Time: TModTime **read fTime write fTime**;

Will be filled by the ORM when this record is written in the database

property User: integer **read fUser write fUser**;

The User ID, if there is an identified Session

TSQLRecordServiceNotifications = class(TSQLRecordServiceLog)

Execution statistics used for DB-based asynchronous notifications

- as used by TServiceFactoryClient.SendNotifications
- here, the Output column may contain the information about an error occurred during process

```
class function LastEventsAsObjects(Rest: TSQLRest; LastKnownID: TID; Limit: integer; Service: TInterfaceFactory; out Dest: TDocVariantData; const MethodName: RawUTF8 = 'Method'; IDAsHexa: boolean = false): boolean;
```

Search for pending events since a supplied ID

- returns FALSE if no notification was found
- returns TRUE and fill a TDocVariant array of JSON Objects, including "ID": field, and Method as "MethodName": field

```
function SaveInputAsObject(Service: TInterfaceFactory; const MethodName: RawUTF8 = 'Method'; IDAsHexa: boolean = false): variant; virtual;
```

Allows to convert the Input array into a proper single JSON Object

- "ID": field will be included, and Method as "MethodName": field

```
class procedure InitializeTable(Server: TSQLRestServer; const FieldName: RawUTF8; Options: TSQLInitializeTableOptions); override;
```

This overridden method will create an index on the 'Sent' column

```
procedure SaveFillInputsAsObjects(Service: TInterfaceFactory; out Dest: TDocVariantData; const MethodName: RawUTF8 = 'Method'; IDAsHexa: boolean = false);
```

Run FillOne and SaveInputAsObject into a TDocVariant array of JSON Objects

- "ID": field will be included, and Method as "MethodName": field

```
property Sent: TTimeLog read fSent write fSent;
```

When this notification has been sent

- equals 0 until it was actually notified

```
TServiceMethodExecute = class(TObject)
```

Execute a method of a TInterfacedObject instance, from/to JSON

```
constructor Create(aMethod: PServiceMethod);
```

Initialize the execution instance

```
destructor Destroy; override;
```

Finalize the execution instance

```
function ExecuteJson(const Instances: array of pointer; Par: PUTF8Char; Res: TTextWriter; Error: PShortString=nil; ResAsJSONObject: boolean=false): boolean;
```

Execute the corresponding method of weak IInvokable references

- will retrieve a JSON array of parameters from Par (as [1,"par2",3])
- will append a JSON array of results in Res, or set an Error message, or a JSON object (with parameter names) in Res if ResultAsJSONObject is set
- if one Instances[] is supplied, any exception will be propagated (unless optIgnoreException is set); if more than one Instances[] is supplied, corresponding ExecutedInstancesFailed[] property will be filled with the JSON serialized exception

```
function ExecuteJsonCallback(Instance: pointer; const params: RawUTF8; output: PRawUTF8): boolean;
```

Execute the corresponding method of one weak IInvokable reference

- expect no output argument, i.e. no returned data, unless output is set
- this version will identify TInterfacedObjectFake implementations, and will call directly fInvoke() if possible, to avoid JSON marshalling
- expect params value to be without [], just like TOnFakeInstanceInvoke

function ExecuteJsonFake(Instance: pointer; params: PUTF8Char): boolean;

Execute directly TInterfacedObjectFake.fInvoke()

- expect params value to be with [], just like ExecuteJson

function TempTextWriter: TJSONSerializer;

Allow to use an instance-specific temporary TJSONSerializer

procedure AddInterceptor(const Hook: TServiceMethodExecuteEvent);

Allow to hook method execution

- if optInterceptInputOutput is defined in Options, then Sender.Input/Output fields will contain the execution data context when Hook is called

property BackgroundExecutionThread: TSynBackgroundThreadMethod read
fBackgroundExecutionThread;

Reference to the background execution thread, if any

property CurrentStep: TServiceMethodExecuteEventStep read fCurrentStep write
fCurrentStep;

The current state of the execution

property ExecutedInstancesFailed: TRawUTF8DynArray read fExecutedInstancesFailed;

Contains exception serialization after ExecuteJson of multiple instances

- follows the Instances[] order as supplied to RawExecute/ExecuteJson

- if only a single Instances[] is supplied, the exception will be propagated to the caller, unless optIgnoreException option is defined

- if more than one Instances[] is supplied, any raised Exception will be serialized using ObjectToJSONDebug(), or this property will be left to its default nil content if no exception occurred

property Input: TDocVariantData read fInput;

Set if optInterceptInputOutput is defined in TServiceFactoryServer.Options

- contains a dvObject with input parameters as "argname":value pairs

- this is a read-only property: you cannot change the input content

property LastException: Exception read fLastException;

Only set during AddInterceptor() callback execution, if Step is smsError

property Method: PServiceMethod read fMethod;

Low-level direct access to the associated method information

property OnCallback: TServiceMethodExecuteCallback read fOnCallback;

Points e.g. to TSQLRestServerURIContext.ExecuteCallback

property Options: TServiceMethodOptions read fOptions write fOptions;

Associated settings, as copied from TServiceFactoryServer.Options

property Output: TDocVariantData read fOutput;

Set if optInterceptInputOutput is defined in TServiceFactoryServer.Options

- contains a dvObject with output parameters as "argname":value pairs

- this is a read-only property: you cannot change the output content

property ServiceCustomAnswerHead: RawUTF8 read fServiceCustomAnswerHead write
fServiceCustomAnswerHead;

Set from output TServiceCustomAnswer.Header result parameter

property ServiceCustomAnswerStatus: cardinal **read** fServiceCustomAnswerStatus **write** fServiceCustomAnswerStatus;

Set from output TServiceCustomAnswer.Status result parameter

property Values: TTPointerDynArray **read** fValues;

Low-level direct access to the current input/output parameter values

- you should not need to access this, but rather set optInterceptInputOutput in Options, and read Input/Output content

TServiceCustomAnswer = record

A record type to be used as result for a function method for custom content for interface-based services

- all answers are pure JSON object by default: using this kind of record as result will allow a response of any type (e.g. binary, HTML or text)
- this kind of answer will be understood by our TServiceContainerClient implementation, and it may be used with plain AJAX or HTML requests (via POST), to retrieve some custom content

Content: RawByteString;

The response body

- corresponding to the response type, as defined in Header

Header: RawUTF8;

Mandatory response type, as encoded in the HTTP header

- useful to set the response mime-type - see e.g. JSON_CONTENT_TYPE_HEADER_VAR TEXT_CONTENT_TYPE_HEADER or BINARY_CONTENT_TYPE_HEADER constants or GetMimeContentType() function
- in order to be handled as expected, this field SHALL be set to NOT " (otherwise TServiceCustomAnswer will be transmitted as raw JSON)

Status: cardinal;

The HTTP response code

- if not overridden, will default to HTTP_SUCCESS = 200 on server side
- on client side, will always contain HTTP_SUCCESS = 200 on success, or any error should be handled as expected by the caller (e.g. using TServiceFactoryClient.GetErrorMessage for decoding REST/SOA errors)

TInterfaceResolver = class(TObject)

Abstract factory class allowing to call interface resolution in cascade

- you can inherit from this class to chain the TryResolve() calls so that several kind of implementations may be asked by a TInjectableObject, e.g. TInterfaceStub, TServiceContainer or TDDDRepositoryRestObjectMapping
- this will implement factory pattern, as a safe and thread-safe DI/IoC

TInterfaceResolverForSingleInterface = class(TInterfaceResolver)

Abstract factory class targetting a single kind of interface

constructor Create(const aInterface: TGUID; aImplementation: TInterfacedObjectClass); overload;

This overridden constructor will check and store the supplied class to implement an interface by TGUID

constructor Create(aInterface: PTypeInfo; aImplementation: TInterfacedObjectClass); overload;

This overridden constructor will check and store the supplied class to implement an interface

function GetOneInstance(out Obj): boolean;

You can use this method to resolve the interface as a new instance

property ImplementationClass: string read GetImplementationName;

The class name which will implement each repository instance

TInterfaceResolverInjected = class(TInterfaceResolver)

Abstract factory class targeting any kind of interface

- you can inherit from this class to customize dependency injection (DI/IOC), defining the resolution via InjectStub/InjectResolver/InjectInstance methods, and doing the instance resolution using the overloaded Resolve*() methods
- TServiceContainer will inherit from this class, as the main entry point for interface-based services of the framework (via TSQLRest.Services)
- you can use RegisterGlobal() class method to define some process-wide DI

destructor Destroy; override;

Release all used instances

- including all TInterfaceStub instances as specified to Inject(aStubsByGUID)
- will call _Release on all TInterfacedObject dependencies

function Resolve(aInterface: PTypeInfo; out Obj): boolean; overload;

Can be used to perform an DI/IOC for a given interface

- will search for the supplied interface to its internal list of resolvers
- returns TRUE and set the Obj variable with a matching instance
- can be used as such to resolve an ICalculator interface:

```
var calc: ICalculator;
begin
  if Catalog.Resolve(TypeInfo(ICalculator),calc) then
    ... use calc methods
```

function Resolve(const aGUID: TGUID; out Obj): boolean; overload;

Can be used to perform an DI/IOC for a given interface

- you shall have registered the interface TGUID by a previous call to TInterfaceFactory.RegisterInterfaces([TypeInfo(ICalculator),...])
- returns TRUE and set the Obj variable with a matching instance
- can be used as such to resolve an ICalculator interface:

```
var calc: ICalculator;
begin
  if ServiceContainer.Resolve(ICalculator,cal) then
    ... use calc methods
```

procedure InjectInstance(const aDependencies: array of TInterfacedObject); overload; virtual;

Prepare and setup interface DI/IOC resolution from a TInterfacedObject instance

- any TInterfacedObject declared as dependency will have its reference count increased, and decreased in Destroy

procedure InjectResolver(**const** aOtherResolvers: **array of** TInterfaceResolver;
 OwnOtherResolvers: boolean=false); overload; **virtual**;

Prepare and setup interface DI/loC resolution with TInterfaceResolver kind of factory
 - e.g. a customized TInterfaceStub/TInterfaceMock, a TServiceContainer, a
 TDDDDepositaryRestObjectMapping or any factory class
 - by default, only TInterfaceStub/TInterfaceMock will be owned by this instance, and released by
 Destroy - unless you set OwnOtherResolvers

procedure InjectStub(**const** aStubsByGUID: **array of** TGUID); overload; **virtual**;

*Prepare and setup interface DI/loC resolution with some blank TInterfaceStub specified by their
 TGUID*

class procedure RegisterGlobal(aInterface: PTypeInfo; aImplementationClass:
 TInterfacedObjectClass); overload;

Define a global class type for interface resolution
 - most of the time, you will need a local DI/loC resolution list; but you may use this method to
 register a set of shared and global resolution patterns, common to the whole injection process
 - by default, TAutoLocker and TLockedDocVariant will be registered by this unit to implement
 IAutoLocker and ILockedDocVariant interfaces

class procedure RegisterGlobal(aInterface: PTypeInfo; aImplementation:
 TInterfacedObject); overload;

Define a global instance for interface resolution
 - most of the time, you will need a local DI/loC resolution list; but you may use this method to
 register a set of shared and global resolution patterns, common to the whole injection process
 - the supplied instance will be owned by the global list (incrementing its internal reference
 count), until it will be released via
 RegisterGlobalDelete()
 - the supplied instance will be freed in the finalization of this unit, if not previously released via
 RegisterGlobalDelete()

class procedure RegisterGlobalDelete(aInterface: PTypeInfo);

Undefine a global instance for interface resolution
 - you can unregister a given instance previously defined via
 RegisterGlobal(aInterface, aImplementation)
 - if you do not call RegisterGlobalDelete(), the remaining instances will be freed in the finalization
 of this unit

procedure Resolve(**const** aInterfaces: **array of** TGUID; **const** aObjs: **array of** pointer;
 aRaiseExceptionIfNotFound: boolean=true); overload;

Can be used to perform several DI/loC for a given set of interfaces
 - here interfaces and instances are provided as TGUID and @Instance
 - you shall have registered the interface TGUID by a previous call to
 TInterfaceFactory.RegisterInterfaces([TypeInfo(ICalculator),...])
 - raise an EServiceException if any interface can't be resolved, unless aRaiseExceptionIfNotFound
 is set to FALSE

```
procedure ResolveByPair(const aInterfaceObjPairs: array of pointer;  
aRaiseExceptionIfNotFound: boolean=true);
```

Can be used to perform several DI/IoC for a given set of interfaces

- here interfaces and instances are provided as TypeInfo,@Instance pairs
- raise an EServiceException if any interface can't be resolved, unless aRaiseExceptionIfNotFound is set to FALSE

```
TInjectableObject = class(TInterfacedObjectWithCustomCreate)
```

Any service implementation class could inherit from this class to allow dependency injection aka SOLID DI/IoC by the framework

- once created, the framework will call AddResolver() member, so that its Resolve*() methods could be used to inject any needed dependency for lazy dependency resolution (e.g. within a public property getter)
- any interface published property will also be automatically injected
- if you implement a SOA service with this class, TSQLRestServer.Services will be auto-injected via TServiceFactoryServer.CreateInstance()

```
constructor CreateInjected(const aStubsByGUID: array of TGUID; const  
aOtherResolvers: array of TInterfaceResolver; const aDependencies: array of  
TInterfacedObject; aRaiseEServiceExceptionIfNotFound: boolean=true); virtual;
```

Initialize an instance, defining one or several mean of dependency resolution

- simple TInterfaceStub could be created directly from their TGUID, then any kind of DI/IoC resolver instances could be specified, i.e. either customized TInterfaceStub/TInterfaceMock, a TServiceContainer or a TDDDRestRepositoryRestObjectMapping, and then any TInterfacedObject instance will be used during dependency resolution:

```
procedure TMyTestCase.OneTestCaseMethod;  
var Test: IServiceToBeTested;  
begin  
  Test := TServiceToBeTested.CreateInjected(  
    [ICalculator],  
    [TInterfaceMock.Create(IPersistence,self).  
      ExpectsCount('SaveItem',qoEqualTo,1),  
      RestInstance.Services],  
    [AnyInterfacedObject]);  
  ...
```

- note that all the injected stubs/mocks instances will be owned by the TInjectableObject, and therefore released with it
- any TInterfacedObject declared as dependency will have its reference count increased, and decreased in Destroy
- once DI/IoC is defined, will call the AutoResolve() protected method

```
constructor CreateWithResolver(aResolver: TInterfaceResolver;  
aRaiseEServiceExceptionIfNotFound: boolean=true); virtual;
```

Initialize an instance, defining one dependency resolver

- the resolver may be e.g. a TServiceContainer
- once the DI/IoC is defined, will call the AutoResolve() protected method
- as called by TServiceFactoryServer.CreateInstance

```
destructor Destroy; override;
```

Release all used instances

- including all TInterfaceStub instances as specified to CreateInjected()

procedure Resolve(const aInterfaces: array of TGUID; const aObjs: array of pointer); overload;

Can be used to perform several DI/IoC for a given set of interfaces
 - here interfaces and instances are provided as TGUID and pointers

procedure Resolve(aInterface: PTypeInfo; out Obj); overload;

Can be used to perform an DI/IoC for a given interface type information

procedure Resolve(const aGUID: TGUID; out Obj); overload;

Can be used to perform an DI/IoC for a given interface TGUID

procedure ResolveByPair(const aInterfaceObjPairs: array of pointer);

Can be used to perform several DI/IoC for a given set of interfaces
 - here interfaces and instances are provided as TypeInfo,@Instance pairs

property Resolver: TInterfaceResolver read fResolver;

Access to the associated dependency resolver, if any

TInjectableObjectRest = class(TInjectableObject)

Service implementation class, with direct access on the associated TServiceFactoryServer/TSQLRestServer instances

- allow dependency injection aka SOLID DI/IoC by the framework using inherited TInjectableObject.Resolve() methods
- allows direct access to the underlying ORM using its Server method
- this class will allow Server instance access outside the scope of remote SOA execution, e.g. when a DI is performed on server side: it is therefore a better alternative to ServiceContext.Factory, ServiceContext.Factory.RestServer or ServiceContext.Request.Server

constructor CreateWithResolverAndRest(aResolver: TInterfaceResolver; aFactory: TServiceFactoryServer; aServer: TSQLRestServer; aRaiseExceptionIfNotFound: boolean=true); virtual;

Initialize an instance, defining associated dependencies
 - the resolver may be e.g. a TServiceContainer
 - once the DI/IoC is defined, will call the AutoResolve() protected method
 - as called by TServiceFactoryServer.CreateInstance

property Factory: TServiceFactoryServer read fFactory;

Access to the associated interface factory
 - this property will be injected by TServiceFactoryServer.CreateInstance, so may be nil if the instance was created outside the SOA context

property Server: TSQLRestServer read fServer;

Access to the associated REST Server, e.g. to its ORM methods
 - slightly faster than Factory.RestServer
 - this value will be injected by TServiceFactoryServer.CreateInstance, so may be nil if the instance was created outside the SOA context

IAutoCreateFieldsResolve = interface(IInterface)

Used to set the published properties of a TInjectableAutoCreateFields

- TInjectableAutoCreateFields.Create will check any resolver able to implement this interface, then run its SetPropertyes() method on it

procedure SetPropertyes(Instance: TObject);

This method will be called once on any TInjectableAutoCreateFields just created instance

TInjectableAutoCreateFields = class(TInjectableObject)

Abstract class which will auto-inject its dependencies (DI/IoC), and also manage the instances of its TPersistent/TSynPersistent published properties

- abstract class able with a virtual constructor, dependency injection (i.e. SOLID DI/IoC), and automatic memory management of all nested class published properties
- will also release any T*ObjArray dynamic array storage of persistents, previously registered via TJSONSerializer.RegisterObjArrayForJSON()
- this class is a perfect parent for any class storing data by value, and dependency injection, e.g. DDD services or daemons
- note that non published (e.g. public) properties won't be instantiated
- please take care that you will not create any endless recursion: you should ensure that at one level, nested published properties won't have any class instance matching its parent type
- since the destructor will release all nested properties, you should never store a reference of any of those nested instances outside
- if any associated resolver implements IAutoCreateFieldsResolve, its SetPropertyes() method will be called on all created T*Persistent published properties, so that it may initialize its values

constructor Create; override;

This overridden constructor will instantiate all its nested

TPersistent/TSynPersistent/TSynAutoCreateFields class published properties

- then resolve and call IAutoCreateFieldsResolve.SetPropertyes(self)

destructor Destroy; override;

Finalize the instance, and release its published properties

TInterfaceFactory = class(TObject)

Class handling interface RTTI and fake implementation class

- a thread-safe global list of such class instances is implemented to cache information for better speed: use class function TInterfaceFactory.Get() and not manual TInterfaceFactory.Create / Free
- if you want to search the interfaces by name or TGUID, call once Get(TypeInfo(IMyInterface)) or RegisterInterfaces() for proper registration
- will use TInterfaceFactoryRTTI classes generated from Delphi RTTI

constructor Create(aInterface: PTypeInfo);

Initialize the internal properties from the supplied interface RTTI

- it will check and retrieve all methods of the supplied interface, and prepare all internal structures for later use
- do not call this constructor directly, but TInterfaceFactory.Get()

function CheckMethodIndex(aMethodName: PUTF8Char): integer; overload;

Find the index of a particular method in internal Methods[] list

- won't find the default AddRef/Release/QueryInterface methods
- will raise an EInterfaceFactoryException if the method is not known

function CheckMethodIndex(const aMethodName: RawUTF8): integer; overload;

Find the index of a particular method in internal Methods[] list

- won't find the default AddRef/Release/QueryInterface methods
- will raise an EInterfaceFactoryException if the method is not known

function FindFullMethodIndex(const aFullMethodName: RawUTF8;
alsoSearchExactMethodName: boolean=false): integer;

Find the index of a particular interface.method in internal Methods[] list

- will search for a match against Methods[].InterfaceDotMethodName property
- won't find the default AddRef/Release/QueryInterface methods
- will return -1 if the method is not known

function FindMethod(const aMethodName: RawUTF8): PServiceMethod;

Find a particular method in internal Methods[] list

- just a wrapper around FindMethodIndex() returning a PServiceMethod
- will return nil if the method is not known

function FindMethodIndex(const aMethodName: RawUTF8): integer;

Find the index of a particular method in internal Methods[] list

- will search for a match against Methods[].URI property
- won't find the default AddRef/Release/QueryInterface methods
- will return -1 if the method is not known
- if aMethodName does not have an exact method match, it will try with a trailing underscore, so that e.g. /service/start will match IService._Start()

class function Get(aInterface: PTypeInfo): TInterfaceFactory; overload;

This is the main entry point to the global interface factory cache

- access to this method is thread-safe
- this method will also register the class to further retrieval

class function Get(const aInterfaceName: RawUTF8): TInterfaceFactory; overload;

Retrieve an interface factory from cache, from its name (e.g. 'IMyInterface')

- access to this method is thread-safe
- you shall have registered the interface by a previous call to the overloaded Get(TypeInfo(IMyInterface)) method or RegisterInterfaces()
- if the supplied TGUID has not been previously registered, returns nil

class function Get(const aGUID: TGUID): TInterfaceFactory; overload;

Retrieve an interface factory from cache, from its TGUID

- access to this method is thread-safe
- you shall have registered the interface by a previous call to the overloaded Get(TypeInfo(IMyInterface)) method or RegisterInterfaces()
- if the supplied TGUID has not been previously registered, returns nil

function GetFullMethodName(aMethodIndex: integer): RawUTF8;

Returns the full 'Interface.MethodName' text, from a method index

- the method index should start at 0 for `_free_/_contract_/_signature_` pseudo-methods, and start at index 3 for real `Methods[]`
- will return plain 'Interface' text, if aMethodIndex is incorrect

function GetMethodName(MethodIndex: integer): RawUTF8;

Returns the method name from its method index

- the method index should start at 0 for `_free_/_contract_/_signature_` pseudo-methods, and start at index 3 for real `Methods[]`

class function GetUsedInterfaces: TSynObjectListLocked;

Returns the list of all declared TInterfaceFactory

- as used by SOA and mocking/stubing features of this unit

class function GUID2TypeInfo(const aGUIDs: array of TGUID): PTypeInfoDynArray; overload;

Could be used to retrieve an array of TypeInfo() from their GUID

class function GUID2TypeInfo(const aGUID: TGUID): PTypeInfo; overload;

Could be used to retrieve an array of TypeInfo() from their GUID

class procedure AddToObjArray(var Obj: TInterfaceFactoryObjArray; const aGUIDs: array of TGUID);

Add some TInterfaceFactory instances from their GUID

procedure CheckMethodIndexes(const aMethodName: array of RawUTF8; aSetAllIfNone: boolean; out aBits: TInterfaceFactoryMethodBits);

Set the Methods[] indexes bit from some methods names

- won't find the default AddRef/Release/QueryInterface methods
- will raise an EInterfaceFactoryException if the method is not known

class procedure RegisterInterfaces(const aInterfaces: array of PTypeInfo);

Register one or several interfaces to the global interface factory cache

- so that you can use TInterfaceFactory.Get(aGUID) or Get(aName)

class procedure RegisterUnsafeSPIType(const Types: array of pointer);

Register some TypeInfo() containing unsafe parameter values

- i.e. any RTTI type containing Sensitive Personal Information, e.g. a bank card number or a plain password
- such values will force associated values to be ignored during logging, as a more tuned alternative to `optNoLogInput` or `optNoLogOutput`

property DocVariantOptions: TDocVariantOptions read fDocVariantOptions write fDocVariantOptions;

How this interface will work with variants (including TDocVariant)

- by default, contains `JSON_OPTIONS_FAST` for best performance - i.e. `[dvoReturnNullForUnknownProperty,dvoValueCopiedByReference]`

property InterfaceIID: TGUID read fInterfaceIID;

The registered Interface GUID

property InterfaceName: RawUTF8 read fInterfaceName;

Will return the interface name, e.g. 'ICalculator'

- published property to be serializable as JSON e.g. for debugging info

property InterfaceTypeInfo: PTypeInfo read fInterfaceTypeInfo;

The registered Interface low-level Delphi RTTI type

property InterfaceURI: RawUTF8 read fInterfaceURI write fInterfaceURI;

The interface name, without its initial 'I'

- e.g. ICalculator -> 'Calculator'

property MethodIndexCallbackReleased: Integer read fMethodIndexCallbackReleased;

Identifies a CallbackReleased() method in this interface

- i.e. the index in Methods[] of the following signature:

procedure CallbackReleased(const callback: IInvokable; const interfaceName: RawUTF8);

- this method will be called e.g. by TInterfacedCallback.Destroy, when a callback is released on the client side so that you may be able e.g. to unsubscribe the callback from an interface list (via InterfaceArrayDelete)

- contains -1 if no such method do exist in the interface definition

property MethodIndexCurrentFrameCallback: Integer read fMethodIndexCurrentFrameCallback;

Identifies a CurrentFrame() method in this interface

- i.e. the index in Methods[] of the following signature:

procedure CurrentFrame(isLast: boolean);

- this method will be called e.g. by TSQLHttpClientWebsockets.CallbackRequest for interface callbacks in case of WebSockets jumbo frames, to allow e.g. faster database access via a batch

- contains -1 if no such method do exist in the interface definition

property Methods: TServiceMethodDynArray read fMethods;

The declared internal methods

- list does not contain default AddRef/Release/QueryInterface methods

- nor the _free/_contract/_signature_ pseudo-methods

property MethodsCount: cardinal read fMethodsCount;

The number of internal methods

- does not include the default AddRef/Release/QueryInterface methods

- nor the _free/_contract/_signature_ pseudo-methods

TInterfaceFactoryRTTI = class(TInterfaceFactory)

Class handling interface RTTI and fake implementation class

- this class only exists for Delphi 6 and up, since FPC does not generate the expected RTTI - see <http://bugs.freepascal.org/view.php?id=26774>

TInterfacedObjectFromFactory = class(TInterfacedObject)

Abstract class handling a generic interface implementation class

constructor Create(aFactory: TInterfaceFactory; aOptions: TInterfacedObjectFromFactoryOptions; aInvoke: TOnFakeInstanceInvoke; aNotifyDestroy: TOnFakeInstanceDestroy);

Create an instance, using the specified interface

destructor Destroy; **override**;

Release the remote server instance (in sicClientDriven mode);

property ClientDrivenID: Cardinal **read** fClientDrivenID;

The ID used in sicClientDriven mode

property Factory: TInterfaceFactory **read** fFactory;

The associated interface factory class

TInterfaceFactoryGenerated = **class**(TInterfaceFactory)

Class handling interface implementation generated from source

- this class targets oldest FPC, which did not generate the expected RTTI - see

<http://bugs.freepascal.org/view.php?id=26774>

- mORMotWrapper.pas will generate a new inherited class, overriding abstract
AddMethodsFromTypeInfo() to define the interface methods

class procedure RegisterInterface(aInterface: PTypeInfo); **virtual**;

Register one interface type definition from the current class

- will be called by mORMotWrapper.pas generated code, in initialization section, so that the
needed type information will be available

TOnInterfaceStubExecuteParamsAbstract = **class**(TObject)

Abstract parameters used by TInterfaceStub.Executes() events callbacks

constructor Create(aSender: TInterfaceStub; aMethod: PServiceMethod; **const**
aParams, aEventParams: RawUTF8); **virtual**;

Constructor of one parameters marshalling instance

procedure Error(**const** Format: RawUTF8; **const** Args: **array of const**); **overload**;

Call this method if the callback implementation failed

procedure Error(**const** aErrorMessage: RawUTF8); **overload**;

Call this method if the callback implementation failed

property EventParams: RawUTF8 **read** fEventParams;

A custom message, defined at TInterfaceStub.Executes() definition

property Failed: boolean **read** fFailed;

Low-level flag, set to TRUE if one of the Error() method was called

property Method: PServiceMethod **read** fMethod;

Pointer to the method which is to be executed

property Result: RawUTF8 **read** fResult;

Outgoing values array encoded as JSON

- every var, out parameter or the function result shall be encoded as a JSON array into this
variable, in the same order than the stubbed method declaration

- use Returns() method to create the JSON array directly, from an array of values

property Sender: TInterfaceStub **read** fSender;

The stubbing / mocking generator

property TestCase: TSynTestCase **read** GetSenderAsMockTestCase;

The mocking generator associated test case

- will raise an exception if the associated Sender generator is not a TInterfaceMock

TOnInterfaceStubExecuteParamsVariant =
class(TOnInterfaceStubExecuteParamsAbstract)

Parameters used by TInterfaceStub.Executes() events callbacks as Variant

- this class will expect input and output parameters to specified as variant arrays properties, so is easier (and a bit slower) than the TOnInterfaceStubExecuteParamsJSON class

constructor Create(aSender: TInterfaceStub; aMethod: PServiceMethod; **const** aParams, aEventParams: RawUTF8); **override**;

Constructor of one parameters marshalling instance

function InputAsDocVariant(Kind: TServiceMethodParamsDocVariantKind; Options: TDocVariantOptions=[dvoReturnNullForUnknownProperty, dvoValueCopiedByReference]): **variant**;

Returns the input parameters as a TDocVariant object or array

function OutputAsDocVariant(Kind: TServiceMethodParamsDocVariantKind; Options: TDocVariantOptions=[dvoReturnNullForUnknownProperty, dvoValueCopiedByReference]): **variant**;

Returns the output parameters as a TDocVariant object or array

procedure AddLog(aLog: TSynLogClass; aOutput: boolean; aLevel: TSynLogInfo=sllTrace);

Log the input or output parameters to a log instance

property Input[Index: Integer]: **variant** **read** GetInput;

Input parameters when calling the method

- order shall follow the method const and var parameters

Stub.Add(10,20) -> Input[0]=10, Input[1]=20

- if the supplied Index is out of range, an EInterfaceStub will be raised

property Named[**const** ParamName: RawUTF8]: **variant** **read** GetInNamed **write** SetOutNamed;

Access to input/output parameters when calling the method

- if the supplied name is incorrect, an EInterfaceStub will be raised

- is a bit slower than Input[]/Output[] indexed properties, but easier to work with, and safer in case of method signature change (like parameter add or rename)

- marked as default property, so you can use it e.g. as such:

```
procedure TFooTestCase.ExecuteBar(Ctxt: TOnInterfaceStubExecuteParamsVariant);
begin
  Ctxt['i'] := Ctxt['i']+1; // i := i+1;
  Ctxt['result'] := 42; // result := 42;
end;
```

to emulate this native implementation:

```
function Bar(var i: Integer): Integer;
begin
  inc(i);
  result := 42;
end;
```

- using this default Named[] property is recommended over the index-based Output[] property

- if an Output[]/Named[] item is not set, a default value will be used

property Output[Index: Integer]: variant write SetOutput;

Output parameters returned after method process

- order shall follow the method var, out parameters and the function result (if method is not a procedure)
- if the supplied Index is out of range, an EInterfaceStub will be raised
- can be used as such:

```
procedure TFooTestCase.ExecuteBar(Ctxt: TOnInterfaceStubExecuteParamsVariant);
begin // Input[0]=i
  Ctxt.Output[0] := Ctxt.Input[0]+1; // i := i+1;
  Ctxt.Output[1] := 42;           // result := 42;
end; // Output[0]=i, Output[1]=result
```

to emulate this native implementation:

```
function Bar(var i: Integer): Integer;
begin
  inc(i);
  result := 42;
end;
```

- consider using the safest Named[] property, to avoid parameters index matching issue
- if an Output[]/Named[] item is not set, a default value will be used

property UTF8[const ParamName: RawUTF8]: RawUTF8 read GetInUTF8;

Access to UTF-8 input parameters when calling the method

- if the supplied name is incorrect, an EInterfaceStub will be raised
- is a bit slower than Input[]/Output[] indexed properties, but easier to work with, and safer in case of method signature change (like parameter add or rename)
- slightly easier to use Ctxt.UTF8['str'] than ToUTF8(Ctxt.Named['str'])

TOnInterfaceStubExecuteParamsJSON =

class(TOnInterfaceStubExecuteParamsAbstract)

Parameters used by TInterfaceStub.Executes() events callbacks as JSON

- this class will expect input and output parameters to be encoded as JSON arrays, so is faster than TOnInterfaceStubExecuteParamsVariant

procedure Returns(const ValuesJsonArray: RawUTF8); overload;

A method to return a JSON array of values into Result

- expected format is e.g. '[43,42]'

procedure Returns(const Values: array of const); overload;

A method to return an array of values into Result

- just a wrapper around JSONEncodeArrayOfConst([...])

- can be used as such:

```
procedure TFooTestCase.ExecuteBar(var Ctxt: TOnInterfaceStubExecuteParamsJSON);
begin // Ctxt.Params := '[i]' -> Ctxt.Result := '[i+1,42]'
  Ctxt.Returns([GetInteger(pointer(Ctxt.Params))+1,42]);
end;
```

to emulate this native implementation:

```
function Bar(var i: Integer): Integer;
begin
  inc(i);
  result := 42;
end;
```

property Params: RawUTF8 read fParams;

Incoming parameters array encoded as JSON array without braces

- order follows the method const and var parameters

Stub.Add(10,20) -> Params = '10,20';

TInterfaceStubRule = record

Define a mocking / stubing rule used internally by TInterfaceStub

ExceptionClass: ExceptClass;

The exception class to be raised

- for TInterfaceStub.Raises(), Values contains Exception.Message

Execute: TMethod;

The event handler to be executed

- for TInterfaceStub.Executes(), Values is transmitted as aResult parameter

- either a TOnInterfaceStubExecuteJSON, or a TOnInterfaceStubExecuteVariant

ExpectedPassCount: cardinal;

Expected pass count value set by TInterfaceStub.ExpectsCount()

- value to be compared to the number of times this rule has been executed

- TInterfaceStub/TInterfaceMock will check it in their Destroy destructor, using the comparison stated by ExpectedPassCountOperator

ExpectedPassCountOperator: TSQLQueryOperator;

Comparison operator set by TInterfaceStub.ExpectsCount()

- only qoEqualTo..qoGreaterThanOrEqualTo are relevant here

ExpectedTraceHash: cardinal;

Log trace value set by TInterfaceStub.ExpectsTrace()

- value to be compared to the Hash32() value of the execution log trace

- TInterfaceStub/TInterfaceMock will check it in their Destroy destructor, using the fLogs[] content

Kind: TInterfaceStubRuleKind;

The type of this rule

- isUndefined is used for a TInterfaceStub.ExpectsCount() weak rule

Params: RawUTF8;

Optional expected parameters, serialized as a JSON array

- if equals "", the rule is not parametrized - i.e. it will be the default for this method

RulePassCount: cardinal;

The number of times this rule has been executed

Values: RawUTF8;

Values associated to the rule

- for TInterfaceStub.Executes(), is the aEventParams parameter transmitted to Execute event handler (could be used to e.g. customize the handler)
- for TInterfaceStub.Raises(), is the Exception.Message associated to one ExceptionClass
- for TInterfaceStub>Returns(), is the returned result, serialized as a JSON array (including var / out parameters then any function result)
- for TInterfaceStub.Fails() is the returned error message for TInterfaceStub exception or TInterfaceMock associated test case

TInterfaceStubRules = object(TObject)

Define the rules for a given method as used internally by TInterfaceStub

DefaultRule: integer;

Index in Rules[] of the default rule, i.e. the one with Params=""

MethodPassCount: cardinal;

The number of times this method has been executed

Rules: array of TInterfaceStubRule;

The mocking / stubbing rules associated to this method

function FindRuleIndex(const aParams: RawUTF8): integer;

Find a rule index from its Params content

function FindStrongRuleIndex(const aParams: RawUTF8): integer;

Find a strong rule index from its Params content

procedure AddRule(Sender: TInterfaceStub; aKind: TInterfaceStubRuleKind; const aParams, aValues: RawUTF8; const aEvent: TNotifyEvent=nil; aExceptionClass: ExceptClass=nil; aExpectedPassCountOperator: TSQLQueryOperator=qoNone; aValue: cardinal=0);

Register a rule

TInterfaceStubLog = object(TObject)

Used to keep track of one stubbed method call

CustomResults: RawUTF8;

Any non default result returned after execution

- if not set (i.e. if equals ""), Method^.DefaultResult has been returned
- if WasError is TRUE, always contain the error message

Method: PServiceMethod;

The method called

- a pointer to the existing information in shared TInterfaceFactory

Params: RawUTF8;

The parameters at execution call, as JSON CSV (i.e. array without [])

Timestamp64: Int64;

Call timestamp, in milliseconds

- is filled with GetTickCount64() API returned value

WasError: boolean;

Set to TRUE if this calls failed

- i.e. if EInterfaceFactoryException was raised for TInterfaceStub, or if TInterfaceMock did notify its associated TSynTestCase via a Check()

- CustomResults/Results will contain the error message

function Results: RawUTF8;

The result returned after execution

- this method will return Method^.DefaultResult if CustomResults=""

procedure AddAsText(WR: TTextWriter; aScope: TInterfaceStubLogLayouts; SepChar: AnsiChar=', ');

Append the log in textual format

- typical output is as such:

Add(10,20)=[30],

or, if WasError is TRUE:

Divide(20,0) error "divide by zero",

TInterfaceStub = class(TInterfaceResolver)

Used to stub an interface implementation

- define the expected workflow in a fluent interface using Executes / Fails / Returns / Raises

- this class will be inherited by TInterfaceMock which will contain some additional methods dedicated to mocking behavior (e.g. including in tests)

- each instance of this class will be owned by its generated fake implementation class (retrieved at constructor out parameter): when the stubbed/mocked interface is freed, its associated TInterfaceStub will be freed - so you do not need to protect TInterfaceStub.Create with a try..finally clause, since it will be released when no more needed

- inherits from TInterfaceResolver so match TInjectableObject expectations

constructor Create(const aInterfaceName: RawUTF8; out aStubbedInterface);
reintroduce; overload;

Initialize an interface stub from an interface name (e.g. 'IMyInterface')

- you shall have registered the interface by a previous call to

TInterfaceFactory.GetTypeInfo(IMyInterface) or RegisterInterfaces([])

- if the supplied name has not been previously registered, raise an Exception

constructor Create(aInterface: PTypeInfo); **reintroduce;** overload;

Prepare an interface stub from TypeInfo(IMyInterface) for later injection

- create several TInterfaceStub instances for a given TInjectableObject

procedure TMyTestCase.OneTestCaseMethod;

var Test: IServiceToBeTested;

begin

Test := TServiceToBeTested.CreateInjected([],

TInterfaceStub.Create(TypeInfo(ICalculator)),

TInterfaceMock.Create(TypeInfo(IPersistence), self).

ExpectsCount('SaveItem', qoEqualTo, 1));

constructor Create(const aGUID: TGUID); reintroduce; overload;

Prepare an interface stub from a given TGUID for later injection

- you shall have registered the interface by a previous call to
 TInterfaceFactory.RegisterInterfaces([TypeInfo(IMyInterface),...])
- then create TInterfaceStub instances for a given TInjectableObject:

```

procedure TMyTestCase.OneTestCaseMethod;
var Test: IServiceToBeTested;
begin
    Test := TServiceToBeTested.CreateInjected(
      [IMyInterface],
      TInterfaceMock.Create(IPersistence,self).
        ExpectsCount('SaveItem',qoEqualTo,1));

```

constructor Create(aFactory: TInterfaceFactory; const aInterfaceName: RawUTF8); reintroduce; overload; virtual;

Low-level internal constructor

- you should not call this method, but the overloaded alternatives

constructor Create(aInterface: PTypeInfo; out aStubbedInterface); reintroduce; overload;

Initialize an interface stub from TypeInfo(IMyInterface)

- assign the fake class instance to a stubbed interface variable:

```

var I: ICalculator;
    TInterfaceStub.Create(TypeInfo(ICalculator),I);
    Check(I.Add(10,20)=0,'Default result');

```

constructor Create(const aGUID: TGUID; out aStubbedInterface); reintroduce; overload;

Initialize an interface stub from an interface GUID

- you shall have registered the interface by a previous call to
 TInterfaceFactory.RegisterInterfaces([TypeInfo(IMyInterface),...])
- once registered, create and use the fake class instance as such:

```

var I: ICalculator;
    TInterfaceStub.Create(ICalculator,I);
    Check(I.Add(10,20)=0,'Default result');

```

- if the supplied TGUID has not been previously registered, raise an Exception

function Executes(const aMethodName: RawUTF8; const aParams: array of const; aEvent: TOnInterfaceStubExecuteVariant; const aEventParams: RawUTF8=''): TInterfaceStub; overload;

Add an execution rule for a given method and a set of parameters, with Variant marshalling

- if execution context matches the supplied aParams value, aEvent is triggered
- optional aEventParams parameter will be transmitted to aEvent handler
- raise an Exception if the method name does not exist for this interface

function Executes(const aMethodName, aParams: RawUTF8; aEvent: TOnInterfaceStubExecuteVariant; const aEventParams: RawUTF8=''): TInterfaceStub; overload;

Add an execution rule for a given method and a set of parameters, with Variant marshalling

- if execution context matches the supplied aParams value, aEvent is triggered
- optional aEventParams parameter will be transmitted to aEvent handler
- raise an Exception if the method name does not exist for this interface

```
function Executes(aLog: TSynLogClass; aLogLevel: TSynLogInfo; aKind: TServiceMethodParamsDocVariantKind): TInterfaceStub; overload;
```

Will add execution rules for all methods to log the input parameters
- aKind will define how the input parameters are serialized in JSON

```
function Executes(aEvent: TOnInterfaceStubExecuteVariant; const aEventParams: RawUTF8=''): TInterfaceStub; overload;
```

Add an execution rule for all methods, with Variant marshalling
- optional aEventParams parameter will be transmitted to aEvent handler
- callback's Ctxt: TOnInterfaceStubExecuteParamsVariant's Method field will identify the executed method

```
function Executes(const aMethodName, aParams: RawUTF8; aEvent: TOnInterfaceStubExecuteJSON; const aEventParams: RawUTF8=''): TInterfaceStub; overload;
```

Add an execution rule for a given method and a set of parameters, with JSON marshalling
- if execution context matches the supplied aParams value, aEvent is triggered
- optional aEventParams parameter will be transmitted to aEvent handler
- raise an Exception if the method name does not exist for this interface

```
function Executes(const aMethodName: RawUTF8; aEvent: TOnInterfaceStubExecuteJSON; const aEventParams: RawUTF8=''): TInterfaceStub; overload;
```

Add an execution rule for a given method, with JSON marshalling
- optional aEventParams parameter will be transmitted to aEvent handler
- raise an Exception if the method name does not exist for this interface

```
function Executes(const aMethodName: RawUTF8; aEvent: TOnInterfaceStubExecuteVariant; const aEventParams: RawUTF8=''): TInterfaceStub; overload;
```

Add an execution rule for a given method, with Variant marshalling
- optional aEventParams parameter will be transmitted to aEvent handler
- raise an Exception if the method name does not exist for this interface

```
function Executes(const aMethodName: RawUTF8; const aParams: array of const; aEvent: TOnInterfaceStubExecuteJSON; const aEventParams: RawUTF8=''): TInterfaceStub; overload;
```

Add an execution rule for a given method and a set of parameters, with JSON marshalling
- if execution context matches the supplied aParams value, aEvent is triggered
- optional aEventParams parameter will be transmitted to aEvent handler
- raise an Exception if the method name does not exist for this interface

```
function ExpectsCount(const aMethodName: RawUTF8; const aParams: array of const; aOperator: TSQLQueryOperator; aValue: cardinal): TInterfaceStub; overload;
```

Add a pass count expectation rule for a given method and a set of parameters
- those rules will be evaluated at Destroy execution
- only qoEqualTo..qoGreaterThanOrEqualTo are relevant here
- it will raise EInterfaceFactoryException for TInterfaceStub, but TInterfaceMock will push the failure to the associated test case
- raise an Exception if the method name does not exist for this interface

```
function ExpectsCount(const aMethodName: RawUTF8; aOperator: TSQLQueryOperator;  
aValue: cardinal): TInterfaceStub; overload;
```

Add a pass count expectation rule for a given method

- those rules will be evaluated at Destroy execution
- only `qoEqualTo..qoGreaterThanOrEqualTo` are relevant here
- it will raise `EInterfaceFactoryException` for `TInterfaceStub`, but `TInterfaceMock` will push the failure to the associated test case
- raise an Exception if the method name does not exist for this interface

```
function ExpectsCount(const aMethodName, aParams: RawUTF8; aOperator:  
TSQLQueryOperator; aValue: cardinal): TInterfaceStub; overload;
```

Add a pass count expectation rule for a given method and a set of parameters

- those rules will be evaluated at Destroy execution
- only `qoEqualTo..qoGreaterThanOrEqualTo` are relevant here
- it will raise `EInterfaceFactoryException` for `TInterfaceStub`, but `TInterfaceMock` will push the failure to the associated test case
- raise an Exception if the method name does not exist for this interface

```
function ExpectsTrace(const aMethodName, aValue: RawUTF8): TInterfaceStub;  
overload;
```

Add a JSON-based execution expectation rule for a given method

- those rules will be evaluated at Destroy execution
- supplied `aValue` is the trace in `LogAsText` format
- it will raise `EInterfaceFactoryException` for `TInterfaceStub`, but `TInterfaceMock` will push the failure to the associated test case
- raise an Exception if the method name does not exist for this interface

```
function ExpectsTrace(const aMethodName: RawUTF8; aValue: cardinal):  
TInterfaceStub; overload;
```

Add a hash-based execution expectation rule for a given method

- those rules will be evaluated at Destroy execution
- supplied `aValue` is a `Hash32()` of the trace in `LogAsText` format
- it will raise `EInterfaceFactoryException` for `TInterfaceStub`, but `TInterfaceMock` will push the failure to the associated test case
- raise an Exception if the method name does not exist for this interface

```
function ExpectsTrace(aValue: cardinal): TInterfaceStub; overload;
```

Add a hash-based execution expectation rule for the whole interface

- those rules will be evaluated at Destroy execution
- supplied `aValue` is a `Hash32()` of the trace in `LogAsText` format
- it will raise `EInterfaceFactoryException` for `TInterfaceStub`, but `TInterfaceMock` will push the failure to the associated test case

```
function ExpectsTrace(const aMethodName, aParams: RawUTF8; aValue: cardinal):  
TInterfaceStub; overload;
```

Add a hash-based execution expectation rule for a given method and a set of parameters

- those rules will be evaluated at Destroy execution
- supplied `aValue` is a `Hash32()` of the trace in `LogAsText` format
- it will raise `EInterfaceFactoryException` for `TInterfaceStub`, but `TInterfaceMock` will push the failure to the associated test case
- raise an Exception if the method name does not exist for this interface

```
function ExpectsTrace(const aMethodName: RawUTF8; const aParams: array of const;  
const aValue: RawUTF8): TInterfaceStub; overload;
```

Add a JSON-based execution expectation rule for a given method and a set of parameters

- those rules will be evaluated at Destroy execution
- supplied aValue is the trace in LogAsText format
- it will raise EInterfaceFactoryException for TInterfaceStub, but TInterfaceMock will push the failure to the associated test case
- raise an Exception if the method name does not exist for this interface

```
function ExpectsTrace(const aValue: RawUTF8): TInterfaceStub; overload;
```

Add a JSON-based execution expectation rule for the whole interface

- those rules will be evaluated at Destroy execution
- supplied aValue is the trace in LogAsText format
- it will raise EInterfaceFactoryException for TInterfaceStub, but TInterfaceMock will push the failure to the associated test case

```
function ExpectsTrace(const aMethodName: RawUTF8; const aParams: array of const;  
aValue: cardinal): TInterfaceStub; overload;
```

Add a hash-based execution expectation rule for a given method and a set of parameters

- those rules will be evaluated at Destroy execution
- supplied aValue is a Hash32() of the trace in LogAsText format
- it will raise EInterfaceFactoryException for TInterfaceStub, but TInterfaceMock will push the failure to the associated test case
- raise an Exception if the method name does not exist for this interface

```
function ExpectsTrace(const aMethodName, aParams, aValue: RawUTF8): TInterfaceStub;  
overload;
```

Add a JSON-based execution expectation rule for a given method and a set of parameters

- those rules will be evaluated at Destroy execution
- supplied aValue is the trace in LogAsText format
- it will raise EInterfaceFactoryException for TInterfaceStub, but TInterfaceMock will push the failure to the associated test case
- raise an Exception if the method name does not exist for this interface

```
function Fails(const aMethodName, aErrorMsg: RawUTF8): TInterfaceStub; overload;
```

Add an error rule for a given method

- an error will be returned to the caller, with aErrorMsg as message
- it will raise EInterfaceFactoryException for TInterfaceStub, but TInterfaceMock will push the failure to the associated test case
- raise an Exception if the method name does not exist for this interface

```
function Fails(const aMethodName, aParams, aErrorMsg: RawUTF8): TInterfaceStub;  
overload;
```

Add an error rule for a given method and a set of parameters

- an error will be returned to the caller, with aErrorMsg as message
- it will raise EInterfaceFactoryException for TInterfaceStub, but TInterfaceMock will push the failure to the associated test case
- raise an Exception if the method name does not exist for this interface

```
function Fails(const aMethodName: RawUTF8; const aParams: array of const; const aErrorMsg: RawUTF8): TInterfaceStub; overload;
```

Add an error rule for a given method and a set of parameters

- an error will be returned to the caller, with aErrorMsg as message
- it will raise EInterfaceFactoryException for TInterfaceStub, but TInterfaceMock will push the failure to the associated test case
- raise an Exception if the method name does not exist for this interface

```
function LogAsText(SepChar: AnsiChar=', '): RawUTF8;
```

The stubbed method execution trace converted as text

- typical output is a list of calls separated by commas:
Add(10,20)=[30],Divide(20,0) error "divide by zero"

```
function Raises(const aMethodName: RawUTF8; aException: ExceptClass; const aMessage: string): TInterfaceStub; overload;
```

Add an exception rule for a given method

- will create and raise the specified exception for this method
- raise an Exception if the method name does not exist for this interface

```
function Raises(const aMethodName, aParams: RawUTF8; aException: ExceptClass; const aMessage: string): TInterfaceStub; overload;
```

Add an exception rule for a given method and a set of parameters

- will create and raise the specified exception for this method, if the execution context matches the supplied aParams value
- raise an Exception if the method name does not exist for this interface

```
function Raises(const aMethodName: RawUTF8; const aParams: array of const; aException: ExceptClass; const aMessage: string): TInterfaceStub; overload;
```

Add an exception rule for a given method and a set of parameters

- will create and raise the specified exception for this method, if the execution context matches the supplied aParams value
- raise an Exception if the method name does not exist for this interface

```
function Returns(const aMethodName: RawUTF8; const aExpectedResults: array of const): TInterfaceStub; overload;
```

Add an evaluation rule for a given method

- aExpectedResults will be returned to the caller after conversion to a JSON array
- raise an Exception if the method name does not exist for this interface

```
function Returns(const aMethodName, aExpectedResults: RawUTF8): TInterfaceStub; overload;
```

Add an evaluation rule for a given method

- aExpectedResults JSON array will be returned to the caller
- raise an Exception if the method name does not exist for this interface

```
function Returns(const aMethodName: RawUTF8; const aParams, aExpectedResults: array of const): TInterfaceStub; overload;
```

Add an evaluation rule for a given method and a set of parameters

- aExpectedResults JSON array will be returned to the caller
- raise an Exception if the method name does not exist for this interface

function Returns(const aMethodName, aParams, aExpectedResults: RawUTF8): TInterfaceStub; overload;

Add an evaluation rule for a given method and a set of parameters

- aExpectedResults JSON array will be returned to the caller
- raise an Exception if the method name does not exist for this interface

function SetOptions(Options: TInterfaceStubOptions): TInterfaceStub;

Set the optional stubbing/mocking options

- same as the Options property, but in a fluent-style interface

procedure ClearLog;

Reset the internal trace

- Log, LogAsText, LogHash and LogCount will be initialized

property InterfaceFactory: TInterfaceFactory read fInterface;

Access to the registered Interface RTTI information

property LastInterfacedObjectFake: TInterfacedObject read fLastInterfacedObjectFake;

Returns the last created TInterfacedObject instance

- e.g. corresponding to the out aStubbedInterface parameter of Create()

property Log: TInterfaceStubLogDynArray read fLogs;

The stubbed method execution trace items

property LogCount: Integer read fLogCount;

The stubbed method execution trace number of items

property LogHash: cardinal read GetLogHash;

The stubbed method execution trace converted as one numerical hash

- returns Hash32(LogAsText)

property Options: TInterfaceStubOptions read fOptions write IntSetOptions;

Optional stubbing/mocking options

- you can use the SetOptions() method in a fluent-style interface

TInterfaceMock = class(TInterfaceStub)

Used to mock an interface implementation via expect-run-verify pattern

- TInterfaceStub will raise an exception on Fails(), ExpectsCount() or ExpectsTrace() rule activation, but TInterfaceMock will call TSynTestCase.Check() with no exception with such rules, as expected by a mocked interface
- this class will follow the expect-run-verify pattern, i.e. expectations are defined before running the test, and verification is performed when the instance is released - use TInterfaceMockSpy if you prefer the more explicit run-verify pattern

constructor Create(aInterface: PTypeInfo; aTestCase: TSynTestCase); reintroduce; overload;

Initialize an interface mock from TypeInfo(IMyInterface) for later injection

- aTestCase.Check() will be called in case of mocking failure

constructor Create(const aGUID: TGUID; aTestCase: TSynTestCase); reintroduce; overload;

Initialize an interface mock from TypeInfo(IMyInterface) for later injection
 - aTestCase.Check() will be called in case of mocking failure

constructor Create(const aInterfaceName: RawUTF8; out aMockedInterface; aTestCase: TSynTestCase); reintroduce; overload;

Initialize an interface mock from an interface name (e.g. 'IMyInterface')
 - aTestCase.Check() will be called in case of mocking failure
 - you shall have registered the interface by a previous call to TInterfaceFactory.Get(TypeInfo(IMyInterface)) or RegisterInterfaces()
 - if the supplied name has not been previously registered, raise an Exception

constructor Create(aInterface: PTypeInfo; out aMockedInterface; aTestCase: TSynTestCase); reintroduce; overload;

Initialize an interface mock from TypeInfo(IMyInterface)
 - aTestCase.Check() will be called in case of mocking failure
procedure TMyTestCase.OneTestCaseMethod;
var Persist: IPersistence;
 ...
 TInterfaceMock.Create(TypeInfo(IPersistence), Persist, self).
 ExpectsCount('SaveItem', qoEqualTo, 1));

constructor Create(const aGUID: TGUID; out aMockedInterface; aTestCase: TSynTestCase); reintroduce; overload;

Initialize an interface mock from an interface TGUID
 - aTestCase.Check() will be called during validation of all Expects*()
 - you shall have registered the interface by a previous call to TInterfaceFactory.RegisterInterfaces([TypeInfo(IPersistence), ...])
 - once registered, create and use the fake class instance as such:
procedure TMyTestCase.OneTestCaseMethod;
var Persist: IPersistence;
 ...
 TInterfaceMock.Create(IPersistence, Persist, self).
 ExpectsCount('SaveItem', qoEqualTo, 1));
 - if the supplied TGUID has not been previously registered, raise an Exception

property TestCase: TSynTestCase read fTestCase;

The associated test case

TInterfaceMockSpy = class(TInterfaceMock)

Used to mock an interface implementation via run-verify pattern
 - this class will implement a so called "test-spy" mocking pattern, i.e. no expectation is to be declared at first, but all calls are internally logged (i.e. it force imoLogMethodCallsAndResults option to be defined), and can afterwards been check via Verify() calls

constructor Create(aFactory: TInterfaceFactory; const aInterfaceName: RawUTF8);
override;

This will set and force imoLogMethodCallsAndResults option as needed
 - you should not call this method, but the overloaded alternatives

```
procedure Verify(const aMethodName, aTrace: RawUTF8; aScope:
TInterfaceMockSpyCheck); overload;
```

Check an execution trace for a specified method

- text trace format will follow specified scope, e.g.

```
Verify('Add', '(10,30),(2,35)', chkNameParams);
```

or include parameters and function results:

```
Verify('Add', '(10,30)=[300],(2,35)=[37]', chkNameParamsResults);
```

- if aMethodName does not exists or aScope=chkName, will raise an exception

```
procedure Verify(const aMethodName, aParams, aTrace: RawUTF8); overload;
```

Check an execution trace for a specified method and parameters

- text trace format shall contain only results, e.g.

```
Verify('Add', '2,35', '[37]');
```

```
procedure Verify(const aMethodName: RawUTF8; const aParams: array of const; const
aTrace: RawUTF8); overload;
```

Check an execution trace for a specified method and parameters

- text trace format shall contain only results, e.g.

```
Verify('Add', [2,35], '[37]');
```

```
procedure Verify(const aTrace: RawUTF8; aScope: TInterfaceMockSpyCheck); overload;
```

Check an execution trace for the global interface

- text trace format shall follow method calls, e.g.

```
Verify('Multiply,Add', chkName);
```

or may include parameters:

```
Verify('Multiply(10,30),Add(2,35)', chkNameParams);
```

or include parameters and function results:

```
Verify('Multiply(10,30)=[300],Add(2,35)=[37]', chkNameParamsResults);
```

```
procedure Verify(const aMethodName: RawUTF8; aOperator:
TSQLQueryOperator=qoGreaterThan; aCount: cardinal=0); overload;
```

Check that a method has been called a specify number of times

```
procedure Verify(const aMethodName, aParams: RawUTF8; aOperator:
TSQLQueryOperator=qoGreaterThan; aCount: cardinal=0); overload;
```

Check a method calls count with a set of parameters

- parameters shall be defined as a JSON array of values

```
procedure Verify(const aMethodName: RawUTF8; const aParams: array of const;
aOperator: TSQLQueryOperator=qoGreaterThan; aCount: cardinal=0); overload;
```

Check a method calls count with a set of parameters

- parameters shall be defined as a JSON array of values

TServiceFactory = class(TObject)

An abstract service provider, as registered in TServiceContainer

- each registered interface has its own TServiceFactory instance, available as one TSQLServiceContainer item from TSQLRest.Services property
- this will be either implemented by a registered TInterfacedObject on the server, or by a on-the-fly generated fake TInterfacedObject class communicating via JSON on a client

- TSQLRestServer will have to register an interface implementation as:

```
Server.ServiceRegister(TServiceCalculator,[TypeInfo(ICalculator)],sicShared);
```

- TSQLRestClientURI will have to register an interface remote access as:

```
Client.ServiceRegister([TypeInfo(ICalculator)],sicShared));
```

note that the implementation (TServiceCalculator) remain on the server side only: the client only needs the ICalculator interface

- then TSQLRestServer and TSQLRestClientURI will both have access to the service, via their Services property, e.g. as:

```
var I: ICalculator;
...
if Services.Info(ICalculator).Get(I) then
  result := I.Add(10,20);
```

which is in practice to be used with the faster wrapper method:

```
if Services.Resolve(ICalculator,I) then
  result := I.Add(10,20);
```

Used for DI-2.1.5 (page 2557).

constructor Create(aRest: TSQLRest; aInterface: PTypeInfo; aInstanceCreation: TServiceInstanceImplementation; **const** aContractExpected: RawUTF8);

Initialize the service provider parameters

- it will check and retrieve all methods of the supplied interface, and prepare all internal structures for its serialized execution

function Get(out Obj): Boolean; **virtual; abstract;**

Retrieve an instance of this interface

- this virtual method will be overridden to reflect the expected behavior of client or server side
- can be used as such to resolve an I: ICalculator interface:

```
var I: ICalculator;
begin
  if fClient.Services.Info(TypeInfo(ICalculator)).Get(I) then
    ... use I
```

function RetrieveSignature: RawUTF8; **virtual; abstract;**

Retrieve the published signature of this interface

- is always available on TServiceFactoryServer, but TServiceFactoryClient will be able to retrieve it only if TServiceContainerServer.PublishSignature is set to TRUE (which is not the default setting, for security reasons)

property Contract: RawUTF8 read fContract;

The service contract, serialized as a JSON object

- a "contract" is in fact the used interface signature, i.e. its implementation mode (InstanceCreation) and all its methods definitions
- a possible value for a one-method interface defined as such:

```
function ICalculator.Add(n1,n2: integer): integer;
```

may be returned as the following JSON object:

```
{ "contract": "Calculator", "implementation": "shared",
  "methods": [ { "method": "Add",
    "arguments": [ { "argument": "Self", "direction": "in", "type": "self" },
      { "argument": "n1", "direction": "in", "type": "integer" },
      { "argument": "n2", "direction": "in", "type": "integer" },
      { "argument": "Result", "direction": "out", "type": "integer" }
    ]
  } ]
}
```

property ContractExpected: RawUTF8 read fContractExpected write fContractExpected;

The published service contract, as expected by both client and server

- by default, will contain ContractHash property value (for security)
- but you can override this value using plain Contract or any custom value (e.g. a custom version number) - in this case, both TServiceFactoryClient and TServiceFactoryServer instances must have a matching ContractExpected
- this value is returned by a '_contract_' pseudo-method name, with the URI:

POST /root/Interface._contract_

or (if TSQLRestRoutingJSON_RPC is used):

```
POST /root/Interface
(...)
{ "method": "_contract_", "params": [] }
```

(e.g. to be checked in TServiceFactoryClient.Create constructor)

- if set to SERVICE_CONTRACT_NONE_EXPECTED (i.e. '*'), the client won't check and ask the server contract for consistency: it may be used e.g. for accessing a plain REST HTTP server which is not based on mORMot, so may not implement POST /root/Interface._contract_

property ContractHash: RawUTF8 read fContractHash;

A hash of the service contract, serialized as a JSON string

- this may be used instead of the JSON signature, to enhance security (i.e. if you do not want to publish the available methods, but want to check for the proper synchronization of both client and server)
- a possible value may be: "C351335A7406374C"

property InstanceCreation: TServiceInstanceImplementation read fInstanceCreation;

How each class instance is to be created

- only relevant on the server side; on the client side, this class will be accessed only to retrieve a remote access instance, i.e. sicSingle

property InterfaceFactory: TInterfaceFactory read fInterface;

Access to the registered Interface RTTI information

property InterfaceIID: TGUID read GetInterfaceIID;

The registered Interface GUID

- just maps InterfaceFactory.InterfaceIID

property InterfaceMangledURI: RawUTF8 read fInterfaceMangledURI;

The registered Interface mangled URI

- in fact this is encoding the GUID using BinToBase64URI(), e.g.

['{c9a646d3-9c61-4cb7-bfcd-ee2522c8f633}'] into '00amyWGct0y_ze41Isj2Mw'

- can be substituted to the clear InterfaceURI name

property InterfaceTypeInfo: PTypeInfo read GetInterfaceTypeInfo;

The registered Interface low-level Delphi RTTI type

- just maps InterfaceFactory.InterfaceTypeInfo

property InterfaceURI: RawUTF8 read fInterfaceURI;

The registered Interface URI

- in fact this is the Interface name without the initial 'I', e.g. 'Calculator' for ICalculator

property Rest: TSQLRest read fRest;

The associated RESTful instance

TServiceFactoryServerInstance = object(TObject)

Server-side service provider uses this to store one internal instance

- used by TServiceFactoryServer in sicClientDriven, sicPerSession, sicPerUser or sicPerGroup mode

Instance: TInterfacedObject;

The implementation instance itself

InstanceID: PtrUInt;

The internal Instance ID, as remotely sent in "id":1

- is set to 0 when an entry in the array is free

LastAccess64: Int64;

GetTickCount64() timestamp corresponding to the last access of this instance

Session: cardinal;

The associated client session

procedure SafeFreeInstance(Factory: TServiceFactoryServer);

Used to release the implementation instance

- direct FreeAndNil(Instance) may lead to A/V if self has been assigned to an interface to any sub-method on the server side -> dec(RefCount)

TServiceFactoryServer = class(TServiceFactory)

A service provider implemented on the server side

- each registered interface has its own TServiceFactoryServer instance, available as one

TSQLServiceContainerServer item from TSQLRest.Services property

- will handle the implementation class instances of a given interface

- by default, all methods are allowed to execution: you can call AllowAll, DenyAll, Allow or Deny in order to specify your exact security policy

Used for DI-2.1.5 (page 2557).

```
constructor Create(aRestServer: TSQLRestServer; aInterface: PTypeInfo;  
aInstanceCreation: TServiceInstanceImplementation; aImplementationClass:  
TInterfacedClass; const aContractExpected: RawUTF8; aTimeOutSec: cardinal;  
aSharedInstance: TInterfacedObject); reintroduce;
```

Initialize the service provider on the server side

- expect an direct server-side implementation class, which may inherit from plain TInterfacedClass, TInterfacedObjectWithCustomCreate if you need an overridden constructor, or TInjectableObject to support DI/IoC
- for sicClientDriven, sicPerSession, sicPerUser or sicPerGroup modes, a time out (in seconds) can be defined (default is 30 minutes) - if the specified aTimeOutSec is 0, interface will be forced in sicSingle mode
- you should usually have to call the TSQLRestServer.ServiceRegister() method instead of calling this constructor directly

```
destructor Destroy; override;
```

Release all used memory

- e.g. any internal TServiceFactoryServerInstance instances (any shared instance, and all still living instances in sicClientDrive mode)

```
function Allow(const aMethod: array of RawUTF8): TServiceFactoryServer;
```

Allow specific methods execution for the all TSQLAuthGroup

- methods names should be specified as an array (e.g. ['Add','Multiply'])
- all Groups will be affected by this method (on both client and server sides)
- this method returns self in order to allow direct chaining of security calls, in a fluent interface

```
function AllowAll: TServiceFactoryServer;
```

Allow all methods execution for all TSQLAuthGroup

- all Groups will be affected by this method (on both client and server sides)
- this method returns self in order to allow direct chaining of security calls, in a fluent interface

```
function AllowAllByID(const aGroupID: array of TID): TServiceFactoryServer;
```

Allow all methods execution for the specified TSQLAuthGroup ID(s)

- the specified group ID(s) will be used to authorize remote service calls from the client side
- you can retrieve a TSQLAuthGroup ID from its identifier, as such:
UserGroupID := fServer.MainFieldID(TSQLAuthGroup, 'User');
- this method returns self in order to allow direct chaining of security calls, in a fluent interface

```
function AllowAllByName(const aGroup: array of RawUTF8): TServiceFactoryServer;
```

Allow all methods execution for the specified TSQLAuthGroup names

- is just a wrapper around the other AllowAllByID() method, retrieving the Group ID from its main field
- this method returns self in order to allow direct chaining of security calls, in a fluent interface

```
function AllowByID(const aMethod: array of RawUTF8; const aGroupID: array of TID):  
TServiceFactoryServer;
```

Allow specific methods execution for the specified TSQLAuthGroup ID(s)

- methods names should be specified as an array (e.g. ['Add','Multiply'])
- the specified group ID(s) will be used to authorize remote service calls from the client side
- you can retrieve a TSQLAuthGroup ID from its identifier, as such:
UserGroupID := fServer.MainFieldID(TSQLAuthGroup, 'User');
- this method returns self in order to allow direct chaining of security calls, in a fluent interface

```
function AllowByName(const aMethod: array of RawUTF8; const aGroup: array of RawUTF8): TServiceFactoryServer;
```

Allow specific methods execution for the specified TSQLAuthGroup name(s)

- is just a wrapper around the other AllowByID() method, retrieving the Group ID from its main field
- methods names should be specified as an array (e.g. ['Add','Multiply'])
- this method returns self in order to allow direct chaining of security calls, in a fluent interface

```
function Deny(const aMethod: array of RawUTF8): TServiceFactoryServer;
```

Deny specific methods execution for the all TSQLAuthGroup

- methods names should be specified as an array (e.g. ['Add','Multiply'])
- all Groups will be affected by this method (on both client and server sides)
- this method returns self in order to allow direct chaining of security calls, in a fluent interface

```
function DenyAll: TServiceFactoryServer;
```

Deny all methods execution for all TSQLAuthGroup

- all Groups will be affected by this method (on both client and server sides)
- this method returns self in order to allow direct chaining of security calls, in a fluent interface

```
function DenyAllByID(const aGroupID: array of TID): TServiceFactoryServer;
```

Deny all methods execution for the specified TSQLAuthGroup ID(s)

- the specified group ID(s) will be used to authorize remote service calls from the client side
- you can retrieve a TSQLAuthGroup ID from its identifier, as such:
UserGroupID := fServer.MainFieldID(TSQLAuthGroup, 'User');
- this method returns self in order to allow direct chaining of security calls, in a fluent interface

```
function DenyAllByName(const aGroup: array of RawUTF8): TServiceFactoryServer;
```

Deny all methods execution for the specified TSQLAuthGroup names

- is just a wrapper around the other DenyAllByID() method, retrieving the Group ID from its main field
- this method returns self in order to allow direct chaining of security calls, in a fluent interface

```
function DenyByID(const aMethod: array of RawUTF8; const aGroupID: array of TID): TServiceFactoryServer; overload;
```

Deny specific methods execution for the specified TSQLAuthGroup ID(s)

- methods names should be specified as an array (e.g. ['Add','Multiply'])
- the specified group ID(s) will be used to unauthorize remote service calls from the client side
- you can retrieve a TSQLAuthGroup ID from its identifier, as such:
UserGroupID := fServer.MainFieldID(TSQLAuthGroup, 'User');
- this method returns self in order to allow direct chaining of security calls, in a fluent interface

```
function DenyByName(const aMethod: array of RawUTF8; const aGroup: array of RawUTF8): TServiceFactoryServer;
```

Deny specific methods execution for the specified TSQLAuthGroup name(s)

- is just a wrapper around the other DenyByID() method, retrieving the Group ID from its main field
- methods names should be specified as an array (e.g. ['Add','Multiply'])
- this method returns self in order to allow direct chaining of security calls, in a fluent interface

function Get(out Obj): Boolean; **override**;

Retrieve an instance of this interface from the server side

- sicShared mode will retrieve the shared instance
- sicPerThread mode will retrieve the instance corresponding to the current running thread
- all other kind of instance creation will behave the same as sicSingle when accessed directly from this method, i.e. from server side: in fact, on the server side, there is no notion of client, session, user nor group
- if ServiceContext.Factory is nil (i.e. if there is no other service context currently associated), this method will also update ServiceContext.Factory, so that the implementation method will be able to access the associated TSQLRestServer instance if needed

function RestServer: TSQLRestServer;

Just type-cast the associated TSQLRest instance to a true TSQLRestServer

function RetrieveSignature: RawUTF8; **override**;

Retrieve the published signature of this interface

- is always available on TServiceFactoryServer, but TServiceFactoryClient will be able to retrieve it only if TServiceContainerServer.PublishSignature is set to TRUE (which is not the default setting, for security reasons)

function RunOnAllInstances(const aEvent: TOnServiceFactoryServerOne; var aOpaque): integer;

Call the supplied aEvent callback for all class instances implementing this service

function SetOptions(const aMethod: array of RawUTF8; aOptions: TServiceMethodOptions; aAction: TServiceMethodOptionsAction=moaReplace): TServiceFactoryServer;

Define execution options for a given set of methods

- methods names should be specified as an array (e.g. ['Add','Multiply'])
- if no method name is given (i.e. []), option will be set for all methods
- include optExecInMainThread will force the method(s) to be called within a RunningThread.Synchronize() call - slower, but thread-safe
- this method returns self in order to allow direct chaining of security calls, in a fluent interface

function SetServiceLog(const aMethod: array of RawUTF8; aLogRest: TSQLRest; aLogClass: TSQLRecordServiceLogClass=nil): TServiceFactoryServer;

Log method execution information to a TSQLRecordServiceLog table

- methods names should be specified as an array (e.g. ['Add','Multiply'])
- if no method name is given (i.e. []), option will be set for all methods
- will write to the specified aLogRest instance, and will disable writing if aLogRest is nil
- will write to a (inherited) TSQLRecordServiceLog table, as available in TSQLRest's model, unless a dedicated table is specified as aLogClass
- this method returns self in order to allow direct chaining of security calls, in a fluent interface

function SetTimeoutSec(value: cardinal): TServiceFactoryServer;

Define the the instance life time-out, in seconds

- for sicClientDriven, sicPerSession, sicPerUser or sicPerGroup modes
- raise an exception for other kind of execution
- this method returns self in order to allow direct chaining of setting calls for the service, in a fluent interface

procedure AddInterceptor(**const** Hook: TServiceMethodExecuteEvent);

Allow to hook the methods execution

- several events could be registered, and will be called directly before and after method execution
- if optInterceptInputOutput is defined in Options, then Sender.Input/Output fields will contain the execution data context when Hook is called
- see OnMethodExecute if you want to implement security features

property ByPassAuthentication: boolean **read** fByPassAuthentication **write** fByPassAuthentication;

Set to TRUE disable Authentication method check for the whole interface

- by default (FALSE), all interface-based services will require valid RESTful authentication (if enabled on the server side); setting TRUE will disable authentication for all methods of this interface (e.g. for returning some HTML content from a public URI, or to implement a public service catalog)

property ExcludeServiceLogCustomAnswer: boolean **read** fExcludeServiceLogCustomAnswer **write** fExcludeServiceLogCustomAnswer;

Disable base64-encoded TSQLRecordServiceLog.Output for methods returning TServiceCustomAnswer record (to reduce storage size)

property ImplementationClass: TInterfacedClass **read** fImplementationClass;

The class type used to implement this interface

property OnMethodExecute: TOnServiceCanExecute **read** fOnMethodExecute **write** fOnMethodExecute;

You can define here an event to allow/deny execution of any method of this service, at runtime

property ResultAsJSONObject: boolean **read** fResultAsJSONObject **write** fResultAsJSONObject;

Set to TRUE to return the interface's methods result as JSON object

- by default (FALSE), any method execution will return a JSON array with all VAR/OUT parameters, in order
- TRUE will generate a JSON object instead, with the VAR/OUT parameter names as field names (and "Result" for any function result) - may be useful e.g. when working with JavaScript clients
- Delphi clients (i.e. TServiceFactoryClient/TInterfacedObjectFake) will transparently handle both formats
- this value can be overridden by setting ForceServiceResultAsJSONObject for a given TSQLRestServerURIContext (e.g. for server-side JavaScript work)

property ResultAsJSONObjectWithoutResult: boolean **read** fResultAsJSONObjectWithoutResult **write** fResultAsJSONObjectWithoutResult;

Set to TRUE to return the interface's methods result as JSON object with no '{"result":{...}}' nesting

- could be used e.g. for plain non mORMot REST Client with in sicSingle or sicShared mode kind of services
- on client side, consider using TSQLRestClientURI.ServiceDefineSharedAPI

property ResultAsXMLObject: boolean **read** fResultAsXMLObject **write** fResultAsXMLObject;

Set to TRUE to return the interface's methods result as XML object

- by default (FALSE), method execution will return a JSON array with all VAR/OUT parameters, or a JSON object if ResultAsJSONObject is TRUE
- TRUE will generate a XML object instead, with the VAR/OUT parameter names as field names (and "Result" for any function result) - may be useful e.g. when working with some XML-only clients
- Delphi clients (i.e. TServiceFactoryClient/TInterfacedObjectFake) does NOT handle this XML format yet
- this value can be overridden by setting ForceServiceResultAsXMLObject for a given TSQLRestServerURIContext instance

property ResultAsXMLObjectIfAcceptOnlyXML: boolean **read** fResultAsJSONObjectIfAccept **write** fResultAsJSONObjectIfAccept;

Set to TRUE to return XML objects for the interface's methods result if the Accept: HTTP header is exactly 'application/xml' or 'text/xml'

- the header should be exactly 'Accept: application/xml' or 'Accept: text/xml' (and no other value)
- in this case, ForceServiceResultAsXMLObject will be set for this particular TSQLRestServerURIContext instance, and result returned as XML
- using this method allows to mix standard JSON requests (from JSON or AJAX clients) and XML requests (from XML-only clients)

property ResultAsXMLObjectNamespace: RawUTF8 **read** fResultAsXMLObjectNamespace **write** fResultAsXMLObjectNamespace;

Specify a custom name space content when returning a XML object

- by default, no name space will be appended - but such rough XML will have potential validation problems
- you may use e.g. XMLUTF8_NAMESPACE, which will append <content ...> ... </content> around the generated XML data

property Stat[const aMethod: RawUTF8]: TSynMonitorInputOutput **read** GetStat;

Retrieve detailed statistics about a method use

- will return a reference to the actual item in Stats[]: caller should not free the returned instance

property Stats: TSynMonitorInputOutputObjArray **read** fStats;

Direct access to per-method detailed process statistics

- this Stats[] array follows Interface.Methods[] order
- see Stat[] property to retrieve information about a method by name

property TimeoutSec: cardinal **read** GetTimeoutSec **write** SetTimeoutSecInt;

The instance life time-out, in seconds

- for sicClientDriven, sicPerSession, sicPerUser or sicPerGroup modes
- raise an exception for other kind of execution
- you can also use the SetTimeOutSec() fluent function instead

TServiceFactoryClient = class(TServiceFactory)

A service provider implemented on the client side

- each registered interface has its own TServiceFactoryClient instance, available as one TSQLServiceContainerClient item from TSQLRest.Services property
- will emulate "fake" implementation class instance of a given interface and call remotely the server to process the actual implementation

Used for DI-2.1.5 (page 2557).

constructor Create(aRest: TSQLRest; aInterface: PTypeInfo; aInstanceCreation: TServiceInstanceImplementation; **const** aContractExpected: RawUTF8='');

Initialize the service provider parameters

- it will check and retrieve all methods of the supplied interface, and prepare all internal structures for its serialized execution
- also set the inherited TServiceInstanceImplementation property
- initialize fSharedInstance if aInstanceCreation is sicShared
- it will also ensure that the corresponding TServiceFactory.Contract matches on both client and server sides, either by comparing the default signature (based on methods and arguments), either by using the supplied expected contract (which may be a custom version number)

destructor Destroy; **override**;

Finalize the service provider used instance

- e.g. the shared fake implementation instance

function Get(out Obj): Boolean; **override**;

Retrieve an instance of this interface from the client side

class function GetErrorMessage(status: integer): RawUTF8;

Convert a HTTP error from mORMot's REST/SOA into an English text message

- will recognize the HTTP_UNAVAILABLE, HTTP_NOTIMPLEMENTED, HTTP_NOTFOUND, HTTP_NOTALLOWED, HTTP_UNAUTHORIZED or HTTP_NOTACCEPTABLE errors, as generated by the TSQLRestServer side
- is used by TServiceFactoryClient.InternalInvoke, but may be called on client side for TServiceCustomAnswer.Status <> HTTP_SUCCESS

function RetrieveSignature: RawUTF8; **override**;

Retrieve the published signature of this interface

- TServiceFactoryClient will be able to retrieve it only if TServiceContainerServer.PublishSignature is set to TRUE (which is not the default setting, for security reasons) - this function is always available on TServiceFactoryServer side

function SendNotificationsPending: integer;

Compute how many pending notifications are waiting for background process initiated by SendNotifications() method

procedure SendNotifications(aRest: TSQLRest; aLogClass: TSQLRecordServiceNotificationsClass; aRetryPeriodSeconds: Integer=30; aRemote: TSQLRestClientURI=nil);

Allow background process of method with no results, via a temporary database, to be used e.g. for safe notifications transmission

- will call StoreNotifications() and start background notification
- expect a REST instance, which will store all methods without any results (i.e. procedure without any var/out parameters) on the associated TSQLRecordServiceNotifications class
- a background thread will be used to check for pending notifications, and send them to the supplied aRemote TSQLRestClient instance, or to the main TServiceFactoryClient.fClient instance
- if the remote client is not reachable, will retry after the specified period of time, in seconds
- this method is not blocking, and will write the pending calls to the aRest/aLogClass table, which will be retrieved asynchronously by the background thread

procedure SendNotificationsWait(aTimeOutSeconds: integer);

Wait for all pending notifications to be sent

- you can supply a time out period after which no wait will take place

procedure SetOptions(const aMethod: array of RawUTF8; aOptions: TServiceMethodOptions; aAction: TServiceMethodOptionsAction=moaReplace);

Define execution options for a given set of methods

- methods names should be specified as an array (e.g. ['Add','Multiply'])
- if no method name is given (i.e. []), option will be set for all methods
- only supports optNoLogInput and optNoLogOutput on the client side, by design of "fake" interface remote execution

procedure StoreNotifications(aRest: TSQLRest; aLogClass: TSQLRecordServiceNotificationsClass);

Persist all service calls into a database instead of calling the client

- expect a REST instance, which will store all methods without any results (i.e. procedure without any var/out parameters) on the associated TSQLRecordServiceNotifications class
- once set, regular fClient.URI() won't be called but a new aLogClass entry will be stored in aRest
- to disable this redirection, set aRest and aLogClass to nil

property DelayedInstance: boolean read fDelayedInstance write fDelayedInstance;

Delay the sicClientDriven server-side instance to the first method call

- by default, CreateFakeInstance will call _instance_server pseudo-method to ensure a fClientDrivenID is safely and properly initialized
- if you are sure that your client's interface variables will be thread-safe, you may define this property to TRUE so that the "id" field as returned at first method call will be used - makes sense only if a lot of short-live interface instances are expected to be generated by the client

property ForcedURI: RawUTF8 read fForcedURI write fForcedURI;

Could be used to force the remote URI to access the service

- by default, the URI will be Root/Calculator or Root/InterfaceMangledURI but you may use this property to use another value, e.g. if you are accessign a non mORMot REST server (probably with aContractExpected set to SERVICE_CONTRACT_NONE_EXPECTED, and running Client.ServerTimestamp := TimeLogNowUTC to avoid an unsupported ServerTimestampSynchronize call)

property NonBlockWithoutAnswer: boolean **read** fNonBlockWithoutAnswer **write** fNonBlockWithoutAnswer;

If methods expecting no result (i.e. plain procedure without var/out parameters) should not block the client waiting for answer

- may be handy e.g. when consuming an event-driven asynchronous service
- will call CallbackNonBlockingSetHeader, currently implemented only in TSQLHttpClientWebsockets, with frame gathering

property ParamsAsJSONObject: boolean **read** fParamsAsJSONObject **write** fParamsAsJSONObject;

Set to TRUE to send the interface's methods parameters as JSON object

- by default (FALSE), any method execution will send a JSON array with all CONST/VAR parameters, in order
- TRUE will generate a JSON object instead, with the CONST/VAR parameter names as field names - may be useful e.g. when working with a non mORMot server, or when the mORMot server exposes a public API
- defined e.g. by TSQLRestClientURI.ServiceDefineSharedAPI() method

property ResultAsJSONObjectWithoutResult: boolean **read** fResultAsJSONObject **write** fResultAsJSONObject;

Set to TRUE if the interface's methods result is expected to be a JSON object without the {"result":... } nesting

- by default (FALSE), any method execution will return a JSON array with all VAR/OUT parameters, within a {"result":..., "id":...} layout
- TRUE will expect a simple JSON object instead, with the VAR/OUT parameter names as field names (and "Result" for any function result) - may be useful e.g. when working with JavaScript clients or any public API
- this value can be overridden by setting ForceServiceResultAsJSONObject for a given TSQLRestServerURIContext (e.g. for server-side JavaScript work)
- defined e.g. by TSQLRestClientURI.ServiceDefineSharedAPI() method

TServiceContainerInterface = record

Used to lookup one service in a global list of interface-based services

InterfaceName: RawUTF8;

One 'service' item, as set at URI, e.g. 'Calculator'

Service: TServiceFactory;

The associated service provider

TServiceContainerInterfaceMethod = record

Used to lookup one method in a global list of interface-based services

InterfaceDotMethodName: RawUTF8;

One 'service.method' item, as set at URI

- e.g. 'Calculator.Add', 'Calculator.Multiply'...

InterfaceMethodIndex: integer;

The index of the method for the given service

- 0..2 indicates `_free/_contract/_signature_` pseudo-methods
- then points to `InterfaceService.Interface.Methods[InterfaceMethodIndex-3]`

InterfaceService: TServiceFactory;

The associated service provider

TServiceContainer = class(TInterfaceResolverInjected)

A global services provider class

- used to maintain a list of interfaces implementation
- inherits from `TInterfaceResolverInjected` and its `Resolve()` methods, compatible with `TInjectableObject`

Used for DI-2.1.5 (page 2557).

constructor Create(aRest: TSQLRest); **virtual;**

Initialize the list

destructor Destroy; **override;**

Release all registered services

function AddInterface(const aInterfaces: array of PTypeInfo; aInstanceCreation: TServiceInstanceImplementation; aContractExpected: RawUTF8=''): boolean; **overload;**

Method called on the client side to register a service via its interface(s)

- will add a `TServiceFactoryClient` instance to the internal list
- is called e.g. by `TSQLRestClientURI.ServiceRegister` or even by `TSQLRestServer.ServiceRegister(aClient: TSQLRest...)` for a remote access - use `TServiceContainerServer.AddImplementation()` instead for normal server side implementation
- will raise an exception on error
- will return true if some interfaces have been added
- will check for the availability of the interfaces on the server side, with an optional custom contract to be used instead of methods signature (only for the first interface)

function AddInterface(aInterface: PTypeInfo; aInstanceCreation: TServiceInstanceImplementation; const aContractExpected: RawUTF8=''): TServiceFactoryClient; **overload;**

Method called on the client side to register a service via one interface

- overloaded method returning the corresponding service factory client, or nil on error

function AsJson: RawJSON;

Retrieve all registered Services contracts as a JSON array

- i.e. a JSON array of `TServiceFactory.Contract` JSON objects

function CallbackUnRegister(const Callback: IInvokable): boolean; **virtual;**

Notify the other side that the given Callback event interface is released

- this default implementation will do nothing

function Count: integer;

Return the number of registered service interfaces

function Index(aIndex: integer): TServiceFactory; overload;

Retrieve a service provider from its index in the list
 - returns nil if out of range index

function Info(const aGUID: TGUID): TServiceFactory; overload;

Retrieve a service provider from its GUID / Interface type
 - you shall have registered the interface by a previous call to
 TInterfaceFactory.RegisterInterfaces([TypeInfo(IMyInterface),...])
 - on match, it will return the service the corresponding interface factory
 - returns nil if the GUID does not match any registered interface
 - can be used as such to resolve an I: ICalculator interface
 if fClient.Services.Info(ICalculator).Get(I) then
 ... use I

function Info(aTypeInfo: PTypeInfo): TServiceFactory; overload; virtual;

Retrieve a service provider from its type information
 - on match, it will return the service the corresponding interface factory
 - returns nil if the type information does not match any registered interface
 - can be used as such to resolve an I: ICalculator interface
 if fClient.Services.Info(TypeInfo(ICalculator)).Get(I) then
 ... use I
 - is defined as virtual so that e.g. TServiceContainerClient will automatically register the interface, if it was not already done

procedure Release;

Release all services of a TSQLRest instance before shutdown
 - will allow to properly release any pending callbacks
 - TSQLRest.Services.Release will call FreeAndNil(fServices)

procedure SetGUIDs(out Services: TGUIDDynArray);

Retrieve all registered Services TGUID

procedure SetInterfaceNames(out Names: TRawUTF8DynArray);

Retrieve all registered Services names
 - i.e. all interface names without the initial 'I', e.g. 'Calculator' for ICalculator

property ExpectMangledURI: boolean read fExpectMangledURI write SetExpectMangledURI;

Set if the URI is expected to be mangled from the GUID
 - by default (FALSE), the clear service name is expected to be supplied at the URI level (e.g. 'Calculator')
 - if this property is set to TRUE, the mangled URI value will be expected instead (may enhance security) - e.g. '00amyWGct0y_ze4llsj2Mw'

property Rest: TSQLRest read fRest;

The associated RESTful instance

property Services[**const** aURI: RawUTF8]: TServiceFactory **read** GetService;

Retrieve a service provider from its URI

- it expects the supplied URI variable to be e.g. '00amyWGct0y_ze4llsj2Mw' or 'Calculator', depending on the ExpectMangledURI property
- on match, it will return the service the corresponding interface factory
- returns nil if the URI does not match any registered interface

property ServicesFactoryClients: TServiceFactoryClientClass **read**
fServicesFactoryClients **write** fServicesFactoryClients;

The services factory client classes

- by default, will use TServiceFactoryClient

IServiceRecordVersionCallback = **interface**(IInvokable)

A callback interface used to notify a TSQLRecord modification in real time

- will be used e.g. by TSQLRestServer.RecordVersionSynchronizeSubscribeMaster()
- all methods of this interface will be called asynchronously when transmitted via our WebSockets implementation, since they are defined as plain procedures
- each callback instance should be private to a specific TSQLRecord

procedure Added(**const** NewContent: RawJSON);

This event will be raised on any Add on a versioned record

- the supplied JSON object will contain the TRecordVersion field

procedure CurrentFrame(isLast: boolean);

Allow to optimize process for WebSockets "jumbo frame" items

- this method may be called with isLast=false before the first method call of this interface, then with isLast=true after the call of the last method of the "jumbo frame"
- match TInterfaceFactory.MethodIndexCurrentFrameCallback signature
- allow e.g. to create a temporary TSQLRestBatch for jumbo frames
- if individual frames are received, this method won't be called

procedure Deleted(**const** ID: TID; **const** Revision: TRecordVersion);

This event will be raised on any Delete on a versioned record

procedure Updated(**const** ModifiedContent: RawJSON);

This event will be raised on any Update on a versioned record

- the supplied JSON object will contain the TRecordVersion field

IServiceRecordVersion = **interface**(IInvokable)

Service definition for master/slave replication notifications subscribe

- implemented by TServiceRecordVersion, as used by TSQLRestServer.RecordVersionSynchronizeMasterStart(), and expected by TSQLRestServer.RecordVersionSynchronizeSlaveStart()

function Subscribe(**const** SQLTableName: RawUTF8; **const** revision: TRecordVersion;
const callback: IServiceRecordVersionCallback): boolean;

Will register the supplied callback for the given table

IServiceWithCallbackReleased = interface(IInvokable)

Service definition with a method which will be called when a callback interface instance is released on the client side

- may be used to implement safe publish/subscribe mechanism using interface callbacks, e.g. over WebSockets

procedure CallbackReleased(**const** callback: IInvokable; **const** interfaceName: RawUTF8);

Will be called when a callback is released on the client side

- this method matches the TInterfaceFactory.MethodIndexCallbackReleased signature, so that it will be called with the interface instance by TServiceContainerServer.FakeCallbackRelease

- you may use it as such - see sample Project31ChatServer.dpr:

```
procedure TChatService.CallbackReleased(const callback: IInvokable;
const interfaceName: RawUTF8);
begin // unsubscribe from fConnected: array of IChatCallback
  if interfaceName='IChatCallback' then
    InterfaceArrayDelete(fConnected, callback);
end;
```

TServiceContainerServer = class(TServiceContainer)

A services provider class to be used on the server side

- this will maintain a list of true implementation classes

Used for DI-2.1.5 (page 2557).

constructor Create(aRest: TSQLRest); **override**;

Initialize the list

destructor Destroy; **override**;

Finalize the service container

function AddImplementation(aImplementationClass: TInterfacedClass; **const** aInterfaces: **array of** PTypeInfo; aInstanceCreation: TServiceInstanceImplementation; aSharedImplementation: TInterfacedObject; **const** aContractExpected: RawUTF8): TServiceFactoryServer;

Method called on the server side to register a service via its interface(s) and a specified implementation class or a shared instance (for sicShared mode)

- will add a TServiceFactoryServer instance to the internal list

- will raise an exception on error

- will return the first of the registered TServiceFactoryServer created on success (i.e. the one corresponding to the first item of the aInterfaces array), or nil if registration failed (e.g. if any of the supplied interfaces is not implemented by the given class)

- the same implementation class can be used to handle several interfaces (just as Delphi allows to do natively)

```
class function CallbackReleasedOnClientSide(const callback: IInterface;  
callbacktext: PShortString=nil): boolean; overload;
```

Class method able to check if a given server-side callback event fake instance has been released on the client side

- may be used to automatically purge a list of subscribed callbacks, e.g. before triggering the interface instance, and avoid an exception
- can optionally append the callback class instance information to a local shortstring variable, e.g. for logging/debug purposes

```
function RecordVersionSynchronizeSubscribeMaster(TableIndex: integer;  
RecordVersion: TRecordVersion; const SlaveCallback:  
IServiceRecordVersionCallback): boolean;
```

Register a callback interface which will be called each time a write operation is performed on a given TSQLRecord with a TRecordVersion field

- called e.g. by TSQLRestServer.RecordVersionSynchronizeSubscribeMaster

```
procedure RecordVersionNotifyAddUpdate(Occasion: TSQLOccasion; TableIndex:  
integer; const Decoder: TJSONObjectDecoder); overload;
```

Notify any TRecordVersion callback for a table Add/Update from a TJSONObjectDecoder content

- used e.g. by TSQLRestStorageMongoDB.DocFromJSON()

```
procedure RecordVersionNotifyAddUpdate(Occasion: TSQLOccasion; TableIndex:  
integer; const Document: TDocVariantData); overload;
```

Notify any TRecordVersion callback for a table Add/Update from a TDocVariant content

- used e.g. by TSQLRestStorageMongoDB.DocFromJSON()

```
procedure RecordVersionNotifyDelete(TableIndex: integer; const ID: TID; const  
Revision: TRecordVersion);
```

Notify any TRecordVersion callback for a table Delete

```
procedure SetServiceLog(aLogRest: TSQLRest; aLogClass:  
TSQLRecordServiceLogClass=nil; const aExcludedMethodNamesCSV: RawUTF8='');
```

Log method execution information to a TSQLRecordServiceLog table

- TServiceFactoryServer.SetServiceLog() will be called for all registered interfaced-based services of this container
- will write to the specified aLogRest instance, and will disable writing if aLogRest is nil
- will write to a (inherited) TSQLRecordServiceLog table, as available in TSQLRest's model, unless a dedicated table is specified as aLogClass
- you could specify a CSV list of method names to be excluded from logging (containing e.g. a password or a credit card number), containing either the interface name (as 'ICalculator.Add'), or not (as 'Add')

```
property CallbackOptions: TServiceCallbackOptions read fCallbackOptions write  
fCallbackOptions;
```

Defines how SOA callbacks will be handled

property OnCallbackReleasedOnClientSide: TOnCallbackReleased **read**
fOnCallbackReleasedOnClientSide;

This event will be launched when a callback interface is notified as released on the Client side
- as an alternative, you may define the following method on the registration service interface type, which will be called when a callback registered via this service is released (e.g. to unsubscribe the callback from an interface list, via InterfaceArrayDelete):
procedure CallbackReleased(**const** callback: IInvokable; **const** interfaceName: RawUTF8);

property OnCallbackReleasedOnServerSide: TOnCallbackReleased **read**
fOnCallbackReleasedOnServerSide;

This event will be launched when a callback interface is released on the Server side

property PublishSignature: boolean **read** fPublishSignature **write** fPublishSignature;

Defines if the "method": "_signature_" or /root/Interface._signature pseudo method is available to retrieve the whole interface signature, encoded as a JSON object
- is set to FALSE by default, for security reasons: only "_contract_" pseudo method is available - see TServiceContainer.ContractExpected

property SessionTimeout: cardinal **read** fSessionTimeout **write** fSessionTimeout;

The default TServiceFactoryServer.TimeoutSec value
- default is 30 minutes
- you can customize each service using its corresponding TimeoutSec property

TServiceRecordVersion = class(TInjectableObjectRest)

This class implements a service, which may be called to push notifications for master/slave replication
- as used by TSQLRestServer.RecordVersionSynchronizeMasterStart(), and expected by TSQLRestServer.RecordVersionSynchronizeSlaveStart()

function Subscribe(**const** SQLTableName: RawUTF8; **const** revision: TRecordVersion; **const** callback: IServiceRecordVersionCallback): boolean;

Will register the supplied callback for the given table

TServiceContainerClient = class(TServiceContainer)

A services provider class to be used on the client side
- this will maintain a list of fake implementation classes, which will remotely call the server to make the actual process

Used for DI-2.1.5 (page 2557).

function CallBackUnRegister(**const** Callback: IInvokable): boolean; **override**;

Notify the other side that the given Callback event interface is released
- this overridden implementation will check the private fFakeCallbacks list

function Info(aTypeInfo: PTypeInfo): TServiceFactory; **overload**; **override**;

Retrieve a service provider from its type information
- this overridden method will register the interface, if was not yet made
- in this case, the interface will be registered with sicClientDriven implementation method, unless DisableAutoRegisterAsClientDriven is TRUE

property DisableAutoRegisterAsClientDriven: boolean **read**
 fDisableAutoRegisterAsClientDriven **write** fDisableAutoRegisterAsClientDriven;
Allow to disable the automatic registration as sicClientDriven in Info()

TInterfacedCallback = **class**(TInterfacedObjectLocked)

TInterfacedObject class which will notify a REST server when it is released
 - could be used when implementing event callbacks as interfaces, so that the other side instance will be notified when it is destroyed

constructor Create(aRest: TSQLRest; **const** aGUID: TGUID); **reintroduce**;
Initialize the instance for a given REST and callback interface

destructor Destroy; **override**;
Finalize the instance, and notify the TSQLRestServer that the callback is now unreachable
 - i.e. will call CallbackRestUnregister

procedure CallbackRestUnregister; **virtual**;
Notify the associated TSQLRestServer that the callback is disconnected
 - i.e. will call TSQLRestServer's TServiceContainer.CallBackUnRegister()
 - this method will process the unsubscription only once

property Rest: TSQLRest **read** fRest;
The associated TSQLRestServer instance, which will be notified when the callback is released

property RestInterface: TGUID **read** fInterface **write** fInterface;
The interface type, implemented by this callback class

TBlockingCallback = **class**(TInterfacedCallback)

Asynchronous callback to emulate a synchronous/blocking process
 - once created, process will block via a WaitFor call, which will be released when CallbackFinished() is called by the process background thread

constructor Create(aTimeOutMs: integer; aRest: TSQLRest; **const** aGUID: TGUID); **reintroduce**;

Initialize the callback instance
 - specify a time out milliseconds period after which blocking execution should be handled as failure (if 0 is set, default 3000 will be used)
 - you can optionally set a REST and callback interface for automatic notification when this TInterfacedCallback will be released

destructor Destroy; **override**;
Finalize the callback instance

function Reset: boolean; **virtual**;
Just a wrapper to reset the internal Event state to evNone
 - may be used to re-use the same TBlockingCallback instance, after a successful WaitFor/CallbackFinished process
 - returns TRUE on success (i.e. status was not beWaiting)
 - if there is a WaitFor currently in progress, returns FALSE

function WaitFor: TBlockingEvent; **virtual**;

Called to wait for the callback to be processed, or trigger timeout

- will block until CallbackFinished() is called by the processing thread
- returns the final state of the process, i.e. beRaised or beTimeOut

procedure CallbackFinished(aRestForLog: TSQLRest; aServerUnregister: boolean=false); **virtual**;

Should be called by the callback when the process is finished

- the caller will then let its WaitFor method return
- if aServerUnregister is TRUE, will also call CallbackRestUnregister to notify the server that the callback is no longer needed
- will optionally log all published properties values to the log class of the supplied REST instance

property Event: TBlockingEvent **read** GetEvent;

The current state of process

- just a wrapper around Process.Event
- use Reset method to re-use this instance after a WaitFor process

property Process: TBlockingProcess **read** fProcess;

The associated blocking process instance

TServiceRecordVersionCallback = **class**(TInterfacedCallback)

This class implements a callback interface, able to write all remote ORM notifications to the local DB

- could be supplied as callback parameter, possibly via WebSockets transmission, to TSQLRestServer.RecordVersionSynchronizeSubscribeMaster()

constructor Create(aSlave: TSQLRestServer; aMaster: TSQLRestClientURI; aTable: TSQLRecordClass; aOnNotify: TOnBatchWrite); **reintroduce**;

Initialize the instance able to apply callbacks for a given table on a local slave REST server from a remote master REST server

- the optional low-level aOnNotify callback will be triggered for each incoming notification, to track the object changes in real-time

destructor Destroy; **override**;

Finalize this callback instance

procedure Added(const NewContent: RawJSON); **virtual**;

This event will be raised on any Add on a versioned record

procedure CurrentFrame(isLast: boolean); **virtual**;

Match TInterfaceFactory.MethodIndexCurrentFrameCallback signature, so that TSQLHttpClientWebsockets.CallbackRequest will call it

- it will create a temporary TSQLRestBatch for the whole "jumbo frame"

procedure Deleted(const ID: TID; const Revision: TRecordVersion); **virtual**;

This event will be raised on any Delete on a versioned record

procedure Updated(const ModifiedContent: RawJSON); **virtual**;

This event will be raised on any Update on a versioned record

property OnNotify: TOnBatchWrite read fOnNotify write fOnNotify;

Low-level event handler triggered by Added/Updated/Deleted methods

IMultiCallbackRedirect = interface(IInterface)

Prototype of a class implementing redirection of a given interface

- as returned e.g. by TSQLRest.MultiRedirect method
- can be used as a main callback, then call Redirect() to manage an internal list of redirections
- when you release this instance, will call Rest.Service.CallbackUnregister with the associated fake callback generated

procedure Redirect(const aCallback: TInterfacedObject; const aMethodsNames: array of RawUTF8; aSubscribe: boolean=true); overload;

Add or remove a class instance callback to the internal redirection list

- will register a callback if aSubscribe is true
- will unregister a callback if aSubscribe is false
- supplied aCallback instance should implement the expected interface GUID
- this method will be implemented as thread-safe
- you can specify some method names, or all methods redirection if []

procedure Redirect(const aCallback: IInvokable; const aMethodsNames: array of RawUTF8; aSubscribe: boolean=true); overload;

Add or remove an interface callback to the internal redirection list

- will register a callback if aSubscribe is true
- will unregister a callback if aSubscribe is false
- supplied aCallback should implement the expected interface GUID
- this method will be implemented as thread-safe
- you can specify some method names, or all methods redirection if []

TSQLRestCacheEntryValue = packed record

For TSQLRestCache, stores a table values

ID: TID;

Corresponding ID

JSON: RawUTF8;

JSON encoded UTF-8 serialization of the record

Tag: cardinal;

Some associated unsigned integer value

- not used by TSQLRestCache, but available at TSQLRestCacheEntry level

Timestamp512: cardinal;

GetTickCount64 shr 9 timestamp when this cached value was stored

- resulting time period has therefore a resolution of 512 ms, and overflows after 70 years without computer reboot
- equals 0 when there is no JSON value cached

TSQLRestCacheEntry = object(TObject)

For TSQLRestCache, stores a table settings and values

CacheAll: boolean;

The whole specified Table content will be cached

CacheEnable: boolean;

TRUE if this table should use caching

- i.e. if was not set, or worth it for this table (e.g. in-memory table)

Count: integer;

The number of entries stored in Values[]

Mutex: TSynLocker;

Used to lock the table cache for multi thread safety

TimeOutMS: Cardinal;

Time out value (in ms)

- if 0, caching will never expire

Value: TDynArray;

TDynArray wrapper around the Values[] array

Values: TSQLRestCacheEntryValueDynArray;

All cached IDs and JSON content

function CachedMemory(FlushedEntriesCount: PInteger=nil): cardinal;

Compute how much memory stored entries are using

- will also flush outdated entries

function RetrieveJSON(aID: TID; aValue: TSQLRecord; aTag: PCardinal=nil): boolean;
overload;

Unserialize a JSON cached record of a given ID

function RetrieveJSON(aID: TID; var aJSON: RawUTF8; aTag: PCardinal=nil): boolean;
overload;

Retrieve a JSON serialization of a given ID from cache

procedure Clear;

Reset all settings corresponding to this table cache

procedure Done;

Finalize this table cache entry

procedure FlushCacheAllEntries;

Flush cache for all Value[]

procedure FlushCacheEntry(Index: Integer);

Flush cache for a given Value[] index

procedure Init;

Initialize this table cache

- will set Value wrapper and Mutex handle - other fields should have been cleared by caller (is the case for a TSQLRestCacheEntryDynArray)

procedure SetCache(aID: TID);

Add the supplied ID to the Value[] array

procedure SetJSON(aID: TID; **const** aJSON: RawUTF8; aTag: cardinal=0); overload;

Update/refresh the cached JSON serialization of a given ID

procedure SetJSON(aRecord: TSQLRecord); overload;

Update/refresh the cached JSON serialization of a supplied Record

TSQLRestCache = class(TObject)

Implement a fast TSQLRecord cache, per ID, at the TSQLRest level

- purpose of this caching mechanism is to speed up retrieval of some common values at either Client or Server level (like configuration settings)
- only caching synchronization is about the following RESTful basic commands: RETRIEVE, ADD, DELETION and UPDATE (that is, a complex direct SQL UPDATE or via TSQLRecordMany pattern won't be taken into account)
- only Simple fields are cached: e.g. the BLOB fields are not stored
- this cache is thread-safe (access is locked per table)
- this caching will be located at the TSQLRest level, that is no automated synchronization is implemented between TSQLRestClient and TSQLRestServer: you shall ensure that your code won't fail due to this restriction

constructor Create(aRest: TSQLRest); **reintroduce**;

Create a cache instance

- the associated TSQLModel will be used internally

destructor Destroy; **override**;

Release the cache instance

function CachedEntries: cardinal;

Returns the number of JSON serialization records within this cache

function CachedMemory(FlushedEntriesCount: PInteger=nil): cardinal;

Returns the memory used by JSON serialization records within this cache

- this method will also flush any outdated entries in the cache

function FillFromQuery(aTable: TSQLRecordClass; **const** FormatSQLWhere: RawUTF8;
const BoundsSQLWhere: **array of const**): integer;

- will fill the internal JSON cache of a given Table with data coming from a REST query
- returns the number of TSQLRecord items actually cached
- may be handy to pre-load a set of values (e.g. a lookup table) from a single REST query, without waiting for each record to be retrieved

function IsCached(aTable: TSQLRecordClass): boolean;

Returns TRUE if the table is part of the current caching policy

function SetCache(aTable: TSQLRecordClass; aID: TID): boolean; overload;

Activate the internal caching for a given TSQLRecord

- if this item is already cached, do nothing
- return true on success

function SetCache(aRecord: TSQLRecord): boolean; overload;

Activate the internal caching for a given TSQLRecord

- will cache the specified aRecord.ID item
- if this item is already cached, do nothing
- return true on success

function SetCache(aTable: TSQLRecordClass; **const** aIDs: **array of** TID): boolean; overload;

Activate the internal caching for a set of specified TSQLRecord

- if these items are already cached, do nothing
- return true on success

function SetCache(aTable: TSQLRecordClass): boolean; overload;

Activate the internal caching for a whole Table

- any cached item of this table will be flushed
- return true on success

function SetTimeOut(aTable: TSQLRecordClass; aTimeoutMS: cardinal): boolean;

Set the internal caching time out delay (in ms) for a given table

- actual resolution is 512 ms
- time out setting is common to all items of the table
- if aTimeOut is left to its default 0 value, caching will never expire
- return true on success

procedure Clear;

Flush the cache, and destroy all settings

- this will flush all stored JSON content, AND destroy the settings (SetCache/SetTimeOut) to default (i.e. no cache enabled)

procedure Flush(aTable: TSQLRecordClass); overload;

Flush the cache for a given table

- this will flush all stored JSON content, but keep the settings (SetCache/SetTimeOut) as before for this table

procedure Flush; overload;

Flush the cache

- this will flush all stored JSON content, but keep the settings (SetCache/SetTimeOut) as before

procedure Flush(aTable: TSQLRecordClass; **const** aIDs: **array of** TID); overload;

Flush the cache for a set of specified records

- this will flush the stored JSON content for these record (and table settings will be kept)

procedure Flush(aTable: TSQLRecordClass; aID: TID); overload;

Flush the cache for a given record

- this will flush the stored JSON content for this record (and table settings will be kept)

procedure Notify(aRecord: TSQLRecord; aAction: TSQLOccasion); overload;

TSQLRest instance shall call this method when a record is added or updated

- this overloaded method will call the other Trace method, serializing the supplied aRecord content as JSON (not in the case of seDelete)

procedure Notify(aTableIndex: integer; aID: TID; **const** aJSON: RawUTF8; aAction: TSQLOccasion); overload;

TSQRest instance shall call this method when a record is retrieved, added or updated
 - this overloaded method expects the content to be specified as JSON object, and
 TSQLRecordClass to be specified as its index in Rest.Model.Tables[]

procedure Notify(aTable: TSQLRecordClass; aID: TID; **const** aJSON: RawUTF8; aAction: TSQLOccasion); overload;

TSQRest instance shall call this method when a record is added or updated
 - this overloaded method expects the content to be specified as JSON object

procedure NotifyDeletion(aTableIndex: integer; aID: TID); overload;

TSQRest instance shall call this method when a record is deleted
 - this method is dedicated for a record deletion
 - TSQLRecordClass to be specified as its index in Rest.Model.Tables[]

procedure NotifyDeletion(aTable: TSQLRecordClass; aID: TID); overload;

TSQRest instance shall call this method when a record is deleted
 - this method is dedicated for a record deletion

procedure NotifyDeletions(aTableIndex: integer; **const** aIDs: array of Int64); overload;

TSQRest instance shall call this method when records are deleted
 - TSQLRecordClass to be specified as its index in Rest.Model.Tables[]

property Rest: TSQRest **read** fRest;

Read-only access to the associated TSQRest instance

TSQRestAcquireExecution = class(TSynPersistentLock)

Used to store the execution parameters for a TSQRest instance

LockedTimeOut: cardinal;

Delay before failing to acquire the lock

Mode: TSQRestServerAcquireMode;

How read or write operations will be executed

Thread: TSynBackgroundThreadMethod;

Background thread instance (if any)

destructor Destroy; **override**;

Finalize the memory structure, and the associated background thread

TSQRestBackgroundTimer = class(TSynBackgroundTimer)

TThread able to run one or several tasks at a periodic pace, or do asynchronous interface or batch execution, with proper TSQRest integration

- used e.g. by TSQRest.TimerEnable/AsynchRedirect/AsynchBatchStart methods
 - TSQRest.BackgroundTimer will define one instance, but you may create other dedicated instances to instantiate separated threads

constructor Create(aRest: TSQLRest; const aThreadName: RawUTF8=''; aStats: TSynMonitorClass=nil); reintroduce; virtual;

Initialize the thread for a periodic task processing

destructor Destroy; override;

Finalize the thread

function AsynchBatchAdd(Value: TSQLRecord; SendData: boolean; ForceID: boolean=false; const CustomFields: TSQLFieldBits=[]; DoNotAutoComputeFields: boolean=false): integer;

Create a new ORM member in a BATCH to be written in a background thread

- should have been preceded by a call to AsynchBatchStart(), or returns -1
- is a wrapper around TSQLRestBatch.Add() sent in the Timer thread, so will return the index in the BATCH rows, not the created TID
- this method is thread-safe

function AsynchBatchDelete(Table: TSQLRecordClass; ID: TID): integer;

Delete an ORM member in a BATCH to be written in a background thread

- should have been preceded by a call to AsynchBatchStart(), or returns -1
- is a wrapper around the TSQLRestBatch.Delete() sent in the Timer thread
- this method is thread-safe

function AsynchBatchRawAdd(Table: TSQLRecordClass; const SendData: RawUTF8): integer;

Append some JSON content in a BATCH to be written in a background thread

- could be used to emulate AsynchBatchAdd() with an already pre-computed JSON object
- is a wrapper around TSQLRestBatch.RawAdd() sent in the Timer thread, so will return the index in the BATCH rows, not the created TID
- this method is thread-safe

function AsynchBatchStart(Table: TSQLRecordClass; SendSeconds: integer; PendingRowThreshold: integer=500; AutomaticTransactionPerRow: integer=1000; Options: TSQLRestBatchOptions=[boExtendedJSON]): boolean;

Prepare an asynchronous ORM BATCH process, executed in a background thread

- will initialize a TSQLRestBatch and call TimerEnable to initialize the background thread, following the given processing period (in seconds), or the TSQLRestBatch.Count threshold to call BatchSend
- actual REST/CRUD commands will take place via AsynchBatchAdd, AsynchBatchUpdate and AsynchBatchDelete methods
- only a single AsynchBatch() call per Table is allowed at a time, unless AsynchBatchStop method is used to flush the current asynchronous BATCH
- using a BATCH in a dedicated thread will allow very fast background asynchronous process of ORM methods, sufficient for most use cases

function AsynchBatchStop(Table: TSQLRecordClass): boolean;

Finalize asynchronous ORM BATCH process, executed in a background thread

- should have been preceded by a call to AsynchBatch(), or returns false
- Table=nil will release all existing batch instances

```
function AsynchBatchUpdate(Value: TSQLRecord; const CustomFields:  
TSQLFieldBits=[]; DoNotAutoComputeFields: boolean=false): integer;
```

Update an ORM member in a BATCH to be written in a background thread

- should have been preceded by a call to AsynchBatchStart(), or returns -1
- is a wrapper around the TSQLRestBatch.Update() sent in the Timer thread
- this method is thread-safe

```
procedure AsynchBatchRawAppend(Table: TSQLRecordClass; SentData: TTextWriter);
```

Append some JSON content in a BATCH to be written in a background thread

- could be used to emulate AsynchBatchAdd() with an already pre-computed JSON object, as stored in a TTextWriter instance
- is a wrapper around TSQLRestBatch.RawAppend.AddNoJSONEscape(SentData) in the Timer thread
- this method is thread-safe

```
procedure AsynchInterning(Interning: TRawUTF8Interning; InterningMaxRefCount:  
integer=2; PeriodMinutes: integer=5);
```

Allows background garbage collection of specified RawUTF8 interning

- will run Interning.Clean(2) every 5 minutes by default
- set InterningMaxRefCount=0 to disable process of the Interning instance

```
procedure AsynchRedirect(const aGUID: TGUID; const aDestinationInterface:  
IInvokable; out aCallbackInterface; const aOnResult: TOnAsynchRedirectResult=nil);  
overload;
```

Define asynchronous execution of interface methods in a background thread

- this method implements any interface via a fake class, which will redirect all methods calls into calls of another interface, but as a FIFO in a background thread, shared with TimerEnable/TimerDisable process
- parameters will be serialized and stored as JSON in the queue
- by design, only procedure methods without any output parameters are allowed, since their execution will take place asynchronously
- of course, a slight delay is introduced in aDestinationInterface methods execution, but the main process thread is not delayed any more, and is free from potential race conditions
- the returned fake aCallbackInterface should be freed before TSQLRest is destroyed, to release the redirection resources
- it is an elegant resolution to the most difficult implementation problem of SOA callbacks, which is to avoid race condition on reentrance, e.g. if a callback is run from a thread, and then the callback code try to execute something in the context of the initial thread, protected by a critical section (mutex)

```
procedure AsynchRedirect(const aGUID: TGUID; const aDestinationInstance:  
TInterfacedObject; out aCallbackInterface; const aOnResult:  
TOnAsynchRedirectResult=nil); overload;
```

Define asynchronous execution of interface methods in a background thread

- this method implements any interface via a fake class, which will redirect all methods calls into calls of another interface, but as a FIFO in a background thread, shared with TimerEnable/TimerDisable process
- parameters will be serialized and stored as JSON in the queue
- by design, only procedure methods without any output parameters are allowed, since their execution will take place asynchronously
- of course, a slight delay is introduced in aDestinationInterface methods execution, but the main process thread is not delayed any more, and is free from potential race conditions
- the returned fake aCallbackInterface should be freed before TSQLRest is destroyed, to release the redirection resources
- it is an elegant resolution to the most difficult implementation problem of SOA callbacks, which is to avoid race condition on reentrance, e.g. if a callback is run from a thread, and then the callback code try to execute something in the context of the initial thread, protected by a critical section (mutex)

```
property Name: RawUTF8 read fThreadName;
```

The identifier of the thread, as logged

```
TSQLRest = class(TObject)
```

A generic REpresentational State Transfer (REST) client/server class

Used for DI-2.1.1 (page 2553), DI-2.1.1.1 (page 2553).

```
QueryCustom: array of TSQLQueryCustom;
```

The custom queries parameters for User Interface Query action

```
constructor Create(aModel: TSQLModel); virtual;
```

Initialize the class, and associate it to a specified database Model

```
destructor Destroy; override;
```

Release internal used instances

- e.g. release associated TSQLModel or TServiceContainer

```
function Add(Value: TSQLRecord; SendData: boolean; ForceID: boolean=false;  
DoNotAutoComputeFields: boolean=false): TID; overload;
```

Create a new member

- implements REST POST collection
- if SendData is true, client sends the current content of Value with the request, otherwise record is created with default values
- if ForceID is true, client sends the Value.ID field to use this ID for adding the record (instead of a database-generated ID)
- on success, returns the new RowID value; on error, returns 0
- on success, Value.ID is updated with the new RowID
- the TSQLRawBlob(BLOB) fields values are not set by this method, to preserve bandwidth - see UpdateBlobFields() and AddWithBlobs() methods
- the TSQLRecordMany fields are not set either: they are separate instances created by TSQLRecordMany.Create, with dedicated methods to access to the separated pivot table
- this method will call EngineAdd() to perform the request

```
function Add(Value: TSQLRecord; const CustomCSVFields: RawUTF8; ForceID:  
boolean=false; DoNotAutoComputeFields: boolean=false): TID; overload;
```

Create a new member, including selected fields

- implements REST POST collection
- if ForceID is true, client sends the Value.ID field to use this ID for adding the record (instead of a database-generated ID)
- this method will call EngineAdd() to perform the request

```
function Add(Value: TSQLRecord; const CustomFields: TSQLFieldBits; ForceID:  
boolean=false; DoNotAutoComputeFields: boolean=false): TID; overload;
```

Create a new member, including selected fields

- implements REST POST collection
- if ForceID is true, client sends the Value.ID field to use this ID for adding the record (instead of a database-generated ID)
- this method will call EngineAdd() to perform the request

```
function AddOrUpdate(Value: TSQLRecord; ForceID: boolean=false): TID;
```

Create or update a member, depending if the Value has already an ID

- implements REST POST if Value.ID=0 or ForceID is set, or a REST PUT collection to update the record pointed by a Value.ID<>0
- will return the created or updated ID

```
function AddSimple(aTable: TSQLRecordClass; const aSimpleFields: array of const;  
ForcedID: TID=0): TID;
```

Create a new member, from a supplied list of field values

- implements REST POST collection
- the aSimpleFields parameters must follow explicitly the order of published properties of the supplied aTable class, excepting the TSQLRawBlob and TSQLRecordMany kind (i.e. only so called "simple fields")
- the aSimpleFields must have exactly the same count of parameters as there are "simple fields" in the published properties
- if ForcedID is set to non null, client sends this ID to be used when adding the record (instead of a database-generated ID)
- on success, returns the new RowID value; on error, returns 0
- call internally the Add virtual method above

function AddWithBlobs(Value: TSQLRecord; ForceID: boolean=false; DoNotAutoComputeFields: boolean=false): TID; **virtual**;

Create a new member, including its BLOB fields

- implements REST POST collection
- this method will create a JSON representation of the document including the BLOB fields as Base64 encoded text, so will be less efficient than a dual Add() + UpdateBlobFields() methods if the binary content has a non trivial size
- this method will call EngineAdd() to perform the request

function AsynchBatchAdd(Value: TSQLRecord; SendData: boolean; ForceID: boolean=false; **const** CustomFields: TSQLFieldBits=[]; DoNotAutoComputeFields: boolean=false): integer;

Create a new ORM member in a BATCH to be written in a background thread

- should have been preceded by a call to AsynchBatchStart(), or returns -1
- is a wrapper around BackgroundTimer.AsynchBatchAdd(), so will return the index in the BATCH rows, not the created TID
- this method is thread-safe

function AsynchBatchDelete(Table: TSQLRecordClass; ID: TID): integer;

Delete an ORM member in a BATCH to be written in a background thread

- should have been preceded by a call to AsynchBatchStart(), or returns -1
- is a wrapper around the TSQLRestBatch.Delete() sent in the Timer thread
- this method is thread-safe

function AsynchBatchRawAdd(Table: TSQLRecordClass; **const** SentData: RawUTF8): integer;

Append some JSON content in a BATCH to be written in a background thread

- could be used to emulate AsynchBatchAdd() with an already pre-computed JSON object
- is a wrapper around BackgroundTimer.AsynchBatchRawAdd(), so will return the index in the BATCH rows, not the created TID
- this method is thread-safe

function AsynchBatchStart(Table: TSQLRecordClass; SendSeconds: integer; PendingRowThreshold: integer=500; AutomaticTransactionPerRow: integer=1000; Options: TSQLRestBatchOptions=[boExtendedJSON]): boolean;

Prepare an asynchronous ORM BATCH process, executed in a background thread

- will initialize a TSQLRestBatch and call TimerEnable to initialize the background thread, following the given processing period (in seconds), or the TSQLRestBatch.Count threshold to call BatchSend
- actual REST/CRUD commands will take place via AsynchBatchAdd, AsynchBatchUpdate and AsynchBatchDelete methods
- only a single AsynchBatch() call per Table is allowed at a time, unless AsynchBatchStop method is used to flush the current asynchronous BATCH
- using a BATCH in a dedicated thread will allow very fast background asynchronous process of ORM methods, sufficient for most use cases
- is a wrapper around BackgroundTimer.AsynchBatchStart()

function AsynchBatchStop(Table: TSQLRecordClass): boolean;

Finalize asynchronous ORM BATCH process, executed in a background thread

- should have been preceded by a call to AsynchBatch(), or returns false
- Table=nil will release all existing batch instances
- is a wrapper around BackgroundTimer.AsynchBatchStop()

function AsynchBatchUpdate(Value: TSQLRecord; **const** CustomFields: TSQLFieldBits=[]; DoNotAutoComputeFields: boolean=false): integer;

- Update an ORM member in a BATCH to be written in a background thread*
- should have been preceded by a call to AsynchBatchStart(), or returns -1
 - is a wrapper around BackgroundTimer.AsynchBatchUpdate()
 - this method is thread-safe

function BatchSend(Batch: TSQLRestBatch): integer; overload;

- Execute a BATCH sequence prepared in a TSQLRestBatch instance*
- just a wrapper around the overloaded BatchSend() method without the Results: TIDDynArray parameter

function BatchSend(Batch: TSQLRestBatch; **var** Results: TIDDynArray): integer; overload; **virtual**;

- Execute a BATCH sequence prepared in a TSQLRestBatch instance*
- implements the "Unit Of Work" pattern, i.e. safe transactional process even on multi-thread environments
 - send all pending Add/Update/Delete statements to the DB or remote server
 - will return the URI Status value, i.e. 200/HTTP_SUCCESS OK on success
 - a dynamic array of integers will be created in Results, containing all ROWID created for each BatchAdd call, 200 (=HTTP_SUCCESS) for all successful BatchUpdate/BatchDelete, or 0 on error
 - any error during server-side process MUST be checked against Results[] (the main URI Status is 200 if about communication success, and won't imply that all statements in the BATCH sequence were successful), or boRollbackOnError should be set in TSQLRestBatchOptions
 - note that the caller shall still free the supplied Batch instance

function CacheOrNil: TSQLRestCache;

- Access the internal caching parameters for a given TSQLRecord*
- will return nil if no TSQLRestCache instance has been defined

class function ClassFrom(aDefinition: TSynConnectionDefinition): TSQLRestClass;

- Retrieve the registered class from the aDefinition.Kind string*

class function CreateFrom(aModel: TSQLModel; aDefinition: TSynConnectionDefinition): TSQLRest;

- Create a new TSQLRest instance from its Model and stored values*
- aDefinition.Kind will define the actual class which will be instantiated: currently TSQLRestServerFullMemory, TSQLRestServerDB, TSQLRestClientURINamedPipe, TSQLRestClientURIMessage, TSQLHttpClientWinSock, TSQLHttpClientWinINet, TSQLHttpClientWinHTTP, and TSQLHttpClientCurl classes are recognized by this method
 - then other aDefinition fields will be used to refine the instance: please refer to each overridden DefinitionTo() method documentation
 - use TSQLRestMongoDBCreate() and/or TSQLRestExternalDBCreate() instead to create a TSQLRest instance will all tables defined as external when aDefinition.Kind is 'MongoDB' or a TSQLDBConnectionProperties class
 - will raise an exception if the supplied definition are not valid

class function CreateFromFile(aModel: TSQLModel; **const** aJSONFile: TFileName; aKey: cardinal=0): TSQLRest;

- Create a new TSQLRest instance from its Model and a JSON file*
- aDefinition.Kind will define the actual class which will be instantiated
 - you can specify a custom Key, if the default is not safe enough for you

```
class function CreateFromJSON(aModel: TSQLModel; const aJSONDefinition: RawUTF8;  
aKey: cardinal=0): TSQLRest;
```

Create a new TSQLRest instance from its Model and JSON stored values

- aDefinition.Kind will define the actual class which will be instantiated
- you can specify a custom Key, if the default is not safe enough for you

```
class function CreateTryFrom(aModel: TSQLModel; aDefinition:  
TSynConnectionDefinition; aServerHandleAuthentication: boolean): TSQLRest;
```

Try to create a new TSQLRest instance from its Model and stored values

- will return nil if the supplied definition are not valid
- if the newly created instance is a TSQLRestServer, will force the supplied aServerHandleAuthentication parameter to enable authentication

```
function DefinitionToJSON(Key: cardinal=0): RawUTF8;
```

Save the properties into a JSON file

- you can then use TSQLRest.CreateFromJSON() to re-instantiate it
- you can specify a custom Key, if the default is not enough for you

```
function Delete(Table: TSQLRecordClass; ID: TID): boolean; overload; virtual;
```

Delete a member

- implements REST DELETE collection
- return true on success
- call internally the EngineDelete() abstract method

```
function Delete(Table: TSQLRecordClass; const FormatSQLWhere: RawUTF8; const  
BoundsSQLWhere: array of const): boolean; overload;
```

Delete a member with a WHERE clause

- implements REST DELETE collection
- return true on success
- for better server speed, the WHERE clause should use bound parameters identified as '?' in the FormatSQLWhere statement, which is expected to follow the order of values supplied in BoundsSQLWhere open array - use DateToSQL/DateTimeToSQL for TDateTime, or directly any integer / double / currency / RawUTF8 values to be bound to the request as parameters
- is a simple wrapper around:
Delete(Table, FormatUTF8(FormatSQLWhere, [], BoundsSQLWhere))

```
function Delete(Table: TSQLRecordClass; const SQLWhere: RawUTF8): boolean;  
overload; virtual;
```

Delete a member with a WHERE clause

- implements REST DELETE collection
- return true on success
- this default method call OneFieldValues() to retrieve all matching IDs, then will delete each row using protected EngineDeleteWhere() virtual method

```
function Execute(const aSQL: RawUTF8): boolean; virtual;
```

Execute directly a SQL statement, without any expected result

- implements POST SQL on ModelRoot URI
- return true on success
- will call EngineExecute() abstract method to run the SQL statement

function ExecuteFmt(**const** SQLFormat: RawUTF8; **const** Args, Bounds: **array of const**): boolean; overload;

Execute directly a SQL statement with supplied parameters, with no result
- expect the same format as FormatUTF8() function, replacing all '%' chars with Args[] values, and all '?' chars with Bounds[] (inlining them with :(...): and auto-quoting strings)
- return true on success

function ExecuteFmt(**const** SQLFormat: RawUTF8; **const** Args: **array of const**): boolean; overload;

Execute directly a SQL statement with supplied parameters, with no result
- expect the same format as FormatUTF8() function, replacing all '%' chars with Args[] values
- return true on success

function ExecuteJson(**const** Tables: **array of** TSQLRecordClass; **const** SQL: RawUTF8; ForceAJAX: Boolean=false; ReturnedRowCount: PPtrInt=nil): RawJSON; **virtual**;

Execute directly a SQL statement, expecting a list of results
- you should not have to use this method, but the ORM versions instead
- return a result set as JSON on success, "" on failure
- will call EngineList() abstract method to retrieve its JSON content

function ExecuteList(**const** Tables: **array of** TSQLRecordClass; **const** SQL: RawUTF8): TSQLTableJSON; **virtual**;

Execute directly a SQL statement, expecting a list of results
- return a result table on success, nil on failure
- will call EngineList() abstract method to retrieve its JSON content

function FTSMATCH(Table: TSQLRecordFTS3Class; **const** MatchClause: RawUTF8; **var** DocID: TIDDynArray; **const** PerFieldWeight: **array of** double; limit: integer=0; offset: integer=0): boolean; overload;

Dedicated method used to retrieve free-text matching DocIDs with enhanced ranking information
- this method works for TSQLRecordFTS3, TSQLRecordFTS4 and TSQLRecordFTS5
- this method will search in all FTS3 columns, and except some floating-point constants for weighing each column (there must be the same number of PerFieldWeight parameters as there are columns in the TSQLRecordFTS3 table)
- example of use: FTSMATCH(TSQLDocuments, "linu*", IntResult, [1,0.5]) which will sort the results by the rank obtained with the 1st column/field being given twice the weighting of those in the 2nd (and last) column
- FTSMATCH(TSQLDocuments, 'linu*', IntResult, [1,0.5]) will perform a SQL query as such, which is the fastest way of ranking according to http://www.sqlite.org/fts3.html#appendix_a
SELECT RowID FROM Documents WHERE Documents MATCH 'linu*'
ORDER BY rank(matchinfo(Documents),1.0,0.5) DESC

function FTSMATCH(Table: TSQLRecordFTS3Class; **const** WhereClause: RawUTF8; **var** DocID: TIDDynArray): boolean; overload;

Dedicated method used to retrieve free-text matching DocIDs
- this method works for TSQLRecordFTS3, TSQLRecordFTS4 and TSQLRecordFTS5
- this method expects the column/field names to be supplied in the MATCH statement clause
- example of use: FTSMATCH(TSQLMessage, 'Body MATCH :("linu*"):', IntResult) (using inlined parameters via :(...): is always a good idea)

function MainFieldID(Table: TSQLRecordClass; **const** Value: RawUTF8): TID;

Return the ID of the record which main field match the specified value

- search field is mainly the "Name" property, i.e. the one with "stored AS_UNIQUE" (i.e. "stored false") definition on most TSQLRecord
- returns 0 if no matching record was found }

function MainFieldIDs(Table: TSQLRecordClass; **const** Values: **array of** RawUTF8; **out** IDs: TIDDynArray): **boolean**;

Return the IDs of the record which main field match the specified values

- search field is mainly the "Name" property, i.e. the one with "stored AS_UNIQUE" (i.e. "stored false") definition on most TSQLRecord
- if any of the Values[] is not existing, then no ID will appear in the IDs[] array - e.g. it will return [] if no matching record was found
- returns TRUE if any matching ID was found (i.e. if length(IDs)>0) }

function MainFieldValue(Table: TSQLRecordClass; ID: TID; ReturnFirstIfNoUnique: **boolean**=false): RawUTF8;

Retrieve the main field (mostly 'Name') value of the specified record

- use GetMainFieldName() method to get the main field name
- use OneFieldValue() method to get the field value
- return "" if no such field or record exists
- if ReturnFirstIfNoUnique is TRUE and no unique property is found, the first RawUTF8 property is returned anyway

function MemberExists(Table: TSQLRecordClass; ID: TID): **boolean**; **virtual**;

Check if a given ID do exist for a given table

function MultiFieldValue(Table: TSQLRecordClass; **const** FieldName: **array of** RawUTF8; **var** FieldValue: **array of** RawUTF8; **const** WhereClause: RawUTF8): **boolean**; **overload**;

Get the UTF-8 encoded value of some fields with a Where Clause

- example of use: MultiFieldValue(TSQLRecord,['Name'],Name,'ID=:(23):') (using inlined parameters via :(...): is always a good idea)
- FieldValue[] will have the same length as FieldName[]
- return true on success, false on SQL error or no result
- call internaly ExecuteList() to get the list

function MultiFieldValue(Table: TSQLRecordClass; **const** FieldName: **array of** RawUTF8; **var** FieldValue: **array of** RawUTF8; WhereID: TID): **boolean**; **overload**;

Get the UTF-8 encoded value of some fields from its ID

- example of use: MultiFieldValue(TSQLRecord,['Name'],Name,23)
- FieldValue[] will have the same length as FieldName[]
- return true on success, false on SQL error or no result
- call internaly ExecuteList() to get the list

```
function MultiFieldValues(Table: TSQLRecordClass; const FieldNames: RawUTF8; const WhereClause: RawUTF8=''): TSQLTableJSON; overload; virtual;
```

Execute directly a SQL statement, expecting a list of results

- return a result table on success, nil on failure
- FieldNames can be the CSV list of field names to be retrieved
- if FieldNames is "", will get all simple fields, excluding BLOBs
- if FieldNames is '*', will get ALL fields, including ID and BLOBs
- call internally ExecuteList() to get the list
- using inlined parameters via :(...): in WhereClause is always a good idea

```
function MultiFieldValues(Table: TSQLRecordClass; const FieldNames: RawUTF8; const WhereClauseFormat: RawUTF8; const BoundsSQLWhere: array of const): TSQLTableJSON; overload;
```

Execute directly a SQL statement, expecting a list of results

- return a result table on success, nil on failure
- FieldNames can be the CSV list of field names to be retrieved
- if FieldNames is "", will get all simple fields, excluding BLOBs
- if FieldNames is '*', will get ALL fields, including ID and BLOBs
- this overloaded function will call FormatUTF8 to create the Where Clause from supplied parameters, binding all '?' chars with Args[] values
- example of use:
`aList := aClient.MultiFieldValues(TSQLRecord, 'Name,FirstName', 'Salary>=?',[aMinSalary]);`
- call overloaded MultiFieldValues() / ExecuteList() to get the list
- note that this method prototype changed with revision 1.17 of the framework: array of const used to be Args and '%' in the WhereClauseFormat statement, whereas it now expects bound parameters as '?'

```
function MultiFieldValues(Table: TSQLRecordClass; const FieldNames: RawUTF8; const WhereClauseFormat: RawUTF8; const Args, Bounds: array of const): TSQLTableJSON; overload;
```

Execute directly a SQL statement, expecting a list of results

- return a result table on success, nil on failure
- FieldNames can be the CSV list of field names to be retrieved
- if FieldNames is "", will get all simple fields, excluding BLOBs
- if FieldNames is '*', will get ALL fields, including ID and BLOBs
- in this version, the WHERE clause can be created with the same format as FormatUTF8() function, replacing all '%' chars with Args[], and all '?' chars with Bounds[] (inlining them with :(...): and auto-quoting strings)
- example of use:
`Table := MultiFieldValues(TSQLRecord, 'Name', '%=?', ['ID'],[aID]);`
- call overloaded MultiFieldValues() / ExecuteList() to get the list

```
function MultiRedirect(const aGUID: TGUID; out aCallbackInterface;
aCallbackUnRegisterNeeded: boolean=true): IMultiCallbackRedirect; overload;
```

Define redirection of interface methods calls in one or several instances

- this class allows to implements any interface via a fake class, which will redirect all methods calls to one or several other interfaces
- returned aCallbackInterface will redirect all its methods (identified by aGUID) into an internal list handled by IMultiCallbackRedirect.Redirect

- typical use is thefore:

```
fSharedCallback: IMyService;
fSharedCallbacks: IMultiCallbackRedirect;
...
if fSharedCallbacks=nil then begin
  fSharedCallbacks := aRest.MultiRedirect(IMyService,fSharedCallback);
  aServices.SubscribeForEvents(fSharedCallback);
end;
fSharedCallbacks.Redirect(TMyCallback.Create,[]);
// now each time fSharedCallback receive one event, all callbacks
// previously registered via Redirect() will receive it
...
fSharedCallbacks := nil; // will stop redirection
                        // and unregister callbacks, if needed
```

```
function NewBackgroundThreadMethod(const Format: RawUTF8; const Args: array of const)
const): TSynBackgroundThreadMethod;
```

Allows to safely execute a processing method in a background thread

- returns a TSynBackgroundThreadMethod instance, ready to execute any background task via its RunAndWait() method
- will properly call BeginCurrentThread/EndCurrentThread methods
- you should supply some runtime information to name the thread, for proper debugging

```
function NewBackgroundThreadProcess(aOnProcess: TOnSynBackgroundThreadProcess;
aOnProcessMS: cardinal; const Format: RawUTF8; const Args: array of const; aStats:
TSynMonitorClass=nil): TSynBackgroundThreadProcess;
```

Allows to safely execute a process at a given pace

- returns a TSynBackgroundThreadProcess instance, ready to execute the supplied aOnProcess event in a loop, as aOnProcessMS periodic task
- will properly call BeginCurrentThread/EndCurrentThread methods
- you should supply some runtime information to name the thread, for proper debugging

```
function NewParallelProcess(ThreadCount: integer; const Format: RawUTF8; const
Args: array of const): TSynParallelProcess;
```

Allows to safely execute a process in parallel

- returns a TSynParallelProcess instance, ready to execute any task in parrallel in a thread-pool given by ThreadCount
- will properly call BeginCurrentThread/EndCurrentThread methods
- you should supply some runtime information to name the thread, for proper debugging

```
function OneFieldValue(Table: TSQLRecordClass; const FieldName: RawUTF8; WhereID:
TID): RawUTF8; overload;
```

Get the UTF-8 encoded value of an unique field from its ID

- example of use: OneFieldValue(TSQLRecord,'Name',23)
- call internaly ExecuteList() to get the value

```
function OneFieldValue(Table: TSQLRecordClass; const FieldName: RawUTF8; const
WhereClauseFmt: RawUTF8; const Args, Bounds: array of const; out Data: Int64):
boolean; overload;
```

Get one integer value of an unique field with a Where Clause
 - this overloaded function will return the field value as integer

```
function OneFieldValue(Table: TSQLRecordClass; const FieldName, WhereClause:
RawUTF8): RawUTF8; overload;
```

Get the UTF-8 encoded value of an unique field with a Where Clause

- example of use - including inlined parameters via :(...):
 aClient.OneFieldValue(TSQLRecord, 'Name', 'ID=:(23):')

you should better call the corresponding overloaded method as such:

```
aClient.OneFieldValue(TSQLRecord, 'Name', 'ID=?',[aID])
```

which is the same as calling:

```
aClient.OneFieldValue(TSQLRecord, 'Name', FormatUTF8('ID=?',[23]))
```

- call internaly ExecuteList() to get the value

```
function OneFieldValue(Table: TSQLRecordClass; const FieldName: RawUTF8; const
FormatSQLWhere: RawUTF8; const BoundsSQLWhere: array of const): RawUTF8; overload;
```

Get the UTF-8 encoded value of an unique field with a Where Clause

- this overloaded function will call FormatUTF8 to create the Where Clause from supplied parameters, binding all '?' chars with Args[] values

- example of use:

```
aClient.OneFieldValue(TSQLRecord, 'Name', 'ID=?',[aID])
```

- call internaly ExecuteList() to get the value

- note that this method prototype changed with revision 1.17 of the framework: array of const used to be Args and '%' in the FormatSQLWhere statement, whereas it now expects bound parameters as '?'

```
function OneFieldValue(Table: TSQLRecordClass; const FieldName: RawUTF8; const
WhereClauseFmt: RawUTF8; const Args, Bounds: array of const): RawUTF8; overload;
```

Get the UTF-8 encoded value of an unique field with a Where Clause

- this overloaded function will call FormatUTF8 to create the Where Clause from supplied parameters, replacing all '%' chars with Args[], and all '?' chars with Bounds[] (inlining them with :(...): and auto-quoting strings)

- example of use:

```
OneFieldValue(TSQLRecord, 'Name', '%=?',[ 'ID' ],[aID])
```

- call internaly ExecuteList() to get the value

```
function OneFieldValueInt64(Table: TSQLRecordClass; const FieldName, WhereClause:
RawUTF8; Default: Int64=0): Int64;
```

Get the Int64 value of an unique field with a Where Clause

- call internaly ExecuteList() to get the value

```
function OneFieldValues(Table: TSQLRecordClass; const FieldName: RawUTF8; const
WhereClause: RawUTF8=''; const Separator: RawUTF8=','): RawUTF8; overload;
```

Get the CSV-encoded UTF-8 encoded values of an unique field with a Where Clause

- example of use: OneFieldValue(TSQLRecord,'FirstName','Name=:(\"Smith\")',Data) (using inlined parameters via :(...): is always a good idea)

- leave WhereClause void to get all records

- call internaly ExecuteList() to get the list

- using inlined parameters via :(...): in WhereClause is always a good idea

```
function OneFieldValues(Table: TSQLRecordClass; const FieldName, WhereClause: RawUTF8; Strings: TStrings; IDToIndex: PID=nil): Boolean; overload;
```

Get the string-encoded values of an unique field into some TStrings

- Items[] will be filled with string-encoded values of the given field)
- Objects[] will be filled with pointer(ID)
- call internaly ExecuteList() to get the list
- returns TRUE on success, FALSE if no data was retrieved
- if IDToIndex is set, its value will be replaced with the index in Strings.Objects[] where ID=IDToIndex^
- using inlined parameters via :(...): in WhereClause is always a good idea

```
function OneFieldValues(Table: TSQLRecordClass; const FieldName: RawUTF8; const WhereClause: RawUTF8; var Data: TInt64DynArray; SQL: PRawUTF8=nil): boolean; overload;
```

Get the integer value of an unique field with a Where Clause

- example of use: OneFieldValue(TSQLRecordPeople,'ID','Name=:"Smith":',Data) (using inlined parameters via :(...): is always a good idea)
- leave WhereClause void to get all records
- call internaly ExecuteList() to get the list

```
function OneFieldValues(Table: TSQLRecordClass; const FieldName: RawUTF8; const WhereClause: RawUTF8; out Data: TRawUTF8DynArray): boolean; overload;
```

Get the UTF-8 encoded values of an unique field with a Where Clause

- example of use: OneFieldValue(TSQLRecord,'FirstName','Name=:"Smith":',Data) (using inlined parameters via :(...): is always a good idea)
- leave WhereClause void to get all records
- call internaly ExecuteList() to get the list
- returns TRUE on success, FALSE if no data was retrieved

```
class function QueryIsTrue(aTable: TSQLRecordClass; aID: TID; FieldType: TSQLFieldType; Value: PUTF8Char; Operator: integer; Reference: PUTF8Char): boolean;
```

Evaluate a basic operation for implementing User Interface Query action

- expect both Value and Reference to be UTF-8 encoded (as in TSQLTable or TSQLTableToGrid)
- aID parameter is ignored in this function implementation (expect only this parameter to be not equal to 0)
- is TSQLQueryEvent prototype compatible
- for qoContains and qoBeginWith, the Reference is expected to be already uppercase
- for qoSoundsLike* operators, Reference is not a PUTF8Char, but a typecase of a prepared TSynSoundEx object instance (i.e. pointer(@SoundEx))

```
function RecordCanBeUpdated(Table: TSQLRecordClass; ID: TID; Action: TSQLEvent; ErrorMsg: PRawUTF8 = nil): boolean; virtual;
```

Override this method to guess if this record can be updated or deleted

- this default implementation returns always true
- e.g. you can add digital signature to a record to disallow record editing
- the ErrorMsg can be set to a variable, which will contain an explicit error message

function Retrieve(Reference: TRecordReference; ForUpdate: boolean=false): TSQLRecord; overload; **virtual**;

Get a member from its TRecordReference property content

- instead of the other Retrieve() methods, this implementation Create an instance, with the appropriated class stored in Reference
- returns nil on any error (invalid Reference e.g.)
- if ForUpdate is true, the REST method is LOCK and not GET: it tries to lock the corresponding record, then retrieve its content; caller has to call UnLock() method after Value usage, to release the record
- the TSQLRawBlob (BLOB) fields are not retrieved by this method, to preserve bandwidth: use the RetrieveBlob() methods for handling BLOB fields, or set either the TSQLRestClientURI.ForceBlobTransfert or TSQLRestClientURI.ForceBlobTransfertTable[] properties
- the TSQLRecordMany fields are not retrieved either: they are separate instances created by TSQLRecordMany.Create, with dedicated methods to access to the separated pivot table

function Retrieve(aPublishedRecord, aValue: TSQLRecord): boolean; overload;

Get a member from a published property TSQLRecord

- those properties are not class instances, but TObject(aRecordID)
- is just a wrapper around Retrieve(aPublishedRecord.ID,aValue)
- return true on success

function Retrieve(aID: TID; Value: TSQLRecord; ForUpdate: boolean=false): boolean; overload; **virtual**;

Get a member from its ID

- return true on success
- Execute 'SELECT * FROM TableName WHERE ID=:(aID): LIMIT 1' SQL Statement
- if ForUpdate is true, the REST method is LOCK and not GET: it tries to lock the corresponding record, then retrieve its content; caller has to call UnLock() method after Value usage, to release the record
- this method will call EngineRetrieve() abstract method
- the TSQLRawBlob (BLOB) fields are not retrieved by this method, to preserve bandwidth: use the RetrieveBlob() methods for handling BLOB fields, or set either the TSQLRestClientURI.ForceBlobTransfert or TSQLRestClientURI.ForceBlobTransfertTable[] properties
- the TSQLRecordMany fields are not retrieved either: they are separate instances created by TSQLRecordMany.Create, with dedicated methods to access to the separated pivot table

function Retrieve(const SQLWhere: RawUTF8; Value: TSQLRecord; const aCustomFieldsCSV: RawUTF8=''): boolean; overload; **virtual**;

Here are REST basic direct calls (works with Server or Client) get a member from a SQL statement

- implements REST GET collection
- return true on success
- Execute 'SELECT * FROM TableName WHERE SQLWhere LIMIT 1' SQL Statement (using inlined parameters via :(...): in SQLWhere is always a good idea)
- since no record is specified, locking is pointless here
- default implementation call ExecuteList(), and fill Value from a temporary TSQLTable
- if aCustomFieldsCSV is "", will get all simple fields, excluding BLOBs and TSQLRecordMany fields (use RetrieveBlob method or set TSQLRestClientURI.ForceBlobTransfert)
- if aCustomFieldsCSV is '*', will get ALL fields, including ID and BLOBs
- if this default set of simple fields does not fit your need, you could specify your own set

```
function Retrieve(const WhereClauseFmt: RawUTF8; const Args, Bounds: array of const;  
Value: TSQLRecord; const aCustomFieldsCSV: RawUTF8=''): boolean; overload;
```

Get a member from a SQL statement

- implements REST GET collection
- return true on success
- same as Retrieve(const SQLWhere: RawUTF8; Value: TSQLRecord) method, but this overloaded function will call FormatUTF8 to create the Where Clause from supplied parameters, replacing all '%' chars with Args[], and all '?' chars with Bounds[] (inlining them with :(...): and auto-quoting strings)
- if aCustomFieldsCSV is "", will get all simple fields, excluding BLOBs
- if aCustomFieldsCSV is '*', will get ALL fields, including ID and BLOBs

```
function RetrieveBlob(Table: TSQLRecordClass; aID: TID; const BlobFieldName:  
RawUTF8; out BlobStream: THeapMemoryStream): boolean; overload;
```

Get a blob field content from its record ID and supplied blob field name

- implements REST GET collection with a supplied member ID and field name
- return true on success
- this method will create a TStream instance (which must be freed by the caller after use) and fill it with the blob data

```
function RetrieveBlob(Table: TSQLRecordClass; aID: TID; const BlobFieldName:  
RawUTF8; out BlobData: TSQLRawBlob): boolean; overload; virtual;
```

Get a blob field content from its record ID and supplied blob field name

- implements REST GET collection with a supplied member ID and a blob field name
- return true on success
- this method is defined as abstract, i.e. there is no default implementation: it must be implemented 100% RestFul with a GET ModelRoot/TableName/TableID/BlobFieldName request for example
- this method retrieve the blob data as a TSQLRawBlob string using EngineRetrieveBlob()

```
function RetrieveBlobFields(Value: TSQLRecord): boolean; virtual;
```

Get all BLOB fields of the supplied value from the remote server

- call several REST GET collection (one for each BLOB) for the member
- call internally e.g. by TSQLRestClient.Retrieve method when ForceBlobTransfert / ForceBlobTransfertTable[] is set

```
function RetrieveDocVariant(Table: TSQLRecordClass; const FormatSQLWhere: RawUTF8;  
const BoundsSQLWhere: array of const; const CustomFieldsCSV: RawUTF8): variant;
```

Get one member from a SQL statement as a TDocVariant

- implements REST GET collection
- the data will be converted to a TDocVariant variant following the TSQLRecord layout, so complex types like dynamic array will be returned as a true array of values

```
function RetrieveDocVariantArray(Table: TSQLRecordClass; const ObjectName,  
CustomFieldsCSV: RawUTF8; FirstRecordID: PID=nil; LastRecordID: PID=nil): variant;  
overload;
```

Get a list of all members from a SQL statement as a TDocVariant

- implements REST GET collection
- if ObjectName="", it will return a TDocVariant of dvArray kind
- if ObjectName is set, it will return a TDocVariant of dvObject kind, with one property containing the array of values: this returned variant can be pasted e.g. directly as parameter to TSynMustache.Render()
- aCustomFieldsCSV can be the CSV list of field names to be retrieved
- if aCustomFieldsCSV is "", will get all simple fields, excluding BLOBs
- if aCustomFieldsCSV is '*', will get ALL fields, including ID and BLOBs
- the data will be converted to variants and TDocVariant following the TSQLRecord layout, so complex types like dynamic array will be returned as a true array of values (in contrast to the RetrieveListJSON method)
- warning: under FPC, we observed that assigning the result of this method to a local variable may circumvent a memory leak FPC bug

```
function RetrieveDocVariantArray(Table: TSQLRecordClass; const ObjectName:  
RawUTF8; const FormatSQLWhere: RawUTF8; const BoundsSQLWhere: array of const; const  
CustomFieldsCSV: RawUTF8; FirstRecordID: PID=nil; LastRecordID: PID=nil): variant;  
overload;
```

Get a list of members from a SQL statement as a TDocVariant

- implements REST GET collection over a specified WHERE clause
- if ObjectName="", it will return a TDocVariant of dvArray kind
- if ObjectName is set, it will return a TDocVariant of dvObject kind, with one property containing the array of values: this returned variant can be pasted e.g. directly as parameter to TSynMustache.Render()
- for better server speed, the WHERE clause should use bound parameters identified as '?' in the FormatSQLWhere statement, which is expected to follow the order of values supplied in BoundsSQLWhere open array - use DateToSQL()/DateTimeToSQL() for TDateTime, or directly any integer, double, currency, RawUTF8 values to be bound to the request as parameters
- aCustomFieldsCSV can be the CSV list of field names to be retrieved
- if aCustomFieldsCSV is "", will get all simple fields, excluding BLOBs
- if aCustomFieldsCSV is '*', will get ALL fields, including ID and BLOBs
- the data will be converted to variants and TDocVariant following the TSQLRecord layout, so complex types like dynamic array will be returned as a true array of values (in contrast to the RetrieveListJSON method)
- warning: under FPC, we observed that assigning the result of this method to a local variable may circumvent a memory leak FPC bug

```
function RetrieveList(Table: TSQLRecordClass; const FormatSQLWhere: RawUTF8; const BoundsSQLWhere: array of const; const aCustomFieldsCSV: RawUTF8=''): TObjectList; overload;
```

Get a list of members from a SQL statement as TObjectList

- implements REST GET collection
- for better server speed, the WHERE clause should use bound parameters identified as '?' in the FormatSQLWhere statement, which is expected to follow the order of values supplied in BoundsSQLWhere open array - use DateToSQL()/DateTimeToSQL() for TDateTime, or directly any integer, double, currency, RawUTF8 values to be bound to the request as parameters
- aCustomFieldsCSV can be the CSV list of field names to be retrieved
- if aCustomFieldsCSV is "", will get all simple fields, excluding BLOBs
- if aCustomFieldsCSV is '*', will get ALL fields, including ID and BLOBs
- return a TObjectList on success (possibly with Count=0) - caller is responsible of freeing the instance
- this TObjectList will contain a list of all matching records
- return nil on error

```
function RetrieveListJSON(Table: TSQLRecordClass; const FormatSQLWhere: RawUTF8; const BoundsSQLWhere: array of const; const aCustomFieldsCSV: RawUTF8=''; aForceAJAX: boolean=false): RawJSON; overload;
```

Get a list of members from a SQL statement as RawJSON

- implements REST GET collection
- for better server speed, the WHERE clause should use bound parameters identified as '?' in the FormatSQLWhere statement, which is expected to follow the order of values supplied in BoundsSQLWhere open array - use DateToSQL()/DateTimeToSQL() for TDateTime, or directly any integer, double, currency, RawUTF8 values to be bound to the request as parameters
- aCustomFieldsCSV can be the CSV list of field names to be retrieved
- if aCustomFieldsCSV is "", will get all simple fields, excluding BLOBs
- if aCustomFieldsCSV is '*', will get ALL fields, including ID and BLOBs
- returns the raw JSON array content with all items on success, with our expanded / not expanded JSON format - so can be used with SOA methods and RawJSON results, for direct process from the client side
- returns "" on error
- the data is directly retrieved from raw JSON as returned by the database without any conversion, so this method will be the fastest, but complex types like dynamic array will be returned as Base64-encoded blob value - if you need proper JSON access to those, see RetrieveDocVariantArray()

```
function RetrieveListJSON(Table: TSQLRecordClass; const SQLWhere: RawUTF8; const aCustomFieldsCSV: RawUTF8=''; aForceAJAX: boolean=false): RawJSON; overload;
```

Get a list of members from a SQL statement as RawJSON

- implements REST GET collection
- this overloaded version expect the SQLWhere clause to be already prepared with inline parameters using a previous FormatUTF8() call
- aCustomFieldsCSV can be the CSV list of field names to be retrieved
- if aCustomFieldsCSV is "", will get all simple fields, excluding BLOBs
- if aCustomFieldsCSV is '*', will get ALL fields, including ID and BLOBs
- returns the raw JSON array content with all items on success, with our expanded / not expanded JSON format - so can be used with SOA methods and RawJSON results, for direct process from the client side
- returns "" on error
- the data is directly retrieved from raw JSON as returned by the database without any conversion, so this method will be the fastest, but complex types like dynamic array will be returned as Base64-encoded blob value - if you need proper JSON access to those, see RetrieveDocVariantArray()

```
function RetrieveListObjArray(var ObjArray; Table: TSQLRecordClass; const FormatSQLWhere: RawUTF8; const BoundsSQLWhere: array of const; const aCustomFieldsCSV: RawUTF8=''): boolean;
```

*Get a list of members from a SQL statement as T*ObjArray*

- implements REST GET collection
- for better server speed, the WHERE clause should use bound parameters identified as '?' in the FormatSQLWhere statement, which is expected to follow the order of values supplied in BoundsSQLWhere open array - use DateToSQL()/DateTimeToSQL() for TDateTime, or directly any integer, double, currency, RawUTF8 values to be bound to the request as parameters
- aCustomFieldsCSV can be the CSV list of field names to be retrieved
- if aCustomFieldsCSV is "", will get all simple fields, excluding BLOBs
- if aCustomFieldsCSV is '*', will get ALL fields, including ID and BLOBs
- set the T*ObjArray variable with all items on success - so that it can be used with SOA methods
- it is up to the caller to ensure that ObjClear(ObjArray) is called when the T*ObjArray list is not needed any more
- returns true on success, false on error

```
function RetrieveOneFieldDocVariantArray(Table: TSQLRecordClass; const FieldName, FormatSQLWhere: RawUTF8; const BoundsSQLWhere: array of const): variant;
```

Get all values of a SQL statement on a single column as a TDocVariant array

- implements REST GET collection on a single field
- for better server speed, the WHERE clause should use bound parameters identified as '?' in the FormatSQLWhere statement, which is expected to follow the order of values supplied in BoundsSQLWhere open array - use DateToSQL()/DateTimeToSQL() for TDateTime, or directly any integer, double, currency, RawUTF8 values to be bound to the request as parameters
- the data will be converted to variants and TDocVariant following the TSQLRecord layout, so complex types like dynamic array will be returned as a true array of values (in contrast to the RetrieveListJSON method)

```
function RTreeMatch(DataTable: TSQLRecordClass; const DataTableBlobFieldName: RawUTF8; RTreeTable: TSQLRecordRTreeClass; const DataTableBlobField: RawByteString; var DataID: TIDDynArray): boolean;
```

Dedicated method used to retrieve matching IDs using a fast R-Tree index

- a TSQLRecordRTree is associated to a TSQLRecord with a specified BLOB field, and will call TSQLRecordRTree BlobToCoord and ContainedIn virtual class methods to execute an optimized SQL query

- as alternative, with SQLite3 >= 3.24.0, you may use Auxiliary Columns

- will return all matching DataTable IDs in DataID[]

- will generate e.g. the following statement

```
SELECT MapData.ID From MapData, MapBox WHERE MapData.ID=MapBox.ID
AND minX>=(-81.0): AND maxX<=(-79.6): AND minY>=(35.0): AND :(maxY<=36.2):
AND MapBox_in(MapData.BlobField,('\'uFFF0base64encoded-81,-79.6,35,36.2')');
```

when the following Delphi code is executed:

```
aClient.RTreeMatch(TSQLRecordMapData, 'BlobField', TSQLRecordMapBox,
aMapData.BlobField, ResultID);
```

```
function ServiceContainer: TServiceContainer; virtual; abstract;
```

Access or initialize the internal IoC resolver, used for interface-based remote services, and more generally any Services.Resolve() call

- create and initialize the internal TServiceContainer if no service interface has been registered yet

- may be used to inject some dependencies, which are not interface-based remote services, but internal IoC, without the ServiceRegister() or ServiceDefine() methods - e.g.

```
aRest.ServiceContainer.InjectResolver([TInfraRepoUserFactory.Create(aRest)], true);
```

- overridden methods will return TServiceContainerClient or TServiceContainerServer instances, on TSQLRestClient or TSQLRestServer

```
function SystemUseTrack(periodSec: integer=10): TSystemUse;
```

Will gather CPU and RAM information in a background thread

- you can specify the update frequency, in seconds

- access to the information via the returned instance, which maps the TSystemUse.Current class function

- do nothing if global TSystemUse.Current was already assigned

```
function TableHasRows(Table: TSQLRecordClass): boolean; virtual;
```

Check if there is some data rows in a specified table

- calls internally a "SELECT RowID FROM TableName LIMIT 1" SQL statement, which is much faster than testing if "SELECT count(*)" equals 0 - see

@<http://stackoverflow.com/questions/8988915>

```
function TableMaxID(Table: TSQLRecordClass): TID; virtual;
```

Search for the last inserted ID in a specified table

- returns -1 on error

- will execute by default "SELECT max(rowid) FROM TableName"

```
function TableRowCount(Table: TSQLRecordClass): Int64; virtual;
```

Get the row count of a specified table

- returns -1 on error

- returns the row count of the table on success

- calls internally the "SELECT Count(*) FROM TableName;" SQL statement

function TimerDisable(aOnProcess: TOnSynBackgroundTimerProcess): boolean;

Undefine a task running on a periodic number of seconds

- should have been registered by a previous call to TimerEnable() method
- returns true on success, false if the supplied task was not registered

function TimerEnable(aOnProcess: TOnSynBackgroundTimerProcess; aOnProcessSecs: cardinal): TSynBackgroundTimer;

Define a task running on a periodic number of seconds in a background thread

- could be used to run background maintenance or monitoring tasks on this TSQLRest instance, at a low pace (typically every few minutes)
- will instantiate and run a shared TSynBackgroundTimer instance for this TSQLRest, so all tasks will share the very same thread
- you can run BackgroundTimer.Enqueue or ExecuteNow methods to implement a FIFO queue, or force immediate execution of the process
- will call BeginCurrentThread/EndCurrentThread as expected e.g. by logs

function TransactionActiveSession: cardinal;

Check current transaction status

- returns the session ID if a transaction is active
- returns 0 if no transaction is active

function TransactionBegin(aTable: TSQLRecordClass; SessionID: cardinal): boolean;
virtual;

Begin a transaction

- implements REST BEGIN collection
- may be used to speed up CRUD statements like Add/Update/Delete
- in the current implementation, nested transactions are not allowed
- must be ended with Commit on success
- must be aborted with Rollback if any SQL statement failed
- default implementation just handle the protected fTransactionActiveSession flag
- return true if no transaction is active, false otherwise
- in aClient-Server environment with multiple Clients connected at the same time, you should better use BATCH process, specifying a positive AutomaticTransactionPerRow parameter to BatchStart()

- in a multi-threaded or Client-Server with multiple concurrent Client connections, you may check the returned value, as such:

```
if Client.TransactionBegin(TSQLRecordPeopleObject) then
try
  //.... modify the database content, raise exceptions on error
  Client.Commit;
except
  Client.Rollback; // in case of error
end;
```

or use the TransactionBeginRetry() method

- the supplied SessionID will allow multi-user transaction safety on the Server-Side: all database modification from another session will wait for the global transaction to be finished; on Client-side, the SessionID is just ignored (TSQLRestClient will override this method with a default SessionID=CONST_AUTHENTICATION_NOT_USED=1 parameter)
- if you have an external database engine which expect transactions to take place in the same thread, ensure TSQLRestServer force execution of this method when accessed from RESTful clients in the same thread, e.g.:

```
AcquireExecutionMode[execORMWrite] := amBackgroundThread;
AcquireWriteMode := amBackgroundThread; // same as previous
```

function UnLock(Rec: TSQLRecord): boolean; overload;

Unlock the corresponding record

- record should have been locked previously e.g. with Retrieve() and forupdate=true, i.e. retrieved not via GET with LOCK REST-like verb
- use our custom UNLOCK REST-like method
- calls internally UnLock() above
- returns true on success

function UnLock(Table: TSQLRecordClass; aID: TID): boolean; overload; **virtual;**
abstract;

Unlock the corresponding record

- record should have been locked previously e.g. with Retrieve() and forupdate=true, i.e. retrieved not via GET with LOCK REST-like verb
- use our custom UNLOCK REST-like verb
- returns true on success

```
function Update(aTable: TSQLRecordClass; aID: TID; const aSimpleFields: array of const): boolean; overload;
```

Update a member from a supplied list of simple field values

- implements REST PUT collection
- the aSimpleFields parameters MUST follow explicitly both count and order of published properties of the supplied aTable class, excepting the TSQLRawBlob and TSQLRecordMany kind (i.e. only so called "simple fields")
- return true on success
- call internally the Update() / EngineUpdate() virtual methods

```
function Update(Value: TSQLRecord; const CustomCSVFields: RawUTF8;  
DoNotAutoComputeFields: boolean=false): boolean; overload;
```

Update a member from Value simple fields content

- implements REST PUT collection
- return true on success
- is an overloaded method to Update(Value,FieldBitsFromCSV())

```
function Update(Value: TSQLRecord; const CustomFields: TSQLFieldBits=[];  
DoNotAutoComputeFields: boolean=false): boolean; overload; virtual;
```

Update a member from Value simple fields content

- implements REST PUT collection
- return true on success
- the TSQLRawBlob(BLOB) fields values are not updated by this method, to preserve bandwidth: use the UpdateBlob() methods for handling BLOB fields
- the TSQLRecordMany fields are not set either: they are separate instances created by TSQLRecordMany.Create, with dedicated methods to access to the separated pivot table
- if CustomFields is left void, the simple fields will be used, or the fields retrieved via a previous FillPrepare() call; otherwise, you can specify your own set of fields to be transmitted (including BLOBs, even if they will be Base64-encoded within the JSON content) - CustomFields could be computed by TSQLRecordProperties.FieldBitsFromCSV() or TSQLRecordProperties.FieldBitsFromRawUTF8()
- this method will always compute and send any TModTime fields
- this method will call EngineUpdate() to perform the request

```
function UpdateBlob(Table: TSQLRecordClass; aID: TID; const BlobFieldName: RawUTF8;  
const BlobData: TSQLRawBlob): boolean; overload; virtual;
```

Update a blob field from its record ID and supplied blob field name

- implements REST PUT collection with a supplied member ID and field name
- return true on success
- call internally the EngineUpdateBlob() abstract method
- this method expect the Blob data to be supplied as TSQLRawBlob, using EngineUpdateBlob()

```
function UpdateBlob(Table: TSQLRecordClass; aID: TID; const BlobFieldName: RawUTF8;  
BlobData: TStream): boolean; overload;
```

Update a blob field from its record ID and blob field name

- implements REST PUT collection with a supplied member ID and field name
- return true on success
- call internally the EngineUpdateBlob() abstract method
- this method expect the Blob data to be supplied as a TStream: it will send the whole stream content (from its beginning position upto its current size) to the database engine

function UpdateBlob(Table: TSQLRecordClass; aID: TID; **const** BlobFieldName: RawUTF8; BlobData: pointer; BlobSize: integer): boolean; overload;

Update a blob field from its record ID and blob field name

- implements REST PUT collection with a supplied member ID and field name
- return true on success
- call internally the EngineUpdateBlob() abstract method
- this method expect the Blob data to be supplied as direct memory pointer and size

function UpdateBlobFields(Value: TSQLRecord): boolean; **virtual**;

Update all BLOB fields of the supplied Value

- call several REST PUT collection (one for each BLOB) for the member
- uses the UpdateBlob() method to send the BLOB properties content to the Server
- called internally by Add and Update methods when ForceBlobTransfert / ForceBlobTransfertTable[] is set
- you can use this method by hand, to avoid several calls to UpdateBlob()
- returns TRUE on success (or if there is no BLOB field)
- returns FALSE on error (e.g. if Value is invalid or with db/transmission)

function UpdateField(Table: TSQLRecordClass; **const** WhereFieldName: RawUTF8; **const** WhereFieldValue: **variant**; **const** FieldName: RawUTF8; **const** FieldValue: **variant**): boolean; overload; **virtual**;

Update one field in one or several members, depending on a WHERE clause, with both update and where values specified as variant

- implements REST PUT collection with one field value on a one where value
- any value can be set in FieldValue, but for BLOBs, you should better use UpdateBlob()
- for security reasons, void WHERE clause will be rejected
- return true on success
- call internally the EngineUpdateField() abstract method
- note that this method won't update the TModTime properties, nor the internal table Cache: you should rather use a classic Retrieve()/FillPrepare() followed by an Update() of the whole record

function UpdateField(Table: TSQLRecordClass; ID: TID; **const** FieldName: RawUTF8; **const** FieldValue: **array of const**): boolean; overload; **virtual**;

Update one field/column value a given member

- implements REST PUT collection with one field value
- only one single field shall be specified in FieldValue, but could be of any kind of value - for BLOBs, you should better use UpdateBlob()
- return true on success
- call internally the EngineUpdateField() abstract method
- note that this method won't update the TModTime properties: you should rather use a classic Retrieve()/FillPrepare() followed by Update(); but it will notify the internal Cache

```
function UpdateField(Table: TSQLRecordClass; const WhereFieldName: RawUTF8; const WhereFieldValue: array of const; const FieldName: RawUTF8; const FieldValue: array of const): boolean; overload; virtual;
```

Update one field in one or several members, depending on a WHERE clause

- implements REST PUT collection with one field value on a one where value
- only one single field shall be specified in FieldValue, but could be of any kind of value - for BLOBs, you should better use UpdateBlob()
- only one single field shall be specified in WhereFieldValue, but could be of any kind of value - for security reasons, void WHERE clause will be rejected
- return true on success
- call internally the EngineUpdateField() abstract method
- note that this method won't update the TModTime properties: you should rather use a classic Retrieve()/FillPrepare() followed by Update(); but it will notify the internal Cache

```
function UpdateField(Table: TSQLRecordClass; ID: TID; const FieldName: RawUTF8; const FieldValue: variant): boolean; overload; virtual;
```

Update one field in a given member with a value specified as variant

- implements REST PUT collection with one field value
- any value can be set in FieldValue, but for BLOBs, you should better use UpdateBlob()
- return true on success
- call internally the EngineUpdateField() abstract method
- note that this method won't update the TModTime properties: you should rather use a classic Retrieve()/FillPrepare() followed by Update(); but it will notify the internal Cache

```
function UpdateField(Table: TSQLRecordClass; const IDs: array of Int64; const FieldName: RawUTF8; const FieldValue: variant): boolean; overload; virtual;
```

Update one field in one or several members, depending on a set of IDs

- return true on success
- note that this method won't update the TModTime properties: you should rather use a classic Retrieve()/FillPrepare() followed by Update(), but it will be much slower, even over a BATCH; anyway, it will update the internal Cache
- will be executed as a regular SQL statement:

```
UPDATE table SET fieldname=fieldvalue WHERE RowID IN (...)
```
- warning: this method will call directly EngineExecute(), and will work just fine with SQLite3, but some other DB engines may not allow a huge number of items within the IN(...) clause

```
function UpdateFieldIncrement(Table: TSQLRecordClass; ID: TID; const FieldName: RawUTF8; Increment: Int64=1): boolean; virtual;
```

Increments one integer field value

- if available, this method will use atomic value modification, e.g.

```
UPDATE table SET field=field+?
```

```
procedure AdministrationExecute(const DatabaseName, SQL: RawUTF8; var result: TServiceCustomAnswer); virtual;
```

Used e.g. by IAdministratedDaemon to implement "pseudo-SQL" commands

- this default implementation will handle #time #model #rest commands

```
procedure AppendListAsJsonArray(Table: TSQLRecordClass; const FormatSQLWhere:
RawUTF8; const BoundsSQLWhere: array of const; const OutputFieldName: RawUTF8; W:
TJSONSerializer; const CustomFieldsCSV: RawUTF8='');
```

Get and append a list of members as an expanded JSON array

- implements REST GET collection
- generates '[{rec1},{rec2},...]' using a loop similar to:

```
while FillOne do .. AppendJsonObject() ..
```
- for better server speed, the WHERE clause should use bound parameters identified as '?' in the FormatSQLWhere statement, which is expected to follow the order of values supplied in BoundsSQLWhere open array - use DateToSQL()/DateTimeToSQL() for TDateTime, or directly any integer, double, currency, RawUTF8 values to be bound to the request as parameters
- if OutputFieldName is set, the JSON array will be written as a JSON, property i.e. surrounded as '"OutputFieldName":[...],' - note ending ','
- CustomFieldsCSV can be the CSV list of field names to be retrieved
- if CustomFieldsCSV is "", will get all simple fields, excluding BLOBs
- if CustomFieldsCSV is '*', will get ALL fields, including ID and BLOBs
- is just a wrapper around TSQLRecord.AppendFillAsJsonArray()

```
procedure AsynchBatchRawAppend(Table: TSQLRecordClass; SentData: TTextWriter);
```

Append some JSON content in a BATCH to be written in a background thread

- could be used to emulate AsynchBatchAdd() with an already pre-computed JSON object, as stored in a TTextWriter instance
- is a wrapper around BackgroundTimer.AsynchBatchRawAppend()
- this method is thread-safe

```
procedure AsynchInterning(Interning: TRawUTF8Interning; InterningMaxRefCount:
integer=2; PeriodMinutes: integer=5);
```

Allows background garbage collection of specified RawUTF8 interning

- will run Interning.Clean(2) every 5 minutes by default
- set InterningMaxRefCount=0 to disable process of the Interning instance
- note that InterningMaxRefCount and PeriodMinutes parameters (if not 0), are common for all TRawUTF8Interning instances (the latest value wins)
- you may e.g. run the following to clean up TDocVariant interned RawUTF8:

```
aRest.AsynchInterning(DocVariantType.InternNames);
aRest.AsynchInterning(DocVariantType.InternValues);
```

```
procedure AsynchRedirect(const aGUID: TGUID; const aDestinationInstance:
TInterfacedObject; out aCallbackInterface; const aOnResult:
TOnAsynchRedirectResult=nil); overload;
```

Define asynchronous execution of interface methods in a background thread

- this class allows to implements any interface via a fake class, which will redirect all methods calls into calls of another interface, but as a FIFO in a background thread, shared with TimerEnable/TimerDisable process
- it is an elegant resolution to the most difficult implementation problem of SOA callbacks, which is to avoid race condition on reentrance, e.g. if a callback is run from a thread, and then the callback code try to execute something in the context of the initial thread, protected by a critical section (mutex)
- is a wrapper around BackgroundTimer.AsynchRedirect()

procedure AsynchRedirect(**const** aGUID: TGUID; **const** aDestinationInterface: IInvokable; **out** aCallbackInterface; **const** aOnResult: TOnAsynchRedirectResult=**nil**); overload;

Define asynchronous execution of interface methods in a background thread

- this class allows to implements any interface via a fake class, which will redirect all methods calls into calls of another interface, but as a FIFO in a background thread, shared with TimerEnable/TimerDisable process
- it is an elegant resolution to the most difficult implementation problem of SOA callbacks, which is to avoid race condition on reentrance, e.g. if a callback is run from a thread, and then the callback code try to execute something in the context of the initial thread, protected by a critical section (mutex)
- is a wrapper around BackgroundTimer.AsynchRedirect()

procedure BeginCurrentThread(Sender: TThread); **virtual**;

You can call this method in TThread.Execute to ensure that the thread will be taken into account during process

- this abstract method won't do anything, but TSQLRestServer's will

procedure Commit(SessionID: cardinal; RaiseException: boolean=false); **virtual**;

End a transaction

- implements REST END collection
- write all pending SQL statements to the disk
- default implementation just reset the protected fTransactionActiveSession flag
- the supplied SessionID will allow multi-user transaction safety on the Server-Side: all database modification from another session will wait for the global transaction to be finished; on Client-side, the SessionID is just ignored (TSQLRestClient will override this method with a default SessionID=CONST_AUTHENTICATION_NOT_USED=1 parameter)
- if you have an external database engine which expect transactions to take place in the same thread, ensure TSQLRestServer force execution of this method when accessed from RESTful clients in the same thread, e.g.:

```
AcquireExecutionMode[execORMWrite] := amBackgroundThread;
AcquireWriteMode := amBackgroundThread; // same as previous
```

- by default, any exception will be catch and ignored, unless RaiseException is set to TRUE so that the caller will be able to handle it

procedure DefinitionTo(Definition: TSynConnectionDefinition); **virtual**;

Save the TSQLRest properties into a persistent storage object

- you can then use TSQLRest.CreateFrom() to re-instantiate it
- current Definition.Key value will be used for the password encryption
- this default implementation will set the class name in Definition.Kind: inherited classes should override this method and serialize other properties, then override RegisteredClassCreateFrom() protected method to initiate the very same instance

procedure DefinitionToFile(**const** aJSONFile: TFileName; aKey: cardinal=0);

Save the properties into a JSON file

- you can then use TSQLRest.CreateFromFile() to re-instantiate it
- you can specify a custom Key, if the default is not enough for you

procedure EndCurrentThread(Sender: TThread); **virtual**;

You can call this method just before a thread is finished to ensure e.g. that the associated external DB connection will be released

- this abstract method will call fLogClass.Add.NotifyThreadEnded but TSQLRestServer.EndCurrentThread will do the main process

procedure QueryAddCustom(aTypeInfo: pointer; aEvent: TSQLQueryEvent; **const** aOperators: TSQLQueryOperators);

Add a custom query

- one event handler with an enumeration type containing all available query names
- and associated operators

procedure RollBack(SessionID: cardinal); **virtual**;

Abort a transaction

- implements REST ABORT collection
- restore the previous state of the database, before the call to TransactionBegin
- default implementation just reset the protected fTransactionActiveSession flag
- the supplied SessionID will allow multi-user transaction safety on the Server-Side: all database modification from another session will wait for the global transaction to be finished; on Client-side, the SessionID is just ignored (TSQLRestClient will override this method with a default SessionID=CONST_AUTHENTICATION_NOT_USED=1 parameter)
- if you have an external database engine which expect transactions to take place in the same thread, ensure TSQLRestServer force execution of this method when accessed from RESTful clients in the same thread, e.g.:

```
AcquireExecutionMode[execORMWrite] := amBackgroundThread;  
AcquireWriteMode := amBackgroundThread; // same as previous
```

procedure SetCustomEncryption(aes: TAESAbstract; sign: PSynSigner; comp: TAlgoCompress; **const** uriignore: RawUTF8='');

Initialize some custom AES encryption and/or digital signature, with optional compression

- will intercept the calls by setting OnDecryptBody/OnEncryptBody events
- will own the supplied aes instance or won't encrypt the content if nil
- will digitally sign the content body and uri with the supplied TSynSigner, or won't compute any digital signature if sign=nil
- if both aes and sign are nil, then call interception is disabled
- you can optionally specify a compression algorithm (like AlgoSynLZ or AlgoDeflate/AlgoDeflateFast) to be applied before encryption
- any URI starting with uriignore characters won't be encrypted: it could be used to define a method-based service for handshake and aes/sign mutual agreement
- TSQLRestServer will require incoming requests to be of the corresponding [aesclass][signalgo]/[originaltype] HTTP content-type e.g. 'aesofb256sha256/application/json' - any plain request will be rejected
- note that it will only encrypt and sign the HTTP requests bodies, so URI or plain GET won't be checked - as such, it is not a replacement of TSQLRestServerAuthentication nor TWebSocketProtocolBinary encryption, but a cheap alternative to HTTPS, when you need to protect HTTP flow from MiM attacks (e.g. in a IoT context) with simple and proven algorithms

procedure WriteLock;

Enter the Mutex associated with the write operations of this instance

- just a wrapper around fAcquireExecution[execORMWrite].Safe.Lock

procedure WriteUnLock;

Leave the Mutex associated with the write operations of this instance
- just a wrapper around fAcquireExecution[execORMWrite].Safe.UnLock

property AcquireExecutionLockedTimeOut[Cmd: TSQLRestServerURIContextCommand]:
cardinal **read** GetAcquireExecutionLockedTimeOut **write**
SetAcquireExecutionLockedTimeOut;

The time (in mili seconds) to try locking internal commands of this class
- this value is used only for AcquireExecutionMode[*]=amLocked
- by default, TSQLRestServer.URI() will lock for Write ORM according to AcquireWriteTimeOut
(i.e. AcquireExecutionLockedTimeOut[execORMWrite]) and other operations won't be locked
nor have any time out set

property AcquireExecutionMode[Cmd: TSQLRestServerURIContextCommand]:
TSQLRestServerAcquireMode **read** GetAcquireExecutionMode **write**
SetAcquireExecutionMode;

How this class execute its internal commands
- by default, TSQLRestServer.URI() will lock for Write ORM according to AcquireWriteMode (i.e.
AcquireExecutionMode[execORMWrite]=amLocked) and other operations won't be protected
(for better scaling)
- you can tune this behavior by setting this property to the expected execution mode, e.g.
execute all method-based services in a dedicated thread via
aServer.AcquireExecutionMode[execSOAByMethod] := amBackgroundThread;
- if you use external DB and a custom ConnectionTimeOutMinutes value, both read and write
access should be locked, so you should set:
aServer.AcquireExecutionMode[execORMGet] := am***;
aServer.AcquireExecutionMode[execORMWrite] := am***;

here, safe blocking am*** modes are any mode but amUnlocked, i.e. either amLocked,
amBackgroundThread, amBackgroundORMSharedThread or amMainThread

property AcquireWriteMode: TSQLRestServerAcquireMode **index** execORMWrite **read**
GetAcquireExecutionMode **write** SetAcquireExecutionMode;

How this class will handle write access to the database
- is a common wrapper to AcquireExecutionMode[execORMWrite] property
- default amLocked mode will wait up to AcquireWriteTimeOut mili seconds to have a single
access to the server write ORM methods
- amBackgroundThread will execute the write methods in a queue, in a dedicated unique thread
(which can be convenient, especially for external database transaction process)
- amBackgroundORMSharedThread will execute all ORM methods in a queue, in a dedicated
unique thread, shared for both execORMWrite and execORMGet, but still dedicated for
execSOAByMethod and execSOAByInterface
- a slower alternative to amBackgroundThread may be amMainThread
- you can set amUnlocked for a concurrent write access, but be aware that it may lead into
multi-thread race condition issues, depending on the database engine used

property `AcquireWriteTimeout: cardinal index execORMWrite read`
`GetAcquireExecutionLockedTimeout write SetAcquireExecutionLockedTimeout;`

The time (in mili seconds) which the class will wait for acquiring a write access to the database, when `AcquireWriteMode` is `amLocked`

- is a common wrapper to `AcquireExecutionLockedTimeout[execORMWrite]`
- in order to handle safe transactions and multi-thread safe writing, the server will identify transactions using the client Session ID: this property will set the time out wait period
- default value is 5000, i.e. `TSQLRestServer.URI` will wait up to 5 seconds in order to acquire the right to write on the database before returning a "408 Request Time-out" status error

property `BackgroundTimer: TSQLRestBackgroundTimer read fBackgroundTimer;`

Low-level background timer thread associated with this `TSQLRest`

- contains nil if `TimerEnable/AsynchInvoke` was never executed
- you may instantiate your own `TSQLRestBackgroundTimer` instances, if more than one working thread is needed

property `Cache: TSQLRestCache read GetCache;`

Access the internal caching parameters for a given `TSQLRecord`

- will always return a `TSQLRestCache` instance, creating one if needed
- purpose of this caching mechanism is to speed up retrieval of some common values at either Client or Server level (like configuration settings)
- by default, this CRUD level per-ID cache is disabled
- use `Cache.SetCache()` and `Cache.SetTimeOut()` methods to set the appropriate configuration for this particular `TSQLRest` instance
- only caching synchronization is about the direct RESTful/CRUD commands: RETRIEVE, ADD, UPDATE and DELETE (that is, a complex direct SQL UPDATE or via `TSQLRecordMany` pattern won't be taken into account - only exception is `TSQLRestStorage` tables accessed as SQLite3 virtual table)
- this caching will be located at the `TSQLRest` level, that is no automated synchronization is implemented between `TSQLRestClient` and `TSQLRestServer` - you shall ensure that your business logic is safe, calling `Cache.Flush()` overloaded methods on purpose: better no cache than unproper cache - "premature optimization is the root of all evil"

property `LogClass: TSynLogClass read GetLogClass write SetLogClass;`

The logging class used for this instance

- is set by default to `SQLite3Log`, but could be set to a custom class

property `LogFamily: TSynLogFamily read fLogFamily;`

The logging family used for this instance

- is set by default to `SQLite3Log.Family`, but could be set to something else by setting a custom class to the `LogClass` property

property `Model: TSQLModel read fModel;`

The Database Model associated with this REST Client or Server

property `OnDecryptBody: TNotifyRestBody read fOnDecryptBody write fOnDecryptBody;`

Event called before `TSQLRestServer.URI` or after `TSQLRestClientURI.URI`

- defined e.g. by `SetCustomEncryption`

property `OnEncryptBody: TNotifyRestBody read fOnEncryptBody write fOnEncryptBody;`

Event called after `TSQLRestServer.URI` or before `TSQLRestClientURI.URI`

- defined e.g. by `SetCustomEncryption`

property PrivateGarbageCollector: TSynObjectList **read** fPrivateGarbageCollector;

A local "Garbage collector" list, for some classes instances which must live during the whole TSQLRestServer process

- is used internally by the class, but can be used for business code

property ServerTimestamp: TTimeLog **read** GetServerTimestamp **write** SetServerTimestamp;

The current UTC Date and Time, as retrieved from the server

- this property will return the timestamp as TTimeLog / Int64 after correction from the Server returned time-stamp (if any)
- is used e.g. by TSQLRecord.ComputeFieldsBeforeWrite to update TModTime and TCreateTime published fields
- default implementation will return the executable UTC time, i.e. NowUTC so that any GUI code should convert this UTC value into local time
- on TSQLRestServer, if you use an external database, the TSQLDBConnection ServerTimestamp value will be set to this property
- you can use this value in a WHERE clause for a query, as such:
`aRec.CreateAndFillPrepare(Client, 'Datum<=?', [TimeLogToSQL(Client.ServerTimestamp)]);`
- or you could use ServerTimestamp everywhere in your code, when you need a reference time base

property Services: TServiceContainer **read** fServices;

Access to the interface-based services list

- may be nil if no service interface has been registered yet: so be aware that the following line may trigger an access violation if no ICalculator is defined on server side:
`if fServer.Services['Calculator'].Get(Calc) then`
`...`
- safer typical use, following the DI/IoC pattern, and which will not trigger any access violation if Services=nil, could be:
`if fServer.Services.Resolve(ICalculator, Calc) then`
`...`

property ServicesRouting: TSQLRestServerURIContextClass **read** fServicesRouting **write** SetRoutingClass;

The routing classs of the service remote request

- by default, will use TSQLRestRoutingREST, i.e. an URI-based layout which is secure (since will use our RESTful authentication scheme), and also very fast
- but TSQLRestRoutingJSON_RPC can e.g. be set (on BOTH client and server sides), if the client will rather use JSON/RPC alternative pattern
- NEVER set the abstract TSQLRestServerURIContext class on this property

TSQLRestThread = class(TThread)

A simple TThread for doing some process within the context of a REST instance

- also define a Start method for compatibility with older versions of Delphi
- inherited classes should override InternalExecute abstract method

constructor Create(aRest: TSQLRest; aOwnRest, aCreateSuspended: boolean);

Initialize the thread

- if aOwnRest is TRUE, the supplied REST instance will be owned by this thread

destructor Destroy; **override**;

Finalize the thread

- and the associated REST instance if OwnRest is TRUE

function SleepOrTerminated(MS: integer): boolean;

Safe version of Sleep() which won't break the thread process

- returns TRUE if the thread was Terminated

- returns FALSE if successfully waited up to MS milliseconds

procedure Start;

Method to be called to start the thread

- Resume is deprecated in the newest RTL, since some OS - e.g. Linux - do not implement this pause/resume feature; we define here this method for older versions of Delphi

procedure Terminate; **reintroduce**;

Reintroduced to call TerminatedSet

procedure TerminatedSet; **virtual**;

Properly terminate the thread

- called by reintroduced Terminate

procedure WaitForNotExecuting(maxMS: integer=500);

Wait for Execute to be ended (i.e. fExecuting=false)

property Event: TEvent **read** fEvent;

A event associated to this thread

property Executing: boolean **read** fExecuting;

Publishes the thread executing state (set when Execute leaves)

property Log: TSynLog **read** fLog;

Read-only access to the TSynLog instance of the associated REST instance

property OwnRest: boolean **read** fOwnRest;

TRUE if the associated REST instance will be owned by this thread

property Rest: TSQLRest **read** FRest;

Read-only access to the associated REST instance

property Safe: TSynLocker **read** fSafe;

A critical section is associated to this thread

- could be used to protect shared resources within the internal process

property Terminated;

Publishes the thread running state

TSQLRestServerNamedPipe = **class**(TSQLRestThread)

Server thread accepting connections from named pipes

constructor Create(aServer: TSQLRestServer; **const** PipeName: TFileName);
reintroduce;

Create the server thread

destructor Destroy; **override**;

Release all associated memory, and wait for all TSQLRestServerNamedPipeResponse children to be terminated

procedure AddChild(new: TSQLRestServerNamedPipeResponse);

Register a new response thread

procedure RemoveChild(new: TSQLRestServerNamedPipeResponse);

Unregister a new response thread

property PipeName: TFileName **read** fPipeName;

The associated pipe name

TSQLRestServerNamedPipeResponse = **class**(TSQLRestThread)

Server child thread dealing with a connection through a named pipe

constructor Create(aServer: TSQLRestServer; aMasterThread:
TSQLRestServerNamedPipe; aPipe: cardinal); **reintroduce**;

Create the child connection thread

destructor Destroy; **override**;

Release all associated memory, and decrement fMasterThread.fChildRunning

TSQLRestServerURIPagingParameters = **record**

Structure used to specify custom request paging parameters for TSQLRestServer

- default values are the one used for YUI component paging (i.e. PAGINGPARAMETERS_YAHOO constant, as set by TSQLRestServer.Create)
- warning: using paging can be VERY expensive on Server side, especially when used with external databases (since all data is retrieved before paging, when SQLite3 works in virtual mode)

Dir: RawUTF8;

Parameter name used to specify the request sort direction
- default value is 'DIR='

Results: RawUTF8;

Parameter name used to specify the request the page size (LIMIT clause)
- default value is 'RESULTS='

Select: RawUTF8;

Parameter name used to specify the request field names
- default value is 'SELECT='

SendTotalRowCountFmt: RawUTF8;

Returned JSON field value of optional total row counts
- default value is nil, i.e. no total row counts field
- computing total row counts can be very expensive, depending on the database back-end used (especially for external databases)
- can be set e.g. to ', "totalRows":%' value (note that the initial ", " is expected by the produced JSON content, and % will be set with the value)

Sort: RawUTF8;

Parameter name used to specify the request sort order
 - default value is 'SORT='

StartIndex: RawUTF8;

Parameter name used to specify the request starting offset
 - default value is 'STARTINDEX='

Where: RawUTF8;

Parameter name used to specify the request WHERE clause
 - default value is 'WHERE='

TSQLAuthGroup = class(TSQLRecord)

Table containing the available user access rights for authentication

- this class should be added to the TSQLModel, together with TSQLAuthUser, to allow authentication support
- you can inherit from it to add your custom properties to each user info: TSQLModel will search for any class inheriting from TSQLAuthGroup to manage per-group authorization data
- by default, it won't be accessible remotely by anyone

class procedure InitializeTable(Server: TSQLRestServer; **const** FieldName: RawUTF8; Options: TSQLInitializeTableOptions); **override;**

Called when the associated table is created in the database

- on a new database, if TSQLAuthUser and TSQLAuthGroup tables are defined in the associated TSQLModel, it this will add 'Admin', 'Supervisor', and 'User' rows in the AuthUser table (with 'synapse' as default password), and associated 'Admin', 'Supervisor', 'User' and 'Guest' groups, with the following access rights to the AuthGroup table:

	POSTSQL	SELECTSQL	Service	AuthR	AuthW	TablesR	TablesW
Admin	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Supervisor	No	Yes	Yes	Yes	No	Yes	Yes
User	No	No	Yes	No	No	Yes	Yes
Guest	No	No	No	No	No	Yes	No

- 'Admin' will be the only able to execute remote not SELECT SQL statements for POST commands (reSQL flag in TSQLAccessRights.AllowRemoteExecute) and modify the Auth tables (i.e. AuthUser and AuthGroup)
- 'Admin' and 'Supervisor' will allow any SELECT SQL statements to be executed, even if the table can't be retrieved and checked (corresponding to the reSQLSelectWithoutTable flag)
- 'User' won't have the reSQLSelectWithoutTable flag, nor the right to retrieve the Auth tables data for other users
- 'Guest' won't have access to the interface-based remote JSON-RPC service (no reService flag), nor perform any modification to a table: in short, this is an ORM read-only limited user
- you **MUST** override the default 'synapse' password to a custom value, or at least customize the global AuthAdminDefaultPassword, AuthSupervisorDefaultPassword, AuthUserDefaultPassword variables
- of course, you can change and tune the settings of the AuthGroup and AuthUser tables, but only 'Admin' group users will be able to remotely modify the content of those two tables

property AccessRights: RawUTF8 **index** 1600 **read** fAccessRights **write** fAccessRights;

A textual representation of a TSQLAccessRights buffer

property Ident: RawUTF8 index 50 read fIdent write fIdent stored AS_UNIQUE;

The access right identifier, ready to be displayed

- the same identifier can be used only once (this column is marked as unique via a "stored AS_UNIQUE" (i.e. "stored false") attribute)
- so you can retrieve a TSQLAuthGroup ID from its identifier, as such:
 UserGroupID := fClient.MainFieldID(TSQLAuthGroup, 'User');

property SessionTimeout: integer read fSessionTimeOut write fSessionTimeOut;

The number of minutes a session is kept alive

property SQLAccessRights: TSQLAccessRights read GetSQLAccessRights write SetSQLAccessRights;

Corresponding TSQLAccessRights for this authentication group

- content is converted into/from text format via AccessRight DB property (so it will be not fixed e.g. by the binary TSQLFieldTables layout, i.e. the MAX_SQLTABLES constant value)

TSQLAuthUser = class(TSQLRecord)

Table containing the Users registered for authentication

- this class should be added to the TSQLModel, together with TSQLAuthGroup, to allow authentication support
- you can inherit from it to add your custom properties to each user info: TSQLModel will search for any class inheriting from TSQLAuthUser to manage per-user authorization data
- by default, it won't be accessible remotely by anyone; to enhance security, you could use the TSynValidatePassWord filter to this table

class function ComputeHashedPassword(const aPasswordPlain: RawUTF8; const aHashSalt: RawUTF8=''; aHashRound: integer=20000): RawUTF8; **virtual**;

Static function allowing to compute a hashed password

- as expected by this class
- defined as virtual so that you may use your own hashing class
- you may specify your own values in aHashSalt/aHashRound, to enable PBKDF2_HMAC_SHA256() use instead of plain SHA256(): it will increase security on storage side (reducing brute force attack via rainbow tables)

procedure SetPassword(const aPasswordPlain, aHashSalt: RawUTF8; aHashRound: integer=20000);

Set the PasswordHashHexa field from a plain password content and salt

- use this method to specify aHashSalt/aHashRound values, enabling PBKDF2_HMAC_SHA256() use instead of plain SHA256(): it will increase security on storage side (reducing brute force attack via rainbow tables)
- you may use an application specific fixed salt, and/or append the user LogonName to make the challenge unique for each TSQLAuthUser
- the default aHashRound=20000 is slow but secure - since the hashing process is expected to be done on client side, you may specify your own higher/slower value, depending on the security level you expect

property Data: TSQLRawBlob **read** fData **write** fData;

Some custom data, associated to the User

- Server application may store here custom data
- its content is not used by the framework but 'may' be used by your application

property DisplayName: RawUTF8 **index** 50 **read** fDisplayName **write** fDisplayName;

The User Name, as may be displayed or printed

property GroupRights: TSQLAuthGroup **read** fGroup **write** fGroup;

The associated access rights of this user

- access rights are managed by group
- in TAuthSession.User instance, GroupRights property will contain a REAL TSQLAuthGroup instance for fast retrieval in TSQLRestServer.URI
- note that 'Group' field name is not allowed by SQLite

property LogonName: RawUTF8 **index** 20 **read** fLogonName **write** fLogonName **stored** AS_UNIQUE;

The User identification Name, as entered at log-in

- the same identifier can be used only once (this column is marked as unique via a "stored AS_UNIQUE" - i.e. "stored false" - attribute), and therefore indexed in the database (e.g. hashed in TSQLRestStorageInMemory)

property PasswordHashHexa: RawUTF8 **index** 64 **read** fPasswordHashHexa **write** fPasswordHashHexa;

The hexa encoded associated SHA-256 hash of the password

- see TSQLAuthUser.ComputeHashedPassword() or SetPassword() methods
- store the SHA-256 32 bytes as 64 hexa chars

property PasswordPlain: RawUTF8 **write** SetPasswordPlain;

Able to set the PasswordHashHexa field from a plain password content

- in fact, PasswordHashHexa := SHA256('salt'+PasswordPlain) in UTF-8
- use SetPassword() method if you want to customize the hash salt value and use the much safer PBKDF2_HMAC_SHA256 algorithm

TAuthSession = class(TSynPersistent)

Class used to maintain in-memory sessions

- this is not a TSQLRecord table so won't be remotely accessible, for performance and security reasons
- the User field is a true instance, copy of the corresponding database content (for better speed)
- you can inherit from this class, to add custom session process

constructor Create(aCtxt: TSQLRestServerURIContext; aUser: TSQLAuthUser);
reintroduce; virtual;

Initialize a session instance with the supplied TSQLAuthUser instance

- this aUser instance will be handled by the class until Destroy
- raise an exception on any error
- on success, will also retrieve the aUser.Data BLOB field content

destructor Destroy; **override;**

Will release the User and User.GroupRights instances

property AccessRights: TSQLAccessRights read fAccessRights;

Copy of the associated user access rights

- extracted from User.TSQLAuthGroup.SQLAccessRights

property GroupID: TID read GetGroupID;

The associated Group ID, as in User.GroupRights.ID

property ID: RawUTF8 read fID;

The session ID number, as text

property IDCardinal: cardinal read fIDCardinal;

The session ID number, as numerical value

- never equals to 1 (CONST_AUTHENTICATION_NOT_USED, i.e. authentication mode is not enabled), nor 0 (CONST_AUTHENTICATION_SESSION_NOT_STARTED, i.e. session still in handshaking phase)

property Interfaces: TSynMonitorInputOutputObjArray read fInterfaces;

Per-session statistics about interface-based services

- Interfaces[] follows TSQLRestServer.Services.fListInterfaceMethod[] array

- is initialized and maintained only if mlSessions is defined in TSQLRestServer.StatLevels property

property Methods: TSynMonitorInputOutputObjArray read fMethods;

Per-session statistics about method-based services

- Methods[] follows TSQLRestServer.fPublishedMethod[] array

- is initialized and maintained only if mlSessions is defined in TSQLRestServer.StatLevels property

property PrivateKey: RawUTF8 read fPrivateKey;

The hexadecimal private key as returned to the connected client as 'SessionID+PrivateKey'

property RemoteIP: RawUTF8 read fRemoteIP;

The remote IP, if any

- is extracted from SentHeaders properties

property SentHeaders: RawUTF8 read fSentHeaders;

The transmitted HTTP headers, if any

- can contain e.g. 'Remotelp: 127.0.0.1' or 'User-Agent: Mozilla/4.0'

property TimeoutShr10: cardinal read fTimeOutShr10;

The timestamp (in numbers of 1024 ms) until a session is kept alive

- extracted from User.TSQLAuthGroup.SessionTimeout

- is used for fast comparison with GetTickCount64 shr 10

property TimeOutTix: cardinal read fTimeOutTix;

Set by the Access() method to the current GetTickCount64 shr 10 timestamp + TimeoutSecs

property User: TSQLAuthUser read fUser;

The associated User

- this is a true TSQLAuthUser instance, and User.GroupRights will contain also a true TSQLAuthGroup instance

property UserID: TID read GetUserID;

The associated User ID, as in User.ID

property UserName: RawUTF8 **read** GetUserName;

The associated User Name, as in User.LogonName

TSQLRestServerAuthentication = class(TObject)

Abstract class used to implement server-side authentication in TSQLRestServer

- inherit from this class to implement expected authentication scheme

constructor Create(aServer: TSQLRestServer); **virtual**;

Initialize the authentication method to a specified server

- you can define several authentication schemes for the same server

function Auth(Ctxt: TSQLRestServerURIContext): boolean; **virtual**; **abstract**;

Called by the Server to implement the Auth RESTful method

- overridden method shall return TRUE if the request has been handled

- returns FALSE to let the next registered TSQLRestServerAuthentication class to try implementing the content

- Ctxt.Parameters has been tested to contain an UserName=... value

- method execution is protected by TSQLRestServer.fSessions.Lock

class function ClientSetUser(Sender: TSQLRestClientURI; **const** aUserName, aPassword: RawUTF8; aPasswordKind: TSQLRestServerAuthenticationClientSetUserPassword=passClear; **const** aHashSalt: RawUTF8=''; aHashRound: integer=20000): boolean; **virtual**;

Class method to be used on client side to create a remote session

- call this method instead of TSQLRestClientURI.SetUser() if you need a custom authentication class

- if saoUserByLogonOrID is defined in the server Options, aUserName may be a TSQLAuthUser.ID and not a TSQLAuthUser.LogonName

- if passClear is used, you may specify aHashSalt and aHashRound, to enable PBKDF2_HMAC_SHA256() use instead of plain SHA256(), and increase security on storage side (reducing brute force attack via rainbow tables)

- will call the ModelRoot/Auth service, i.e. call TSQLRestServer.Auth() published method to create a session for this user

- returns true on success

function RetrieveSession(Ctxt: TSQLRestServerURIContext): TAuthSession; **virtual**; **abstract**;

Called by the Server to check if the execution context match a session

- returns a session instance corresponding to the remote request, and fill Ctxt.Session* members according to in-memory session information

- returns nil if this remote request does not match this authentication

- method execution should be protected by TSQLRestServer.fSessions.Lock

class procedure ClientSessionSign(Sender: TSQLRestClientURI; **var** Call: TSQLRestURIParams); **virtual**; **abstract**;

Class method to be called on client side to sign an URI

- used by TSQLRestClientURI.URI()

- shall match the method as expected by RetrieveSession() virtual method

property Options: TSQLRestServerAuthenticationOptions **read** fOptions **write** fOptions;
Allow to tune the authentication process
- default value is [saoUserByLogonOrID]

TSQLRestServerAuthenticationURI = class(TSQLRestServerAuthentication)
Weak authentication scheme using URL-level parameter

function RetrieveSession(Ctxt: TSQLRestServerURIContext): TAuthSession; **override**;
Will check URI-level signature
- retrieve the session ID from 'session_signature=...' parameter
- method execution should be protected by TSQLRestServer.fSessions.Lock

class procedure ClientSessionSign(Sender: TSQLRestClientURI; **var** Call: TSQLRestURIParams); **override**;
Class method to be called on client side to add the SessionID to the URI
- append '&session_signature=SessionID' to the url

TSQLRestServerAuthenticationSignedURI = class(TSQLRestServerAuthenticationURI)
Secure authentication scheme using URL-level digital signature
- default suaCRC32 format of session_signature is
Hexa8(SessionID)+
Hexa8(Timestamp)+
Hexa8(crc32('SessionID+HexaSessionPrivateKey'+Sha256('salt'+PassWord)+
Hexa8(Timestamp)+url))

constructor Create(aServer: TSQLRestServer); **override**;
Initialize the authentication method to a specified server

function RetrieveSession(Ctxt: TSQLRestServerURIContext): TAuthSession; **override**;
Will check URI-level signature
- check session_signature=... parameter to be a valid digital signature
- method execution should be protected by TSQLRestServer.fSessions.Lock

class procedure ClientSessionSign(Sender: TSQLRestClientURI; **var** Call: TSQLRestURIParams); **override**;
Class method to be called on client side to sign an URI
- generate the digital signature as expected by overridden RetrieveSession()
- timestamp resolution is about 256 ms in the current implementation

property Algorithm: TSQLRestServerAuthenticationSignedURIAlgo **write** SetAlgorithm;
Customize the session_signature signing algorithm
- you need to set this value on the server side only; those known algorithms will be recognized by TSQLRestClientURI on the client side during the session handshake, to select the matching ComputeSignature function

property ComputeSignature: TSQLRestServerAuthenticationSignedURIComputeSignature
read fComputeSignature **write** fComputeSignature;

Customize the session_signature signing algorithm with a specific function

- the very same function should be set on TSQLRestClientURI
- to select a known hash algorithm, you may change the Algorithm property

property NoTimestampCoherencyCheck: Boolean **read** fNoTimestampCoherencyCheck **write** SetNoTimestampCoherencyCheck;

Allow any order when creating sessions

- by default, signed sessions are expected to be sequential, and new signed session signature can't be older in time than the last one, with a tolerance of TimestampCoherencySeconds
- but if your client is asynchronous (e.g. for AJAX requests), session may be rejected due to the delay involved on the client side: you can set this property to TRUE to enabled a weaker but more tolerant behavior

```
(aServer.AuthenticationRegister(TSQLRestServerAuthenticationDefault) as  
TSQLRestServerAuthenticationSignedURI).NoTimestampCoherencyCheck := true;
```

property TimestampCoherencySeconds: cardinal **read** fTimestampCoherencySeconds **write** SetTimestampCoherencySeconds;

Time tolerance in seconds for the signature timestamps coherency check

- by default, signed sessions are expected to be sequential, and new signed session signature can't be older in time than the last one, with a tolerance time defined by this property
- default value is 5 seconds, which cover most kind of clients (AJAX or WebSockets), even over a slow Internet connection

TSQLRestServerAuthenticationDefault =
class(TSQLRestServerAuthenticationSignedURI)

MORMot secure RESTful authentication scheme

- this method will use a password stored via safe SHA-256 hashing in the TSQLAuthUser ORM table

function Auth(Ctxt: TSQLRestServerURIContext): boolean; **override**;

Will try to handle the Auth RESTful method with mORMot authentication

- to be called in a two pass "challenging" algorithm:

```
GET ModelRoot/auth?UserName=...
-> returns an hexadecimal nonce contents (valid for 5 minutes)
GET ModelRoot/auth?UserName=...&PassWord=...&ClientNonce=...
-> if password is OK, will open the corresponding session
    and return 'SessionID+HexaSessionPrivateKey'
```

The Password parameter as sent for the 2nd request will be computed as
 Sha256(ModelRoot+Nonce+ClientNonce+UserName+Sha256('salt'+PassWord))

- the returned HexaSessionPrivateKey content will identify the current user logged and its corresponding session (the same user may have several sessions opened at once, each with its own private key)

- then the private session key must be added to every query sent to the server as a session_signature=???? parameter, which will be computed as such:

```
ModelRoot/url?A=1&B=2&session_signature=012345670123456701234567
```

were the session_signature= parameter will be computed as such:

```
Hexa8(SessionID)+Hexa8(Timestamp)+
Hexa8(crc32('SessionID+HexaSessionPrivateKey'+Sha256('salt'+PassWord)+
Hexa8(Timestamp)+url))
with url='ModelRoot/url?A=1&B=2'
```

this query authentication uses crc32 for hashing instead of SHA-256 in in order to lower the Server-side CPU consumption; the salted password (i.e. TSQLAuthUser.PasswordHashHexa) and client-side Timestamp are inserted inside the session_signature calculation to prevent naive man-in-the-middle attack (MITM)

- the session ID will be used to retrieve the rights associated with the user which opened the session via a successful call to the Auth service

- when you don't need the session any more (e.g. if the TSQLRestClientURI instance is destroyed), you can call the service as such:

```
GET ModelRoot/auth?UserName=...&Session=...
```

- for a way of computing SHA-256 in JavaScript, see for instance
[@http://www.webtoolkit.info/javascript-sha256.html](http://www.webtoolkit.info/javascript-sha256.html)

TSQLRestServerAuthenticationNone = class(TSQLRestServerAuthenticationURI)

MORMot weak RESTful authentication scheme

- this method will authenticate with a given username, but no signature

- on client side, this scheme is not called by TSQLRestClientURI.SetUser() method - so you have to write:

```
TSQLRestServerAuthenticationNone.ClientSetUser(Client, 'User', '');
```

function Auth(Ctxt: TSQLRestServerURIContext): boolean; **override**;

Will try to handle the Auth RESTful method with mORMot authentication

- to be called in a weak one pass request:

```
GET ModelRoot/auth?UserName=...
-> if the specified user name exists, will open the corresponding
    session and return 'SessionID+HexaSessionPrivateKey'
```

```
TSQLEstServerAuthenticationHttpAbstract =  
class(TSQLEstServerAuthentication)
```

Abstract class for implementing HTTP authentication

- do not use this abstract class, but e.g. TSQLEstServerAuthenticationHttpBasic
- this class will transmit the session_signature as HTTP cookie, not at URI level, so is expected to be used only from browsers or old clients

```
class function ClientSetUser(Sender: TSQLEstClientURI; const aUserName, aPassword:  
RawUTF8; aPasswordKind:  
TSQLEstServerAuthenticationClientSetUserPassword=passClear; const aHashSalt:  
RawUTF8=''; aHashRound: integer=20000): boolean; override;
```

Class method to be used on client side to create a remote session

- call TSQLEstServerAuthenticationHttpBasic.ClientSetUser() instead of TSQLEstClientURI.SetUser(), and never the method of this abstract class
- needs the plain aPassword, so aPasswordKind should be passClear
- returns true on success

```
function RetrieveSession(Ctxt: TSQLEstServerURIContext): TAuthSession; override;
```

Will check the caller signature

- retrieve the session ID from "Cookie: mORMot_session_signature=..." HTTP header
- method execution should be protected by TSQLEstServer.fSessions.Lock

```
class procedure ClientSessionSign(Sender: TSQLEstClientURI; var Call:  
TSQLEstURIParams); override;
```

Class method to be called on client side to sign an URI in Auth Basic resolution is about 256 ms in the current implementation

- set "Cookie: mORMot_session_signature=..." HTTP header

```
class procedure ClientSetUserHttpOnly(Sender: TSQLEstClientURI; const aUserName,  
aPasswordClear: RawUTF8); virtual;
```

Class method to be used on client side to force the HTTP header for the corresponding HTTP authentication, without creating any remote session

- call virtual protected method ComputeAuthenticateHeader()
- here the password should be given as clear content
- potential use case is to use a mORMot client through a HTTPS proxy, e.g. with TSQLEstServerAuthenticationHttpBasic authentication
- then you can use TSQLEstServerAuthentication*.ClientSetUser() to define any another "mORMot only" authentication
- this method is also called by the ClientSetUser() method of this class for a full client + server authentication via HTTP TSQLEstServerAuthenticationHttp*.ClientSetUser()

```
TSQRestServerAuthenticationHttpBasic =  
class(TSQRestServerAuthenticationHttpAbstract)
```

Authentication using HTTP Basic scheme

- this protocol send both name and password as clear (just base-64 encoded) so should only be used over SSL / HTTPS, or for compatibility reasons
- will rely on TSQRestServerAuthenticationNone for authorization
- on client side, this scheme is not called by TSQRestClientURI.SetUser() method - so you have to write:

```
TSQRestServerAuthenticationHttpBasic.ClientSetUser(Client, 'User', 'password');
```

- for a remote proxy-only authentication (without creating any mORMot session), you can write:

```
TSQRestServerAuthenticationHttpBasic.ClientSetUserHttpOnly(Client, 'proxyUser', 'proxyPass');
```

```
function Auth(Ctxt: TSQRestServerURIContext): boolean; override;
```

Handle the Auth RESTful method with HTTP Basic

- will first return HTTP_UNAUTHORIZED (401), then expect user and password to be supplied as incoming "Authorization: Basic" headers

```
function RetrieveSession(Ctxt: TSQRestServerURIContext): TAuthSession; override;
```

Will check URI-level signature

- retrieve the session ID from 'session_signature=...' parameter
- will also check incoming "Authorization: Basic" HTTP header
- method execution should be protected by TSQRestServer.fSessions.Lock

```
TSQRestServerAuthenticationSSPI =  
class(TSQRestServerAuthenticationSignedURI)
```

Authentication of the current logged user using Windows Security Support Provider Interface (SSPI) or GSSAPI library on Linux

- is able to authenticate the currently logged user on the client side, using either NTLM (Windows only) or Kerberos - it will allow to safely authenticate on a mORMot server without prompting the user to enter its password
- if ClientSetUser() receives aUserName as "", aPassword should be either "" if you expect NTLM authentication to take place, or contain the SPN registration (e.g. 'mymormotservice/myserver.mydomain.tld') for Kerberos authentication
- if ClientSetUser() receives aUserName as 'DomainName\UserName', then authentication will take place on the specified domain, with aPassword as plain password value

```
constructor Create(aServer: TSQRestServer); override;
```

Initialize the authentication method to a specified server

```
destructor Destroy; override;
```

Finalize internal memory structures

```
function Auth(Ctxt: TSQRestServerURIContext): boolean; override;
```

Will try to handle the Auth RESTful method with Windows SSPI API

- to be called in a two pass algorithm, used to cypher the password
- the client-side logged user will be identified as valid, according to a Windows SSPI API secure challenge

TSQLHttpServerDefinition = class(TSynPersistentWithPassword)

Parameters supplied to publish a TSQLRestServer via HTTP

- used by the overloaded TSQLHttpServer.Create(TSQLHttpServerDefinition) constructor in mORMotHttpServer.pas, and also in dddInfraSettings.pas

property Authentication: TSQLHttpServerRestAuthentication **read** FAuthentication
write FAuthentication;

Which authentication is expected to be published

property BindPort: RawByteString **read** FBindPort **write** FBindPort;

Defines the port to be used for REST publishing

- may include an optional IP address to bind, e.g. '127.0.0.1:8888'

property EnableCORS: RawUTF8 **read** FEnableCORS **write** FEnableCORS;

Allow Cross-origin resource sharing (CORS) access

- set this property to '*' if you want to be able to access the REST methods from an HTML5 application hosted in another location, or define a CSV white list of TMatch-compatible origins
- will set e.g. the following HTTP header:

Access-Control-Allow-Origin: *

property Https: boolean **read** FHttps **write** FHttps;

Defines if https:// protocol should be used

- implemented only by http.sys server under Windows, not by socket servers

property HttpSysQueueName: SynUnicode **read** FHttpSysQueueName **write** FHttpSysQueueName;

The displayed name in the http.sys queue

- used only by http.sys server under Windows, not by socket-based servers

property RemoteIPHeader: RawUTF8 **read** fRemoteIPHeader **write** fRemoteIPHeader;

The value of a custom HTTP header containing the real client IP

- by default, the RemoteIP information will be retrieved from the socket layer - but if the server runs behind some proxy service, you should define here the HTTP header name which indicates the true remote client IP value, mostly as 'X-Real-IP' or 'X-Forwarded-For'

property ThreadCount: byte **read** fThreadCount **write** fThreadCount;

How many threads the thread pool associated with this HTTP server should create

- if set to 0, will use default value 32

- this parameter may be ignored depending on the actual HTTP server used, which may not have any thread pool

property WebSocketPassword: RawUTF8 **read** fPassword **write** fPassword;

If defined, this HTTP server will use WebSockets, and our secure encrypted binary protocol

- when stored in the settings JSON file, the password will be safely encrypted as defined by TSynPersistentWithPassword

- use the inherited PlainPassword property to set or read its value

TSynAuthenticationRest = class(TSynAuthenticationAbstract)

TSynAuthentication class using TSQLAuthUser/TSQLAuthGroup for credentials*

- could be used e.g. for SynDBRemote access in conjunction with mORMot

constructor Create(aServer: TSQLRestServer; **const** aAllowedGroups: **array of integer**); **reintroduce**;

Initialize the authentication scheme

- you can optionally set the groups allowing to use SynDBRemote - if none is specify, username/password is enough

class function ComputeHash(Token: Int64; **const** UserName, Password: RawUTF8): cardinal; **override**;

To be used to compute a Hash on the client side, for a given Token

- the password will be hashed as expected by the GetPassword() method

procedure RegisterAllowedGroups(**const** aAllowedGroups: **array of integer**);

Add some new groups to validate an user authentication

TSQLRecordModification = class(TSQLRecord)

Common ancestor for tracking TSQLRecord modifications

- e.g. TSQLRecordHistory and TSQLRecordVersion will inherit from this class to track TSQLRecord changes

function ModifiedID: TID;

Returns the modified record ID, as stored in ModifiedRecord

function ModifiedTable(Model: TSQLModel): TSQLRecordClass;

Returns the modified record table, as stored in ModifiedRecord

function ModifiedTableIndex: integer;

Returns the record table index in the TSQLModel, as stored in ModifiedRecord

property ModifiedRecord: TID **read** fModifiedRecord **write** fModifiedRecord;

Identifies the modified record

- ID and table index in TSQLModel is stored as one RecordRef integer

- you can use ModifiedTable/ModifiedID to retrieve the TSQLRecord item

- in case of the record deletion, all matching TSQLRecordHistory won't be touched by TSQLRestServer.AfterDeleteForceCoherency(): so this property is a plain TID/Int64, not a TRecordReference field

property Timestamp: TModTime **read** fTimestamp **write** fTimestamp;

When the modification was recorded

- even if in most cases, this timestamp may be synchronized over TSQLRest instances (thanks to TSQLRestClientURI.ServerTimestampSynchronize), it is not safe to use this field as absolute: you should rather rely on pure monotonic ID/RowID increasing values (see e.g. TSQLRecordVersion)

TSQLRecordHistory = class(TSQLRecordModification)

Common ancestor for tracking changes on TSQLRecord tables

- used by TSQLRestServer.TrackChanges() method for simple fields history
- TSQLRestServer.InternalUpdateEvent will use this table to store individual row changes as SentDataJSON, then will compress them in History BLOB
- note that any layout change of the tracked TSQLRecord table (e.g. adding a new property) will break the internal data format, so will void the table

constructor CreateHistory(aClient: TSQLRest; aTable: TSQLRecordClass; aID: TID);

Load the change history of a given record

- then you can use HistoryGetLast, HistoryCount or HistoryGet() to access all previous stored versions

destructor Destroy; **override**;

Finalize any internal memory

function HistoryCount: integer;

Returns how many revisions are stored in the History BLOB

- HistoryOpen() or CreateHistory() should have been called before
- this method will ignore any previous HistoryAdd() call

function HistoryGet(Index: integer; Rec: TSQLRecord): boolean; **overload**;

Retrieve an historical version

- HistoryOpen() or CreateHistory() should have been called before
- this method will ignore any previous HistoryAdd() call
- will fill all simple properties of the supplied TSQLRecord instance

function HistoryGet(Index: integer): TSQLRecord; **overload**;

Retrieve an historical version

- HistoryOpen() or CreateHistory() should have been called before
- this method will ignore any previous HistoryAdd() call
- will return either nil, or a TSQLRecord with all simple properties set

function HistoryGet(Index: integer; **out** Event: TSQLHistoryEvent; **out** Timestamp: TModTime; Rec: TSQLRecord): boolean; **overload**;

Retrieve an historical version

- HistoryOpen() or CreateHistory() should have been called before
- this method will ignore any previous HistoryAdd() call
- if Rec=nil, will only retrieve Event and Timestamp
- if Rec is set, will fill all simple properties of this TSQLRecord

function HistoryGetLast(Rec: TSQLRecord): boolean; **overload**;

Retrieve the latest stored historical version

- HistoryOpen() or CreateHistory() should have been called before
- this method will ignore any previous HistoryAdd() call
- you should not have to use it, since a TSQLRest.Retrieve() is faster

function HistoryGetLast: TSQLRecord; overload;

Retrieve the latest stored historical version

- HistoryOpen() or CreateHistory() should have been called before, otherwise it will return nil
- this method will ignore any previous HistoryAdd() call
- you should not have to use it, since a TSQLRest.Retrieve() is faster

function HistoryOpen(Model: TSQLModel): boolean;

Prepare to access the History BLOB content

- ModifiedRecord should have been set to a proper value
- returns FALSE if the History BLOB is incorrect (e.g. TSQLRecord layout changed): caller shall flush all previous history

function HistorySave(Server: TSQLRestServer; LastRec: TSQLRecord=nil): boolean;

Update the History BLOB field content

- HistoryOpen() should have been called before using this method - CreateHistory() won't allow history modification
- if HistoryAdd() has not been used, returns false
- ID field should have been set for proper persistence on Server
- otherwise compress the data into History BLOB, deleting the oldest versions if resulting size is bigger than expected, and returns true
- if Server is set, write save the History BLOB to database
- if Server and LastRec are set, its content will be compared with the current record in DB (via a Retrieve() call) and stored: it will allow to circumvent any issue about inconsistent use of tracking, e.g. if the database has been modified directly, by-passing the ORM

procedure HistoryAdd(Rec: TSQLRecord; Hist: TSQLRecordHistory);

Add a record content to the History BLOB

- HistoryOpen() should have been called before using this method - CreateHistory() won't allow history modification
- use then HistorySave() to compress and replace the History field

class procedure InitializeTable(Server: TSQLRestServer; const FieldName: RawUTF8; Options: TSQLInitializeTableOptions); **override**;

Called when the associated table is created in the database

- create index on History(ModifiedRecord,Event) for process speed-up

property Event: TSQLHistoryEvent **read** fEvent **write** fEvent;

The kind of modification stored

- is heArchiveBlob when this record stores the compress BLOB in History
- otherwise, SentDataJSON may contain the latest values as JSON

property History: TSQLRawBlob **read** fHistory **write** fHistory;

After some events are written as individual SentData content, they will be gathered and compressed within one BLOB field

- use HistoryOpen/HistoryCount/HistoryGet to access the stored data after a call to CreateHistory() constructor
- as any BLOB field, this one won't be retrieved by default: use explicitly TSQLRest.RetrieveBlobFields(aRecordHistory) to get it if you want to access it directly, and not via CreateHistory()

property SentDataJSON: RawUTF8 **index** 4000 **read** fSentData **write** fSentData;

For heAdd/heUpdate, the data is stored as JSON

- note that we defined a default maximum size of 4KB for this column, to avoid using a CLOB here - perhaps it may not be enough for huge records - feedback is welcome...

TSQLRecordTableDeleted = **class**(TSQLRecord)

ORM table used to store the deleted items of a versioned table

- the ID/RowID primary key of this table will be the version number (i.e. value computed by TSQLRestServer.InternalRecordVersionCompute), mapped with the corresponding 'TableIndex shl 58' (so that e.g. TSQLRestServer.RecordVersionSynchronizeToBatch() could easily ask for the deleted rows of a given table with a single WHERE clause on the ID/RowID)

property Deleted: Int64 **read** fDeleted **write** fDeleted;

This Deleted published field will track the deleted row

- defined as Int64 and not TID, to avoid the generation of the index on this column, which is not needed here (all requests are about ID/RowID)

TSQLRestTempStorageItem = **record**

Used to store an entry in the TSQLRestTempStorage class

ID: TID;

The ID of this entry

- after an AddCopy(ForcelD=false), is a "fake" ID, which is > maxInt

Kind: TSQLRestTempStorageItemKind;

What is stored in this entry

Value: TSQLRecord;

The stored item, either after adding or updating

- equals nil if the item has been deleted

ValueFields: TSQLFieldBits;

Identify the fields stored in the Value instance

- e.g. an Update() - or even an Add() - may only have set only simple or specific fields

TSQLRestTempStorage = **class**(TSynPersistentLock)

Abstract class used for temporary in-memory storage of TSQLRecord

- purpose of this class is to gather write operations (Add/Update/Delete)
- inherited implementations may send all updates at once to a server (i.e. "asynchronous write"), or maintain a versioned image of the content
- all public methods (AddCopy/AddOwned/Update/Delete/FlushAsBatch) are thread-safe, protected by a mutex lock

constructor Create(aClass: TSQLRecordClass); **reintroduce**; **virtual**;

Initialize the temporary storage for a given class

destructor Destroy; **override**;

Finalize this temporary storage instance

function AddCopy(Value: TSQLRecord; ForceID: boolean; **const** FieldNames: RawUTF8=''): TID; overload;

Add a copy of a TSQLRecord to the internal storage list

- if ForceID is true, Value.ID will be supplied with the ID to add
- if ForceID is false, a "fake" ID is returned, which may be used later on for Update() calls - WARNING: but this ID should not be stored as a cross reference in another record, since it is private to this storage; the definitive ID will be returned eventually after proper persistence (e.g. sent as TSQLRestBatch to a mORMot server)
- FieldNames can be the CSV list of field names to be set
- if FieldNames is "", will set all simple fields, excluding BLOBs
- if FieldNames is '*', will set ALL fields, including BLOBs
- this method will clone the supplied Value, and make its own copy for its internal storage - consider use AddOwned() if the caller does not need to store the instance afterwards

function AddOwned(Value: TSQLRecord; ForceID: boolean; **const** Fields: TSQLFieldBits): TID; overload;

Add and own a TSQLRecord in the internal storage list

- if ForceID is true, Value.ID will be supplied with the ID to add
- if ForceID is false, a "fake" ID is returned, which may be used later on for Update() calls - WARNING: but this ID should not be stored as a cross reference in another record, since it is private to this storage; the definitive ID will be returned eventually after proper persistence (e.g. sent as TSQLRestBatch to a mORMot server)
- this overloaded version expects the fields to be specified as bits
- this method will store the supplied Value, and let its internal storage owns it and manage its lifetime - consider use AddCopy() if the caller does need to store this instance afterwards
- returns 0 in case of error (e.g. ForceID and no or duplicated Value.ID)

function AddOwned(Value: TSQLRecord; ForceID: boolean; **const** FieldNames: RawUTF8=''): TID; overload;

Add and own a TSQLRecord in the internal storage list

- if ForceID is true, Value.ID will be supplied with the ID to add
- if ForceID is false, a "fake" ID is returned, which may be used later on for Update() calls - WARNING: but this ID should not be stored as a cross reference in another record, since it is private to this storage; the definitive ID will be returned eventually after proper persistence (e.g. sent as TSQLRestBatch to a mORMot server)
- FieldNames can be the CSV list of field names to be set
- if FieldNames is "", will set all simple fields, excluding BLOBs
- if FieldNames is '*', will set ALL fields, including BLOBs
- this method will store the supplied Value, and let its internal storage owns it and manage its lifetime - consider use AddCopy() if the caller does need to store this instance afterwards
- returns 0 in case of error (e.g. ForceID and no or duplicated Value.ID)

function FlushAsBatch(Rest: TSQLRest; AutomaticTransactionPerRow: cardinal=1000): TSQLRestBatch;

Convert the internal list as a TSQLRestBatch instance, ready to be sent to the server

function FromEvent(Event: TSQLEvent; ID: TID; **const** JSON: RawUTF8): boolean;

Add, update or delete a TSQLRecord in the internal storage list

- could be used from a TNotifySQLEvent/InternalUpdateEvent(seAdd) callback
- here the value to be added is supplied as a JSON object and a ID field
- returns false in case of error (e.g. duplicated ID or void JSON)

function Update(Value: TSQLRecord; **const** Fields: TSQLFieldBits): boolean; overload;

Update a TSQLRecord and store the new values in the internal storage list

- Value.ID is used to identify the record to be updated (which may be a just added "fake" ID)
- this overloaded version expects the fields to be specified as bits
- the supplied Value won't be owned by this instance: the caller should release it when Value is no longer needed
- returns false in case of error (e.g. unknown ID or no field set)

function Update(Value: TSQLRecord; **const** FieldNames: RawUTF8=''): boolean; overload;

Update a TSQLRecord and store the new values in the internal storage list

- Value.ID is used to identify the record to be updated (which may be a just added "fake" ID)
- FieldNames can be the CSV list of field names to be updated
- if FieldNames is "", will update all simple fields, excluding BLOBs
- if FieldNames is '*', will update ALL fields, including BLOBs
- the supplied Value won't be owned by this instance: the caller should release it when Value is no longer needed
- returns false in case of error (e.g. unknown ID or invalid fields)

procedure Delete(**const** ID: TID);

Mark a TSQLRecord as deleted in the internal storage list

property Count: integer **read** fCount;

How many entries are stored in the low-level storage list

property Item: TSQLRestTempStorageItemDynArray **read** fItem;

Direct access to the low-level storage list

- the Count property is the number of items, length(Item) is the capacity
- the list is stored in increasing ID order

TSQLRestServerMonitor = **class**(TSynMonitorServer)

Used for high-level statistics in TSQLRestServer.URI()

constructor Create(aServer: TSQLRestServer); **reintroduce**;

No overridden Changed: TSQLRestServer.URI will do it in finally block initialize the instance

destructor Destroy; **override**;

Finalize the instance

function NotifyThreadCount(delta: integer): integer;

Update and returns the CurrentThreadCount property

- this method is thread-safe

procedure NotifyORM(aMethod: TSQLURIMethod);

Update the Created/Read/Updated/Deleted properties

- this method is thread-safe

procedure NotifyORMTable(TableIndex, DataSize: integer; Write: boolean; **const** MicroSecondsElapsed: QWord);

Update the per-table statistics

- this method is thread-safe

procedure ProcessSuccess(IsOutcomingFile: boolean); **virtual**;

Should be called when a task successfully ended
 - thread-safe method

property Created: TSynMonitorCount64 **read** fCreated;

How many Create / Add ORM operations did take place

property CurrentThreadCount: TSynMonitorOneCount **read** fCurrentThreadCount;

Number of current declared thread counts
 - as registered by BeginCurrentThread/EndCurrentThread

property Deleted: TSynMonitorCount64 **read** fDeleted;

How many Delete ORM operations did take place

property OutcomingFiles: TSynMonitorCount64 **read** fOutcomingFiles;

Count of files transmitted directly (not part of Output size property)
 - i.e. when the service uses STATICFILE_CONTENT_TYPE/HTTP_RESP_STATICFILE as content type to let the HTTP server directly serve the file content

property Read: TSynMonitorCount64 **read** fRead;

How many Read / Get ORM operations did take place

property ServiceInterface: TSynMonitorCount64 **read** fServiceInterface;

Count of the remote interface-based service calls

property ServiceMethod: TSynMonitorCount64 **read** fServiceMethod;

Count of the remote method-based service calls

property StartDate: RawUTF8 **read** fStartDate;

When this monitoring instance (therefore the server) was created

property Success: TSynMonitorCount64 **read** fSuccess;

Number of valid responses
 - i.e. which returned status code 200/HTTP_SUCCESS or 201/HTTP_CREATED
 - any invalid request will increase the TSynMonitor.Errors property

property Updated: TSynMonitorCount64 **read** fUpdated;

How many Update ORM operations did take place

TSQLMonitorUsage = class(TSQLRecordNoCaseExtended)

ORM table used to store TSynMonitorUsage information in TSynMonitorUsageRest
 - the ID primary field is the TSynMonitorUsageID (accessible from UsageID public property) shifted by 16 bits (by default) to include a TSynUniquelIdentifierProcess value

function UsageID(aProcessIDShift: integer=16): integer;

Compute the corresponding 23 bit TSynMonitorUsageID.Value time slice
 - according to the stored Process field, after bit shift
 - allows a custom aProcessIDShift if it is not set as default 16 bits

property Comment: RawUTF8 **read** fComment **write** fComment;

A custom text, which may be used e.g. by support or developpers

property Gran: TSynMonitorUsageGranularity read fGran write fGran;

The granularity of the statistics of this entry

property Info: variant read fInfo write fInfo;

The actual statistics information, stored as a TDocVariant JSON object

property Process: Int64 read fProcess write fProcess;

Identify which application is monitored

- match the lower bits of each record ID

- by default, is expected to be a TSynUniqueIdentifierProcess 16-bit value

TSynMonitorUsageRest = class(TSynMonitorUsage)

Will store TSynMonitorUsage information in TSQLMonitorUsage ORM tables

- TSQLRecord.ID will be the TSynMonitorUsageID shifted by ProcessIDShift bits

constructor Create(aStorage: TSQLRest; aProcessID: Int64; aStoredClass: TSQLMonitorUsageClass=nil; aProcessIDShift: integer=16); reintroduce; virtual;

Initialize storage via ORM

- if a 16-bit TSynUniqueIdentifierProcess is supplied, it will be used to identify the generating process by shifting TSynMonitorUsageID values by aProcessIDShift bits (default 16 but you may increase it up to 40 bits)

- will use TSQLMonitorUsage table, unless another one is specified

destructor Destroy; override;

Finalize the process, saving pending changes

property ProcessID: Int64 read fProcessID;

How the information could be stored for several processes

- e.g. when several SOA nodes gather monitoring information in a shared (MongoDB) database

- is by default a TSynUniqueIdentifierProcess value, but may be any integer up to ProcessIDShift bits as set in Create()

property ProcessIDShift: integer read fProcessIDShift;

How process ID are stored within the mORMot TSQLRecord.ID

- equals 16 bits by default, to match TSynUniqueIdentifierProcess resolution

property SaveBatch: TSQLRestBatch read fSaveBatch write fSaveBatch;

You can set an optional Batch instance to speed up DB writing

- when calling the Modified() method

property StoredClass: TSQLMonitorUsageClass read fStoredClass;

The actual ORM class used for persistence

TSQLRestServerURI = object(TObject)

Used to access a TSQLRestServer from its TSQLRestServerURIString URI

- URI format is 'address:port/root', and may be transmitted as TSQLRestServerURIString text instances

Address: RawUTF8;

The TSQLRestServer IP Address or DNS name

Port: RawUTF8;

The TSQLRestServer IP port

Root: RawUTF8;

The TSQLRestServer model Root

function Equals(const other: TSQLRestServerURI): boolean;

Returns TRUE if all field values do match, case insensitively

property URI: TSQLRestServerURIString **read** GetURI **write** SetURI;

Property which allows to read or set the Address/Port/Root fields as one UTF-8 text field (i.e. a TSQLRestServerURIString instance)

- URI format is 'address:port/root', but port or root are optional

TServicesPublishedInterfaces = object(TObject)

Used to publish all Services supported by a TSQLRestServer instance

- as expected by TSQLRestServer.ServicesPublishedInterfaces

- can be serialized as a JSON object via RecordLoadJSON/RecordSaveJSON

Names: TRawUTF8DynArray;

The list of supported services names

- in fact this is the Interface name without the initial 'I', e.g. 'Calculator' for ICalculator

PublicURI: TSQLRestServerURI;

How this TSQLRestServer could be accessed

TServicesPublishedInterfacesList = class(TSynPersistentLock)

Used e.g. by TSQLRestServer to store a list of TServicesPublishedInterfaces

Count: Integer;

How many items are actually stored in List[]

List: TServicesPublishedInterfacesDynArray;

The internal list of published services

- the list is stored in-order, i.e. it will follow the RegisterFromJSON() execution order: the latest registrations will appear last

constructor Create(aTimeoutMS: integer); **reintroduce;** **virtual;**

Initialize the storage

- an optional time out period, in milliseconds, may be defined - but the clients should ensure that RegisterFromClientJSON() is called in order to refresh the list (e.g. from _contract_ HTTP body)

function FindService(const aServiceName: RawUTF8): TSQLRestServerURIDynArray;

Search for the latest registrations of a service, by name

- will lookup for the Interface name without the initial 'I', e.g. 'Calculator' for ICalculator -

warning: research is case-sensitive

- if the service name has been registered several times, all registration will be returned, the latest in first position

function FindServiceAll(const aServiceName: RawUTF8):
 TSQLRestServerURIStringDynArray; overload;

Return all services URI by name, from the registration list, as URIs

- will lookup for the Interface name without the initial 'I', e.g. 'Calculator' for ICalculator - warning: research is case-sensitive
- the returned string will contain all matching server URI, the latest registration being the first to appear, e.g.
 ["addresslast:port/root", "addressprevious:port/root", "addressfirst:port/root"]

function FindURI(const aPublicURI: TSQLRestServerURI): integer;
Search for a public URI in the registration list

function RegisterFromServer(Client: TSQLRestClientURI): boolean;
Set the list from a remote TSQLRestServer
 - will call /root/Stat?findservice=* URI, then RegisterFromServerJSON()

procedure FindServiceAll(const aServiceName: RawUTF8; aWriter: TTextWriter);
 overload;

Return all services URI by name, from the registration list, as JSON

- will lookup for the Interface name without the initial 'I', e.g. 'Calculator' for ICalculator - warning: research is case-sensitive
- the returned JSON array will contain all matching server URI, encoded as a TSQLRestServerURI JSON array, the latest registration being the first to appear, e.g.
 [{"Address": "addresslast", "Port": "port", "Root": "root"}, ...]
- if aServiceName='*', it will return ALL registration items, encoded as a TServicesPublishedInterfaces JSON array, e.g.
 [{"PublicURI": {"Address": "1.2.3.4", "Port": "123", "Root": "root"}, "Names": ['Calculator']}, ...]

procedure RegisterFromClientJSON(var PublishedJson: RawUTF8);

Add the JSON serialized TServicesPublishedInterfaces to the list

- called by TSQLRestServerURIContext.InternalExecuteSOABYInterface when the client provides its own services as _contract_ HTTP body
- warning: supplied PublishedJson will be parsed in place, so modified

procedure RegisterFromServerJSON(var PublishedJson: RawUTF8);

Set the list from JSON serialized TServicesPublishedInterfacesDynArray

- may be used to duplicate the whole TSQLRestServer.AssociatedServices content, as returned from /root/Stat?findservice=*
- warning: supplied PublishedJson will be parsed in place, so modified

property Timeout: integer read fTimeout write fTimeout;

The number of milliseconds after which an entry expires

- is 0 by default, meaning no expiration
- you can set it to a value so that any service URI registered with RegisterFromJSON() AFTER this property modification may expire

TSQLRestServer = class(TSQLRest)

A generic REpresentational State Transfer (REST) server

- descendent must implement the protected EngineList() Retrieve() Add() Update() Delete() methods
- automatic call of this methods by a generic URI() RESTful function
- any published method of descendants must match TSQLRestServerCallBack prototype, and is expected to be thread-safe

Used for DI-2.1.1 (page 2553), DI-2.1.1.1 (page 2553), DI-2.1.1.2.1 (page 2554), DI-2.1.1.2.2 (page 2554), DI-2.1.1.2.3 (page 2554), DI-2.1.1.2.4 (page 2555), DI-2.2.1 (page 2558).

InternalState: Cardinal;

This integer property is incremented by the database engine when any SQL statement changes the database contents (i.e. on any not SELECT statement)

- its value can be published to the client on every remote request
- it may be used by client to avoid retrieve data only if necessary
- if its value is 0, this feature is not activated on the server, and the client must ignore it and always retrieve the content

OnAfterURI: TNotifyAfterURI;

Event triggered when URI() finished to process a request

- the supplied Ctxt parameter will give access to the command which has been executed, e.g. via Ctxt.Call.OutStatus or Ctxt.MicroSecondsElapsed
- since this event will be executed by every TSQLRestServer.URI call, it should better not make any slow process (like writing to a remote DB)
- see also TSQLRest.OnDecryptBody/OnEncryptBody, which is common to the client side, so may be better to implement shared process (e.g. encryption)

OnAuthenticationFailed: TNotifyAuthenticationFailed;

This event handler will be executed when a session failed to initialize (DenyOfService attack?) or the request is not valid (ManInTheMiddle attack?)

- e.g. if the URI signature is invalid, or OnSessionCreate event handler aborted the session creation by returning TRUE (in this later case, the Session parameter is not nil)
- you can access the current execution context from the Ctxt parameter, e.g. to retrieve the caller's IP and ban aggressive users in Ctxt.RemoteIP or the text error message corresponding to Reason in Ctxt.CustomErrorMsg

OnAuthenticationUserRetrieve: TOnAuthenticationUserRetrieve;

A custom method to retrieve the TSQLAuthUser instance for authentication

- will be called by TSQLRestServerAuthentication.GetUser() instead of plain SQLAuthUserClass.Create()

OnBeforeURI: TNotifyBeforeURI;

Event triggered when URI() starts to process a request

- the supplied Ctxt parameter will give access to the command about to be executed, e.g. Ctxt.Command=execSOABByInterface will identify a SOA service execution, with the corresponding Service and ServiceMethodIndex parameters as set by TSQLRestServerURIContext.URIDecodeSOABByInterface
- should return TRUE if the method can be executed
- should return FALSE if the method should not be executed, and the callback should set the corresponding error to the supplied context e.g.
`Ctxt.Error('Unauthorized method', HTTP_NOTALLOWED);`
- since this event will be executed by every TSQLRestServer.URI call, it should better not make any slow process (like writing to a remote DB)
- see also TSQLRest.OnDecryptBody, which is common to the client side, so may be a better place for implementing shared process (e.g. encryption)

OnBlobUpdateEvent: TNotifyFieldSQLEvent;

A method can be specified here to trigger events after any blob update

- is called AFTER update of one or several blobs, never on delete nor insert
- to be used only server-side, not to synchronize some clients: the framework is designed around a stateless RESTful architecture (like HTTP/1.1), in which clients ask the server for refresh (see TSQLRestClientURI.UpdateFromServer)

OnErrorURI: TNotifyErrorURI;

Event triggered when URI() failed to process a request

- if Ctxt.ExecuteCommand raised an exception, this callback will be run with all needed information
- should return TRUE to execute Ctxt.Error(E,...), FALSE if returned content has already been set as expected by the client

OnIdle: TNotifyEvent;

Event triggered when URI() is called, and at least 128 ms is elapsed

- could be used to execute some additional process after a period of time
- note that if TSQLRestServer.URI is not called by any client, this callback won't be executed either

OnInternalInfo: TOnInternalInfo;

Event to customize the information returned by root/timestamp/info

- called by TSQLRestServer.InternalInfo method
- you can add some application-level information for monitoring

OnNotifyCallback: TSQLRestServerNotifyCallback;

This event will be executed to push notifications from the server to a remote client, using a (fake) interface parameter

- is nil by default, but may point e.g. to TSQLHttpServer.NotifyCallback

OnServiceCreateInstance: TOnServiceCreateInstance;

This event will be executed by TServiceFactoryServer.CreateInstance

- you may set a callback to customize a server-side service instance, i.e. inject class-level dependencies:

```
procedure TMyClass.OnCreateInstance(
  Sender: TServiceFactoryServer; Instance: TInterfacedObject);
begin
  if Sender.ImplementationClass=TLegacyStockQuery then
    TLegacyStockQuery(Instance).fDbConnection := fDbConnection;
end;
```

- consider using a TInjectableObjectClass implementation for pure IoC/DI

OnSessionClosed: TNotifySQLSession;

A method can be specified to be notified when a session is closed

- for OnSessionClosed, the returning boolean value is ignored
- Ctxt is nil if the session is closed due to a timeout
- Ctxt is not nil if the session is closed explicitly by the client

OnSessionCreate: TNotifySQLSession;

A method can be specified to be notified when a session is created

- for OnSessionCreate, returning TRUE will abort the session creation - and you can set Ctxt.Call^.OutStatus to a corresponding error code
- it could be used e.g. to limit the number of client sessions

OnUpdateEvent: TNotifySQLEvent;

A method can be specified here to trigger events after any table update

- is called BEFORE deletion, and AFTER insertion or update
- note that the aSentData parameter does not contain all record fields, but only transmitted information: e.g. if only one field is updated, only this single field (and the ID) is available
- to be used only server-side, not to synchronize some clients: the framework is designed around a stateless RESTful architecture (like HTTP/1.1), in which clients ask the server for refresh (see TSQLRestClientURI.UpdateFromServer)

URIPagingParameters: TSQLRestServerURIPagingParameters;

This property can be used to specify the URI parameters to be used for query paging

- is set by default to PAGINGPARAMETERS_YAHOO constant by TSQLRestServer.Create() constructor

constructor Create(aModel: TSQLModel; aHandleUserAuthentication: boolean=false);
reintroduce; virtual;

Server initialization with a specified Database Model

- if HandleUserAuthentication is false, will set URI access rights to 'Supervisor' (i.e. all R/W access) by default
- if HandleUserAuthentication is true, will add TSQLAuthUser and TSQLAuthGroup to the TSQLModel (if not already there)

constructor CreateWithOwnModel(const Tables: array of TSQLRecordClass;
 aHandleUserAuthentication: boolean=false; const aRoot: RawUTF8='root');

Server initialization with a temporary Database Model

- a Model will be created with supplied tables, and owned by the server
- if you instantiate a TSQLRestServerFullMemory or TSQLRestServerDB with this constructor, an in-memory engine will be created, with enough abilities to run regression tests, for instance

destructor Destroy; **override**;

Release memory and any existing pipe initialized by ExportServer()

function AfterDeleteForceCoherency(aTableIndex: integer; aID: TID): boolean;
virtual;

This method is called internally after any successful deletion to ensure relational database coherency

- reset all matching TRecordReference properties in the database Model, for database coherency, into 0
- delete all records containing a matched TRecordReferenceToBeDeleted property value in the database Model (e.g. TSQLRecordHistory)
- reset all matching TSQLRecord properties in the database Model, for database coherency, into 0
- important notice: we don't use FOREIGN KEY constraints in this framework, and handle all integrity check within this method (it's therefore less error-prone, and more cross-database engine compatible)

function AuthenticationRegister(aMethod: TSQLRestServerAuthenticationClass): TSQLRestServerAuthentication; **overload**;

Call this method to add an authentication method to the server

- will return the just created TSQLRestServerAuthentication instance, or the existing instance if it has already been registered

- you can use this method to tune the authentication, e.g. if you have troubles with AJAX asynchronous callbacks:

```
(aServer.AuthenticationRegister(TSQLRestServerAuthenticationDefault) as
  TSQLRestServerAuthenticationDefault).NoTimestampCoherencyCheck := true;
```

- or if you want to customize the session_signature parameter algorithm:

```
(aServer.AuthenticationRegister(TSQLRestServerAuthenticationDefault) as
  TSQLRestServerAuthenticationDefault).Algorithm := suaMD5;
```

function BanIP(const aIP: RawUTF8; aRemoveBan: boolean=false): boolean;

(un)register a banned IPv4 value

- any connection attempt from this IP Address will be rejected by

function CloseServerMessage: boolean;

End any currently initialized message-oriented server

function CloseServerNamedPipe: boolean;

End any currently initialized named pipe server

class function CreateInMemoryForAllVirtualTables(aModel: TSQLModel;
 aHandleUserAuthentication: boolean): TSQLRestServer;

Create a new minimal TSQLRestServer instance, to be used with external SQL or NoSQL storage

- will try to instantiate an in-memory TSQLRestServerDB, and if mORMotSQLite3.pas is not linked, fallback to a TSQLRestServerFullMemory
- used e.g. by TSQLRestMongoDBCreate() and TSQLRestExternalDBCreate()

function CreateSQLIndex(Table: TSQLRecordClass; const FieldName: RawUTF8; Unique: boolean; const IndexName: RawUTF8=''): boolean; **overload**;

Create an index for the specific FieldName

- will call CreateSQLMultiIndex() internally

```
function CreateSQLIndex(Table: TSQLRecordClass; const FieldNames: array of RawUTF8;  
Unique: boolean): boolean; overload;
```

Create one or multiple index(es) for the specific FieldName(s)

```
function CreateSQLMultiIndex(Table: TSQLRecordClass; const FieldNames: array of  
RawUTF8; Unique: boolean; IndexName: RawUTF8=''): boolean; virtual;
```

Create one index for all specific FieldNames at once

- will call any static engine for the index creation of such tables, or execute a CREATE INDEX IF NOT EXISTS on the main engine

- note that with SQLite3, your database schema should never contain two indices where one index is a prefix of the other, e.g. if you defined:

```
aServer.CreateSQLMultiIndex(TEmails, ['Email', 'GroupID'], True);
```

Then the following index is not mandatory for SQLite3:

```
aServer.CreateSQLIndex(TEmails, 'Email', False);
```

see "1.6 Multi-Column Indices" in @<http://www.sqlite.org/queryplanner.html>

```
function Delete(Table: TSQLRecordClass; const SQLWhere: RawUTF8): boolean;  
override;
```

Implement Server-Side TSQLRest deletion with a WHERE clause

- will process all ORM-level validation, coherency checking and notifications together with a low-level SQL deletion work (if possible)

```
function Delete(Table: TSQLRecordClass; ID: TID): boolean; override;
```

Implement Server-Side TSQLRest deletion

- uses internally EngineDelete() function for calling the database engine

- call corresponding fStaticData[] if necessary

- this record is also erased in all available TRecordReference properties in the database Model, for relational database coherency

```
function ExportedAsMessageOrNamedPipe: Boolean;
```

Returns TRUE if remote connection is possible via named pipes or Windows messages

```
function ExportServer: boolean; overload;
```

Grant access to this database content from a dll using the global URIRequest() function

- returns true if the URIRequest() function is set to this TSQLRestServer

- returns false if a TSQLRestServer was already exported

- client must release all memory acquired by URIRequest() with GlobalFree()

function ExportServerMessage(const ServerWindowName: string): boolean;

Declare the server on the local machine to be accessible for local client connection, by using Windows messages

- the data is sent and received by using the standard and fast WM_COPYDATA message
- Windows messages are very fast (faster than named pipe and much faster than HTTP), but only work locally on the same computer
- create a new Window Class with the supplied class name (UnicodeString since Delphi 2009 for direct use of Wide Win32 API), and instantiate a window which will handle pending WM_COPYDATA messages
- the main server instance has to process the windows messages regularly (e.g. with Application.ProcessMessages)
- ServerWindowName ('DBSERVER' e.g.) will be used to create a Window name identifier
- allows only one ExportServer*() by running process
- returns true on success, false otherwise (ServerWindowName already used?)

Used for DI-2.1.1.2.3 (page 2554).

function ExportServerNamedPipe(const ServerApplicationName: TFileName): boolean;

Declare the server on the local machine as a Named Pipe: allows TSQLRestClientURINamedPipe local or remote client connection

- ServerApplicationName ('DBSERVER' e.g.) will be used to create a named pipe server identifier, it is of UnicodeString type since Delphi 2009 (use of Unicode FileOpen() version)
- this server identifier is appended to '\\.\pipe\mORMot_' to obtain the full pipe name to initiate ('\\.\pipe\mORMot_DBSERVER' e.g.)
- this server identifier may also contain a fully qualified path ('\\.\pipe\ApplicationName' e.g.)
- allows only one ExportServer*() by running process
- returns true on success, false otherwise (ServerApplicationName already used?)

Used for DI-2.1.1.2.2 (page 2554).

function InternalUpdateEvent(aEvent: TSQLEvent; aTableIndex: integer; aID: TID; const aSentData: RawUTF8; aIsBlobFields: PSQLFieldBits): boolean; **virtual**;

Virtual method called when a record is updated

- default implementation will call the OnUpdateEvent/OnBlobUpdateEvent methods, if defined
- will also handle TSQLRecordHistory tables, as defined by TrackChanges()
- returns true on success, false if an error occurred (but action must continue)
- you can override this method to implement a server-wide notification, but be aware it may be the first step to break the stateless architecture of the framework

function InternalUpdateEventNeeded(aTableIndex: integer): boolean;

Check if OnUpdateEvent or change tracked has been defined for this table

- is used internally e.g. by TSQLRestServerDB.MainEngineUpdateField to ensure that the updated ID fields will be computed as expected

function JWTForUnauthenticatedRequestWhiteIP(const aIP: RawUTF8; aRemoveWhite: boolean=false): boolean;

(un)register a an IPv4 value to the JWT white list

- by default, a JWT validated by JWTForUnauthenticatedRequest will be accepted
- to avoid MiM (Man-In-the-Middle) attacks, if a JWT white list is defined using this method, any connection from a non registered IP will be rejected, even with a valid JWT
- WebSockets connections are secure enough to bypass this list

function MemberExists(Table: TSQLRecordClass; ID: TID): boolean; **override;**

Overridden method for direct static class call (if any)

function RecordVersionCompute: TRecordVersion;

Will compute the next monotonic value for a TRecordVersion field

function RecordVersionCurrent: TRecordVersion;

Read only access to the current monotonic value for a TRecordVersion field

function RecordVersionSynchronizeMasterStart(ByPassAuthentication: boolean=false): boolean;

Initiate asynchronous master/slave replication on a master TSQLRest

- allow synchronization of a TSQLRecord table, using its TRecordVersion field, for real-time master/slave replication on the master side
- this method will register the IServiceRecordVersion service on the server side, so that RecordVersionSynchronizeStartSlave() will be able to receive push notifications of any updates
- this method expects the communication channel to be bidirectional, e.g. a mORMotHTTPServer's TSQLHttpServer in useBidirSocket mode

function RecordVersionSynchronizeSlave(Table: TSQLRecordClass; Master: TSQLRest; ChunkRowLimit: integer=0; OnWrite: TOnBatchWrite=nil): TRecordVersion;

Synchronous master/slave replication from a slave TSQLRest

- apply all the updates from another (distant) master TSQLRest for a given TSQLRecord table, using its TRecordVersion field, to the calling slave
- both remote Master and local slave TSQLRestServer should have the supplied Table class in their data model (maybe in diverse order)
- by default, all pending updates are retrieved, but you can define a value to ChunkRowLimit, so that the updates will be retrieved by smaller chunks
- returns -1 on error, or the latest applied revision number (which may be 0 if there is no data in the table)
- this method will use regular REST ORM commands, so will work with any communication channels: for real-time push synchronization, consider using RecordVersionSynchronizeMasterStart and RecordVersionSynchronizeSlaveStart over a bidirectionnal communication channel like WebSockets
- you can use RecordVersionSynchronizeSlaveToBatch if your purpose is to access the updates before applying to the current slave storage

function RecordVersionSynchronizeSlaveStart(Table: TSQLRecordClass; MasterRemoteAccess: TSQLRestClientURI; OnNotify: TOnBatchWrite=nil): boolean;

Initiate asynchronous master/slave replication on a slave TSQLRest

- start synchronization of a TSQLRecord table, using its TRecordVersion field, for real-time master/slave replication on the slave side
- this method will first retrieve any pending modification by regular REST calls to RecordVersionSynchronizeSlave, then create and register a callback instance using RecordVersionSynchronizeSubscribeMaster()
- this method expects the communication channel to be bidirectional, e.g. a TSQLHttpClientWebsockets
- the modifications will be pushed by the master, then applied to the slave storage, until RecordVersionSynchronizeSlaveStop method is called
- an optional OnNotify event may be defined, which will be triggered for all incoming change, supplying the updated TSQLRecord instance

function RecordVersionSynchronizeSlaveStop(Table: TSQLRecordClass): boolean;

Finalize asynchronous master/slave replication on a slave TSQLRest

- stop synchronization of a TSQLRecord table, using its TRecordVersion field, for real-time master/slave replication on the slave side
- expect a previous call to RecordVersionSynchronizeSlaveStart

function RecordVersionSynchronizeSlaveToBatch(Table: TSQLRecordClass; Master: TSQLRest; **var** RecordVersion: TRecordVersion; MaxRowLimit: integer=0; OnWrite: TOnBatchWrite=nil): TSQLRestBatch; **virtual**;

Synchronous master/slave replication from a slave TSQLRest into a Batch

- will retrieve all the updates from a (distant) master TSQLRest for a given TSQLRecord table, using its TRecordVersion field, and a supplied TRecordVersion monotonic value, into a TSQLRestBatch instance
- both remote Source and local TSQLRestSever should have the supplied Table class in each of their data model
- by default, all pending updates are retrieved, but you can define a value to MaxRowLimit, so that the updates will be retrieved by smaller chunks
- returns nil if nothing new was found, or a TSQLRestBatch instance containing all modifications since RecordVersion revision
- when executing the returned TSQLRestBatch on the database, you should set TSQLRestServer.RecordVersionDeleteIgnore := true so that the TRecordVersion fields will be forced from the supplied value
- usually, you should not need to use this method, but rather the more straightforward RecordVersionSynchronizeSlave()

function RecordVersionSynchronizeSubscribeMaster(Table: TSQLRecordClass; RecordVersion: TRecordVersion; **const** SlaveCallback: IServiceRecordVersionCallback): boolean; overload;

Low-level callback registration for asynchronous master/slave replication

- you should not have to use this method, but rather RecordVersionSynchronizeMasterStart and RecordVersionSynchronizeSlaveStart RecordVersionSynchronizeSlaveStop methods
- register a callback interface on the master side, which will be called each time a write operation is performed on a given TSQLRecord with a TRecordVersion field
- the callback parameter could be a TServiceRecordVersionCallback instance, which will perform all update operations as expected
- the callback process will be blocking for the ORM write point of view: so it should be as fast as possible, or asynchronous - note that regular callbacks using WebSockets, as implemented by SynBidirSock.pas and mORMotHTTPServer's TSQLHttpServer in useBidirSocket mode, are asynchronous
- if the supplied RecordVersion is not the latest on the server side, this method will return FALSE and the caller should synchronize again via RecordVersionSynchronize() to avoid any missing update
- if the supplied RecordVersion is the latest on the server side, this method will return TRUE and put the Callback notification in place

```
function RemoteDataCreate(aClass: TSQLRecordClass; aRemoteRest: TSQLRest):  
TSQLRestStorageRemote; virtual;
```

Create an external static redirection for a specific class

- call it just after Create, before TSQLRestServerDB.CreateMissingTables; warning: if you don't call this method before CreateMissingTable method is called, the table will be created as a regular table by the main database engine, and won't be static
- the specified TSQLRecord will have all its CRUD / ORM methods be redirected to aRemoteRest, which may be a TSQLRestClient or another TSQLRestServer instance (e.g. a fast SQLITE_MEMORY_DATABASE_NAME)
- if aRemoteRest is a TSQLRestClient, it should have been authenticated to the remote TSQLRestServer, so that CRUD / ORM operations will pass
- this will enable easy creation of proxies, or local servers, with they own cache and data model - e.g. a branch office server which may serve its local clients over Ethernet, but communicating to a main mORMot server via Internet, storing the corporate data in the main office server
- you may also share some tables (e.g. TSQLAuthUser and TSQLAuthGroup) between TSQLRestServer instances in a single service

```
function RetrieveBlobFields(Value: TSQLRecord): boolean; override;
```

Get all BLOB fields of the supplied value from the remote server

- this overridden method will execute the direct static class, if any

```
function ServiceContainer: TServiceContainer; override;
```

Access or initialize the internal IoC resolver, used for interface-based remote services, and more generally any Services.Resolve() call

- create and initialize the internal TServiceContainerServer if no service interface has been registered yet
- may be used to inject some dependencies, which are not interface-based remote services, but internal IoC, without the ServiceRegister() or ServiceDefine() methods - e.g.

```
aRest.ServiceContainer.InjectResolver([TInfraRepoUserFactory.Create(aRest)], true);
```
- this overridden method will return a TServiceContainerServer instance
- you may enable SOA audit trail for all methods execution:

```
(aRestSOAServer.ServiceContainer as TServiceContainerServer).SetServiceLog(  
aRestLogServer, TSQLRecordServiceLog);
```

```
function ServiceDefine(aImplementationClass: TInterfacedClass; const aInterfaces:  
array of TGUID; aInstanceCreation: TServiceInstanceImplementation=sicSingle; const  
aContractExpected: RawUTF8=''): TServiceFactoryServer; overload;
```

Register a Service class on the server side

- this method expects the interface(s) to have been registered previously:

```
TInterfaceFactory.RegisterInterfaces([TypeInfo(IMyInterface), ...]);
```
- will return the first of the registered TServiceFactoryServer created on success (i.e. corresponding to aInterfaces[0] - not to the others), or nil if registration failed (e.g. if any of the supplied interfaces is not implemented by the given class)

```
function ServiceDefine(aSharedImplementation: TInterfacedObject; const
aInterfaces: array of TGUID; const aContractExpected: RawUTF8=''):
TServiceFactoryServer; overload;
```

Register a Service instance on the server side

- this method expects the interface(s) to have been registered previously:
TInterfaceFactory.RegisterInterfaces([TypeInfo(IMyInterface),...]);
- the supplied aSharedImplementation will be owned by this Server instance
- will return the first of the registered TServiceFactoryServer created on success (i.e. corresponding to aInterfaces[0] - not to the others), or nil if registration failed (e.g. if any of the supplied interfaces is not implemented by the given class)

```
function ServiceDefine(aClient: TSQLRest; const aInterfaces: array of TGUID;
aInstanceCreation: TServiceInstanceImplementation=sicSingle; const
aContractExpected: RawUTF8=''): boolean; overload;
```

Register a remote Service via its interface

- this method expects the interface(s) to have been registered previously:
TInterfaceFactory.RegisterInterfaces([TypeInfo(IMyInterface),...]);

```
function ServiceMethodByPassAuthentication(const aMethodName: RawUTF8): integer;
```

Call this method to disable Authentication method check for a given published method-based service name

- by default, only Auth and Timestamp methods do not require the RESTful authentication of the URI; you may call this method to add another method to the list (e.g. for returning some HTML content from a public URI)
- if the supplied aMethodName="", all method-based services will bypass the authentication process
- returns the method index number

```
function ServiceRegister(aImplementationClass: TInterfacedClass; const
aInterfaces: array of PTypeInfo; aInstanceCreation:
TServiceInstanceImplementation=sicSingle; const aContractExpected: RawUTF8=''):
TServiceFactoryServer; overload; virtual;
```

Register a Service class on the server side

- this methods expects a class to be supplied, and the exact list of interfaces to be registered to the server (e.g. [TypeInfo(IMyInterface)]) and implemented by this class
- class can be any TInterfacedObject, but TInterfacedObjectWithCustomCreate can be used if you need an overridden constructor
- instance implementation pattern will be set by the appropriate parameter
- will return the first of the registered TServiceFactoryServer created on success (i.e. corresponding to aInterfaces[0] - not to the others), or nil if registration failed (e.g. if any of the supplied interfaces is not implemented by the given class)
- you can use the returned TServiceFactoryServer instance to set the expected security parameters for aInterfaces[0] - warning: only the the first interface options are returned
- the same implementation class can be used to handle several interfaces (just as Delphi allows to do natively)

```
function ServiceRegister(aSharedImplementation: TInterfacedObject; const  
aInterfaces: array of PTypeInfo; const aContractExpected: RawUTF8=''):  
TServiceFactoryServer; overload; virtual;
```

Register a Service instance on the server side

- this methods expects a class instance to be supplied, and the exact list of interfaces to be registered to the server (e.g. [TypeInfo(IMyInterface)]) and implemented by this shared instance
- as a consequence, instance implementation pattern will always be sicShared
- will return the first of the registered TServiceFactoryServer created on success (i.e. the one corresponding to the first item of the aInterfaces array), or nil if registration failed (e.g. if any of the supplied interfaces is not implemented by the given class)
- will return the first of the registered TServiceFactoryServer created on success (i.e. corresponding to aInterfaces[0] - not to the others), or nil if registration failed (e.g. if any of the supplied interfaces is not implemented by the given class)
- the same implementation class can be used to handle several interfaces (just as Delphi allows to do natively)

```
function ServiceRegister(aClient: TSQLRest; const aInterfaces: array of PTypeInfo;  
aInstanceCreation: TServiceInstanceImplementation=sicSingle; const  
aContractExpected: RawUTF8=''): boolean; overload; virtual;
```

Register a remote Service via its interface

- this overloaded method will register a remote Service, accessed via the supplied TSQLRest(ClientURI) instance: it can be available in the main TSQLRestServer.Services property, but execution will take place on a remote server - may be used e.g. for dedicated hosting of services (in a DMZ for instance)
- this methods expects a list of interfaces to be registered to the client (e.g. [TypeInfo(IMyInterface)])
- instance implementation pattern will be set by the appropriate parameter
- will return true on success, false if registration failed (e.g. if any of the supplied interfaces is not correct or is not available on the server)
- that is, server side will be called to check for the availability of each interface
- you can specify an optional custom contract for the first interface

```
function ServicesPublishedInterfaces: RawUTF8;
```

Compute a JSON description of all available services, and its public URI

- the JSON object matches the TServicesPublishedInterfaces record type
- used by TSQLRestClientURI.ServicePublishOwnInterfaces to register all the services supported by the client itself
- warning: the public URI should have been set via SetPublicURI()

```
function SessionGetUser(aSessionID: Cardinal): TSQLAuthUser;
```

Returns a copy of the user associated to a session ID

- returns nil if the session does not exist (e.g. if authentication is disabled)
- caller MUST release the TSQLAuthUser instance returned (if not nil)
- this method IS thread-safe, and calls internaly Sessions.Lock (the returned TSQLAuthUser is a private copy from Sessions[].User instance, in order to be really thread-safe)
- the returned TSQLAuthUser instance will have GroupRights=nil but will have ID, LogonName, DisplayName, PasswordHashHexa and Data fields available

```
function SessionsAsJson: RawJSON;
```

Retrieve all current session information as a JSON array

function SleepOrShutdown(MS: integer): boolean;

Wait for the specified number of milliseconds

- if Shutdown is called in-between, returns true
- if the thread waited the supplied time, returns false

function StaticDataAdd(aStaticData: TSQLRestStorage): boolean;

Register an external static storage for a given table

- will be added to StaticDataServer[] internal list
- called e.g. by StaticDataCreate(), RemoteDataCreate() or StaticMongoDBRegister()

function StaticDataCreate(aClass: TSQLRecordClass; **const** aFileName: TFileName='';
aBinaryFile: boolean=false; aServerClass: TSQLRestStorageInMemoryClass=nil):
TSQLRestStorage;

Create an external static in-memory database for a specific class

- call it just after Create, before TSQLRestServerDB.CreateMissingTables; warning: if you don't call this method before CreateMissingTable method is called, the table will be created as a regular table by the main database engine, and won't be static
- can load the table content from a file if a file name is specified (could be either JSON or compressed Binary format on disk)
- you can define a particular external engine by setting a custom class - by default, it will create a TSQLRestStorageInMemory instance
- this data handles basic REST commands, since no complete SQL interpreter can be implemented by TSQLRestStorage; to provide full SQL process, you should better use a Virtual Table class, inheriting e.g. from TSQLRecordVirtualTableAutoID associated with TSQLVirtualTableJSON/Binary via a Model.VirtualTableRegister() call before TSQLRestServer.Create
- return nil on any error, or an EModelException if the class is not in the database model

function StatsAsDocVariant(Flags:
TSQLRestServerAddStats=[withTables..withSessions]): **variant**;

Compute the statistics about this server, as a TDocVariant document

- is a wrapper around the Stats() method-based service

function StatsAsJson(Flags: TSQLRestServerAddStats=[withTables..withSessions]):
RawUTF8; **virtual**;

Compute the statistics about this server, as JSON

- is a wrapper around the Stats() method-based service

function TableHasRows(Table: TSQLRecordClass): boolean; **override**;
Overridden method for direct static class call (if any)

function TableRowCount(Table: TSQLRecordClass): Int64; **override**;
Overridden method for direct static class call (if any)

function UnLock(Table: TSQLRecordClass; aID: TID): boolean; **override**;

Implement Server-Side TSQLRest unlocking

- to be called e.g. after a Retrieve() with forupdate=TRUE
- implements our custom UNLOCK REST-like verb
- locking is handled by TSQLServer.Model
- returns true on success

function UpdateBlobFields(Value: TSQLRecord): boolean; **override;**

Update all BLOB fields of the supplied Value

- this overridden method will execute the direct static class, if any

procedure Auth(Ctxt: TSQLRestServerURIContext);

REST service accessible from ModelRoot/Auth URI

- called by the clients for authentication and session management
- this method won't require an authenticated client, since it is used to initiate authentication
- this global callback method is thread-safe

procedure Batch(Ctxt: TSQLRestServerURIContext);

REST service accessible from the ModelRoot/Batch URI

- will execute a set of RESTful commands, in a single step, with optional automatic SQL transaction generation

- this method will require an authenticated client, for safety

- expect input as JSON commands:

`'{"Table":["cmd":values,...}]'`

or for multiple tables:

`'["cmd@Table":values,...]'`

with cmd in POST/PUT with {object} as value or DELETE with ID

- returns an array of integers: '[200,200,...]' or '["OK"]' if all returned status codes are 200 (HTTP_SUCCESS)

- URI are either 'ModelRoot/TableName/Batch' or 'ModelRoot/Batch'

procedure CacheFlush(Ctxt: TSQLRestServerURIContext);

REST service accessible from the ModelRoot/CacheFlush URI

- it will flush the server result cache

- this method shall be called by the clients when the Server cache may be not consistent any more (e.g. after a direct write to an external database)

- this method will require an authenticated client, for safety

- GET ModelRoot/CacheFlush URI will flush the whole Server cache, for all tables

- GET ModelRoot/CacheFlush/TableName URI will flush the specified table cache

- GET ModelRoot/CacheFlush/TableName/TableID URI will flush the content of the specified record

- POST ModelRoot/CacheFlush/_callback_ URI will be called by the client to notify the server that an interface callback instance has been released

- POST ModelRoot/CacheFlush/_ping_ URI will be called by the client after every half session timeout (or at least every hour) to notify the server that the connection is still alive

procedure Stat(Ctxt: TSQLRestServerURIContext);

REST service accessible from ModelRoot/Stat URI to gather detailed information

- returns the current execution statistics of this server, as a JSON object
- this method will require an authenticated client, for safety
- by default, will return the high-level information of this server
- will return human-readable JSON layout if ModelRoot/Stat/json is used, or the corresponding XML content if ModelRoot/Stat/xml is used
- you can define withtables, withmethods, withinterfaces, withsessions or withsqlite3 additional parameters to return detailed information about method-based services, interface-based services, per session statistics, or prepared SQLite3 SQL statement timing (for a TSQLRestServerDB instance)

```
Client.CallBackGet('stat',[ 'withtables',true,'withmethods',true,
  'withinterfaces',true,'withsessions',true,'withsqlite3',true],stats);
```

- defining a 'withall' parameter will retrieve all available statistics
- note that TSQLRestServer.StatLevels property will enable statistics gathering for tables, methods, interfaces, sqlite3 or sessions
- a specific findservice=ServiceName parameter will not return any statistics, but matching URIs from the server AssociatedServices list

procedure Timestamp(Ctxt: TSQLRestServerURIContext);

REST service accessible from the ModelRoot/Timestamp URI

- returns the server time stamp TTimeLog/Int64 value as UTF-8 text
- this method will not require an authenticated client
- hidden ModelRoot/Timestamp/info command will return basic execution information, less verbose (and sensitive) than Stat(), calling virtual InternalInfo() protected method

procedure AdministrationExecute(const DatabaseName,SQL: RawUTF8; var result: TServiceCustomAnswer); **override**;

Used e.g. by IAdministratedDaemon to implement "pseudo-SQL" commands

procedure AnswerToMessage(var Msg: TWMCopyData); **message** WM_COPYDATA;

Implement a message-based server response

- this method is called automatically if ExportServerMessage() method was initialized
- you can also call this method from the WM_COPYDATA message handler of your main form, and use the TSQLRestClientURIMessage class to access the server instance from your clients
- it will answer to the Client with another WM_COPYDATA message
- message oriented architecture doesn't need any thread, but will use the main thread of your application

procedure AuthenticationRegister(const aMethods: array of TSQLRestServerAuthenticationClass); **overload**;

Call this method to add several authentication methods to the server

- if TSQLRestServer.Create() constructor is called with aHandleUserAuthentication set to TRUE, it will register the two following classes:

```
AuthenticationRegister([TSQLRestServerAuthenticationDefault,TSQLRestServerAuthenticationSSPI
]);
```

procedure AuthenticationUnregister(const aMethods: array of TSQLRestServerAuthenticationClass); **overload**;

Call this method to remove several authentication methods to the server

procedure AuthenticationUnregister(aMethod: TSQLRestServerAuthenticationClass);
overload;

Call this method to remove an authentication method to the server

procedure AuthenticationUnregisterAll;

Call this method to remove all authentication methods to the server

procedure BeginCurrentThread(Sender: TThread); **override**;

You can call this method in TThread.Execute to ensure that the thread will be taken into account during process

- caller must specify the TThread instance running
- used e.g. for optExecInMainThread option in TServiceMethodExecute
- this default implementation will call the methods of all its internal TSQLRestStorage instances
- this method shall be called from the thread just initiated: e.g. if you call it from the main thread, it may fail to prepare resources

procedure Commit(SessionID: cardinal; RaiseException: boolean); **override**;

End a transaction

- implements REST END collection
- write all pending TSQLVirtualTableJSON data to the disk

procedure CreateMissingTables(user_version: cardinal=0; options:
TSQLInitializeTableOptions=[]); **virtual**;

Missing tables are created if they don't exist yet for every TSQLRecord class of the Database Model

- you must call explicitly this before having called StaticDataCreate()
- all table description (even Unique feature) is retrieved from the Model
- this method should also create additional fields, if the TSQLRecord definition has been modified; only field adding is mandatory, field renaming or field deleting are not allowed in the Framework (in such cases, you must create a new TSQLRecord type)
- this virtual method do nothing by default - overridden versions should implement it as expected by the underlying storage engine (e.g. SQLite3 or TSQLRestServerFullInMemory)
- you can tune some options transmitted to the TSQLRecord.InitializeTable virtual methods, e.g. to avoid the automatic create of indexes

procedure EndCurrentThread(Sender: TThread); **override**;

You can call this method just before a thread is finished to ensure e.g. that the associated external DB connection will be released

- this default implementation will call the methods of all its internal TSQLRestStorage instances, allowing e.g. TSQLRestStorageExternal instances to clean their thread-specific connections
- this method shall be called from the thread about to be terminated: e.g. if you call it from the main thread, it may fail to release resources
- it is set e.g. by TSQLite3HttpServer to be called from HTTP threads, or by TSQLRestServerNamedPipeResponse for named-pipe server cleaning

procedure FlushInternalDBCache; **virtual**;

Call this method when the internal DB content is known to be invalid

- by default, all REST/CRUD requests and direct SQL statements are scanned and identified as potentially able to change the internal SQL/JSON cache used at SQLite3 database level; but some virtual tables (e.g. TSQLRestStorageExternal classes defined in mORMotDB) could flush the database content without proper notification
- this default implementation will just do nothing, but mORMotSQLite3 unit will call TSQLDataBase.CacheFlush method

procedure InitializeTables(Options: TSQLInitializeTableOptions);

Run the TSQLRecord.InitializeTable methods for all void tables of the model

- can be used instead of CreateMissingTables e.g. for MongoDB storage
- you can specify the creation options, e.g. INITIALIZETABLE_NOINDEX

procedure ServiceMethodRegister(aMethodName: RawUTF8; **const** aEvent: TSQLRestServerCallBack; aByPassAuthentication: boolean=false);

Direct registration of a method for a given low-level event handler

procedure ServiceMethodRegisterPublishedMethods(**const** aPrefix: RawUTF8; aInstance: TObject);

Add all published methods of a given object instance to the method-based list of services

- all those published method signature should match TSQLRestServerCallBack

procedure SessionsLoadFromFile(**const** aFileName: TFileName; andDeleteExistingFileAfterRead: boolean);

Re-create all in-memory sessions from a compressed binary file

- typical use is after a server restart, with the file supplied to the Shutdown() method: it could be used e.g. for a short maintenance server shutdown, without losing the current logged user sessions
- WARNING: this method will restore authentication sessions for the ORM, but not any complex state information used by interface-based services, like sicClientDriven class instances - DO NOT use this feature with SOA
- this method IS thread-safe, and call internally Sessions.Lock

procedure SessionsSaveToFile(**const** aFileName: TFileName);

Persist all in-memory sessions into a compressed binary file

- you should not call this method directly, but rather use Shutdown() with a StateFileName parameter - to be used e.g. for a short maintenance server shutdown, without losing the current logged user sessions
- this method IS thread-safe, and call internally Sessions.Lock

procedure SetPublicURI(**const** Address,Port: RawUTF8);

The HTTP server should call this method so that ServicesPublishedInterfaces registration will be able to work

procedure Shutdown(**const** aStateFileName: TFileName=''); **virtual**;

You can call this method to prepare the server for shutting down

- it will reject any incoming request from now on, and will wait until all pending requests are finished, for proper server termination
- you could optionally save the current server state (e.g. user sessions) into a file, ready to be retrieved later on using SessionsLoadFromFile - note that this will work only for ORM sessions, NOT complex SOA state
- this method is called by Destroy itself

procedure TrackChanges(**const** aTable: **array of** TSQLRecordClass; aTableHistory: TSQLRecordHistoryClass=**nil**; aMaxHistoryRowBeforeBlob: **integer**=1000; aMaxHistoryRowPerRecord: **integer**=10; aMaxUncompressedBlobSize: **integer**=64*1024); **virtual**;

Initialize change tracking for the given tables

- by default, it will use the TSQLRecordHistory table to store the changes - you can specify a dedicated class as aTableHistory parameter
- if aTableHistory is not already part of the TSQLModel, it will be added
- note that this setting should be consistent in time: if you disable tracking for a while, or did not enable tracking before adding a record, then the content history won't be consistent (or disabled) for this record
- at every change, aTableHistory.SentDataJSON records will be added, up to aMaxHistoryRowBeforeBlob items - then aTableHistory.History will store a compressed version of all previous changes
- aMaxHistoryRowBeforeBlob is the maximum number of JSON rows per Table before compression into BLOB is triggered
- aMaxHistoryRowPerRecord is the maximum number of JSON rows per record, above which the versions will be compressed as BLOB
- aMaxUncompressedBlobSize is the maximum BLOB size per record
- you can specify aMaxHistoryRowBeforeBlob=0 to disable change tracking
- you should call this method after the CreateMissingTables call
- note that change tracking may slow down the writing process, and may increase storage space a lot (even if BLOB maximum size can be set), so should be defined only when necessary

procedure TrackChangesFlush(aTableHistory: TSQLRecordHistoryClass); **virtual**;

Force compression of all aTableHistory.SentDataJson into History BLOB

- by default, this will take place in InternalUpdateEvent() when aMaxHistoryRowBeforeBlob - as set by TrackChanges() method - is reached
- you can manually call this method to force History BLOB update, e.g. when the server is in Idle state, and ready for process

procedure URI(**var** Call: TSQLRestURIParams); **virtual**;

Implement a generic local, piped or HTTP/1.1 provider

- this is the main entry point of the server, from the client side
- default implementation calls protected methods EngineList() Retrieve() Add() Update() Delete() UnLock() EngineExecute() above, which must be overridden by the TSQLRestServer child
- for 'GET ModelRoot/TableName', url parameters can be either "select" and "where" (to specify a SQL Query, from the SQLFromSelectWhere function), either "sort", "dir", "startIndex", "results", as expected by the YUI DataSource Request Syntax for data pagination - see <http://developer.yahoo.com/yui/datatable/#data>
- execution of this method could be monitored via OnBeforeURI and OnAfterURI event handlers

Used for DI-2.1.1.2.4 (page 2555).

property AssociatedServices: TServicesPublishedInterfacesList **read** fAssociatedServices;

A list of the services associated by all clients of this server instance

- when a client connects to this server, it will publish its own services (when checking its interface contract), so that they may be identified

property AuthenticationSchemes: TSQLRestServerAuthenticationDynArray **read** fSessionAuthentication;

Read-only access to the list of registered server-side authentication methods, used for session creation

- note that the exact number of registered services in this list is stored in the AuthenticationSchemesCount property

property AuthenticationSchemesCount: integer **read** GetAuthenticationSchemesCount;
How many authentication methods are registered in AuthenticationSchemes

property BypassORMAuthentication: TSQLURIMethods **read** fBypassORMAuthentication
write fBypassORMAuthentication;

Allow to by-pass Authentication for a given set of HTTP verbs

- by default, RESTful access to the ORM will follow HandleAuthentication setting: but you could define some HTTP verb to this property, which will by-pass the authentication - may be used e.g. for public GET of the content by an AJAX client

property CreateMissingTablesOptions: TSQLInitializeTableOptions **read** fCreateMissingTablesOptions;

The options specified to TSQLRestServer.CreateMissingTables

- as expected by TSQLRecord.InitializeTable methods

property HandleAuthentication: boolean **read** fHandleAuthentication;

Set to true if the server will handle per-user authentication and access right management

- i.e. if the associated TSQLModel contains TSQLAuthUser and TSQLAuthGroup tables (set by constructor)

property JWTForUnauthenticatedRequest: TJWTAbstract read
 fJWTForUnauthenticatedRequest write fJWTForUnauthenticatedRequest;

Define if unsecure connections (i.e. not in-process or encrypted WebSockets) with no session can be authenticated via JWT

- once set, this instance will be owned by the TSQLRestServer
- by definition, such JWT authentication won't identify any mORMot user nor session (it just has to be valid), so only sicSingle, sicShared or sicPerThread interface-based services execution are possible
- typical usage is for a public API, in conjunction with ServiceDefine(...).ResultAsJSONObjectWithoutResult := true on the server side and TSQLRestClientURI.ServiceDefineSharedAPI() method for the client
- see also JWTForUnauthenticatedRequestWhiteIP() for additional security

property NoAJAXJSON: boolean read GetNoAJAXJSON write SetNoAJAXJSON;

Set this property to true to transmit the JSON data in a "not expanded" format

- not directly compatible with Javascript object list decode: not to be used in AJAX environnement (like in TSQLite3HttpServer)
- but transmitted JSON data is much smaller if set it's set to FALSE, and if you use a Delphi Client, parsing will be also faster and memory usage will be lower
- By default, the NoAJAXJSON property is set to TRUE in TSQLRestServer.ExportServerNamedPipe: if you use named pipes for communication, you probably won't use javascript because browser communicates via HTTP!
- But otherwise, NoAJAXJSON property is set to FALSE. You could force its value to TRUE and you'd save some bandwidth if you don't use javascript: even the parsing of the JSON Content will be faster with Delphi client if JSON content is not expanded
- the "expanded" or standard/AJAX layout allows you to create pure JavaScript objects from the JSON content, because the field name / JavaScript object property name is supplied for every value
- the "not expanded" layout, NoAJAXJSON property is set to TRUE, reflects exactly the layout of the SQL request - first line contains the field names, then all next lines are the field content
- is in fact stored in rsoNoAJAXJSON item in Options property

property Options: TSQLRestServerOptions read fOptions write fOptions;

Allow to customize how TSQLRestServer.URI process the requests

- e.g. if HTTP_SUCCESS with no body should be translated into HTTP_NOCONTENT

property RecordVersionDeleteIgnore: boolean read fRecordVersionDeleteIgnore write fRecordVersionDeleteIgnore;

You can force this property to TRUE so that any Delete() will not write to the TSQLRecordTableDelete table for TRecordVersion tables

- to be used when applying a TSQLRestBatch instance as returned by RecordVersionSynchronizeToBatch()

property RootRedirectGet: RawUTF8 read fRootRedirectGet write fRootRedirectGet;

The URI to redirect any plain GET on root URI, without any method

- could be used to ease access from web browsers URI

property ServiceMethodStat[const aMethod: RawUTF8]: TSynMonitorInputOutput read GetServiceMethodStat;

Retrieve detailed statistics about a method-based service use

- will return a reference to the actual alive item: caller should not free the returned instance

property SessionClass: TAuthSessionClass read fSessionClass write fSessionClass;

The class inheriting from TAuthSession to handle in-memory sessions

- since all sessions data remain in memory, ensure they are not taking too much resource (memory or process time)

property Sessions: TSynObjectListLocked read fSessions;

Read-only access to the internal list of sessions

- ensure you protect its access calling Sessions.Lock/Sessions.Unlock

property SQLAuthGroupClass: TSQLAuthGroupClass read fSQLAuthGroupClass;

The class inheriting from TSQLAuthGroup, as defined in the model

- during authentication, this class will be used for every TSQLAuthGroup table access

property SQLAuthUserClass: TSQLAuthUserClass read fSQLAuthUserClass;

The class inheriting from TSQLAuthUser, as defined in the model

- during authentication, this class will be used for every TSQLAuthUser table access
- see also the OnAuthenticationUserRetrieve optional event handler

property SQLRecordVersionDeleteTable: TSQLRecordTableDeletedClass read fSQLRecordVersionDeleteTable;

The class inheriting from TSQLRecordTableDeleted, as defined in the model

- during authentication, this class will be used for storing a trace of every deletion of table rows containing a TRecordVersion published field

property StaticDataServer[aClass: TSQLRecordClass]: TSQLRest read GetStaticDataServer;

Retrieve the TSQLRestStorage instance used to store and manage a specified TSQLRecordClass in memory

- has been associated by the StaticDataCreate method

property StaticTable[aClass: TSQLRecordClass]: TSQLRest read GetStaticTable;

Fast get the associated static server or virtual table, if any

- same as a dual call to StaticDataServer[aClass] + StaticVirtualTable[aClass]

property StaticVirtualTable[aClass: TSQLRecordClass]: TSQLRest read GetVirtualTable;

Retrieve a running TSQLRestStorage virtual table

- associated e.g. to a 'JSON' or 'Binary' virtual table module, or may return a TSQLRestStorageExternal instance (as defined in mORMotDB)
- this property will return nil if there is no Virtual Table associated or if the corresponding module is not a TSQLVirtualTable (e.g. "pure" static tables registered by StaticDataCreate will be accessible only via StaticDataServer[], not via StaticVirtualTable[])
- has been associated by the TSQLModel.VirtualTableRegister method or the VirtualTableExternalRegister() global function

property StaticVirtualTableDirect: boolean read fVirtualTableDirect write fVirtualTableDirect;

This property can be left to its TRUE default value, to handle any TSQLVirtualTableJSON static tables (module JSON or BINARY) with direct calls to the storage instance

- is set to TRUE by default to enable faster Direct mode
- in Direct mode, GET/POST/PUT/DELETE of individual records (or BLOB fields) from URI() will call directly the corresponding TSQLRestStorage instance, for better speed for most used RESTful operations; but complex SQL requests (e.g. joined SELECT) will rely on the main SQL engine
- if set to false, will use the main SQLite3 engine for all statements (should not to be used normally, because it will add unnecessary overhead)

property StatLevels: TSQLRestServerMonitorLevels read fStatLevels write fStatLevels;

Which level of detailed information is gathered

- by default, contains SERVERDEFAULTMONITORLEVELS, i.e.
[m1Tables, m1Methods, m1Interfaces, m1SQLite3]
- you can add m1Sessions to maintain per-session statistics: this will lead into a slightly higher memory consumption, for each session

property Stats: TSQLRestServerMonitor read fStats;

Read-only access to the high-level Server statistics

- see ServiceMethodStat[] for information about method-based services, or TServiceFactoryServer.Stats / Stat[] for interface-based services
- statistics are available remotely as JSON from the Stat() method

property StatUsage: TSynMonitorUsage read fStatUsage write SetStatUsage;

Could be set to track statistic from Stats information

- it may be e.g. a TSynMonitorUsageRest instance for REST storage

TSQLRestStorage = class(TSQLRest)

REST class with direct access to an external database engine

- you can set an alternate per-table database engine by using this class
- this abstract class is to be overridden with a proper implementation (e.g. TSQLRestStorageInMemory in this unit, or TSQLRestStorageExternal from mORMotDB unit, or TSQLRestStorageMongoDB from mORMotMongoDB unit)

constructor Create(aClass: TSQLRecordClass; aServer: TSQLRestServer); **reintroduce; virtual;**

Initialize the abstract storage data

destructor Destroy; **override;**

Finalize the storage instance

function CreateSQLMultiIndex(Table: TSQLRecordClass; const FieldNames: array of RawUTF8; Unique: boolean; IndexName: RawUTF8=''): boolean; **virtual;**

Create one index for all specific FieldNames at once

- do nothing method: will return FALSE (aka error)

function RecordCanBeUpdated(Table: TSQLRecordClass; ID: TID; Action: TSQLEvent; ErrorMsg: PRawUTF8 = nil): boolean; **override;**

Overridden method calling the owner (if any) to guess if this record can be updated or deleted

function SearchField(const FieldName: RawUTF8; FieldValue: Int64; out ResultID: TIDDynArray): boolean; overload; **virtual**;

Search for a numerical field value

- return true on success (i.e. if some values have been added to ResultID)
- store the results into the ResultID dynamic array
- faster than OneFieldValues method, which creates a temporary JSON content
- this default implementation will call the overloaded SearchField() value after conversion of the FieldValue into RawUTF8

function SearchField(const FieldName, FieldValue: RawUTF8; out ResultID: TIDDynArray): boolean; overload; **virtual**; **abstract**;

Search for a field value, according to its SQL content representation

- return true on success (i.e. if some values have been added to ResultID)
- store the results into the ResultID dynamic array
- faster than OneFieldValues method, which creates a temporary JSON content

function ServiceContainer: TServiceContainer; **override**;

Access or initialize the internal IoC resolver

- this overridden method will return always nil, since IoC only makes sense at TSQLRestClient and TSQLRestServer level

function Unlock(Table: TSQLRecordClass; aID: TID): boolean; **override**;

Implement TSQLRest unlocking (UNLOCK verb)

- to be called e.g. after a Retrieve() with forupdate=TRUE
- locking is handled at (Owner.)Model level
- returns true on success

procedure BeginCurrentThread(Sender: TThread); **override**;

You can call this method in TThread.Execute to ensure that the thread will be taken into account during process

- this overridden method will do nothing (should have been already made at TSQLRestServer caller level)
- children classes may inherit from this method to notify e.g. a third party process (like proper OLE initialization)

procedure EndCurrentThread(Sender: TThread); **override**;

You can call this method just before a thread is finished to ensure e.g. that the associated external DB connection will be released

- this overridden method will do nothing (should have been already made at TSQLRestServer caller level)
- children classes may inherit from this method to notify e.g. a third party process (like proper OLE initialization)

procedure StorageLock(WillModifyContent: boolean; const msg: RawUTF8); **virtual**;

Should be called before any access to the storage content

- and protected with a try ... finally StorageUnlock; end section

procedure StorageUnlock; **virtual**;

Should be called after any StorageLock-protected access to the content

- e.g. protected with a try ... finally StorageUnlock; end section

property Modified: boolean **read** fModified **write** fModified;

Read only access to a boolean value set to true if table data was modified

property Owner: TSQLRestServer **read** fOwner;

Read only access to the TSQLRestServer using this storage engine

property StorageLockLogTrace: boolean **read** fStorageLockLogTrace **write** fStorageLockLogTrace;

*Enable low-level trace of StorageLock/StorageUnlock methods
 - may be used to resolve low-level race conditions*

property StoredClass: TSQLRecordClass **read** fStoredClass;

Read only access to the class defining the record type stored in this REST storage

property StoredClassName: RawUTF8 **read** GetStoredClassName;

Name of the class defining the record type stored in this REST storage

property StoredClassProps: TSQLModelRecordProperties **read** fStoredClassProps;

*Read only access to the ORM properties of the associated record type
 - may be nil if this instance is not associated with a TSQLModel*

property StoredClassRecordProps: TSQLRecordProperties **read** fStoredClassRecordProps;

Read only access to the RTTI properties of the associated record type

TSQLRestStorageRecordBased = class(TSQLRestStorage)

Abstract REST storage exposing some internal TSQLRecord-based methods

function AddOne(Rec: TSQLRecord; ForceID: boolean; **const** SentData: RawUTF8): TID;
virtual; abstract;

Manual Add of a TSQLRecord
 - returns the ID created on success
 - returns -1 on failure (not UNIQUE field value e.g.)
 - on success, the Rec instance is added to the Values[] list: caller doesn't need to Free it

function GetOne(aID: TID): TSQLRecord; **virtual; abstract;**

Manual Retrieval of a TSQLRecord field values
 - an instance of the associated static class is created
 - and all its properties are filled from the Items[] values
 - caller can modify these properties, then use UpdateOne() if the changes have to be stored inside the Items[] list
 - caller must always free the returned instance
 - returns NIL if any error occurred, e.g. if the supplied aID was incorrect
 - method available since a TSQLRestStorage instance may be created stand-alone, i.e. without any associated Model/TSQLRestServer

function UpdateOne(ID: TID; **const** Values: TSQLVarDynArray): boolean; **overload; virtual;**

Manual Update of a TSQLRecord field values from an array of TSQLVar
 - will update all properties, including BLOB fields and such
 - returns TRUE on success, FALSE on any error (e.g. invalid Rec.ID)
 - method available since a TSQLRestStorage instance may be created stand-alone, i.e. without any associated Model/TSQLRestServer
 - this default implementation will create a temporary TSQLRecord instance with the supplied Values[], and will call overloaded UpdateOne() method

function UpdateOne(Rec: TSQLRecord; const SentData: RawUTF8): boolean; overload;
virtual; abstract;

Manual Update of a TSQLRecord field values

- Rec.ID specifies which record is to be updated
- will update all properties, including BLOB fields and such
- returns TRUE on success, FALSE on any error (e.g. invalid Rec.ID)
- method available since a TSQLRestStorage instance may be created stand-alone, i.e. without any associated Model/TSQLRestServer

TSQLRestStorageInMemoryUnique = class(TObject)

Class able to handle a O(1) hashed-based search of a property

- used e.g. to hash TSQLRestStorageInMemory field values

constructor Create(aOwner: TSQLRestStorageInMemory; aField: TSQLPropInfo);

Match TEventDynArrayHashOne initialize a hash for a record array field

- aField maps the "stored AS_UNIQUE" published property

function AddedAfterFind(Rec: TSQLRecord): boolean;

Called by TSQLRestStorageInMemory.AddOne after a precious Find()

function Find(Rec: TSQLRecord): integer;

Fast search using O(1) internal hash table

- returns -1 if not found or not indexed (self=nil)

property CaseInsensitive: boolean **read** fCaseInsensitive;

If the string comparison shall be case-insensitive

property Hasher: TDynArrayHasher **read** fHasher;

Access to the internal hash table

property PropInfo: TSQLPropInfo **read** fPropInfo;

The corresponding field RTTI

TSQLRestStorageInMemory = class(TSQLRestStorageRecordBased)

REST storage with direct access to a TObjectList memory-stored table

- store the associated TSQLRecord values in memory
- handle one TSQLRecord per TSQLRestStorageInMemory instance
- must be registered individually in a TSQLRestServer to access data from a common client, by using the TSQLRestServer.StaticDataCreate method: it allows an unique access for both SQLite3 and Static databases
- handle basic REST commands, no SQL interpreter is implemented: only valid SQL command is "SELECT Field1,Field2 FROM Table WHERE ID=120;", i.e a one Table SELECT with one optional "WHERE fieldname = value" statement; if used within a TSQLVirtualTableJSON, you'll be able to handle any kind of SQL statement (even joined SELECT or such) with this memory-stored database
- our TSQLRestStorage database engine is very optimized and is a lot faster than SQLite3 for such queries - but its values remain in RAM, therefore it is not meant to deal with more than 100,000 rows
- data can be stored and retrieved from a file (JSON format is used by default, if BinaryFile parameter is left to false; a proprietary compressed binary format can be used instead) if a file name is supplied at creating the TSQLRestStorageInMemory instance

constructor Create(aClass: TSQLRecordClass; aServer: TSQLRestServer; **const** aFileName: TFileName = ''; aBinaryFile: boolean=false); **reintroduce; virtual;**

Initialize the table storage data, reading it from a file if necessary

- data encoding on file is UTF-8 JSON format by default, or should be some binary format if aBinaryFile is set to true

destructor Destroy; **override;**

Free used memory

- especially release all fValue[] instances

function AddOne(Rec: TSQLRecord; ForceID: boolean; **const** SentData: RawUTF8): TID; **override;**

Low-level Add of a TSQLRecord instance

- returns the ID created on success
- returns -1 on failure (not UNIQUE field value e.g.)
- on success, the Rec instance is added to the Values[] list: caller doesn't need to Free it, since it will be owned by the storage
- in practice, SentData is used only for OnUpdateEvent/OnBlobUpdateEvent and the history feature
- warning: this method should be protected via StorageLock/StorageUnlock

function DeleteOne(aIndex: integer): boolean; **virtual;**

Direct deletion of a TSQLRecord, from its index in Values[]

- warning: this method should be protected via StorageLock/StorageUnlock

function EngineDelete(TableModelIndex: integer; ID: TID): boolean; **override;**

Overridden method for direct in-memory database engine call

- made public since a TSQLRestStorage instance may be created stand-alone, i.e. without any associated Model/TSQLRestServer

function EngineUpdateField(TableModelIndex: integer; **const** SetFieldName, SetValue, WhereFieldName, WhereValue: RawUTF8): boolean; **override**;

Overridden method for direct in-memory database engine call

- made public since a TSQLRestStorage instance may be created stand-alone, i.e. without any associated Model/TSQLRestServer

function EngineUpdateFieldIncrement(TableModelIndex: integer; ID: TID; **const** FieldName: RawUTF8; Increment: Int64): boolean; **override**;

Overridden method for direct in-memory database engine call

- made public since a TSQLRestStorage instance may be created stand-alone, i.e. without any associated Model/TSQLRestServer

function FindMax(WhereField: integer; **out** max: Int64): boolean;

Search the maximum value of a given column

- will only handle integer/Int64 kind of column

function FindWhereEqual(WhereField: integer; **const** WhereValue: RawUTF8; OnFind: TFindWhereEqualEvent; Dest: pointer; FoundLimit, FoundOffset: PtrInt; CaseInsensitive: boolean=true): PtrInt; **overload**;

Optimized search of WhereValue in WhereField (0=RowID, 1..=RTTI)

- will use fast O(1) hash for fUnique[] fields
- will use SYSTEMNOCASE case-insensitive search for text values, unless CaseInsensitive is set to FALSE
- warning: this method should be protected via StorageLock/StorageUnlock

function FindWhereEqual(**const** WhereFieldName, WhereValue: RawUTF8; OnFind: TFindWhereEqualEvent; Dest: pointer; FoundLimit, FoundOffset: integer; CaseInsensitive: boolean=true): PtrInt; **overload**;

Optimized search of WhereValue in a field, specified by name

- will use fast O(1) hash for fUnique[] fields
- will use SYSTEMNOCASE case-insensitive search for text values, unless CaseInsensitive is set to FALSE
- warning: this method should be protected via StorageLock/StorageUnlock

function GetOne(aID: TID): TSQLRecord; **override**;

Manual Retrieval of a TSQLRecord field values

- an instance of the associated static class is created, and filled with the actual properties values
- and all its properties are filled from the Items[] values
- caller can modify these properties, then use UpdateOne() if the changes have to be stored inside the Items[] list
- caller must always free the returned instance
- returns NIL if any error occurred, e.g. if the supplied aID was incorrect
- method available since a TSQLRestStorage instance may be created stand-alone, i.e. without any associated Model/TSQLRestServer

function IDToIndex(ID: TID): PtrInt;

Retrieve the index in Items[] of a particular ID

- return -1 if this ID was not found
- use internally fast O(1) hashed search algorithm
- warning: this method should be protected via StorageLock/StorageUnlock

function LoadFromBinary(Stream: TStream): boolean; overload;

Load the values from binary file/stream

- the binary format is a custom compressed format (using our SynLZ fast compression algorithm), with variable-length record storage
- the binary content is first checked for consistency, before loading
- warning: the field layout should be the same at SaveToBinary call; for instance, it won't be able to read a file content with a renamed or modified field type
- will return false if the binary content is invalid

function LoadFromBinary(const Buffer: RawByteString): boolean; overload;

Load the values from binary data

- uses the same compressed format as the overloaded stream/file method
- will return false if the binary content is invalid

function MemberExists(Table: TSQLRecordClass; ID: TID): boolean; **override**;

Overridden method for direct in-memory database engine call

function RetrieveBlobFields(Value: TSQLRecord): boolean; **override**;

Overridden method for direct in-memory database engine call

function SaveToBinary(Stream: TStream): integer; overload;

Save the values into a binary file/stream

- the binary format is a custom compressed format (using our SynLZ fast compression algorithm), with variable-length record storage: e.g. a 27 KB Dali1.json content is stored into a 6 KB Dali2.data file (this data has a text redundant field content in its FirstName field); 502 KB People.json content is stored into a 92 KB People.data file
- returns the number of bytes written into Stream

function SaveToBinary: RawByteString; overload;

Save the values into a binary buffer

- uses the same compressed format as the overloaded stream/file method

function SaveToJSON(Expand: Boolean): RawUTF8; overload;

Save the values into JSON data

function SearchCopy(const FieldName, FieldValue: RawUTF8): pointer;

Search for a field value, according to its SQL content representation

- return a copy of the found TSQLRecord on success, nil if no match
- you should use SearchCopy() instead of SearchInstance(), unless you are sure that the internal TSQLRecord list won't change

function SearchCount(const FieldName, FieldValue: RawUTF8): integer;

Search and count for a field value, according to its SQL content representation

- return the number of found entries on success, 0 if it was not found

function SearchEvent(const FieldName, FieldValue: RawUTF8; OnFind: TFindWhereEqualEvent; Dest: pointer; FoundLimit, FoundOffset: PtrInt): integer;

Search for a field value, according to its SQL content representation

- call the supplied OnFind event on match
- returns the number of found entries
- is just a wrapper around FindWhereEqual() with StorageLock protection

```
function SearchField(const FieldName, FieldValue: RawUTF8; out ResultID:  
TIDDynArray): boolean; override;
```

Search for a field value, according to its SQL content representation

- return true on success (i.e. if some values have been added to ResultID)
- store the results into the ResultID dynamic array
- faster than OneFieldValues method, which creates a temporary JSON content

```
function SearchIndex(const FieldName, FieldValue: RawUTF8): integer;
```

Search for a field value, according to its SQL content representation

- return the found TSQLRecord index on success, -1 if none did match
- warning: it returns a reference to the current index of the unlocked internal list, so you should NOT use without StorageLock/StorageUnlock

```
function SearchInstance(const FieldName, FieldValue: RawUTF8): pointer;
```

Search for a field value, according to its SQL content representation

- return the found TSQLRecord on success, nil if none did match
 - warning: it returns a reference to one item of the unlocked internal list, so you should NOT use this on a read/write table, but rather use the slightly slower but safer SearchCopy() method or make explicit
- ```
StorageLock ... try ... SearchInstance ... finally StorageUnlock end
```

```
function TableHasRows(Table: TSQLRecordClass): boolean; override;
```

*Overridden method for direct in-memory database engine call*

```
function TableRowCount(Table: TSQLRecordClass): Int64; override;
```

*Overridden method for direct in-memory database engine call*

```
function UpdateBlobFields(Value: TSQLRecord): boolean; override;
```

*Overridden method for direct in-memory database engine call*

```
function UpdateOne(ID: TID; const Values: TSQLVarDynArray): boolean; override;
```

*Manual Update of a TSQLRecord field values from a TSQLVar array*

- will update all properties, including BLOB fields and such
- returns TRUE on success, FALSE on any error (e.g. invalid Rec.ID)
- method available since a TSQLRestStorage instance may be created stand-alone, i.e. without any associated Model/TSQLRestServer

```
function UpdateOne(Rec: TSQLRecord; const SentData: RawUTF8): boolean; override;
```

*Manual Update of a TSQLRecord field values*

- Rec.ID specifies which record is to be updated
- will update all properties, including BLOB fields and such
- returns TRUE on success, FALSE on any error (e.g. invalid Rec.ID)
- method available since a TSQLRestStorage instance may be created stand-alone, i.e. without any associated Model/TSQLRestServer

```
class procedure DoAddToListEvent(aDest: pointer; aRec: TSQLRecord; aIndex:
integer);
```

*Low-level TFindWhereEqualEvent callback calling TSynList(aDest).Add(aRec)*

```
class procedure DoCopyEvent(aDest: pointer; aRec: TSQLRecord; aIndex: integer);
```

*Low-level TFindWhereEqualEvent callback setting PPointer(aDest)^ := aRec.CreateCopy*

**class procedure** DoIndexEvent(aDest: pointer; aRec: TSQLRecord; aIndex: integer);  
*Low-level TFindWhereEqualEvent callback setting PInteger(aDest)^ := aIndex*

**class procedure** DoInstanceEvent(aDest: pointer; aRec: TSQLRecord; aIndex: integer);  
*Low-level TFindWhereEqualEvent callback setting PPointer(aDest)^ := aRec*

**class procedure** DoNothingEvent(aDest: pointer; aRec: TSQLRecord; aIndex: integer);  
*Low-level TFindWhereEqualEvent callback doing nothing*

**procedure** DropValues(andUpdateFile: boolean=true);

*Clear all the values of this table*  
 - will reset the associated database file, if any

**procedure** ForEach(WillModifyContent: boolean; OnEachProcess: TFindWhereEqualEvent;  
 Dest: pointer);

*Execute a method on every TSQLRecord item*  
 - the loop execution will be protected via StorageLock/StorageUnlock

**procedure** GetAllIDs(out ID: TIDDynArray);

*Retrieve all IDs stored at once*  
 - will make a thread-safe copy, for unlocked use

**procedure** LoadFromJSON(const aJSON: RawUTF8); overload;

*Load the values from JSON data*  
 - a temporary copy of aJSON is made to ensure it won't be modified in-place  
 - consider using the overloaded PUTF8Char/len method if you don't need this copy

**procedure** LoadFromJSON(JSONBuffer: PUTF8Char; JSONBufferLen: integer); overload;

*Load the values from JSON data*

**procedure** LoadFromResource(ResourceName: string=''; Instance: THandle=0);

*Load the values from binary resource*  
 - the resource name is expected to be the TSQLRecord class name, with a resource type of 10  
 - uses the same compressed format as the overloaded stream/file method  
 - you can specify a library (dll) resource instance handle, if needed

**procedure** ReloadFromFile;

*Will reload all content from the current disk file*  
 - any not saved modification will be lost (e.g. if Updatefile has not been called since)

**procedure** SaveToJSON(Stream: TStream; Expand: Boolean); overload;

*Save the values into JSON data*

**procedure** UpdateFile;

*If file was modified, the file is updated on disk*  
 - this method is called automatically when the TSQLRestStorage instance is destroyed: should  
 should want to call in in some cases, in order to force the data to be saved regularly  
 - do nothing if the table content was not modified  
 - will write JSON content by default, or binary content if BinaryFile property was set to true

**property** BinaryFile: boolean **read** fBinaryFile **write** SetBinaryFile;

*If set to true, file content on disk will expect binary format*

- default format on disk is JSON but can be overridden at constructor call
- binary format should be more efficient in term of speed and disk usage, but can be proprietary
- if you change manually the file format from this property, the storage will be marked as "modified" so that UpdateFile will save the content

**property** CommitShouldNotUpdateFile: boolean **read** fCommitShouldNotUpdateFile **write** fCommitShouldNotUpdateFile;

*Set this property to TRUE if you want the COMMIT statement not to update the associated TSQLVirtualTableJSON*

**property** Count: integer **read** fCount;

*Read-only access to the number of TSQLRecord values*

**property** ExpandedJSON: boolean **read** fExpandedJSON **write** fExpandedJSON;

*JSON writing, can set if the format should be expanded or not*

- by default, the JSON will be in the custom non-expanded format, to save disk space and time
- you can force the JSON to be emitted as an array of objects, e.g. for better human friendliness (reading and modification)

**property** FileName: TFileName **read** fFileName **write** SetFileName;

*Read only access to the file name specified by constructor*

- you can call the TSQLRestServer.StaticDataCreate method to update the file name of an already instantiated static table
- if you change manually the file name from this property, the storage will be marked as "modified" so that UpdateFile will save the content

**property** ID[Index: integer]: TID **read** GetID;

*Read-only access to the ID of a TSQLRecord values*

- warning: this method should be protected via StorageLock/StorageUnlock

**property** Items[Index: integer]: TSQLRecord **read** GetItem;

*Read-only access to the TSQLRecord values, storing the data*

- this returns directly the item class instance stored in memory: if you change the content, it will affect the internal data - so for instance DO NOT change the ID values, unless you may have unexpected behavior
- warning: this method should be protected via StorageLock/StorageUnlock

**property** Value: TSQLRecordObjArray **read** fValue;

*Direct access to the memory of the internal dynamic array storage*

- Items[] is preferred, since it will check the index, but is slightly slower, e.g. in a loop or after a IDToIndex() call
- warning: this method should be protected via StorageLock/StorageUnlock

**TSQLRestStorageInMemoryExternal = class(TSQLRestStorageInMemory)**

*REST storage with direct access to a memory database, to be used as an external SQLite3 Virtual table*

- this is the kind of in-memory table expected by TSQLVirtualTableJSON, in order to be consistent with the internal DB cache

```
constructor Create(aClass: TSQLRecordClass; aServer: TSQLRestServer; const
aFileName: TFileName = ''; aBinaryFile: boolean=false); override;
```

*Initialize the table storage data, reading it from a file if necessary*

- data encoding on file is UTF-8 JSON format by default, or should be some binary format if aBinaryFile is set to true

```
procedure StorageLock(WillModifyContent: boolean; const msg: RawUTF8); override;
```

*This overridden method will notify the Owner when the internal DB content is known to be invalid*

- by default, all REST/CRUD requests and direct SQL statements are scanned and identified as potentially able to change the internal SQL/JSON cache used at SQLite3 database level; but TSQLVirtualTableJSON virtual tables could flush the database content without proper notification
- this overridden implementation will call Owner.FlushInternalDBCACHE

```
TSQLRestStorageRemote = class(TSQLRestStorage)
```

*REST storage with redirection to another REST instance*

- allows redirection of all CRUD operations for a table to another TSQLRest instance, may be a remote TSQLRestClient or a TSQLRestServer
- will be used by TSQLRestServer.RemoteDataCreate() method

```
constructor Create(aClass: TSQLRecordClass; aServer: TSQLRestServer; aRemoteRest:
TSQLRest); reintroduce; virtual;
```

*Initialize the table storage redirection*

- you should not have to use this constructor, but rather the TSQLRestServer.RemoteDataCreate() method which will create and register one TSQLRestStorageRemote instance

```
property RemoteRest: TSQLRest read fRemoteRest;
```

*The remote ORM instance used for data persistence*

- may be a TSQLRestClient or a TSQLRestServer instance

```
TSQLRestStorageShard = class(TSQLRestStorage)
```

*Abstract REST storage with redirection to several REST instances, implementing range ID partitioning for horizontal scaling*

- such database shards will allow to scale with typical BigData storage
- this storage will add items on a server, initializing a new server when the ID reached a defined range
- it will maintain a list of previous storages, then redirect reading and updates to the server managing this ID (if possible - older shards may be deleted/ignored to release resources)
- inherited class should override InitShards/InitNewShard to customize the kind of TSQLRest instances to be used for each shard (which may be local or remote, a SQLite3 engine or an external SQL/NoSQL database)
- see inherited TSQLRestStorageShardDB as defined in mORMotSQLite3.pas

**constructor** Create(aClass: TSQLRecordClass; aServer: TSQLRestServer; aShardRange: TID; aOptions: TSQLRestStorageShardOptions; aMaxShardCount: integer); **reintroduce; virtual;**

*Initialize the table storage redirection for sharding*

- you should not have to use this constructor, but e.g. TSQLRestStorageShardDB.Create on a main TSQLRestServer.StaticDataAdd()
- the supplied aShardRange should be < 1000 - and once set, you should NOT change this value on an existing shard, unless process will be broken

**destructor** Destroy; **override;**

*Finalize the table storage, including Shards[] instances*

**function** ShardFromID(aID: TID; **out** aShardTableIndex: integer; **out** aShard: TSQLRest; aOccasion: TSQLOccasion=soSelect; aShardIndex: PInteger=nil): boolean; **virtual;**

*Retrieve the ORM shard instance corresponding to an ID*

- may return false if the corresponding shard is not available any more
- may return true, and a TSQLRestHookClient or a TSQLRestHookServer instance with its associated index in TSQLRest.Model.Tables[]
- warning: this method should be protected via StorageLock/StorageUnlock

**function** TableHasRows(Table: TSQLRecordClass): boolean; **override;**

*Check if there is some data rows in a specified table*

**function** TableRowCount(Table: TSQLRecordClass): Int64; **override;**

*Get the row count of a specified table*

**procedure** ConsolidateShards; **virtual;**

*You may call this method sometimes to consolidate the sharded data*

- may e.g. merge/compact shards, depending on scaling expectations
- also called by Destroy - do nothing by default

**procedure** RemoveShard(aShardIndex: integer); **virtual;**

*Remove a shard database from the current set*

- it will allow e.g. to delete a \*.dbs file at runtime, without restarting the server
- this default implementation will free and nil fShard[aShardIndex], which is enough for most implementations (e.g. TSQLRestStorageShardDB)

**property** MaxShardCount: integer **read** fMaxShardCount;

*How many shards should be maintained at most*

- if some older shards are available on disk, they won't be loaded by InitShards, and newly added shard via InitNewShard will trigger RemoveShard if the total number of shards

**property** Options: TSQLRestStorageShardOptions **read** fOptions **write** fOptions;

*Defines how this instance will handle its sharding process*

- by default, update/delete operations or per ID retrieval will take place on all shards, whereas EngineList and EngineExecute will only run only on the latest shard (to save resources)

**property** ShardRange: TID **read** fShardRange;

*How much IDs should store each ORM shard instance*

- once set, you should NEVER change this value on an existing shard, otherwise the whole ID partition will fail
- each shard will hold [ShardIndex\*ShardRange..(ShardIndex+1)\*ShardRange-1] IDs

**TSQLRestServerFullMemory = class(TSQLRestServer)**

*A REST server using only in-memory tables*

- this server will use TSQLRestStorageInMemory instances to handle the data in memory, and optionally persist the data on disk as JSON or binary files
- so it will not handle all SQL requests, just basic CRUD commands on separated tables
- at least, it will compile as a TSQLRestServer without complaining for pure abstract methods; it can be used to host some services if database and ORM needs are basic (e.g. if only authentication and CRUD are needed), without the need to link the SQLite3 engine

**constructor** Create(aModel: TSQLModel; **const** aFileName: TFileName; aBinaryFile: boolean=false; aHandleUserAuthentication: boolean=false); **reintroduce**; **overload**; **virtual**;

*Initialize an in-memory REST server with a database file*

- all classes of the model will be created as TSQLRestStorageInMemory
- then data persistence will be initialized using aFileName, but no file will be written to disk, unless you call explicitly UpdateToFile
- if aFileName is left void (''), data will not be persistent

**constructor** Create(aModel: TSQLModel; aHandleUserAuthentication: boolean=false); **overload**; **override**;

*Initialize an in-memory REST server with no database file*

**constructor** CreateWithOwnedAuthenticatedModel( **const** Tables: array of TSQLRecordClass; **const** aUserName, aHashedPassword: RawUTF8; aRoot: RawUTF8='root');

*Initialize an in-memory REST server with a temporary Database Model, and optional authentication by a single user*

- a Model will be created with supplied tables, and owned by the server
- if aUserName is set, authentication will be enabled, and the supplied credentials will be used to authenticate a single user, member of the 'Supervisor' group - in this case, aHashedPassword value should match TSQLAuthUser.PasswordHashHexa expectations

**destructor** Destroy; **override**;

*Finalize the REST server*

- this overridden destructor will write any modification on file (if needed), and release all used memory

**procedure** Flush(Ctxt: TSQLRestServerURIContext);

*This method-base service will be accessible from ModelRoot/Flush URI, and will write any modification into file*

- method parameters signature matches TSQLRestServerCallBack type
- do nothing if file name was not assigned
- can be used from a remote client to ensure that any Add/Update/Delete will be stored to disk, via  
aClient.CallBackPut('Flush', '', dummy)

**procedure** CreateMissingTables(user\_version: cardinal=0; Options: TSQLInitializeTableOptions=[]); **override**;

*Missing tables are created if they don't exist yet for every TSQLRecord class of the Database Model*

- you must call explicitly this before having called StaticDataCreate()
- all table description (even Unique feature) is retrieved from the Model
- this method also create additional fields, if the TSQLRecord definition has been modified; only field adding is available, field renaming or field deleting are not allowed in the FrameWork (in such cases, you must create a new TSQLRecord type)

**procedure** DefinitionTo(Definition: TSynConnectionDefinition); **override**;

*Save the TSQLRestFullMemory properties into a persistent storage object*

- CreateFrom() will expect Definition.ServerName to store the FileName, and use binary storage if Definition.DatabaseName is not void

**procedure** DropDatabase; **virtual**;

*Clear all internal storage content*

**procedure** LoadFromFile; **virtual**;

*Load the content from the specified file name*

- do nothing if file name was not assigned

**procedure** LoadFromStream(aStream: TStream); **virtual**;

*Load the content from the supplied resource*

**procedure** UpdateToFile; **virtual**;

*Write any modification into file*

- do nothing if file name was not assigned

**property** BinaryFile: Boolean **read** fBinaryFile **write** fBinaryFile;

*Set if the file content is to be compressed binary, or standard JSON*

- it will use TSQLRestStorageInMemory LoadFromJSON/LoadFromBinary SaveToJSON/SaveToBinary methods for optimized storage

**property** FileName: TFileName **read** fFileName **write** fFileName;

*The file name used for data persistence*

**property** Storage[aTable: TSQLRecordClass]: TSQLRestStorageInMemory **read** GetStorage;

*Direct access to the storage instances*

- you can then access to Storage[Table].Count and Storage[Table].Items[]

**property** Storages: TSQLRestStorageInMemoryDynArray **read** fStorage;

*Direct access to the storage instances*

- you can then access via Storage[TableIndex].Count and Items[]

## **TSQLRestServerRemoteDB = class(TSQLRestServer)**

*A REST server using another TSQLRest instance for all its ORM process*

- this server will use an internal TSQLRest instance to handle all ORM operations (i.e. access to objects) - e.g. TSQLRestClient for remote access
- it can be used e.g. to host some services on a stand-alone server, with all ORM and data access retrieved from another server: it will allow to easily implement a proxy architecture (for instance, as a DMZ for publishing services, but letting ORM process stay out of scope)
- for per-table redirection, consider using the TSQLRestStorageRemote class via a call to the TSQLRestServer.RemoteDataCreate() method

**constructor** Create(aRemoteRest: TSQLRest; aHandleUserAuthentication: boolean=false); **reintroduce; virtual;**

*Initialize a REST server associated to a given TSQLRest instance*

- the specified TSQLRest will be used for all ORM and data process
- you could use a TSQLRestClient or a TSQLRestServer instance
- the supplied TSQLRest.Model will be used for TSQLRestServerRemoteDB
- note that the TSQLRest instance won't be freed - caller shall ensure that it will stay available at least until TSQLRestServerRemoteDB.Free

**function** AfterDeleteForceCoherency(TableIndex: integer; aID: TID): boolean;  
**override;**

*This method is called internally after any successful deletion to ensure relational database coherency*

- this overridden method will just return TRUE: in this remote access, true coherency will be performed on the ORM server side

**property** RemoteRest: TSQLRest **read** fRemoteRest;

*The remote ORM instance used for data persistence*

- may be a TSQLRestClient or a TSQLRestServer instance

## **TSQLRestClient = class(TSQLRest)**

*A generic REpresentational State Transfer (REST) client*

- is RESTful (i.e. URI) remotely implemented (TSQLRestClientURI e.g.)
- is implemented for direct access to a database (TSQLRestClientDB e.g.)

**function** List(const Tables: array of TSQLRecordClass; const SQLSelect: RawUTF8 = 'RowID'; const SQLWhere: RawUTF8 = ''): TSQLTableJSON; **virtual; abstract;**

*Retrieve a list of members as a TSQLTable*

- implements REST GET collection
- default SQL statement is 'SELECT ID FROM TableName;' (i.e. retrieve the list of all ID of this collection members)
- optional SQLSelect parameter to change the returned fields as in 'SELECT SQLSelect FROM TableName;'
- optional SQLWhere parameter to change the search range or ORDER as in 'SELECT SQLSelect FROM TableName WHERE SQLWhere;'
- using inlined parameters via :(...): in SQLWhere is always a good idea
- for one TClass, you should better use TSQLRest.MultiFieldValues()

```
function ListFmt(const Tables: array of TSQLRecordClass; const SQLSelect,
SQLWhereFormat: RawUTF8; const Args: array of const): TSQLTableJSON; overload;
```

*Retrieve a list of members as a TSQLTable*

- implements REST GET collection
- in this version, the WHERE clause can be created with the same format as FormatUTF8() function, replacing all '%' chars with Args[] values
- using inlined parameters via :(...): in SQLWhereFormat is always a good idea
- for one TClass, you should better use TSQLRest.MultiFieldValues()
- will call the List virtual method internaly

```
function ListFmt(const Tables: array of TSQLRecordClass; const SQLSelect,
SQLWhereFormat: RawUTF8; const Args, Bounds: array of const): TSQLTableJSON;
overload;
```

*Retrieve a list of members as a TSQLTable*

- implements REST GET collection
- in this version, the WHERE clause can be created with the same format as FormatUTF8() function, replacing all '%' chars with Args[], and all '?' chars with Bounds[] (inlining them with :(...): and auto-quoting strings)
- example of use:  

```
Table := ListFmt([TSQLRecord], 'Name', 'ID=?', [], [aID]);
```
- for one TClass, you should better use TSQLRest.MultiFieldValues()
- will call the List virtual method internaly

```
function Refresh(aID: TID; Value: TSQLRecord; var Refreshed: boolean): boolean;
```

*Get a member from its ID*

- implements REST GET collection
- URI is 'ModelRoot/TableName/TableID' with GET method
- returns true on server returned 200/HTTP\_SUCCESS OK success, false on error
- set Refreshed to true if the content changed

```
function Retrieve(aID: TID; Value: TSQLRecord; ForUpdate: boolean=false): boolean;
override;
```

*Get a member from its ID*

- implements REST GET collection
- URI is 'ModelRoot/TableName/TableID' with GET method
- server must return Status 200/HTTP\_SUCCESS OK on success
- if ForUpdate is true, the REST method is LOCK and not GET: it tries to lock the corresponding record, then retrieve its content; caller has to call Unlock() method after Value usage, to release the record

```
function ServiceContainer: TServiceContainer; override;
```

*Access or initialize the internal IoC resolver, used for interface-based remote services, and more generally any Services.Resolve() call*

- create and initialize the internal TServiceContainerClient if no service interface has been registered yet
- may be used to inject some dependencies, which are not interface-based remote services, but internal IoC, without the ServiceRegister() or ServiceDefine() methods - e.g.  

```
aRest.ServiceContainer.InjectResolver([TInfraRepoUserFactory.Create(aRest)], true);
```

```
function TransactionBegin(aTable: TSQLRecordClass; SessionID:
cardinal=CONST_AUTHENTICATION_NOT_USED): boolean; override;
```

*Begin a transaction (calls REST BEGIN Member)*

- by default, Client transaction will use here a pseudo session
- in aClient-Server environment with multiple Clients connected at the same time, you should better use BATCH process, specifying a positive AutomaticTransactionPerRow parameter to BatchStart()

```
function Update(Value: TSQLRecord; const CustomFields: TSQLFieldBits=[];
DoNotAutoComputeFields: boolean=false): boolean; override;
```

*Update a member*

- implements REST PUT collection
- URI is 'ModelRoot/TableName/TableID' with PUT method
- server must return Status 200/HTTP\_SUCCESS OK on success
- this overridden method will call BeforeUpdateEvent and also update BLOB fields, if any ForceBlobTransfert is set and CustomFields=[]

```
procedure Commit(SessionID: cardinal=CONST_AUTHENTICATION_NOT_USED;
RaiseException: boolean=false); override;
```

*End a transaction (calls REST END Member)*

- by default, Client transaction will use here a pseudo session

```
procedure RollBack(SessionID: cardinal=CONST_AUTHENTICATION_NOT_USED); override;
```

*Abort a transaction (calls REST ABORT Member)*

- by default, Client transaction will use here a pseudo session

```
property ForceBlobTransfert: boolean read GetForceBlobTransfert write
SetForceBlobTransfert;
```

*If set to TRUE, all BLOB fields of all tables will be transferred between the Client and the remote Server*

- i.e. Add() Update() will use Blob-related RESTful PUT/POST request
- i.e. Retrieve() will use Blob-related RESTful GET request
- note that the Refresh method won't handle BLOB fields, even if this property setting is set to TRUE
- by default, this property is set to FALSE, which setting will spare bandwidth and CPU
- this property is global to all tables of the model - you can also use ForceBlobTransfertTable[] to force it for a particular table

```
property ForceBlobTransfertTable[aTable: TSQLRecordClass]: Boolean read
GetForceBlobTransfertTable write SetForceBlobTransfertTable;
```

*If set to TRUE for a specified table of the model, all BLOB fields of this tables will be transferred between the Client and the remote Server*

- i.e. Add() Update() will use BLOB-related RESTful PUT/POST request for this table
- i.e. Retrieve() will use BLOB-related RESTful GET request for this table
- note that the Refresh method won't handle BLOB fields, even if this property setting is set to TRUE
- by default, all items of this property are set to FALSE, which setting will spare bandwidth and CPU
- this property is particular to a given tables of the model - you can also use ForceBlobTransfert to force it for a all tables of this model

**property** OnRecordUpdate: TOnRecordUpdate **read** fOnRecordUpdate **write** fOnRecordUpdate;

*This Event is called by Update() to let the client perform the record update (refresh associated report e.g.)*

**property** OnTableUpdate: TOnTableUpdate **read** fOnTableUpdate **write** fOnTableUpdate;

*This Event is called by UpdateFromServer() to let the Client adapt to some rows update (for Marked[] e.g.)*

**TSQLRestClientCallbackItem = record**

*Store information about registered interface callbacks*

**Factory:** TInterfaceFactory;

*/ information about the associated IInvokable*

**ID:** integer;

*The identifier of the callback, as sent to the server side  
- computed from TSQLRestClientURICallbacks.fCurrentID counter*

**Instance:** pointer;

*Weak pointer typecast to the associated IInvokable variable*

**ReleasedFromServer:** boolean;

*Set to TRUE if the instance was released from the server*

**TSQLRestClientCallbacks = class(TSynPersistentLock)**

*Store the references to active interface callbacks on a REST Client*

**Count:** integer;

*How many callbacks are registered*

**List:** array of TSQLRestClientCallbackItem;

*List of registered interface callbacks*

**Owner:** TSQLRestClientURI;

*The associated REST instance*

**constructor** Create(aOwner: TSQLRestClientURI); **reintroduce;**

*Initialize the storage list*

**function** DoRegister(aInstance: pointer; aFactory: TInterfaceFactory): integer;  
**overload;**

*Register a callback event interface instance from a new computed ID*

**function** FindAndRelease(aID: integer): boolean;

*Find a matching entry  
- will call FindIndex(aID) within Safe.Lock/Safe.Unlock  
- returns TRUE if aID was found and aInstance/aFactory set, FALSE otherwise*

**function** FindEntry(**var** aItem: TSQLRestClientCallbackItem): boolean;

*Find a matching callback*

- will call FindIndex(altem.ID) within Safe.Lock/Safe.Unlock
- returns TRUE if altem.ID was found and altem filled, FALSE otherwise

**function** FindIndex(aID: integer): integer;

*Find the index of the ID in the internal list*

- warning: this method should be called within Safe.Lock/Safe.Unlock

**function** UnRegister(aInstance: pointer): boolean; overload;

*Delete all callback events from the internal list, as specified by its instance*

- note that the same IInokable instance may be registered for several IDs

**procedure** DoRegister(aID: Integer; aInstance: pointer; aFactory: TInterfaceFactory); overload;

*Register a callback event interface instance from its supplied ID*

**TSQLRestClientURI = class(TSQLRestClient)**

*A generic REpresentational State Transfer (REST) client with URI*

- URI are standard Collection/Member implemented as ModelRoot/TableName/TableID
- handle RESTful commands GET POST PUT DELETE LOCK UNLOCK

*Used for DI-2.1.1 (page 2553), DI-2.1.1.1 (page 2553), DI-2.1.1.2.2 (page 2554), DI-2.1.1.2.3 (page 2554), DI-2.1.1.2.4 (page 2555).*

**constructor** Create(aModel: TSQLModel); **override**;

*Initialize REST client instance*

**destructor** Destroy; **override**;

*Release memory and close client connection*

- also unlock all still locked records by this client

**function** BatchAdd(Value: TSQLRecord; SendData: boolean; ForceID: boolean=false; **const** CustomFields: TSQLFieldBits=[]): integer;

*Create a new member in current BATCH sequence*

- is a wrapper around TSQLRestBatch.Add() which will be stored in this TSQLRestClientURI instance - be aware that this won't be thread safe

**function** BatchCount: integer;

*Retrieve the current number of pending transactions in the BATCH sequence*

- every call to BatchAdd/Update/Delete methods increases this count

**function** BatchDelete(ID: TID): integer; overload;

*Delete a member in current BATCH sequence*

- is a wrapper around TSQLRestBatch.Delete() which will be stored in this TSQLRestClientURI instance - be aware that this won't be thread safe

**function** BatchDelete(Table: TSQLRecordClass; ID: TID): integer; overload;

*Delete a member in current BATCH sequence*

- is a wrapper around TSQLRestBatch.Delete() which will be stored in this TSQLRestClientURI instance - be aware that this won't be thread safe

**function** BatchSend(**var** Results: TIDynArray): integer; overload;

*Execute a BATCH sequence started by BatchStart method*

- send all pending BatchAdd/Update/Delete statements to the remote server
- URI is 'ModelRoot/TableName/0' with POST (or PUT) method
- will return the URI Status value, i.e. 200/HTTP\_SUCCESS OK on success
- a dynamic array of integers will be created in Results, containing all ROWID created for each BatchAdd call, 200 (=HTTP\_SUCCESS) for all successful BatchUpdate/BatchDelete, or 0 on error
- any error during server-side process MUST be checked against Results[] (the main URI Status is 200 if about communication success, and won't imply that all statements in the BATCH sequence were successful)

**function** BatchStart(aTable: TSQLRecordClass; AutomaticTransactionPerRow: cardinal=0; Options: TSQLRestBatchOptions=[]): boolean; **virtual**;

*Begin a BATCH sequence to speed up huge database change for a given table*

- is a wrapper around TSQLRestBatch.Create() which will be stored in this TSQLRestClientURI instance - be aware that this won't be thread-safe
- if you need a thread-safe "Unit Of Work" process, please use a private TSQLRestBatch instance and the overloaded TSQLRest.BatchSend() method
- call BatchStartAny() or set the aTable parameter to nil if you want to use any kind of TSQLRecord objects within the process, not a single one

**function** BatchStartAny(AutomaticTransactionPerRow: cardinal; Options: TSQLRestBatchOptions=[]): boolean;

*Begin a BATCH sequence to speed up huge database change for any table*

- will call the BatchStart() method with aTable = nil so that you may be able to use any kind of TSQLRecord class within the process
- is a wrapper around TSQLRestBatch.Create() which will be stored in this TSQLRestClientURI instance - be aware that this won't be thread-safe

**function** BatchUpdate(Value: TSQLRecord; **const** CustomFields: TSQLFieldBits=[]; DoNotAutoComputeFields: boolean=false): integer;

*Update a member in current BATCH sequence*

- is a wrapper around TSQLRestBatch.Update() which will be stored in this TSQLRestClientURI instance - be aware that this won't be thread safe
- this method will call BeforeUpdateEvent before TSQLRestBatch.Update

**function** Callback(method: TSQLURIMethod; **const** aMethodName, aSentData: RawUTF8; **out** aResponse: RawUTF8; aTable: TSQLRecordClass=nil; aID: TID=0; aResponseHead: PRawUTF8=nil): integer;

*Wrapper to the protected URI method to call a method on the server, using a ModelRoot/[TableName/[ID/]]MethodName RESTful with any kind of request*

- returns the HTTP error code (e.g. 200/HTTP\_SUCCESS on success)
- for GET/PUT methods, you should better use CallbackGet/CallbackPut

**function** CallbackGet(**const** aMethodName: RawUTF8; **const** aNameValueParameters: **array of const**; **out** aResponse: RawUTF8; aTable: TSQLRecordClass=nil; aID: TID=0; aResponseHead: PRawUTF8=nil): integer;

*Wrapper to the protected URI method to call a method on the server, using a ModelRoot/[TableName/[ID/]]MethodName RESTful GET request*

- returns the HTTP error code (e.g. 200/HTTP\_SUCCESS on success)
- this version will use a GET with supplied parameters (which will be encoded with the URL)

```
function CallbackGetResult(const aMethodName: RawUTF8; const aNameValueParameters:
array of const; aTable: TSQLRecordClass=nil; aID: TID=0): RawUTF8;
```

*Wrapper to the protected URI method to call a method on the server, using a  
ModelRoot/[TableName/[ID/]]MethodName RESTful GET request*

- returns the UTF-8 decoded JSON result (server must reply with one "result": "value" JSON object)
- this version will use a GET with supplied parameters (which will be encoded with the URL)

```
function CallbackPut(const aMethodName, aSentData: RawUTF8; out aResponse: RawUTF8;
aTable: TSQLRecordClass=nil; aID: TID=0; aResponseHead: PRawUTF8=nil): integer;
```

*Wrapper to the protected URI method to call a method on the server, using a  
ModelRoot/[TableName/[ID/]]MethodName RESTful PUT request*

- returns the HTTP error code (e.g. 200/HTTP\_SUCCESS on success)
- this version will use a PUT with the supplied raw UTF-8 data

```
function ExecuteList(const Tables: array of TSQLRecordClass; const SQL: RawUTF8):
TSQLTableJSON; override;
```

*Execute directly a SQL statement, expecting a list of results*

- URI is 'ModelRoot' with GET method, and SQL statement sent as UTF-8
- return a result table on success, nil on failure

```
function List(const Tables: array of TSQLRecordClass; const SQLSelect: RawUTF8 =
'RowID'; const SQLWhere: RawUTF8 = ''): TSQLTableJSON; override;
```

*Retrieve a list of members as a TSQLTable*

- implements REST GET collection
- URI is 'ModelRoot/TableName' with GET method
- SQLSelect and SQLWhere are encoded as 'select=' and 'where=' URL parameters (using inlined parameters via :(...): in SQLWhere is always a good idea)
- server must return Status 200/HTTP\_SUCCESS OK on success

```
function ServerCacheFlush(aTable: TSQLRecordClass=nil; aID: TID=0): boolean;
virtual;
```

*Send a flush command to the remote Server cache*

- this method will remotely call the Cache.Flush() methods of the server instance, to force cohesion of the data
- ServerCacheFlush() with no parameter will flush all stored JSON content
- ServerCacheFlush(aTable) will flush the cache for a given table
- ServerCacheFlush(aTable,aID) will flush the cache for a given record

```
function ServerInternalState: cardinal;
```

*Ask the server for its current internal state revision counter*

- this counter is incremented every time the database is modified
- the returned value is 0 if the database doesn't support this feature
- TSQLTable does compare this value with its internal one to check if its content must be updated

```
function ServerRemoteLog(Sender: TTextWriter; Level: TSynLogInfo; const Text: RawUTF8): boolean; overload; virtual;
```

*Asynchronous call a 'RemoteLog' remote logging method on the server*

- as implemented by mORMot's LogView tool in server mode
- to be used via ServerRemoteLogStart/ServerRemoteLogStop methods
- a dedicated background thread will run the transmission process without blocking the main program execution, gathering log rows in chunks in case of high activity
- map TOnTextWriterEcho signature, so that you will be able to set e.g.:  
TSQLLog.Family.EchoCustom := aClient.ServerRemoteLog;

```
function ServerRemoteLog(Level: TSynLogInfo; const FormatMsg: RawUTF8; const Args: array of const): boolean; overload;
```

*Internal method able to emulate a call to TSynLog.Add.Log()*

- will compute timestamp and event text, than call the overloaded ServerRemoteLog() method

```
function ServerTimestampSynchronize: boolean;
```

*You can call this method to call the remote URI root/Timestamp*

- this can be an handy way of testing the connection, since this method is always available, even without authentication
- returns TRUE if the client time correction has been retrieved
- returns FALSE on any connection error - check LastErrorMessage and LastErrorException to find out the exact connection error

```
function ServiceDefine(const aInterfaces: array of TGUID; aInstanceCreation: TServiceInstanceImplementation=sicSingle; const aContractExpected: RawUTF8=''): boolean; overload;
```

*Register one or several Services on the client side via their interfaces*

- this method expects the interface(s) to have been registered previously:  
TInterfaceFactory.RegisterInterfaces([TypeInfo(IMyInterface), ...]);

```
function ServiceDefine(const aInterface: TGUID; aInstanceCreation: TServiceInstanceImplementation=sicSingle; const aContractExpected: RawUTF8=''; aIgnoreAnyException: boolean=true): TServiceFactoryClient; overload;
```

*Register a Service on the client side via its interface*

- this method expects the interface to have been registered previously:  
TInterfaceFactory.RegisterInterfaces([TypeInfo(IMyInterface), ...]);

```
function ServiceDefineClientDriven(const aInterface: TGUID; out Obj; const aContractExpected: RawUTF8=''): boolean;
```

*Register and retrieve the sicClientDriven Service instance*

- this method expects the interface to have been registered previously:  
TInterfaceFactory.RegisterInterfaces([TypeInfo(IMyInterface), ...]);

```
function ServiceDefineSharedAPI(const aInterface: TGUID; const aContractExpected:
RawUTF8=SERVICE_CONTRACT_NONE_EXPECTED; aIgnoreAnyException: boolean=false):
TServiceFactoryClient;
```

*Register a sicShared Service instance communicating via JSON objects*

- will force SERVICE\_CONTRACT\_NONE\_EXPECTED, ParamsAsJSONObject=true and ResultAsJSONObjectWithoutResult=true
- may be used e.g. for accessing a sessionless public REST/JSON API, i.e.  
 TSQLRestServer.ServiceDefine(...).ResultAsJSONObjectWithoutResult := true
- this method expects the interface to have been registered previously:  
 TInterfaceFactory.RegisterInterfaces([TypeInfo(IMyInterface),...]);
- aIgnoreAnyException may be set to TRUE if the server is likely to not propose this service, and any exception is to be caught

```
function ServiceRegister(const aInterfaces: array of PTypeInfo; aInstanceCreation:
TServiceInstanceImplementation=sicSingle; const aContractExpected: RawUTF8=''):
boolean; overload; virtual;
```

*Register one or several Services on the client side via their interfaces*

- this methods expects a list of interfaces to be registered to the client (e.g. [TypeInfo(IMyInterface)])
- instance implementation pattern will be set by the appropriate parameter
- will return true on success, false if registration failed (e.g. if any of the supplied interfaces is not correct or is not available on the server)
- that is, server side will be called to check for the availability of each interface
- you can specify an optional custom contract for the first interface

```
function ServiceRegister(aInterface: PTypeInfo; aInstanceCreation:
TServiceInstanceImplementation=sicSingle; const aContractExpected: RawUTF8='';
aIgnoreAnyException: boolean=true): TServiceFactory; overload;
```

*Register a Service on the client side via its interface*

- this methods expects one interface to be registered to the client, as  
 Client.ServiceRegister(TypeInfo(IMyInterface),sicShared);
- instance implementation pattern will be set by the appropriate parameter
- will return the corresponding fake class factory on success, nil if registration failed (e.g. if any of supplied interfaces is not correct or is not available on the server)
- that is, server side will be called to check for the availability of each interface
- you can specify an optional custom contract for the first interface

```
function ServiceRegisterClientDriven(aInterface: PTypeInfo; out Obj; const
aContractExpected: RawUTF8=''): boolean; overload;
```

*Register and retrieve the sicClientDriven Service instance*

- will return TRUE on success, filling Obj output variable with the corresponding interface instance
- will return FALSE on error

```
function ServiceRetrieveAssociated(const aServiceName: RawUTF8; out URI:
TSQLRestServerURIDynArray): boolean; overload;
```

*Return all REST server URI associated to this client, for a given service name, the latest registered in first position*

- will lookup for the Interface name without the initial 'I', e.g. 'Calculator' for ICalculator - warning: research is case-sensitive
- this methods is the reverse from ServicePublishOwnInterfaces: it allows to guess an associated REST server which may implement a given service

```
function ServiceRetrieveAssociated(const aInterface: TGUID; out URI:
TSQLRestServerURIDynArray): boolean; overload;
```

*Return all REST server URI associated to this client, for a given service*

- here the service is specified as its TGUID, e.g. IMyInterface
- this method expects the interface to have been registered previously:  
TInterfaceFactory.RegisterInterfaces([TypeInfo(IMyInterface), ...]);
- the URI[] output array contains the matching server URIs, the latest registered in first position
- this methods is the reverse from ServicePublishOwnInterfaces: it allows to guess an associated REST server which may implement a given service

```
function SetUser(const aUserName, aPassword: RawUTF8; aHashedPassword:
Boolean=false): boolean;
```

*Authenticate an User to the current connected Server*

- will call the ModelRoot/Auth service, i.e. call TSQLRestServer.Auth() published method to create a session for this user, with our secure TSQLRestServerAuthenticationDefault authentication scheme
- returns true on success
- calling this method is optional, depending on your user right policy: your Server need to handle authentication
- if saoUserByLogonOrID is defined in the server Options, aUserName may be a TSQLAuthUser.ID integer value and not a TSQLAuthUser.LogonName
- on success, the SessionUser property map the logged user session on the server side
- if aHashedPassword is TRUE, the aPassword parameter is expected to contain the already-hashed value, just as stored in PasswordHashHexa (i.e. SHA256('salt'+Value) as in TSQLAuthUser.SetPasswordPlain method)
- if SSPIAUTH conditional is defined, and aUserName="", a Windows authentication will be performed via TSQLRestServerAuthenticationSSPI - in this case, aPassword will contain the SPN domain for Kerberos (otherwise NTLM will be used), and table TSQLAuthUser shall contain an entry for the logged Windows user, with the LoginName in form 'DomainName\UserName'
- you can directly create the class method ClientSetUser() of a given TSQLRestServerAuthentication inherited class, if neither TSQLRestServerAuthenticationDefault nor TSQLRestServerAuthenticationSSPI match your need

```
function TransactionBegin(aTable: TSQLRecordClass; SessionID:
cardinal=CONST_AUTHENTICATION_NOT_USED): boolean; override;
```

*Begin a transaction*

- implements REST BEGIN collection
- in aClient-Server environment with multiple Clients connected at the same time, you should better use BATCH process, specifying a positive AutomaticTransactionPerRow parameter to BatchStart()
- may be used to speed up some SQL statements as Add/Update/Delete methods
- must be ended with Commit on success
- in the current implementation, the aTable parameter is not used yet
- must be aborted with Rollback if any SQL statement failed
- return true if no transaction is active, false otherwise

```
if Client.TransactionBegin(TSQLRecordPeopleObject) then
try
 // modify the database content, raise exceptions on error
 Client.Commit;
except
 Client.Rollback; // in case of error
end;
```

- you may use the dedicated TransactionBeginRetry() method in case of potential Client concurrent access

```
function TransactionBeginRetry(aTable: TSQLRecordClass; Retries: integer=10):
boolean;
```

*Begin a transaction*

- implements REST BEGIN collection
- in aClient-Server environment with multiple Clients connected at the same time, you should better use BATCH process, specifying a positive AutomaticTransactionPerRow parameter to BatchStart()
- this version retries a TransactionBegin() to be successful within a supplied number of times
- will retry every 100 ms for "Retries" times (excluding the connection time in this 100 ms time period)
- default is to retry 10 times, i.e. within 2 second timeout
- in the current implementation, the aTable parameter is not used yet
- typical usage should be for instance:

```
if Client.TransactionBeginRetry(TSQLRecordPeopleObject,20) then
try
 // modify the database content, raise exceptions on error
 Client.Commit;
except
 Client.Rollback; // in case of error
end;
```

```
function UnLock(Table: TSQLRecordClass; aID: TID): boolean; override;
```

*Unlock the corresponding record*

- URI is 'ModelRoot/TableName/TableID' with UNLOCK method
- returns true on success

**function** UpdateFromServer(const Data: array of TObject; out Refreshed: boolean; PCurrentRow: PInteger=nil): boolean; **virtual**;

*Check if the data may have changed of the server for this objects, and update it if possible*

- only working types are TSQLTableJSON and TSQLRecord descendants
- make use of the InternalState function to check the data content revision
- return true if Data is updated successfully, or false on any error during data retrieval from server (e.g. if the TSQLRecord has been deleted)
- if Data contains only one TSQLTableJSON, PCurrentRow can point to the current selected row of this table, in order to refresh its value
- use this method to refresh the client UI, e.g. via a timer

**function** URI(const url, method: RawUTF8; Resp: PRawUTF8=nil; Head: PRawUTF8=nil; SendData: PRawUTF8=nil): Int64Rec;

*Method calling the remote Server via a RESTful command*

- calls the InternalURI abstract method, which should be overridden with a local, piped or HTTP/1.1 provider
- this method will sign the url with the appropriate digital signature according to the current SessionUser property
- this method will retry the connection in case of authentication failure (i.e. if the session was closed by the remote server, for any reason - mostly a time out) if the OnAuthenticationFailed event handler is set

**procedure** BatchAbort;

*Abort a BATCH sequence started by BatchStart method*

- in short, nothing is sent to the remote server, and current BATCH sequence is closed
- will Free the TSQLRestBatch stored in this TSQLRestClientURI instance

**procedure** CallbackNonBlockingSetHeader(out Header: RawUTF8); **virtual**;

*To be called before CallBack() if the client could ignore the answer*

- do nothing by default, but overridden e.g. in TSQLHttpClientWebsockets

**procedure** Commit(SessionID: cardinal=CONST\_AUTHENTICATION\_NOT\_USED; RaiseException: boolean=false); **override**;

*End a transaction*

- implements REST END collection
- write all pending SQL statements to the disk }

**procedure** DefinitionTo(Definition: TSynConnectionDefinition); **override**;

*Save the TSQLRestClientURI properties into a persistent storage object*

- CreateFrom() will expect Definition.UserName/Password to store the credentials which will be used by SetUser()

**procedure** RollBack(SessionID: cardinal=CONST\_AUTHENTICATION\_NOT\_USED); **override**;

*Abort a transaction*

- implements REST ABORT collection
- restore the previous state of the database, before the call to TransactionBegin }

**procedure** ServerRemoteLogStart(aLogClass: TSynLogClass; aClientOwnedByFamily: boolean);

*Start to send all logs to the server 'RemoteLog' method-based service*

- will associate the EchoCustom callback of the running log class to the ServerRemoteLog() method
- if aClientOwnedByFamily is TRUE, this TSQLRestClientURI instance lifetime will be managed by TSynLogFamily - which is mostly wished
- if aClientOwnedByFamily is FALSE, you should manage this instance life time, and may call ServerRemoteLogStop to stop remote logging
- warning: current implementation will disable all logging for this TSQLRestClientURI instance, to avoid any potential concern (e.g. for multi-threaded process, or in case of communication error): you should therefore use this TSQLRestClientURI connection only for the remote log server, e.g. via TSQLHttpClientGeneric.CreateForRemoteLogging() - do not call ServerRemoteLogStart() from a high-level business client!

**procedure** ServerRemoteLogStop;

*Stop sending all logs to the server 'RemoteLog' method-based service*

- do nothing if aClientOwnedByFamily was TRUE for ServerRemoteLogStart

**class procedure** ServiceNotificationMethodExecute(var Msg: TMessage);

*Event to be triggered when a WM\_\* message is received from the internal asynchronous notification system, to run the callback in the main UI thread*

- WM\_\* message identifier should have been set e.g. via the associated ServiceNotificationMethodViaMessages(Form.Handle, WM\_USER)
- message will be sent for any interface-based service method callback which expects no result (i.e. no out parameter nor function result), so is safely handled as asynchronous notification
- is defines as a class procedure, since the underlying TSQLRestClientURI instance has no impact here: a single WM\_\* handler is enough for several TSQLRestClientURI instances

**procedure** ServiceNotificationMethodViaMessages(hWnd: HWND; Msg: UINT);

*Set a HWND/WM\_\* pair to let interface-based services notification callbacks be processed safely in the main UI thread, via Windows messages*

- by default callbacks are executed in the transmission thread, e.g. the WebSockets client thread: using VCL Synchronize() method may trigger some unexpected race conditions, e.g. when asynchronous notifications are received during a blocking REST command - this message-based mechanism will allow safe and easy notification for any VCL client application
- the associated ServiceNotificationMethodExecute() method shall be called in the client HWND TForm for the defined WM\_\* message

**procedure** ServicePublishOwnInterfaces(OwnServer: TSQLRestServer);

*Allow to notify a server the services this client may be actually capable*

- when this client will connect to a remote server to access its services, it will register its own services, supplying its TSQLRestServer instance, and its corresponding public URI, within its '\_contract\_' internal call
- it will allow automatic service discovery of Peer To Peer Servers, without the need of an actual centralized SOA catalog service: any client could retrieve an associated REST server for a given service, via the ServiceRetrieveAssociated method

**procedure** SessionClose;

*Clear session and call the /auth service on the server to notify shutdown*

- is called by Destroy and SetUser/ClientSetUser methods, so you should not have usually to call this method directly

**property** ComputeSignature: TSQLRestServerAuthenticationSignedURIComputeSignature  
**read** fComputeSignature **write** fComputeSignature;

*Customize the session\_signature signing algorithm with a specific function*

- will be used by TSQLRestServerAuthenticationSignedURI classes, e.g. TSQLRestServerAuthenticationDefault instead of the algorithm specified by the server at session handshake

**property** LastErrorCode: integer **read** fLastErrorCode;

*Low-level error code, as returned by server*

- check this value about HTTP\_\* constants
- HTTP\_SUCCESS or HTTP\_CREATED mean no error
- otherwise, check LastErrorMessage property for additional information
- this property value will record status codes returned by URI() method

**property** LastErrorException: ExceptClass **read** fLastErrorException;

*Low-level exception class, if any*

- will record any Exception class raised within URI() method
- contains nil if URI() execution did not raise any exception (which is the most expected behavior, since server-side errors are trapped into LastErrorCode/LastErrorMessage properties)

**property** LastErrorMessage: RawUTF8 **read** fLastErrorMessage;

*Low-level error message, as returned by server*

- this property value will record content returned by URI() method in case of an error, or "" if LastErrorCode is HTTP\_SUCCESS or HTTP\_CREATED

**property** MaximumAuthenticationRetry: Integer **read** fMaximumAuthenticationRetry  
**write** fMaximumAuthenticationRetry;

*Maximum additional retry occurrence*

- default is 1, i.e. will retry once
- set OnAuthenticationFailed to nil in order to avoid any retry

**property** OnAuthenticationFailed: TOnAuthenticationFailed **read** fOnAuthenticationFailed  
**write** fOnAuthenticationFailed;

*This Event is called in case of remote authentication failure*

- client software can ask the user to enter a password and user name
- if no event is specified, the URI() method will return directly an HTTP\_FORBIDDEN "403 Forbidden" error code

**property** OnFailed: TOnClientFailed **read** fOnFailed **write** fOnFailed;

*This Event is called if URI() was not successful*

- the callback will have all needed information
- e.g. Call^.OutStatus=HTTP\_NOTIMPLEMENTED indicates a broken connection

**property** OnIdle: TOnIdleSynBackgroundThread read fOnIdle write fOnIdle;

*Set a callback event to be executed in loop during remote blocking process, e.g. to refresh the UI during a somewhat long request*

- if not set, the request will be executed in the current thread, so may block the User Interface
- you can assign a callback to this property, calling for instance Application.ProcessMessages, to execute the remote request in a background thread, but let the UI still be reactive: the TLoginForm.OnIdleProcess and OnIdleProcessForm methods of mORMotUILogin.pas will match this property expectations

**property** OnIdleBackgroundThreadActive: Boolean read GetOnIdleBackgroundThreadActive;

*TRUE if the background thread is active, and OnIdle event is called during process*

- to be used e.g. to ensure no re-entrance from User Interface messages

**property** OnSetUser: TOnRestClientNotify read fOnSetUser write fOnSetUser;

*This Event is called when a user is authenticated*

- is called always, on each TSQLRestClientURI.SetUser call
- you can check the Sender.SessionUser property pointing to the current authenticated user, or nil if authentication failed
- could be used to refresh the User Interface layout according to current authenticated user rights, or to subscribe to some services via callbacks

**property** RetryOnceOnTimeout: Boolean read fRetryOnceOnTimeout write fRetryOnceOnTimeout;

*If the client shall retry once after "408 REQUEST TIMEOUT" server error*

- this is about an HTTP error 408 returned by the server, e.g. when the ORM lock or transaction could not be acquired in a good enough time: this value does not apply to the client side timeout, e.g. at HTTP level

**property** SessionHeartbeatSeconds: integer read fSessionHeartbeatSeconds write SetSessionHeartbeatSeconds;

*Frequency of Callback/\_ping\_ calls to maintain session and services*

- will be used to call SessionRenewEvent at the specified period, so that the session and all sicClientDriven instances will be maintained on the server side as long as the client connection stands
- equals half SessionServerTimeout or 25 minutes (if lower) by default - 25 minutes matches the default service timeout of 30 minutes
- you may set 0 to disable this SOA-level heartbeat feature

**property** SessionHTTPHeader: RawUTF8 read fSessionHTTPHeader write fSessionHTTPHeader;

*Access to the low-level HTTP header used for authentication*

- you can force here your own header, e.g. a JWT as authentication bearer or as in TSQLRestServerAuthenticationHttpAbstract.ClientSetUserHttpOnlyUser

**property** SessionID: cardinal read fSessionID;

*The current session ID as set after a successfull SetUser() method call*

- equals 0 (CONST\_AUTHENTICATION\_SESSION\_NOT\_STARTED) if the session is not started yet - i.e. if SetUser() call failed
- equals 1 (CONST\_AUTHENTICATION\_NOT\_USED) if authentication mode is not enabled - i.e. after a fresh Create() without SetUser() call

**property** SessionServer: RawUTF8 read fSessionServer;

*The remote server executable name, as retrieved after a SetUser() success*

**property** SessionServerTimeout: integer read fSessionServerTimeout;

*The remote server session timeout in minutes, as retrieved after a SetUser() success*  
 - will be used to set SessionHeartbeatSeconds default

**property** SessionUser: TSQLAuthUser read fSessionUser;

*The current user as set by SetUser() method*  
 - contains nil if no User is currently authenticated  
 - once authenticated, a TSQLAuthUser instance is set, with its ID, LogonName, DisplayName, PasswordHashHexa and GroupRights (filled with a TSQLAuthGroup ID casted as a pointer) properties - you can retrieve any optional binary data associated with this user via RetrieveBlobFields()

**property** SessionVersion: RawUTF8 read fSessionVersion;

*The remote server version, as retrieved after a SetUser() success*

**TSQLRestClientURIDll = class(TSQLRestClientURI)**

*Rest client with remote access to a server through a dll*

- use only one TURIMapRequest function for the whole communication
- the data is stored in Global system memory, and freed by GlobalFree()

*Used for DI-2.1.1.2.1 (page 2554).*

**constructor** Create(aModel: TSQLModel; const DllName: TFileName); reintroduce; overload;

*Connect to a server contained in a shared library*  
 - this dll must contain at least a URIRequest entry  
 - raise an exception if the shared library is not found or invalid

*Used for DI-2.1.1.2.1 (page 2554).*

**constructor** Create(aModel: TSQLModel; aRequest: TURIMapRequest); reintroduce; overload;

*Connect to a server from a remote function*

*Used for DI-2.1.1.2.1 (page 2554).*

**destructor** Destroy; override;

*Release memory and handles*

**TSQLRestClientRedirect = class(TSQLRestClientURI)**

*Rest client with redirection to another TSQLRest instance*

**constructor** Create(aRedirected: TSQLRest); reintroduce; overload;

*Will pass all client commands to the supplied TSQLRest instance*  
 - aRedirected is expected to be either a TSQLRestClientURI or a TSQLRestServer  
 - will make a copy of the aRedirected.Model, and own it

**constructor** Create(aModel: TSQLModel); overload; override;

*Prepare the redirection, to be enabled later via RedirectTo()*  
- the supplied aModel instance will be owned by this class

**constructor** CreateOwned(aRedirected: TSQLRestServer); reintroduce;

*Will pass all client commands to the supplied TSQLRestServer instance*  
- aRedirected will be owned by this TSQLRestClientRedirect

**procedure** RedirectTo(aRedirected: TSQLRest);

*Allows to change redirection to a client on the fly*  
- if aRedirected is nil, redirection will be disabled and any URI() call will return an HTTP\_GATEWAYTIMEOUT 504 error status

**TSQLRestClientURIMessage = class(TSQLRestClientURI)**

*Rest client with remote access to a server through Windows messages*  
- use only one TURIMapRequest function for the whole communication  
- the data is sent and received by using the standard and fast WM\_COPYDATA message  
- named pipes seems to be somewhat better for bigger messages under XP  
- this class is thread-safe, since its URI() method is protected by a lock

*Used for DI-2.1.1.2.3 (page 2554).*

**constructor** Create(aModel: TSQLModel; const ServerWindowName, ClientWindowName: string; TimeOutMS: cardinal); reintroduce; overload;

*Connect to a server from its window name*  
- ServerWindowName is of UnicodeString type since Delphi 2009 (direct use of FindWindow()=FindWindowW() Win32 API)  
- this version will instantiate and create a Client Window from a Window Name, by using low level Win32 API: therefore, the Forms unit is not needed with this constructor (save some KB)

*Used for DI-2.1.1.2.3 (page 2554).*

**constructor** Create(aModel: TSQLModel; const ServerWindowName: string; ClientWindow: HWND; TimeOutMS: cardinal); reintroduce; overload;

*Connect to a server from its window name*  
- ServerWindowName is of UnicodeString type since Delphi 2009 (direct use of FindWindow()=FindWindowW() Win32 API)  
- this version must supply a Client Window handle

*Used for DI-2.1.1.2.3 (page 2554).*

**destructor** Destroy; override;

*Release the internal Window class created, if any*

**procedure** DefinitionTo(Definition: TSynConnectionDefinition); override;

*Save the TSQLRestClientURIMessage properties into a persistent storage object*  
- CreateFrom() will expect Definition.ServerName to store the ServerWindowName, and Definition.DatabaseName to be the ClientWindowName

**procedure** WMCopyData(var Msg : TWMCopyData); message WM\_COPYDATA;

*Event to be triggered when a WM\_COPYDATA message is received from the server*  
- to be called by the corresponding "message WM\_COPYDATA;" method in the client TForm instance

**property** DoNotProcessMessages: boolean **read** fDoNotProcessMessages **write** fDoNotProcessMessages;

*Define if the client will process the Windows Messages loop*  
- set to TRUE if the client is used outside the main GUI application thread

**TSQLRestClientURINamedPipe = class(TSQLRestClientURI)**

*Rest client with remote access to a server through a Named Pipe*  
- named pipe is fast and optimized under Windows  
- can be accessed locally or remotely  
- this class is thread-safe, since its URI() method is protected by a lock

*Used for DI-2.1.1.2.2 (page 2554).*

**constructor** Create(aModel: TSQLModel; **const** ApplicationName: TFileName);  
**reintroduce;**

*Connect to a server contained in a running application*  
- the server must have been declared by a previous TSQLRestServer.ExportServer(ApplicationName) call with ApplicationName as user-defined server identifier ('DBSERVER' e.g.)  
- ApplicationName is of UnicodeString type since Delphi 2009 (direct use of Wide Win32 API version)  
- this server identifier is appended to '\\.\pipe\mORMot\_' to obtain the full pipe name to connect to ('\\.\pipe\mORMot\_\_DBSERVER' e.g.)  
- this server identifier may also contain a remote computer name, and must be fully qualified ('\\ServerName\pipe\ApplicationName' e.g.)  
- raise an exception if the server is not running or invalid

*Used for DI-2.1.1.2.2 (page 2554).*

**procedure** DefinitionTo(Definition: TSynConnectionDefinition); **override;**

*Save the TSQLRestClientURI Message properties into a persistent storage object*  
- CreateFrom() will expect Definition.ServerName to store the expected ApplicationName

**TSynValidateRest = class(TSynValidate)**

*Will define a validation to be applied to a TSQLRecord field, using if necessary an associated TSQLRest instance and a TSQLRecord class*  
- a typical usage is to validate a value to be unique in the table (implemented in the TSynValidateUniqueField class)  
- the optional associated parameters are to be supplied JSON-encoded  
- ProcessRest and ProcessRec properties will be filled before Validate method call by TSQLRecord.Validate()

**property** ProcessRec: TSQLRecord **read** fProcessRec;

*The associated TSQLRecord instance*  
- this value is updated by Validate with the current TSQLRecord instance to be validated  
- it can be used in the overridden DoValidate method

**property** ProcessRest: TSQLRest read fProcessRest;

*The associated TSQLRest instance*

- this value is updated by Validate with the current TSQLRest used for the validation
- it can be used in the overridden DoValidate method

**TSynValidateUniqueField = class**(TSynValidateRest)

*Will define a validation for a TSQLRecord Unique text field*

- this class will handle only textual fields, not numeric values
- it will check that the field value is not void
- it will check that the field value is not a duplicate

**TSynValidateUniqueFields = class**(TSynValidateRest)

*Will define an unicity validation for a set of TSQLRecord text fields*

- field names should be specified as CSV in the JSON "FieldNames" property in the constructor, or the Parameters field, e.g. like

```
TSQLSampleRecord.AddFilterOrValidate('propA',
 TSynValidateUniqueFields.Create('{"FieldNames":"propA,propB"}'));
```

- this class will handle only textual fields, not numeric values
- it will check that the field values are not a duplicate

**property** FieldNames: TRawUTF8DynArray read fFieldNames;

*The validated field names*

**TSQLVirtualTablePreparedConstraint = packed record**

*A WHERE constraint as set by the TSQLVirtualTable.Prepare() method*

**Column: integer;**

*Column on left-hand side of constraint*

- The first column of the virtual table is column 0
- The RowID of the virtual table is column -1
- Hidden columns are counted when determining the column index
- if this field contains VIRTUAL\_TABLE\_IGNORE\_COLUMN (-2), TSQLVirtualTable.Prepare() should ignore this entry

**OmitCheck: boolean;**

*If true, the constraint is assumed to be fully handled by the virtual table and is not checked again by SQLite*

- By default (OmitCheck=false), the SQLite core double checks all constraints on each row of the virtual table that it receives
- TSQLVirtualTable.Prepare() can set this property to true

**Operation: TCompareOperator;**

*Constraint operator*

- MATCH keyword is parsed into soBeginWith, and should be handled as soBeginWith, soContains or soSoundsLike\* according to the effective expression text value ('text\*', '%text'...)

**Value: TSQLVar;**

*The associated expression*

- TSQLVirtualTable.Prepare() must set Value.VType to not svtUnknown (e.g. to svtNull), if an expression is expected at vt\_BestIndex() call
- TSQLVirtualTableCursor.Search() will receive an expression value, to be retrieved e.g. via sqlite3\_value\_\*() functions

**TSQLVirtualTablePreparedOrderBy = record**

*An ORDER BY clause as set by the TSQLVirtualTable.Prepare() method*

- warning: this structure should match exactly TSQLite3IndexOrderBy as defined in SynSQLite3

**Column: Integer;**

*Column number*

- The first column of the virtual table is column 0
- The RowID of the virtual table is column -1
- Hidden columns are counted when determining the column index.

**Desc: boolean;**

*True for DESCending order, false for ASCending order.*

**TSQLVirtualTablePrepared = object(TObject)**

*The WHERE and ORDER BY statements as set by TSQLVirtualTable.Prepare*

- Where[] and OrderBy[] are fixed sized arrays, for fast and easy code

**EstimatedCost: TSQLVirtualTablePreparedCost;**

*Estimated cost of using this prepared index*

- SQLite uses this value to make a choice between several calls to the TSQLVirtualTable.Prepare() method with several expressions

**EstimatedRows: Int64;**

*Estimated number of rows of using this prepared index*

- does make sense only if EstimatedCost=costFullScan
- SQLite uses this value to make a choice between several calls to the TSQLVirtualTable.Prepare() method with several expressions
- is used only starting with SQLite 3.8.2

**OmitOrderBy: boolean;**

*If true, the ORDER BY statement is assumed to be fully handled by the virtual table and is not checked again by SQLite*

- By default (OmitOrderBy=false), the SQLite core sort all rows of the virtual table that it receives according in order

**OrderBy: array[0..MAX\_SQLFIELDS-1] of TSQLVirtualTablePreparedOrderBy;**

*ORDER BY statement parameters*

**OrderByCount: integer;**

*Numver of ORDER BY statement parameters in OrderBy[]*

**Where: array[0..MAX\_SQLFIELDS-1] of TSQLVirtualTablePreparedConstraint;**

*WHERE statement parameters, in TSQLVirtualTableCursor.Search() order*

**WhereCount: integer;**

*Number of WHERE statement parameters in Where[] array*

**function** IsWhereIDEquals(CalledFromPrepare: Boolean): boolean;

*Returns TRUE if there is only one ID=? statement in this search*

**function** IsWhereOneFieldEquals: boolean;

*Returns TRUE if there is only one FieldName=? statement in this search*

**TSQVirtualTableModuleProperties = record**

*Used to store and handle the main specifications of a TSQVirtualTableModule*

**CursorClass: TSQVirtualTableCursorClass;**

*The associated cursor class*

**Features: TSQVirtualTableFeatures;**

*A set of features of a Virtual Table*

**FileExtension: TFileName;**

*Can be used to customize the extension of the filename*

*- the '.' is not to be included*

**RecordClass: TSQRecordClass;**

*The associated TSQRecord class*

*- used to retrieve the field structure with all collations*

**StaticClass: TSQRestStorageClass;**

*The associated TSQRestStorage class used for storage*

*- is e.g. TSQRestStorageInMemory for TSQVirtualTableJSON, TSQRestStorageExternal for TSQVirtualTableExternal, or nil for TSQVirtualTableLog*

**TSQVirtualTableModule = class(TObject)**

*Parent class able to define a Virtual Table module*

*- in order to implement a new Virtual Table type, you'll have to define a so called "Module" to handle the fields and data access and an associated TSQVirtualTableCursorClass for handling the SELECT statements*

*- for our framework, the SQLite3 unit will inherit from this class to define a TSQVirtualTableModuleSQLite3 class, which will register the associated virtual table definition into a SQLite3 connection, on the server side*

*- children should override abstract methods in order to implement the association with the database engine itself*

**constructor** Create(aTableClass: TSQVirtualTableClass; aServer: TSQRestServer);  
**virtual;**

*Create the Virtual Table instance according to the supplied class*

*- inherited constructors may register the Virtual Table to the specified database connection*

**function** FileName(const aTableName: RawUTF8): TFileName; **virtual;**

*Retrieve the file name to be used for a specific Virtual Table*

*- returns by default a file located in the executable folder, with the table name as file name, and module name as extension*

**property** CursorClass: TSQLVirtualTableCursorClass **read** fFeatures.CursorClass;

*The associated virtual table cursor class*

**property** Features: TSQLVirtualTableFeatures **read** fFeatures.Features;

*The Virtual Table module features*

**property** FileExtension: TFileName **read** fFeatures.FileExtension;

*The extension of the filename (without any left '.')*

**property** FilePath: TFileName **read** fFilePath **write** fFilePath;

*The full path to be used for the filename*

- is "" by default, i.e. will use the executable path
- you can specify here a custom path, which will be used by the FileName method to retrieve the .json/.data full file

**property** ModuleName: RawUTF8 **read** fModuleName;

*The corresponding module name*

**property** RecordClass: TSQLRecordClass **read** fFeatures.RecordClass;

*The associated TSQLRecord class*

- is mostly nil, e.g. for TSQLVirtualTableJSON
- used to retrieve the field structure for TSQLVirtualTableLog e.g.

**property** Server: TSQLRestServer **read** fServer;

*The associated Server instance*

- may be nil, in case of direct access to the virtual table

**property** StaticClass: TSQLRestStorageClass **read** fFeatures.StaticClass;

*The associated TSQLRestStorage class used for storage*

- e.g. returns TSQLRestStorageInMemory for TSQLVirtualTableJSON, or TSQLRestStorageExternal for TSQLVirtualTableExternal, or either nil for TSQLVirtualTableLog

**property** TableClass: TSQLVirtualTableClass **read** fTableClass;

*The associated virtual table class*

**TSQLVirtualTable = class(TObject)**

*Abstract class able to access a Virtual Table content*

- override the Prepare/Structure abstract virtual methods for reading access to the virtual table content
- you can optionally override Drop/Delete/Insert/Update/Rename/Transaction virtual methods to allow content writing to the virtual table
- the same virtual table mechanism can be used with several database module, with diverse database engines

**constructor** Create(aModule: TSQLVirtualTableModule; **const** aTableName: RawUTF8; FieldCount: integer; Fields: PPUTF8CharArray); **virtual**;

*Create the virtual table access instance*

- the created instance will be released when the virtual table will be disconnected from the DB connection (e.g. xDisconnect method for SQLite3)
- shall raise an exception in case of invalid parameters (e.g. if the supplied module is not associated to a TSQLRestServer instance)
- aTableName will be checked against the current aModule.Server.Model to retrieve the corresponding TSQLRecordVirtualTableAutoID class and create any associated Static: TSQLRestStorage instance

**destructor** Destroy; **override**;

*Release the associated memory, especially the Static instance*

**function** Delete(aRowID: Int64): boolean; **virtual**;

*Called to delete a virtual table row*

- should return true on success, false otherwise
- does nothing by default, and returns false, i.e. always fails

**function** Drop: boolean; **virtual**;

*Called when a DROP TABLE statement is executed against the virtual table*

- should return true on success, false otherwise
- does nothing by default, and returns false, i.e. always fails

**function** Insert(aRowID: Int64; **var** Values: TSQLVarDynArray; **out** insertedRowID: Int64): boolean; **virtual**;

*Called to insert a virtual table row content from an array of TSQLVar*

- should return true on success, false otherwise
- should return the just created row ID in insertedRowID on success
- does nothing by default, and returns false, i.e. always fails

**class function** ModuleName: RawUTF8;

*Retrieve the corresponding module name*

- will use the class name, trimming any T/TSQ/TSQVirtual/TSQVirtualTable\*
- when the class is instanciated, it will be faster to retrieve the same value via Module.ModuleName

**function** Prepare(**var** Prepared: TSQLVirtualTablePrepared): boolean; **virtual**;

*Called to determine the best way to access the virtual table*

- will prepare the request for TSQLVirtualTableCursor.Search()
- in Where[], Expr must be set to not 0 if needed for Search method, and OmitCheck to true if double check is not necessary
- OmitOrderBy must be set to true if double sort is not necessary
- EstimatedCost and EstimatedRows should receive the estimated cost
- default implementation will let the DB engine perform the search, and prepare for ID=? statement if vtWhereIDPrepared was set

**function** Rename(**const** NewName: RawUTF8): boolean; **virtual**;

*Called to rename the virtual table*

- by default, returns false, i.e. always fails

**function** Structure: RawUTF8; **virtual**;

*Should retrieve the format (the names and datatypes of the columns) of the virtual table, as expected by sqlite3\_declare\_vtab()*

- default implementation is to retrieve the structure for the associated Module.RecordClass property (as set by GetTableModuleProperties) or the Static.StoredClass: in both cases, column numbering will follow the TSQLRecord published field order (TSQLRecord.RecordProps.Fields[])

**class function** StructureFromClass(aClass: TSQLRecordClass; **const** aTableName: RawUTF8): RawUTF8;

*A generic method to get a 'CREATE TABLE' structure from a supplied TSQLRecord class*

- is called e.g. by the Structure method

**function** Transaction(aState: TSQLVirtualTableTransaction; aSavePoint: integer): boolean; **virtual**;

*Called to begin a transaction to the virtual table row*

- do nothing by default, and returns false in case of RollBack/RollBackto

- aSavePoint is used for vttSavePoint, vttRelease and vttRollBackTo only

- note that if you don't nest your writing within a transaction, SQLite will call vttCommit for each INSERT/UPDATE/DELETE, just like a regular SQLite database - it could make bad written code slow even with Virtual Tables

**function** Update(oldRowID, newRowID: Int64; **var** Values: TSQLVarDynArray): boolean; **virtual**;

*Called to update a virtual table row content from an array of TSQLVar*

- should return true on success, false otherwise

- does nothing by default, and returns false, i.e. always fails

**class procedure** GetTableModuleProperties( **var** aProperties: TVirtualTableModuleProperties); **virtual**; **abstract**;

*Should return the main specifications of the associated TSQLVirtualTableModule*

**property** Module: TSQLVirtualTableModule **read** fModule;

*The associated Virtual Table module*

**property** Static: TSQLRest **read** fStatic;

*The associated virtual table storage instance*

- can be e.g. a TSQLRestStorageInMemory for TSQLVirtualTableJSON, or a

TSQLRestStorageExternal for TSQLVirtualTableExternal, or nil for TSQLVirtualTableLog

**property** StaticStorage: TSQLRestStorage **read** fStaticStorage;

*The associated virtual table storage instance, if is a TSQLRestStorage*

**property** StaticTable: TSQLRecordClass **read** fStaticTable;

*The associated virtual table storage table*

**property** StaticTableIndex: integer **read** fStaticTableIndex;

*The associated virtual table storage index in its Model.Tables[] array*

**property** TableName: RawUTF8 **read** fTableName;

*The name of the Virtual Table, as specified following the TABLE keyword in the CREATE VIRTUAL TABLE statement*

**TSQLVirtualTableCursor = class(TObject)**

*Abstract class able to define a Virtual Table cursor*

- override the Search/HasData/Column/Next abstract virtual methods to implement the search process

**constructor** Create(aTable: TSQLVirtualTable); **virtual;**

*Create the cursor instance*

- it will be destroyed when by the DB engine (e.g. via xClose in SQLite3)

**function** Column(aColumn: integer; var aResult: TSQLVar): boolean; **virtual; abstract;**

*Called to retrieve a column value of the current data row into a TSQLVar*

- if aColumn=-1, should return the row ID as varInt64 into aResult

- should return false in case of an error, true on success

**function** HasData: boolean; **virtual; abstract;**

*Called after Search() to check if there is data to be retrieved*

- should return false if reached the end of matching data

**function** Next: boolean; **virtual; abstract;**

*Called to go to the next row of matching data*

- should return false on low-level database error (but true in case of a valid call, even if HasData will return false, i.e. no data match)

**function** Search(const Prepared: TSQLVirtualTablePrepared): boolean; **virtual; abstract;**

*Called to begin a search in the virtual table*

- the TSQLVirtualTablePrepared parameters were set by TSQLVirtualTable.Prepare and will contain both WHERE and ORDER BY statements (retrieved e.g. by x\_BestIndex() from a TSQLite3IndexInfo structure)

- Prepared will contain all prepared constraints and the corresponding expressions in the Where[].Value field

- should move cursor to first row of matching data

- should return false on low-level database error (but true in case of a valid call, even if HasData will return false, i.e. no data match)

**property** Table: TSQLVirtualTable **read** fTable;

*The associated Virtual Table class instance*

**TSQLVirtualTableCursorIndex = class(TSQLVirtualTableCursor)**

*A generic Virtual Table cursor associated to Current/Max index properties*

**function** HasData: boolean; **override;**

*Called after Search() to check if there is data to be retrieved*

- will return false if reached the end of matching data, according to the fCurrent/fMax protected properties values

**function** Next: boolean; **override**;

*Called to go to the next row of matching data*

- will return false on low-level database error (but true in case of a valid call, even if HasData will return false, i.e. no data match)
- will check the fCurrent/fMax protected properties values

**function** Search(const Prepared: TSQLVirtualTablePrepared): boolean; **override**;

*Called to begin a search in the virtual table*

- this no-op version will mark EOF, i.e. fCurrent=0 and fMax=-1

TSQLVirtualTableCursorJSON = **class**(TSQLVirtualTableCursorIndex)

*A Virtual Table cursor for reading a TSQLRestStorageInMemory content*

- this is the cursor class associated to TSQLVirtualTableJSON

**function** Column(aColumn: integer; var aResult: TSQLVar): boolean; **override**;

*Called to retrieve a column value of the current data row into a TSQLVar*

- if aColumn=-1, will return the row ID as varInt64 into aResult
- will return false in case of an error, true on success

**function** Search(const Prepared: TSQLVirtualTablePrepared): boolean; **override**;

*Called to begin a search in the virtual table*

- the TSQLVirtualTablePrepared parameters were set by TSQLVirtualTable.Prepare and will contain both WHERE and ORDER BY statements (retrieved by x\_BestIndex from a TSQLite3IndexInfo structure)
- Prepared will contain all prepared constraints and the corresponding expressions in the Where[].Value field
- will move cursor to first row of matching data
- will return false on low-level database error (but true in case of a valid call, even if HasData will return false, i.e. no data match)
- only handled WHERE clause is for "ID = value" - other request will return all records in ID order, and let the database engine handle it

TSQLVirtualTableJSON = **class**(TSQLVirtualTable)

*A TSQLRestStorageInMemory-based virtual table using JSON storage*

- for ORM access, you should use TSQLModel.VirtualTableRegister method to associated this virtual table module to a TSQLRecordVirtualTableAutoID class
- transactions are not handled by this module
- by default, no data is written on disk: you will need to call explicitly aServer.StaticVirtualTable[aClass].UpdateToFile for file creation or refresh
- file extension is set to '.json'

**constructor** Create(aModule: TSQLVirtualTableModule; **const** aTableName: RawUTF8; FieldCount: integer; Fields: PPUTF8CharArray); **override**;

*Create the virtual table access instance*

- the created instance will be released when the virtual table will be disconnected from the DB connection (e.g. xDisconnect method for SQLite3)
- shall raise an exception in case of invalid parameters (e.g. if the supplied module is not associated to a TSQLRestServer instance)
- aTableName will be checked against the current aModule.Server.Model to retrieve the corresponding TSQLRecordVirtualTableAutoID class and create any associated Static: TSQLRestStorage instance

**function** Delete(aRowID: Int64): boolean; **override**;

*Called to delete a virtual table row*

- returns true on success, false otherwise

**function** Drop: boolean; **override**;

*Called when a DROP TABLE statement is executed against the virtual table*

- returns true on success, false otherwise

**function** Insert(aRowID: Int64; **var** Values: TSQLVarDynArray; **out** insertedRowID: Int64): boolean; **override**;

*Called to insert a virtual table row content from a TSQLVar array*

- column order follows the Structure method, i.e. StoredClassRecordProps.Fields[] order
- returns true on success, false otherwise
- returns the just created row ID in insertedRowID on success
- does nothing by default, and returns false, i.e. always fails

**function** Prepare(**var** Prepared: TSQLVirtualTablePrepared): boolean; **override**;

*Called to determine the best way to access the virtual table*

- will prepare the request for TSQLVirtualTableCursor.Search()
- only prepared WHERE statement is for "ID = value"
- only prepared ORDER BY statement is for ascending IDs

**function** Update(oldRowID, newRowID: Int64; **var** Values: TSQLVarDynArray): boolean; **override**;

*Called to update a virtual table row content from a TSQLVar array*

- column order follows the Structure method, i.e. StoredClassRecordProps.Fields[] order
- returns true on success, false otherwise
- does nothing by default, and returns false, i.e. always fails

**class procedure** GetTableModuleProperties( **var** aProperties: TVirtualTableModuleProperties); **override**;

*Returns the main specifications of the associated TSQLVirtualTableModule*

- this is a read/write table, without transaction, associated to the TSQLVirtualTableCursorJSON cursor type, with 'JSON' as module name
- no particular class is supplied here, since it will depend on the associated Static instance

```
TSQLVirtualTableBinary = class(TSQLVirtualTableJSON)
```

*A TSQLRestStorageInMemory-based virtual table using Binary storage*

- for ORM access, you should use TSQLModel.VirtualTableRegister method to associated this virtual table module to a TSQLRecordVirtualTableAutoID class
- transactions are not handled by this module
- by default, no data is written on disk: you will need to call explicitly `aServer.StaticVirtualTable[aClass].UpdateToFile` for file creation or refresh
- binary format is more efficient in term of speed and disk usage than the JSON format implemented by TSQLVirtualTableJSON
- binary format will be set by TSQLVirtualTableJSON.CreateTableInstance
- file extension is set to '.data'

```
TSQLVirtualTableLog = class(TSQLVirtualTable)
```

*Implements a read/only virtual table able to access a .log file, as created by TSynLog*

- to be used e.g. by a TSQLRecordLog\_Log ('Log\_' will identify this 'Log' module)
- the .log file name will be specified by the Table Name, to which a '.log' file extension will be appended before loading it from the current directory

```
constructor Create(aModule: TSQLVirtualTableModule; const aTableName: RawUTF8;
FieldCount: integer; Fields: PPUTF8CharArray); override;
```

*Creates the TSQLVirtualTable according to the supplied parameters*

- aTableName will be checked against the current aModule.Server.Model to retrieve the corresponding TSQLRecordVirtualTableAutoID class

```
destructor Destroy; override;
```

*Release the associated .log file mapping and all internal structures*

```
class procedure GetTableModuleProperties(var aProperties:
TVirtualTableModuleProperties); override;
```

*Returns the main specifications of the associated TSQLVirtualTableModule*

- this is a read only table, with transaction, associated to the TSQLVirtualTableCursorLog cursor type, with 'Log' as module name, and associated to TSQLRecordLog\_Log table field layout

```
TSQLVirtualTableCursorLog = class(TSQLVirtualTableCursorIndex)
```

*A Virtual Table cursor for reading a TSynLogFile content*

- this is the cursor class associated to TSQLVirtualTableLog

```
function Column(aColumn: integer; var aResult: TSQLVar): boolean; override;
```

*Called to retrieve a column value of the current data row as TSQLVar*

```
function Search(const Prepared: TSQLVirtualTablePrepared): boolean; override;
```

*Called to begin a search in the virtual table*

**TSQLRecordVirtualTableForcedID = class(TSQLRecordVirtual)**

*Record associated to a Virtual Table implemented in Delphi, with ID forced at INSERT*

- will use TSQLVirtualTableModule / TSQLVirtualTable / TSQLVirtualTableCursor classes for a generic Virtual table mechanism on the Server side
- call Model.VirtualTableRegister() before TSQLRestServer.Create on the Server side (not needed for Client) to associate such a record with a particular Virtual Table module, otherwise an exception will be raised:

```
Model.VirtualTableRegister(TSQLRecordDali1,TSQLVirtualTableJSON);
```

**TSQLRecordVirtualTableAutoID = class(TSQLRecordVirtual)**

*Record associated to Virtual Table implemented in Delphi, with ID generated automatically at INSERT*

- will use TSQLVirtualTableModule / TSQLVirtualTable / TSQLVirtualTableCursor classes for a generic Virtual table mechanism
- call Model.VirtualTableRegister() before TSQLRestServer.Create on the Server side (not needed for Client) to associate such a record with a particular Virtual Table module, otherwise an exception will be raised:

```
Model.VirtualTableRegister(TSQLRecordDali1,TSQLVirtualTableJSON);
```

## Types implemented in the mORMot unit

**IServiceRecordVersionCallbackDynArray = array of IServiceRecordVersionCallback;**

*A list of callback interfaces to notify TSQLRecord modifications*

- you can use InterfaceArray\*() wrapper functions to manage the list

**PClassInstance = ^TClassInstance;**

*Points to information about a class, able to create new instances*

**PClassProp = ^TClassProp;**

*Pointer to TClassProp*

**PID = ^TID;**

*A pointer to a ORM primary key, i.e. TSQLRecord.ID: TID*

**PIDDynArray = ^TIDDynArray;**

*Pointer to a dynamic array of ORM primary keys, i.e. TSQLRecord.ID*

**PMethod = ^TMethod;**

*Delphi compiler use packed/unaligned structs for most internal types*

**PPropInfoDynArray = array of PPropInfo;**

*Used to store a chain of properties RTTI*

- could be used e.g. by TSQLPropInfo to handled flattened properties

**PServiceContainerInterface = ^TServiceContainerInterface;**

*Pointer to one lookup in a global list of interface-based services*

**PServiceContainerInterfaceMethod = ^TServiceContainerInterfaceMethod;**

*Pointer to one method lookup in a global list of interface-based services*

**PServiceFactoryExecution = ^TServiceFactoryExecution;**

*Points to the execution context of one method within TServiceFactory*

**PServiceMethod = ^TServiceMethod;**

*A pointer to an interface-based service provider method description*

- since TInterfaceFactory instances are shared in a global list, we can safely use such pointers in our code to refer to a particular method

**PServiceMethodArgument = ^TServiceMethodArgument;**

*Pointer to a service provider method argument*

**PServiceRunningContext = ^TServiceRunningContext;**

*Points to the currently running service on the server side*

- your code may use such a local pointer to retrieve the ServiceContext threadvar once in a method, since threadvar access does cost some CPU

```
var context: PServiceRunningContext;
begin
 context := @ServiceContext; // threadvar access once
 ...
```

**PSQLRecordPropertiesMapping = ^TSQLRecordPropertiesMapping;**

*Pointer to external database properties for ORM*

- is used e.g. to allow a "fluent" interface for MapField() method

**PSQLRestClientCallbackItem = ^TSQLRestClientCallbackItem;**

*Points to information about registered interface callbacks*

**PSQLRestServerKind = ^TSQLRestServerKind;**

*Pointer to the kind of (static) database server implementation*

**PSQLRestServerMethod = ^TSQLRestServerMethod;**

*Pointer to a description of a method-based service*

**PSQLRestURIParams = ^TSQLRestURIParams;**

*Used to map set of parameters for a Client or Server method call*

**PSQLTableRowVariantData = ^TSQLTableRowVariantData;**

*Pointer to the memory structure used for TSQLTableRowVariant storage*

**PTypeInfo = ^TTypeInfo;**

*Not defined on older Delphi revisions*

**TAuthSessionClass = class of TAuthSession;**

*Class-reference type (metaclass) used to define overridden session instances*

- since all sessions data remain in memory, ensure they are not taking too much resource (memory or process time)

- if you plan to use session persistence, ensure you override the TAuthSession.SaveTo/CreateFrom methods in the inherited class

**TCallingConvention = ( ccRegister, ccCdecl, ccPascal, ccStdCall, ccSafeCall );**

*The available methods calling conventions*

- this is by design only relevant to the x86 model

- Win64 has one unique calling convention

**TClassInstanceItemCreate = ( cicUnknown, cicTSQLRecord, cicTObjectList, cicTPersistentWithCustomCreate, cicTSynPersistent, cicTInterfacedCollection, cicTInterfacedObjectWithCustomCreate, cicTCollection, cicTCollectionItem, cicTComponent, cicTObject );**

*The class kind as handled by TClassInstance object*

**TCreateTime = type TTimeLog;**

*An Int64-encoded date and time of the record creation*

- can be used as published property field in TSQLRecord for sftCreateTime: if any such property is defined in the table, it will be auto-filled with the server timestamp corresponding to the record creation
- use internally for computation an abstract "year" of 16 months of 32 days of 32 hours of 64 minutes of 64 seconds - faster than TDateTime
- use TimeLogFromDate/TimeLogToDate/TimeLogNow/Iso8601ToTimeLog functions, or type-cast the value with a TTimeLogBits memory structure for direct access to its bit-oriented content (or via PTimeLogBits pointer)
- could be defined as value in a TSQLRecord property as such:  
**property** CreatedAt: TModTime **read** fCreatedAt **write** fCreatedAt;

**TFindWhereEqualEvent = procedure(aDest: pointer; aRec: TSQLRecord; aIndex: integer) of object;**

*Event prototype called by TSQLRestStorageInMemory.FindWhereEqual() or TSQLRestStorageInMemory.ForEach() methods*

- aDest is an opaque pointer, as supplied to FindWhereEqual(), which may point e.g. to a result list, or a shared variable to apply the process
- aRec will point to the corresponding item
- aIndex will identify the item index in the internal list

**TID = type Int64;**

*This is the type to be used for our ORM primary key, i.e. TSQLRecord.ID*

- it maps the SQLite3 RowID definition
- when converted to plain TSQLRecord published properties, you may loose some information under Win32 when stored as a 32-bit pointer
- could be defined as value in a TSQLRecord property as such:  
**property** AnotherRecord: TID **read** fAnotherRecord **write** fAnotherRecord;

**TIDDynArray = array of TID;**

*Used to store a dynamic array of ORM primary keys, i.e. TSQLRecord.ID*

**TInjectableObjectClass = class of TInjectableObject;**

*Class-reference type (metaclass) of a TInjectableObject type*

**TInjectableObjectRestClass = class of TInjectableObjectRest;**

*Class-reference type (metaclass) of a TInjectableObjectRest type*

**TInterfacedCollectionClass = class of TInterfacedCollection;**

*Class-reference type (metaclass) of a TInterfacedCollection kind*

**TInterfacedObjectFromFactoryOption = ( ifoJsonAsExtended, ifoDontStoreVoidJSON );**

*How TInterfacedObjectFromFactory will perform its execution*

- by default, flnvoke() will receive standard JSON content, unless ifoJsonAsExtended is set, and extended JSON is used
- ifoDontStoreVoidJSON will ensure objects and records won't include default void fields in JSON serialization

**TInterfacedObjectFromFactoryOptions = set of TInterfacedObjectFromFactoryOption;**

*Defines how TInterfacedObjectFromFactory will perform its execution*

**TInterfacedObjectObjArray = array of TInterfacedObject;**

*Used to store a list of TInterfacedObject instances*

**TInterfaceFactoryMethodBits = set of 0..MAX\_METHOD\_COUNT-1;**

*May be used to store the Methods[] indexes of a TInterfaceFactory*

- current implementation handles up to 128 methods, a limit above which "Interface Segregation" principles is obviously broken

**TInterfaceFactoryObjArray = array of TInterfaceFactory;**

*A dynamic array of TInterfaceFactory instances*

**TInterfaceMockSpyCheck = ( chkName, chkNameParams, chkNameParamsResults );**

*How TInterfaceMockSpy.Verify() shall generate the calls trace*

**TInterfaceResolverObjArray = array of TInterfaceResolver;**

*Used to store a list of TInterfaceResolver instances*

**TInterfaceStubLogDynArray = array of TInterfaceStubLog;**

*Used to keep track of all stubbed methods calls*

**TInterfaceStubLogLayout = ( wName, wParams, wResults );**

*Every potential part of TInterfaceStubLog.AddAsText() log entry*

**TInterfaceStubLogLayouts = set of TInterfaceStubLogLayout;**

*Set the output layout of TInterfaceStubLog.AddAsText() log entry*

**TInterfaceStubObjArray = array of TInterfaceStub;**

*Used to store a list of TInterfaceStub instances*

**TInterfaceStubOption = ( imoLogMethodCallsAndResults,  
imoFakeInstanceWontReleaseTInterfaceStub, imoRaiseExceptionIfNoRuleDefined,  
imoReturnErrorIfNoRuleDefined, imoMockFailsWillPassTestCase );**

*Diverse options available to TInterfaceStub*

- by default, method execution stack is not recorded - include imoLogMethodCallsAndResults in the options to track all method calls and the returned values; note that ExpectsTrace() method will set it  
- by default, TInterfaceStub will be released when the stubbed/mocked interface is released - include imoFakeInstanceWontReleaseTInterfaceStub in the options to force manual memory handling of TInterfaceStubs

- by default, all interfaces will return some default values, unless imoRaiseExceptionIfNoRuleDefined or imoReturnErrorIfNoRuleDefined is included in the options

- by default, any TInterfaceMock.Fails() rule execution will notify the TSynTestCase, unless imoMockFailsWillPassTestCase which will let test pass

**TInterfaceStubOptions = set of TInterfaceStubOption;**

*Set of options available to TInterfaceStub*

**TInterfaceStubRuleKind = ( isUndefined, isExecutesJSON, isExecutesVariant, isRaises,  
isReturns, isFails );**

*Diverse types of stubbing / mocking rules*

- isUndefined is the first, since it will be a ExpectsCount() weak rule which may be overwritten by the other real run-time rules

**TJSONObjectDecoderFieldType = ( ftaNumber, ftaBoolean, ftaString, ftaDate, ftaNull,  
ftaBlob, ftaObject, ftaArray );**

*Define how TJSONObjectDecoder.FieldTypeApproximation[] is identified*

```
TJSONObjectDecoderParams = (pInlined, pQuoted, pNonQuoted);
```

*Define how TJSONObjectDecoder.Decode() will handle JSON string values*

```
TJSONSerializerCustomReader = function(const aValue: TObject; aFrom: PUTF8Char; var
aValid: Boolean; aOptions: TJSONToJSONObjectOptions): PUTF8Char of object;
```

*Method prototype to be used for custom un-serialization of a class*

- to be used with TJSONSerializer.RegisterCustomSerializer() method
- note that the read JSON content is not required to start with '{', as a normal JSON object (you may e.g. read a JSON string for some class) - as a consequence, custom code could explicitly start with "if aFrom^='{...'"
- implementation code shall follow function JSONToObject() patterns, i.e. calling low-level GetJSONField() function to decode the JSON content
- implementation code shall follow the same exact format for the associated TJSONSerializerCustomWriter callback

```
TJSONSerializerCustomWriter = procedure(const aSerializer: TJSONSerializer; aValue:
TObject; aOptions: TTextWriterWriteObjectOptions) of object;
```

*Method prototype to be used for custom serialization of a class*

- to be used with TJSONSerializer.RegisterCustomSerializer() method
- note that the generated JSON content is not required to start with '{', as a normal JSON object (you may e.g. write a JSON string for some class) - as a consequence, custom code could explicitly start with Add('{')
- implementation code shall follow function TJSONSerializer.WriteObject() patterns, i.e. aSerializer.Add/AddInstanceName/AddJSONEscapeString...
- implementation code shall follow the same exact format for the associated TJSONSerializerCustomReader callback

```
TJSONSerializerSQLRecordOption = (jwoAsJsonNotAsString, jwoID_str);
```

*Several options to customize how TSQLRecord will be serialized*

- e.g. if properties storing JSON should be serialized as an object, and not escaped as a string (which is the default, matching ORM column storage)
- if an additional "ID\_str": "12345" field should be added to the standard "ID": 12345 field, which may exceed 53-bit integer precision of JavaScript

```
TJSONSerializerSQLRecordOptions = set of TJSONSerializerSQLRecordOption;
```

*Options to customize how TSQLRecord will be written by TJSONSerializer*

```
TJSONToJSONObjectOption = (j2oIgnoreUnknownProperty, j2oIgnoreStringType,
j2oIgnoreUnknownEnum, j2oHandleCustomVariants, j2oHandleCustomVariantsWithinString,
j2oSetterExpectsToFreeTempInstance, j2oSetterNoCreate, j2oAllowInt64Hex);
```

*Available options for JSONToObject() parsing process*

- by default, function will fail if a JSON field name is not part of the object published properties, unless j2oIgnoreUnknownProperty is defined - this option will also ignore read-only properties (i.e. with only a getter)
- by default, function will check that the supplied JSON value will be a JSON string when the property is a string, unless j2oIgnoreStringType is defined and JSON numbers are accepted and stored as text
- by default any unexpected value for enumerations will be marked as invalid, unless j2oIgnoreUnknownEnum is defined, so that in such case the ordinal 0 value is left, and loading continues
- by default, only simple kind of variant types (string/numbers) are handled: set j2oHandleCustomVariants if you want to handle any custom - in this case, it will handle direct JSON

[array] of {object}: but if you also define j2oHandleCustomVariantsWithinString, it will also try to un-escape a JSON string first, i.e. handle "[array]" or "{object}" content (may be used e.g. when JSON has been retrieved from a database TEXT column)

- by default, a temporary instance will be created if a published field has a setter, and the instance is expected to be released later by the owner class: set j2oSetterExpectsToFreeTempInstance to let JSONToObject (and TPropInfo.ClassFromJSON) release it when the setter returns, and j2oSetterNoCreate to avoid the published field instance creation
- set j2oAllowInt64Hex to let Int64/QWord fields accept hexadecimal string (as generated e.g. via the wolnt64AsHex option)

**TJSONToObjectOptions = set of TJSONToObjectOption;**

*Set of options for JSONToObject() parsing process*

**TModTime = type TTimeLog;**

*An Int64-encoded date and time of the latest update of a record*

- can be used as published property field in TSQLRecord for sftModTime: if any such property is defined in the table, it will be auto-filled with the server timestamp corresponding to the latest record update
- use internally for computation an abstract "year" of 16 months of 32 days of 32 hours of 64 minutes of 64 seconds - faster than TDateTime
- use TimeLogFromDate/TimeLogToDate/TimeLogNow/Iso8601ToTimeLog functions, or type-cast the value with a TTimeLogBits memory structure for direct access to its bit-oriented content (or via PTimeLogBits pointer)
- could be defined as value in a TSQLRecord property as such:  
**property LastModif: TModTime read fLastModif write fLastModif;**

**TNotifyAfterURI = procedure(Ctxt: TSQLRestServerURIContext) of object;**

*Callback raised after TSQLRestServer.URI execution*

**TNotifyAuthenticationFailed = procedure(Sender: TSQLRestServer; Reason: TNotifyAuthenticationFailedReason; Session: TAuthSession; Ctxt: TSQLRestServerURIContext) of object;**

*Callback raised in case of authentication failure*

- as used by TSQLRestServerURIContext.AuthenticationFailed event

**TNotifyAuthenticationFailedReason = ( afInvalidSignature, afRemoteServiceExecutionNotAllowed, afUnknownUser, afInvalidPassword, afSessionAlreadyStartedForThisUser, afSessionCreationAborted, afSecureConnectionRequired, afJWTRequired );**

*Used to identify the authentication failure reason*

- as transmitted e.g. by TSQLRestServerURIContext.AuthenticationFailed or TSQLRestServer.OnAuthenticationFailed

**TNotifyBeforeURI = function(Ctxt: TSQLRestServerURIContext): boolean of object;**

*Callback raised before TSQLRestServer.URI execution*

- should return TRUE to execute the command, FALSE to cancel it

**TNotifyErrorURI = function(Ctxt: TSQLRestServerURIContext; E: Exception): boolean of object;**

*Callback raised if TSQLRestServer.URI execution failed*

- should return TRUE to execute Ctxt.Error(E,...), FALSE if returned content has already been set as expected by the client

**TNotifyFieldSQLEvent = function**(Sender: TSQLRestServer; Event: TSQLEvent; aTable: TSQLRecordClass; **const** aID: TID; **const** aAffectedFields: TSQLFieldBits): boolean **of object**;

*Used to define how to trigger Events on record field update*

- see TSQLRestServer.OnBlobUpdateEvent property and InternalUpdateEvent() method
- returns true on success, false if an error occurred (but action must continue)
- to be used only server-side, not to synchronize some clients: the framework is designed around a stateless RESTful architecture (like HTTP/1.1), in which clients ask the server for refresh (see TSQLRestClientURI.UpdateFromServer)

**TNotifyRestBody = procedure**(Sender: TSQLRest; **var** Body,Head,URL: RawUTF8) **of object**;

*Callback event signature before/after a Client or Server method call*

- to allow low-level interception of the request bodies e.g. for low-level logging/audit, or on-the-fly encryption and/or signature of the content
- used by TSQLRest.OnDecryptBody and TSQLRest.OnEncryptBody - so the very same callbacks may be used on both client and server sides
- for server-only process (e.g. to check for authorization), see rather TSQLRestServer.OnBeforeURI and TSQLRestServer.OnAfterURI events
- used e.g. by TSQLRest.SetCustomEncryption method

**TNotifySQLEvent = function**(Sender: TSQLRestServer; Event: TSQLEvent; aTable: TSQLRecordClass; **const** aID: TID; **const** aSentData: RawUTF8): boolean **of object**;

*Used to define how to trigger Events on record update*

- see TSQLRestServer.OnUpdateEvent property and InternalUpdateEvent() method
- returns true on success, false if an error occurred (but action must continue)
- to be used only server-side, not to synchronize some clients: the framework is designed around a stateless RESTful architecture (like HTTP/1.1), in which clients ask the server for refresh (see TSQLRestClientURI.UpdateFromServer)

**TNotifySQLSession = function**(Sender: TSQLRestServer; Session: TAuthSession; Ctxt: TSQLRestServerURIContext): boolean **of object**;

*Session-related callbacks triggered by TSQLRestServer*

- for OnSessionCreate, returning TRUE will abort the session creation - and you can set Ctxt.Call^.OutStatus to a corresponding error code

**TOnAsynchRedirectResult = procedure**(**const** aMethod: TServiceMethod; **const** aInstance: IInvokable; **const** aParams, aResult: RawUTF8) **of object**;

*Optionally called after TSQLRest.AsynchRedirect background execution*

- to retrieve any output result value, as JSON-encoded content
- as used in TSQLRestBackgroundTimer.AsynchBackgroundExecute protected method

**TOnAuthenticationUserRetrieve = function**(Sender: TSQLRestServerAuthentication; Ctxt: TSQLRestServerURIContext; aUserID: TID; **const** aUserName: RawUTF8): TSQLAuthUser **of object**;

*Callback allowing to customize the retrieval of an authenticated user*

- as defined in TSQLRestServer.OnAuthenticationUserRetrieve
- and executed by TSQLRestServerAuthentication.GetUser
- on call, either aUserID will be <> 0, or aUserName is to be used
- if the function returns nil, default Server.SQLAuthUserClass.Create() methods won't be called, and the user will be reported as not found

**TOnAuthenticationFailed = function**(Retry: integer; **var** aUserName, aPassword: string; **out** aPasswordHashed: boolean): boolean **of object**;

*Used by TSQLRestClientURI.URI() to let the client ask for an User name and password, in order to retry authentication to the server*

- should return TRUE if aUserName and aPassword both contain some entered values to be sent for remote secure authentication
- should return FALSE if the user pressed cancel or the number of Retry reached a defined limit
- here input/output parameters are defined as plain string, to match the type expected by the client's User Interface, via VCL properties, or e.g. from TLoginForm as defined in mORMotUILogin.pas unit

**TOnBatchWrite = procedure(Sender: TSQLRestBatch; Event: TSQLOccasion; Table: TSQLRecordClass; const ID: TID; Value: TSQLRecord; const ValueFields: TSQLFieldBits) of object;**

*Event signature triggered by TSQLRestBatch.OnWrite*

- also used by TSQLRestServer.RecordVersionSynchronizeSlave\*() methods

**TOnCallbackReleased = procedure(Sender: TServiceContainer; Instance: TInterfacedObject; Callback: pointer) of object;**

*Event signature triggered when a callback instance is released*

- used by TServiceContainerServer.OnCallbackReleasedOnClientSide and TServiceContainerServer.OnCallbackReleasedOnServerSide event properties
- the supplied Instance will be a TInterfacedObjectFakeServer, and the Callback will be a pointer to the corresponding interface value
- assigned implementation should be as fast as possible, since this event will be executed in a global lock for all server-side callbacks

**TOnClientFailed = procedure(Sender: TSQLRestClientURI; E: Exception; Call: TSQLRestURIParams) of object;**

*Called by TSQLRestClientURI.URI() when an error occurred*

- so that you may have a single entry point for all client-side issues
- information will be available in Sender's LastErrorCode and LastErrorMessage properties
- if the error comes from an Exception, it will be supplied as parameter
- the REST context (if any) will be supplied within the Call parameter, and in this case Call^.OutStatus=HTTP\_NOTIMPLEMENTED indicates a broken connection

**TOnFakeInstanceDestroy = procedure(aClientDrivenID: cardinal) of object;**

*Event called when destroying a TInterfaceFactory's fake instance*

- this method will be run when the fake class instance is destroyed (e.g. if aInstanceCreation is sicClientDriven, to notify the server than the client life time just finished)

**TOnFakeInstanceInvoke = function(const aMethod: TServiceMethod; const aParams: RawUTF8; aResult, aErrorMsg: PRawUTF8; aClientDrivenID: PCardinal; aServiceCustomAnswer: TServiceCustomAnswer): boolean of object;**

*Event used by TInterfaceFactory to run a method from a fake instance*

- aMethod will specify which method is to be executed
- aParams will contain the input parameters, encoded as a JSON array, without the [ ] characters (e.g. '1,"arg2",3')
- shall return TRUE on success, or FALSE in case of failure, with a corresponding explanation in aErrorMsg
- method results shall be serialized as JSON in aResult; if aServiceCustomAnswer is not nil, the result shall use this record to set HTTP custom content and headers, and ignore aResult content
- aClientDrivenID can be set optionally to specify e.g. an URI-level session

**TOnInterfaceStubExecuteJSON = procedure(Ctxt: TOnInterfaceStubExecuteParamsJSON) of**

## **object;**

*Event called by the TInterfaceStub.Executes() fluent method for JSON process*

- by default Ctxt.Result shall contain the default JSON array result for this method - use Ctxt.Named[] default properties, e.g. as

```
P := pointer(Ctxt.Params);
Ctxt.Returns([GetNextItemDouble(P)-GetNextItemDouble(P)]);
```

- you can call Ctxt.Error() to notify the caller for an execution error

**TOnInterfaceStubExecuteVariant = procedure(Ctxt: TOnInterfaceStubExecuteParamsVariant) of object;**

*Event called by the TInterfaceStub.Executes() fluent method for variant process*

- by default Ctxt.Result shall contain the default JSON array result for this method - use Ctxt.Named[] default properties, e.g. as

```
Ctxt['result'] := Ctxt['n1']-Ctxt['n2'];
```

or with Input[] / Output[] properties:

```
with Ctxt do Output[0] := Input[0]-Input[1];
```

- you can call Ctxt.Error() to notify the caller for an execution error

**TOnInternalInfo = procedure(Sender: TSQLRestServer; var info: TDocVariantData) of object;**

*Callback allowing to customize the information returned by root/timestamp/info*

**TOnRecordUpdate = procedure(Value: TSQLRecord) of object;**

*Used by TSQLRestClientURI.Update() to let the client perform the record update (refresh associated report e.g.)*

**TOnRestClientNotify = procedure(Sender: TSQLRestClientURI) of object;**

*Signature e.g. of the TSQLRestClientURI.OnSetUser event handler*

**TOnServiceCanExecute = function(Ctxt: TSQLRestServerURIContext; const Method: TServiceMethod): boolean of object;**

*Callback called before any interface-method service execution to allow its execution*

- see Ctxt.Service, Ctxt.ServiceMethodIndex and Ctxt.ServiceParameters to identify the executed method context

- Method parameter will help identify easily the corresponding method, and will contain in fact PServiceMethod(Ctxt.ServiceMethod)^

- should return TRUE if the method can be executed

- should return FALSE if the method should not be executed, and set the corresponding error to the supplied context e.g.

```
Ctxt.Error('Unauthorized method',HTTP_NOTALLOWED);
```

- i.e. called by TSQLRestServerURIContext.InternalExecuteSOABByInterface

**TOnServiceCreateInstance = procedure( Sender: TServiceFactoryServer; Instance: TInterfacedObject) of object;**

*Event signature used by TSQLRestServer.OnServiceCreateInstance*

- as called by TServiceFactoryServer.CreateInstance

- the actual Instance class can be quickly retrieved from Sender.ImplementationClass

**TOnServiceFactoryServerOne = function(Sender: TServiceFactoryServer; var Instance: TServiceFactoryServerInstance; var Opaque): integer of object;**

*Callback used by TServiceFactoryServer.RunOnAllInstances method*

**TOnSQLPropInfoRecord2Data = procedure(Text: PUTF8Char; var Data: RawByteString);**

*Optional event handler used by TSQLPropInfoRecord to handle textual storage*

- by default, TSQLPropInfoRecord content will be stored as sftBlobCustom; specify such a callback event to allow storage as UTF-8 textual field and use a sftUTF8Custom kind of column
- event implementation shall convert Text into Data binary value

**TOnSQLPropInfoRecord2Text = procedure(Data: pointer; DataLen: integer; var Text: RawUTF8);**

*Optional event handler used by TSQLPropInfoRecord to handle textual storage*

- by default, TSQLPropInfoRecord content will be stored as sftBlobCustom; specify such a callback event to allow storage as UTF-8 textual field and use a sftUTF8Custom kind of column
- event implementation shall convert data/datalen binary value into Text

**TOnSQLTableGetValue = function(Sender: TSQLTable; Row, Field: integer; HumanFriendly: boolean): RawJSON of object;**

*Allow on-the-fly translation of a TSQLTable grid value*

- should return valid JSON value of the given cell (i.e. quoted strings, or valid JSON object/array) unless HumanFriendly is defined
- e.g. TSQLTable.OnExportValue property will customize TSQLTable's GetJSONValues, GetHtmlTable, and GetCSVValues methods returned content

**TOnTableUpdate = procedure(aTable: TSQLTableJSON; State: TOnTableUpdateState) of object;**

*Used by TSQLRestClientURI.UpdateFromServer() to let the client perform the rows update (for Marked[] e.g.)*

**TOnTableUpdateState = ( tusPrepare, tusChanged, tusNoChange );**

*Possible call parameters for TOnTableUpdate Event*

**TParamFlag = ( pfVar, pfConst, pfArray, pfAddress, pfReference, pfOut, pfResult );**

*The available kind of method parameters*

**TParamFlags = set of TParamFlag;**

*A set of kind of method parameters*

**TPropInfoCall = ( picNone, picField, picMethod, picIndexed );**

*How a RTTI property definition access its value*

- as returned by TPropInfo.Getter/Setter methods

**TRawUTF8ObjectCacheClass = class of TRawUTF8ObjectCache;**

*Class-reference type (metaclass) of a TRawUTF8ObjectCache*

- used e.g. by TRawUTF8ObjectCacheClass.Create to generate the expected cache instances

**TRecordReference = type Int64;**

*A reference to another record in any table in the database Model*

- stored as a 64-bit signed integer (just like the TID type)
- type cast any value of TRecordReference with the RecordRef object below for easy access to its content
- use TSQLRest.Retrieve(Reference) to get a record value
- don't change associated TSQLModel tables order, since TRecordReference depends on it to store the Table type in its highest bits
- when the pointed record will be deleted, this property will be set to 0 by TSQLRestServer.AfterDeleteForceCoherency()
- could be defined as value in a TSQLRecord property as such:  
**property AnotherRecord: TRecordReference read fAnotherRecord write fAnotherRecord;**

**TRecordReferenceToBeDeleted = type TRecordReference;**

*A reference to another record in any table in the database Model*

- stored as a 64-bit signed integer (just like the TID type)
- type cast any value of TRecordReference with the RecordRef object below for easy access to its content
- use TSQLRest.Retrieve(Reference) to get a record value
- don't change associated TSQLModel tables order, since TRecordReference depends on it to store the Table type in its highest bits
- when the pointed record will be deleted, any record containing a matching property will be deleted by TSQLRestServer.AfterDeleteForceCoherency()
- could be defined as value in a TSQLRecord property as such:  
**property** AnotherRecord: TRecordReferenceToBeDeleted  
**read** fAnotherRecord **write** fAnotherRecord;

**TRecordVersion = type Int64;**

*A monotonic version number, used to track changes on a table*

- add such a published field to any TSQLRecord will allow tracking of record modifications - note that only a single field of this type should be defined for a given record
- note that this published field is NOT part of the record "simple fields": by default, the version won't be retrieved from the DB, nor will be sent from a client - the Engine\*() CRUD method will take care of computing the monotonic version number, just before storage to the persistence engine
- such a field will use a separated TSQLRecordTableDeletion table to track the deleted items
- could be defined as value in a TSQLRecord property as such:  
**property** TrackedVersion: TRecordVersion **read** fVersion **write** fVersion;

**TServiceCallbackOptions = set of ( coRaiseExceptionIfReleasedByClient);**

*How TServiceContainerServer will handle SOA callbacks*

- by default, a callback released on the client side will log a warning and continue the execution (relying e.g. on a CallbackReleased() method to unsubscribe the event), but coRaiseExceptionIfReleasedByClient can be defined to raise an EInterfaceFactoryException in this case

**TServiceContainerInterfaceMethodBits = set of 0..255;**

*Used in TServiceContainer to identify fListInterfaceMethod[] entries*

**TServiceContainerInterfaceMethods = array of TServiceContainerInterfaceMethod;**

*Used to store all methods in a global list of interface-based services*

**TServiceContainerInterfaces = array of TServiceContainerInterface;**

*Used to store all s in a global list of interface-based services*

**TServiceFactoryClientClass = class of TServiceFactoryClient;**

*Class-reference type (metaclass) of a TServiceFactoryClient kind*

**TServiceFactoryServerInstanceDynArray = array of TServiceFactoryServerInstance;**

*Server-side service provider uses this to store its internal instances*

- used by TServiceFactoryServer in sicClientDriven, sicPerSession, sicPerUser or sicPerGroup mode

**TServiceInstanceImplementation = ( sicSingle, sicShared, sicClientDriven, sicPerSession, sicPerUser, sicPerGroup, sicPerThread );**

*The possible Server-side instance implementation patterns for interface-based services*

- each interface-based service will be implemented by a corresponding class instance on the server: this parameter is used to define how class instances are created and managed
- on the Client-side, each instance will be handled depending on the server side implementation (i.e. with sicClientDriven behavior if necessary)
- sicSingle: one object instance is created per call - this is the most expensive way of implementing the service, but is safe for simple workflows (like a one-type call); this is the default setting for TSQLRestServer.ServiceRegister method
- sicShared: one object instance is used for all incoming calls and is not recycled subsequent to the calls - the implementation should be thread-safe on the server side
- sicClientDriven: one object instance will be created in synchronization with the client-side lifetime of the corresponding interface: when the interface will be released on client, it will be released on the server side - a numerical identifier will be transmitted for all JSON requests
- sicPerSession, sicPerUser and sicPerGroup modes will maintain one object instance per running session / user / group (only working if RESTful authentication is enabled) - since it may be shared among users or groups, the sicPerUser and sicPerGroup implementation should be thread-safe
- sicPerThread will maintain one object instance per calling thread - it may be useful instead of sicShared mode if the service process expects some per-heavy thread initialization, for instance

**TServiceInstanceImplementations = set of TServiceInstanceImplementation;**  
*Set of Server-side instance implementation patterns for interface-based services*

**TServiceMethodArgumentDynArray = array of TServiceMethodArgument;**  
*Describe a service provider method arguments*

**TServiceMethodDynArray = array of TServiceMethod;**  
*Describe all mtehdos of an interface-based service provider*

**TServiceMethodExecuteCallback = procedure(var Par: PUTF8Char; ParamInterfaceInfo: PTypeInfo; out Obj) of object;**  
*Callback called by TServiceMethodExecute to process an interface callback parameter*  
 - implementation should set the Obj local variable to an instance of a fake class implementing the aParamInfo interface

**TServiceMethodExecuteEvent = procedure(Sender: TServiceMethodExecute; Step: TServiceMethodExecuteEventStep) of object;**  
*The TServiceMethodExecute.OnExecute signature*

**TServiceMethodExecuteEventStep = ( smsUndefined, smsBefore, smsAfter, smsError );**  
*The current step of a TServiceMethodExecute.OnExecute call*

**TServiceMethodOption = ( optExecLockedPerInterface, optExecInPerInterfaceThread, optFreeInPerInterfaceThread, optExecInMainThread, optFreeInMainThread, optVariantCopiedByReference, optInterceptInputOutput, optNoLogInput, optNoLogOutput, optErrorOnMissingParam, optForceStandardJSON, optDontStoreVoidJSON, optIgnoreException );**  
*Possible service provider method options, e.g. about logging or execution*  
 - see TServiceMethodOptions for a description of each available option

**TServiceMethodOptions = set of TServiceMethodOption;**  
*Set of per-method execution options for an interface-based service provider*  
 - by default, mehthod executions are concurrent, for better server responsiveness; if you set optExecLockedPerInterface, all methods of a given interface will be executed with a critical section  
 - optExecInMainThread will force the method to be called within a RunningThread.Synchronize() call  
 - it can be used e.g. if your implementation rely heavily on COM servers - by default, service methods

are called within the thread which received them, on multi-thread server instances (e.g. TSQLite3HttpServer or TSQLRestServerNamedPipeResponse), for better response time and CPU use (this is the technical reason why service implementation methods have to handle multi-threading safety carefully, e.g. by using TRTLCriticalSection mutex on purpose)

- optFreeInMainThread will force the \_Release/Destroy method to be run in the main thread: setting this option for any method will affect the whole service class - is not set by default, for performance reasons

- optExecInPerInterfaceThread and optFreeInPerInterfaceThread will allow creation of a per-interface dedicated thread

- if optInterceptInputOutput is set, TServiceFactoryServer.AddInterceptor() events will have their Sender.Input/Output values defined

- if optNoLogInput/optNoLogOutput is set, TSynLog and ServiceLog() database won't log any parameter values at input/output - this may be useful for regulatory/safety purposes, e.g. to ensure that no sensitive information (like a credit card number or a password), is logged during process - consider using TInterfaceFactory.RegisterUnsafeSPIType() instead if you prefer a more tuned filtering, for specific high-level types

- when parameters are transmitted as JSON object, any missing parameter will be replaced by their default value, unless optErrorOnMissingParam is defined to reject the call

- by default, it will check for the client user agent, and use extended JSON if none is found (e.g. from WebSockets), or if it contains 'mORMot': you can set optForceStandardJSON to ensure standard JSON is always returned

- optDontStoreVoidJSON will reduce the JSON object verbosity by not writing void (e.g. 0 or "") properties when serializing objects and records

- any exceptions will be propagated during execution, unless optIgnoreException is set and the exception is trapped (not to be used unless you know what you are doing)

```
TServiceMethodOptionsAction = (moaReplace, moaInclude, moaExclude);
```

*How TServiceFactoryServer.SetOptions() will set the options value*

```
TServiceMethodParamsDocVariantKind = (pdvArray, pdvObject, pdvObjectFixed);
```

*How TServiceMethod.TServiceMethod method will return the generated document*

- will return either a dvObject or dvArray TDocVariantData, depending on the expected returned document layout

- returned content could be "normalized" (for any set or enumerate) if Kind is pdvObjectFixed

```
TServiceMethodValueAsm = set of (vIsString, vPassedByReference, vIsObjArray, vIsSPI, vIsQword, vIsDynArrayString, vIsDateTimeMS);
```

*Set of low-level processing options at assembly level*

- vIsString is included for smvRawUTF8, smvString, smvRawByteString and smvWideString kind of parameter (smvRecord has it to false, even if they are Base-64 encoded within the JSON content, and also smvVariant/smvRawJSON)

- vPassedByReference is included if the parameter is passed as reference (i.e. defined as var/out, or is a record or a reference-counted type result)

- vIsObjArray is set if the dynamic array is a T\*ObjArray, so should be cleared with ObjArrClear() and not TDynArray.Clear

- vIsSPI indicates that the value contains some Sensitive Personal Information (e.g. a bank card number or a plain password), which type has been previously registered via TInterfaceFactory.RegisterUnsafeSPIType so that low-level logging won't include such values

- vIsQword is set for ValueType=smvInt64 over a QWord unsigned 64-bit value

- vIsDynArrayString is set for ValueType=smvDynArray of string values

- vIsDateTimeMS is set for ValueType=smvDateTime and TDateTimeMS value

```
TServiceMethodValueDirection = (smdConst, smdVar, smdOut, smdResult);
```

*Handled kind of parameters direction for an interface-based service method*

- IN, IN/OUT, OUT directions can be applied to arguments, and will be available through our JSON-serialized remote access: smdVar and smdOut kind of parameters will be returned within the "result": JSON array
- smdResult is used for a function method, to handle the returned value

```
TServiceMethodValueDirections = set of TServiceMethodValueDirection;
```

*Set of parameters direction for an interface-based service method*

```
TServiceMethodValueType = (smvNone, smvSelf, smvBoolean, smvEnum, smvSet, smvInteger, smvCardinal, smvInt64, smvDouble, smvDateTime, smvCurrency, smvRawUTF8, smvString, smvRawByteString, smvWideString, smvBinary, smvRecord, smvVariant, smvObject, smvRawJSON, smvDynArray, smvInterface);
```

*Handled kind of parameters for an interface-based service provider method*

- we do not handle all kind of Delphi variables, but provide some enhanced types handled by JSONToObject/ObjectToJSON functions (smvObject) or TDynArray.LoadFromJSON / TTextWriter.AddDynArrayJSON methods (smvDynArray)
- records will be serialized as Base64 string, with our RecordSave/RecordLoad low-level format by default, or as true JSON objects since Delphi 2010 or after registration via a TTextWriter.RegisterCustomJSONSerializer call
- smvRawJSON will transmit the raw JSON content, without serialization

```
TServiceMethodValueTypes = set of TServiceMethodValueType;
```

*Set of parameters for an interface-based service provider method*

```
TServiceMethodValueVar = (smvvNone, smvvSelf, smvv64, smvvRawUTF8, smvvString, smvvWideString, smvvRecord, smvvObject, smvvDynArray, smvvInterface);
```

*Handled kind of parameters internal variables for an interface-based method*

- reference-counted variables will have their own storage
- all non referenced-counted variables are stored within some 64-bit content
- smvVariant kind of parameter will be handled as a special smvvRecord

```
TServicesPublishedInterfacesDynArray = array of TServicesPublishedInterfaces;
```

*Store a list of published Services supported by a TSQLRestServer instance*

```
TSessionUserID = type TID;
```

*The Int64/TID of the TSQLAuthUser currently logged*

- can be used as published property field in TSQLRecord for sftSessionUserID: if any such property is defined in the table, it will be auto-filled with the current TSQLAuthUser.ID value at update, or 0 if no session is running
- could be defined as value in a TSQLRecord property as such:  

```
property User: TSessionUserID read fUser write fUser;
```

```
TSQLAction = (actNoAction, actMark, actUnmarkAll, actmarkAllEntries, actmarkToday, actmarkThisWeek, actmarkThisMonth, actmarkYesterday, actmarkLastWeek, actmarkLastMonth, actmarkOlderThanOneDay, actmarkOlderThanOneWeek, actmarkOlderThanOneMonth, actmarkOlderThanSixMonths, actmarkOlderThanOneYear, actmarkInverse);
```

*Standard actions for User Interface generation*

- actNoAction for not defined action
- actMark (standard action) to Mark rows, i.e. display sub-menu with actmarkAllEntries..actmarkOlderThanOneYear items

- actUnmarkAll (standard action) to UnMark all rows
- actmarkAllEntries to Mark all rows
- actmarkToday to Mark rows for today
- actmarkThisWeek to Mark rows for this Week
- actmarkThisMonth to Mark rows for this month
- actmarkYesterday to Mark rows for today
- actmarkLastWeek to Mark rows for Last Week
- actmarkLastMonth to Mark rows for Last month
- actmarkOlderThanOneDay to Mark rows After one day
- actmarkOlderThanOneWeek to Mark rows older than one week
- actmarkOlderThanOneMonth to Mark rows older than one month
- actmarkOlderThanSixMonths to Mark rows older than one half year
- actmarkOlderThanOneYear to Mark rows older than one year
- actmarkInverse to Inverse Mark values (ON->OFF, OFF->ON)

```
TSQLActions = set of TSQLAction;
```

*Set of standard actions for User Interface generation*

```
TSQLAllowRemoteExecute = set of (reSQL, reService, reUrlEncodedSQL,
reUrlEncodedDelete, reOneSessionPerUser, reSQLSelectWithoutTable,
reUserCanChangeOwnPassword);
```

*A set of potential actions to be executed from the server*

- reSQL will indicate the right to execute any POST SQL statement (not only SELECT statements)
- reService will indicate the right to execute the interface-based JSON-RPC service implementation
- reUrlEncodedSQL will indicate the right to execute a SQL query encoded at the URI level, for a GET (to be used e.g. with XMLHttpRequest, which forced SentData=" by definition), encoded as sql=... inline parameter
- reUrlEncodedDelete will indicate the right to delete items using a WHERE clause for DELETE verb at /root/TableName?WhereClause
- reOneSessionPerUser will force that only one session may be created for one user, even if connection comes from the same IP: in this case, you may have to set the SessionTimeout to a small value, in case the session is not closed gracefully
- reSQLSelectWithoutTable will allow executing a SELECT statement with arbitrary content via GET/LOCK (simple SELECT .. FROM aTable will be checked against TSQLAccessRights.GET[] per-table right
- by default, read/write access to the TSQLAuthUser table is disallowed, for obvious security reasons: but you can define reUserCanChangeOwnPassword so that the current logged user will be able to change its own password
- order of this set does matter, since it will be stored as a byte value e.g. by TSQLAccessRights.ToString: ensure that new items will always be appended to the list, not inserted within

```
TSQLAuthGroupClass = class of TSQLAuthGroup;
```

*Class-reference type (metaclass) of the table containing the available user access rights for authentication, defined as a group*

```
TSQLAuthUserClass = class of TSQLAuthUser;
```

*Class-reference type (metaclass) of a table containing the Users registered for authentication*  
 - see also TSQLRestServer.OnAuthenticationUserRetrieve custom event

```
TSQLCheckTableName = (ctnNoCheck, ctnMustExist, ctnTrimExisting);
```

*The possible options for handling table names*

```
TSQLEvent = (seAdd, seUpdate, seDelete, seUpdateBlob);
```

*Used to define the triggered Event types for TNotifySQLEvent*

- some Events can be triggered via TSQLRestServer.OnUpdateEvent when a Table is modified, and actions can be authorized via overriding the TSQLRest.RecordCanBeUpdated method
- OnUpdateEvent is called BEFORE deletion, and AFTER insertion or update; it should be used only server-side, not to synchronize some clients: the framework is designed around a stateless RESTful architecture (like HTTP/1.1), in which clients ask the server for refresh (see TSQLRestClientURI.UpdateFromServer)
- is used also by TSQLRecord.ComputeFieldsBeforeWrite virtual method

```
TSQLFieldTables = set of 0..MAX_SQLTABLES-1;
```

*Used to store bit set for all available Tables in a Database Model*

```
TSQLFieldType = (sftUnknown, sftAnsiText, sftUTF8Text, sftEnumerate, sftSet,
sftInteger, sftID, sftRecord, sftBoolean, sftFloat, sftDateTime, sftTimeLog,
sftCurrency, sftObject, sftVariant, sftNullable, sftBlob, sftBlobDynArray,
sftBlobCustom, sftUTF8Custom, sftMany, sftModTime, sftCreateTime, sftTID,
sftRecordVersion, sftSessionUserID, sftDateTimeMS, sftUnixTime, sftUnixMSTime);
```

*The available types for any SQL field property, as managed with the database driver*

- sftUnknown: unknown or not defined field type
- sftAnsiText: a WinAnsi encoded TEXT, forcing a NOCASE collation (TSQLRecord Delphi property was declared as AnsiString or string before Delphi 2009)
- sftUTF8Text is UTF-8 encoded TEXT, forcing a SYSTEMNOCASE collation, i.e. using UTF8Comp() (TSQLRecord property was declared as RawUTF8, RawUnicode or WideString - or string in Delphi 2009+) - you may inherit from TSQLRecordNoCase to use the NOCASE standard SQLite3 collation
- sftEnumerate is an INTEGER value corresponding to an index in any enumerate Delphi type; storage is an INTEGER value (fast, easy and size efficient); at display, this integer index will be converted into the left-trimmed lowercased chars of the enumerated type text conversion: TOpenType(1) = otDone -> 'Done'
- sftSet is an INTEGER value corresponding to a bitmapped set of enumeration; storage is an INTEGER value (fast, easy and size efficient); displayed as an integer by default, sets with an enumeration type with up to 64 elements is allowed yet (stored as an Int64)
- sftInteger is an INTEGER (Int64 precision, as expected by SQLite3) field
- sftID is an INTEGER field pointing to the ID/RowID of another record of a table, defined by the class type of the TSQLRecord inherited property; coherency is always ensured: after a delete, all values pointing to it is reset to 0
- sftRecord is an INTEGER field pointing to the ID/RowID of another record: TRecordReference=Int64 Delphi property which can be typecasted to RecordRef; coherency is always ensured: after a delete, all values pointing to it are reset to 0 by the ORM
- sftBoolean is an INTEGER field for a boolean value: 0 is FALSE, anything else TRUE (encoded as JSON 'true' or 'false' constants)
- sftFloat is a FLOAT (floating point double precision, cf. SQLite3) field, defined as double (or single) published properties definition
- sftDateTime is a ISO 8601 encoded (SQLite3 compatible) TEXT field, corresponding to a TDateTime Delphi property: a ISO8601 collation is forced for such column, for proper date/time sorting and searching
- sftDateTimeMS is a ISO 8601 encoded (SQLite3 compatible) TEXT field, corresponding to a TDateTimeMS Delphi property, i.e. a TDateTime with millisecond resolution, serialized with '.sss' suffix: a ISO8601 collation is forced for such column, for proper date/time sorting and searching
- sftTimeLog is an INTEGER field for coding a date and time (not SQLite3 compatible), which should be defined as TTimeLog=Int64 Delphi property, ready to be typecasted to the TTimeLogBits

optimized type for efficient timestamp storage, with a second resolution

- sftCurrency is a FLOAT containing a 4 decimals floating point value, compatible with the Currency Delphi type, which minimizes rounding errors in monetary calculations which may occur with sftFloat type

- sftObject is a TEXT containing an ObjectToJSON serialization, able to handle published properties of any not TPersistent as JSON object, TStrings or TRawUTF8List as JSON arrays of strings, TCollection or TObjectList as JSON arrays of JSON objects

- sftVariant is a TEXT containing a variant value encoded as JSON: string values are stored between quotes, numerical values directly stored, and JSON objects or arrays will be handled as TDocVariant custom types

- sftNullable is a INTEGER/DOUBLE/TEXT field containing a Nullable value, stored as a local variant property, identifying TNullableInteger, TNullableBoolean, TNullableFloat, TNullableCurrency, TNullableDateTime, TNullableTimeLog and TNullableUTF8Text types

- sftBlob is a BLOB field (TSQLRawBlob Delphi property), and won't be retrieved by default (not part of ORM "simple types"), to save bandwidth

- sftBlobDynArray is a dynamic array, stored as BLOB field: this kind of property will be retrieved by default, i.e. is recognized as a "simple field", and will use Base64 encoding during JSON transmission, or a true JSON array, depending on the database back-end (e.g. MongoDB)

- sftBlobCustom is a custom property, stored as BLOB field: such properties are defined by adding a TSQLPropInfoCustom instance, overriding TSQLRecord.InternalRegisterCustomProperties virtual method - they will be retrieved by default, i.e. recognized as "simple fields"

- sftUTF8Custom is a custom property, stored as JSON in a TEXT field, defined by overriding TSQLRecord.InternalRegisterCustomProperties virtual method, and adding a TSQLPropInfoCustom instance, e.g. via RegisterCustomPropertyFromTypeName() or RegisterCustomPropertyFromRTTI(); they will be retrieved by default, i.e. recognized as "simple fields"

- sftMany is a 'many to many' field (TSQLRecordMany Delphi property); nothing is stored in the table row, but in a separate pivot table: so there is nothing to retrieve here; in contrast to other TSQLRecord published properties, which contains an INTEGER ID, the TSQLRecord.Create will instantiate a true TSQLRecordMany instance to handle this pivot table via its dedicated ManyAdd/FillMany/ManySelect methods - as a result, such properties won't be retrieved by default, i.e. not recognized as "simple fields" unless you used the dedicated methods

- sftModTime is an INTEGER field containing the TModTime value, aka time of the record latest update; TModTime (just like TTimeLog or TCreateTime) published property can be typecasted to the TTimeLogBits memory structure; the value of this field is automatically updated with the current date and time each time a record is updated (with external DB, it will use the Server time, as retrieved from SynDB) - see ComputeFieldsBeforeWrite virtual method of TSQLRecord; note also that only RESTful PUT/POST access will change this field value: manual SQL statements (like 'UPDATE Table SET Column=0') won't change its content; note also that this is automated on Delphi client side, so only within TSQLRecord ORM use (a pure AJAX application should fill such fields explicitly before sending)

- sftCreateTime is an INTEGER field containing the TCreateTime time of the record creation; TCreateTime (just like TTimeLog or TModTime) published property can be typecasted to the TTimeLogBits memory structure; the value of this field is automatically updated with the current date and time when the record is created (with external DB, it will use the Server time, as retrieved from SynDB) - see ComputeFieldsBeforeWrite virtual method of TSQLRecord; note also that only RESTful PUT/POST access will set this field value: manual SQL statements (like 'INSERT INTO Table ...') won't set its content; note also that this is automated on Delphi client side, so only within TSQLRecord ORM use (a pure AJAX application should fill such fields explicitly before sending)

- sftTID is an INTEGER field containing a TID pointing to another record; since regular TSQLRecord published properties (i.e. sftID kind of field) can not be greater than 2,147,483,647 (i.e. a signed

32-bit value) under Win32, defining TID published properties will allow to store the ID as signed 64-bit, e.g. up to 9,223,372,036,854,775,808; despite to sftID kind of record, coherency is NOT ensured: after a deletion, all values pointing to are NOT reset to 0 - it is up to your business logic to ensure data coherency as expected

- sftRecordVersion is an INTEGER field containing a TRecordVersion monotonic number: adding such a published field to any TSQLRecord will allow tracking of record modifications, at storage level; by design, such a field won't be part of "simple types", so won't be transmitted between the clients and the server, but will be updated at any write operation by the low-level Engine\*() storage methods - such a field will use a TSQLRecordTableDeletion table to track the deleted items

- sftSessionUserID is an INTEGER field containing the TSQLAuthUser.ID of the record modification; the value of this field is automatically updated with the current User ID of the active session; note also that only RESTful PUT/POST access will change this field value: manual SQL statements (like 'UPDATE Table SET Column=0') won't change its content; this is automated on Delphi client side, so only within TSQLRecord ORM use (a pure AJAX application should fill such fields explicitly before sending)

- sftUnixTime is an INTEGER field for coding a date and time as second-based Unix Time (SQLite3 compatible), which should be defined as TUnixTime=Int64 TSQLRecord property

- sftUnixMSTime is an INTEGER field for coding a date and time as millisecond-based Unix Time (JavaScript compatible), which should be defined as TUnixMSTime=Int64 TSQLRecord property

- WARNING: do not change the order of items below, otherwise some methods (like TSQLRecordProperties.CheckBinaryHeader) may be broken and fail

```
TSQLFieldTypeArray = array[0..MAX_SQLFIELDS] of TSQLFieldType;
```

*/ a fixed array of SQL field property types*

```
TSQLFieldTypes = set of TSQLFieldType;
```

*Set of available SQL field property types*

```
TSQLHistoryEvent = (heAdd, heUpdate, heDelete, heArchiveBlob);
```

*Used to define the triggered Event types for TSQLRecordHistory*

- TSQLRecordHistory.History will be used for heArchiveBlob

- TSQLRecordHistory.SentDataJSON will be used for other kind of events

```
TSQLHttpServerRestAuthentication = (adDefault, adHttpBasic, adWeak, adSSPI);
```

*Supported REST authentication schemes*

- used by the overloaded TSQLHttpServer.Create(TSQLHttpServerDefinition) constructor in mORMotHttpServer.pas, and also in dddInfraSettings.pas

- asSSPI won't be defined under Linux, since it is a Windows-centric feature

```
TSQLInitializeTableOption = (itoNoAutoCreateGroups, itoNoAutoCreateUsers,
itoNoCreateMissingField, itoNoIndex4ID, itoNoIndex4UniqueField,
itoNoIndex4NestedRecord, itoNoIndex4RecordReference, itoNoIndex4TID,
itoNoIndex4RecordVersion);
```

*The possible options for TSQLRestServer.CreateMissingTables and TSQLRecord.InitializeTable methods*

- itoNoAutoCreateGroups and itoNoAutoCreateUsers will avoid TSQLAuthGroup.InitializeTable to fill the TSQLAuthGroup and TSQLAuthUser tables with default records

- itoNoCreateMissingField will avoid to create the missing fields on a table

- itoNoIndex4ID won't create the index for the main ID field (do nothing on SQLite3, by design - but may be used for tables on external databases)

- itoNoIndex4UniqueField won't create indexes for "stored AS\_UNIQUE" fields

- itoNoIndex4NestedRecord won't create indexes for TSQLRecord fields

- itoNoIndex4RecordReference won't create indexes for TRecordReference fields
- itoNoIndex4TID won't create indexes for TID fields
- itoNoIndex4RecordVersion won't create indexes for TRecordVersion fields
- INITIALIZETABLE\_NOINDEX constant contain all itoNoIndex\* items

**TSQLInitializeTableOptions = set of TSQLInitializeTableOption;**

*The options to be specified for TSQLRestServer.CreateMissingTables and TSQLRecord.InitializeTable methods*

**TSQLListLayout = ( llLeft, llUp, llClient, llLeftUp );**

*Defines the way the TDrawGrid is displayed by User Interface generation*

**TSQLLog = TSynLog;**

*Logging class with enhanced RTTI*

- will write TObject/TSQLRecord, enumerations and sets content as JSON
- is the default logging family used by the mORMot framework
- mORMotDB.pas unit will set SynDBLog := TSQLLog
- mORMotSQLite3.pas unit will set SynSQLite3Log := TSQLLog

**TSQLModelRecordPropertiesObjArray = array of TSQLModelRecordProperties;**

*Dynamic array of TSQLModelRecordProperties*

- used by TSQLModel to store the non-shared information of all its tables

**TSQLMonitorUsageClass = class of TSQLMonitorUsage;**

*Class-reference type (metaclass) of a TSQLMonitorUsage table*

**TSQLOccasion = ( soSelect, soInsert, soUpdate, soDelete );**

*Used to defined the CRUD associated SQL statement of a command*

- used e.g. by TSQLRecord.GetJSONValues methods and SimpleFieldsBits[] array (in this case, soDelete is never used, since deletion is global for all fields)
- also used for cache content notification

**TSQLOccasions = set of TSQLOccasion;**

*Used to defined a set of CRUD associated SQL statement of a command*

**TSQLPropInfoAttribute = ( aIsUnique, aAuxiliaryRTreeField, aBinaryCollation );**

*ORM attributes for a TSQLPropInfo definition*

**TSQLPropInfoAttributes = set of TSQLPropInfoAttribute;**

*Set of ORM attributes for a TSQLPropInfo definition*

**TSQLPropInfoClass = class of TSQLPropInfo;**

*Class-reference type (metaclass) of a TSQLPropInfo information*

**TSQLPropInfoListOptions = set of ( pilRaiseEORMExceptionIfNotHandled, pilAllowIDFields, pilSubClassesFlattening, pilIgnoreIfGetter, pilSingleHierarchyLevel, pilAuxiliaryFields);**

*Define how the published properties RTTI is to be interpreted*

- i.e. how TSQLPropInfoList.Create() and TSQLPropInfoRTTI.CreateFrom() will handle the incoming RTTI

**TSQLPropInfoObjArray = array of TSQLPropInfo;**

*Dynamic array of ORM fields information for published properties*

**TSQLPropInfoRTTIClass = class of TSQLPropInfoRTTI;**

*Class-reference type (metaclass) of a TSQLPropInfoRTTI information*

```
TSQLPropInfoRTTIPtrInt = TSQLPropInfoRTTIInt32;
```

*Information about a PtrInt published property, according to the native CPU*

- not a real stand-alone class, but a convenient wrapper type

```
TSQLQueryEvent = function(aTable: TSQLRecordClass; aID: TID; FieldType: TSQLFieldType;
Value: PUTF8Char; Operator: integer; Reference: PUTF8Char): boolean of object;
```

*User Interface Query action evaluation function prototype*

- Operator is ord(TSQLQueryOperator) by default (i.e. for class function TSQLRest.QueryIsTrue), or is a custom enumeration index for custom queries (see TSQLQueryCustom.EnumIndex below, and TSQLRest.QueryAddCustom() method)
- for default Operator as ord(TSQLQueryOperator), qoContains and qoBeginWith expect the Reference to be already uppercase
- qoEqualTo to qoGreaterThanOrEqualTo apply to all field kind (work with either numeric either UTF-8 values)
- qoEqualToWithCase to qoSoundsLikeSpanish handle the field as UTF-8 text, and make the comparison using the phonetic algorithm corresponding to a language family
- for default Operator as ord(TSQLQueryOperator), qoSoundsLike\* operators expect the Reference not to be a PUTF8Char, but a typecast of a prepared TSynSoundEx object instance (i.e. pointer(@SoundEx)) by the caller
- for custom query (from TSQLQueryCustom below), the event must handle a special first call with Value=nil to select if this custom Operator/Query is available for the specified aTable: in this case, returning true indicates that this custom query is available for this table
- for custom query (from TSQLQueryCustom below), the event is called with FieldType := TSQLFieldType(TSQLQueryCustom.EnumIndex)+64

```
TSQLQueryOperator = (qoNone, qoEqualTo, qoNotEqualTo, qoLessThan, qoLessThanOrEqualTo,
qoGreaterThan, qoGreaterThanOrEqualTo, qoEqualToWithCase, qoNotEqualToWithCase,
qoContains, qoBeginWith, qoSoundsLikeEnglish, qoSoundsLikeFrench, qoSoundsLikeSpanish
);
```

*UI Query comparison operators*

- these operators are e.g. used to mark or unmark some lines in a UI Grid or for TInterfaceStub.ExpectsCount() methods

```
TSQLQueryOperators = set of TSQLQueryOperator;
```

*Set of UI Query comparison operators*

```
TSQLRawBlob = type RawByteString;
```

*A String used to store the BLOB content*

- equals RawByteString for byte storage, to force no implicit charset conversion, whatever the codepage of the resulting string is
- will identify a sftBlob field type, if used to define such a published property
- by default, the BLOB fields are not retrieved or updated with raw TSQLRest.Retrieve() method, that is "Lazy loading" is enabled by default for blobs, unless TSQLRestClientURI.ForceBlobTransfert property is TRUE (for all tables), or ForceBlobTransfertTable[] (for a particular table); so use RetrieveBlob() methods for handling BLOB fields
- could be defined as value in a TSQLRecord property as such:  

```
property Blob: TSQLRawBlob read fBlob write fBlob;
```

```
TSQLRecordClass = class of TSQLRecord;
```

*Class-reference type (metaclass) of TSQLRecord*

```
TSQLRecordClassDynArray = array of TSQLRecordClass;
```

*A dynamic array used to store the TSQLRecord classes in a Database Model*

```
TSQLRecordFTS3Class = class of TSQLRecordFTS3;
```

*Class-reference type (metaclass) of a FTS3/FTS4/FTS5 virtual table*

```
TSQLRecordHistoryClass = class of TSQLRecordHistory;
```

*Class-reference type (metaclass) to specify the storage table to be used for tracking TSQLRecord changes*

- you can create your custom type from TSQLRecordHistory, even for a particular table, to split the tracked changes storage in several tables:

```
type
 TSQLRecordMyHistory = class(TSQLRecordHistory);
```

- as expected by TSQLRestServer.TrackChanges() method

```
TSQLRecordManyJoinKind = (jkDestID, jkPivotID, jkDestFields, jkPivotFields,
jkPivotAndDestFields);
```

*The kind of fields to be available in a Table resulting of a TSQLRecordMany.DestGetJoinedTable() method call*

- Source fields are not available, because they will be always the same for a same SourceID, and they should be available from the TSQLRecord which hold the TSQLRecordMany instance
- jkDestID and jkPivotID will retrieve only DestTable.ID and PivotTable.ID
- jkDestFields will retrieve DestTable.\* simple fields, or the fields specified by aCustomFieldsCSV (the Dest table name will be added: e.g. for aCustomFieldsCSV='One,Two', will retrieve DestTable.One, DestTable.Two)
- jkPivotFields will retrieve PivotTable.\* simple fields, or the fields specified by aCustomFieldsCSV (the Pivot table name will be added: e.g. for aCustomFieldsCSV='One,Two', will retrieve PivotTable.One, PivotTable.Two)
- jkPivotAndDestAllFields for PivotTable.\* and DestTable.\* simple fields, or will retrieve the specified aCustomFieldsCSV fields (with the table name associated: e.g. 'PivotTable.One, DestTable.Two')

```
TSQLRecordManyObjArray = array of TSQLRecordMany;
```

*A dynamic array of TSQLRecordMany instances*

```
TSQLRecordObjArray = array of TSQLRecord;
```

*A dynamic array storing TSQLRecord instances*

- not used directly, but as specialized T\*ObjArray types

```
TSQLRecordPropertiesMappingOptions = set of (rpmAutoMapKeywordFields,
rpmNoCreateMissingTable, rpmNoCreateMissingField, rpmMissingFieldNameCaseSensitive,
rpmQuoteFieldName, rpmClearPoolOnConnectionIssue);
```

*Used by TSQLRecordPropertiesMapping.Options for custom field mapping of a TSQLRecord on an external database process*

- rpmAutoMapKeywordFields is set if MapAutoKeywordFields has been defined, i.e. if field names which may conflict with a keyword should be automatically mapped to a harmless symbol name
- rpmNoCreateMissingTable will bypass the existing table check, e.g. to circumvent some specific DB provider or case sensitivity issue on tables
- rpmNoCreateMissingField will bypass the existing field check, e.g. to circumvent some specific DB provider or case sensitivity issue on fields
- by default, check of missing field name will be case insensitive, unless the rpmMissingFieldNameCaseSensitive option is set
- rpmQuoteFieldName will quote the field names - to be used e.g. with FireBird in its Dialect 3
- rpmClearPoolOnConnectionIssue will enable detecting connection loss

**TSQLRecordRTreeClass = class of TSQLRecordRTreeAbstract;**

*Class-reference type (metaclass) of a RTREE virtual table*  
 - either a TSQLRecordRTree or a TSQLRecordRTreeInteger

**TSQLRecordServiceLogClass = class of TSQLRecordServiceLog;**

*Class-reference type (metaclass) for storing interface-based service execution statistics*  
 - you could inherit from TSQLRecordServiceLog, and specify additional fields corresponding to the execution context

**TSQLRecordServiceNotificationsClass = class of TSQLRecordServiceNotifications;**

*Class-reference type (metaclass) for storing interface-based service execution statistics used for DB-based asynchronous notifications*  
 - as used by TServiceFactoryClient.SendNotifications

**TSQLRecordTableDeletedClass = class of TSQLRecordTableDeleted;**

*Class-reference type (metaclass) to specify the storage table to be used for tracking TSQLRecord deletion*

**TSQLRecordTreeCoords = array[0..RTREE\_MAX\_DIMENSION-1] of packed record min, max: double; end;**

*This kind of record array can be used for direct floating-point coordinates storage as in TSQLRecordRTree.BlobToCoord*

**TSQLRecordTreeCoordsInteger = array[0..RTREE\_MAX\_DIMENSION-1] of packed record min, max: integer; end;**

*This kind of record array can be used for direct 32-bit integer coordinates storage as in TSQLRecordRTreeInteger.BlobToCoord*

**TSQLRecordVirtualKind = ( rSQLite3, rFTS3, rFTS4, rFTS5, rRTree, rRTreeInteger, rCustomForcedID, rCustomAutoID );**

*The kind of SQLite3 (virtual) table*  
 - TSQLRecordFTS3/4/5 will be associated with vFTS3/vFTS4/vFTS5 values, TSQLRecordRTree/TSQLRecordRTreeInteger with rRTree/rRTreeInteger, any native SQLite3 table as vSQLite3, and a TSQLRecordVirtualTable\*ID as rCustomForcedID/rCustomAutoID  
 - a plain TSQLRecord class can be defined as rCustomForcedID (e.g. for TSQLRecordMany) after registration for an external DB via a call to VirtualTableExternalRegister() from mORMotDB unit

**TSQLRestBatchOption = ( boInsertOrIgnore, boInsertOrReplace, boExtendedJSON, boPostNoSimpleFields, boPutNoCacheFlush, boRollbackOnError );**

*The available options for TSQLRest.BatchStart() process*  
 - boInsertOrIgnore will create 'INSERT OR IGNORE' statements instead of plain 'INSERT' - by now, only the direct mORMotSQLite3 engine supports it  
 - boInsertOrReplace will create 'INSERT OR REPLACE' statements instead of plain 'INSERT' - by now, only the direct mORMotSQLite3 engine supports it  
 - boExtendedJSON will force the JSON to unquote the column names, e.g. writing col1:...,col2:... instead of "col1":..., "col2" ...  
 - boPostNoSimpleFields will avoid to send a TSQLRestBatch.Add() with simple fields as "SIMPLE":[val1,val2...] or "SIMPLE@tablename":[val1,val2...], without the field names  
 - boPutNoCacheFlush won't force the associated Cache entry to be flushed: it is up to the caller to ensure cache coherency  
 - boRollbackOnError will raise an exception and Rollback any transaction if any step failed - default if to continue batch processs, but setting a value <> 200/HTTP\_SUCCESS in Results[]

**TSQLRestBatchOptions = set of TSQLRestBatchOption;**

*A set of options for TSQLRest.BatchStart() process*

- TJSONObjectDecoder will use it to compute the corresponding SQL

**TSQLRestCacheEntryDynArray = array of TSQLRestCacheEntry;**

*For TSQLRestCache, stores all table settings and values*

- this dynamic array will follow TSQLRest.Model.Tables[] layout, i.e. one entry per TSQLRecord class in the data model

**TSQLRestCacheEntryValueDynArray = array of TSQLRestCacheEntryValue;**

*For TSQLRestCache, stores all tables values*

**TSQLRestClass = class of TSQLRest;**

*Class-reference type (metaclass) of a TSQLRest kind*

**TSQLRestDynArray = array of TSQLRest;**

*A dynamic array of TSQLRest instances*

**TSQLRestModelMatch = ( rmNoMatch, rmMatchExact, rmMatchWithCaseChange );**

*How TSQLModel.URIMatch() will compare an URI*

- will allow to make a difference about case-sensitivity

**TSQLRestObjArray = array of TSQLRest;**

*A dynamic array of TSQLRest instances, owning the instances*

**TSQLRestServerAcquireMode = ( amUnlocked, amLocked, amBackgroundThread, amBackgroundORMSharedThread, amMainThread );**

*How a TSQLRest class may execute read or write operations*

- used e.g. for TSQLRestServer.AcquireWriteMode or TSQLRestServer.AcquireExecutionMode/AcquireExecutionLockedTimeOut

**TSQLRestServerAddStat = ( withTables, withMethods, withInterfaces, withSessions );**

*The flags used for TSQLRestServer.AddStats*

**TSQLRestServerAddStats = set of TSQLRestServerAddStat;**

*Some flags used for TSQLRestServer.AddStats*

**TSQLRestServerAuthenticationClass = class of TSQLRestServerAuthentication;**

*Class-reference type (metaclass) used to define an authentication scheme*

**TSQLRestServerAuthenticationClientSetUserPassword = ( passClear, passHashed, passKerberosSPN );**

*Define how TSQLRestServerAuthentication.ClientSetUser() should interpret the supplied password*

- passClear means that the password is not encrypted, e.g. as entered by the user in the login screen  
- passHashed means that the password is already hashed as in TSQLAuthUser.PasswordHashHexa i.e. SHA256('salt'+Value)  
- passKerberosSPN indicates that the password is the Kerberos SPN domain

**TSQLRestServerAuthenticationDynArray = array of TSQLRestServerAuthentication;**

*Maintain a list of TSQLRestServerAuthentication instances*

**TSQLRestServerAuthenticationOption = ( saoUserByLogonOrID, saoHandleUnknownLogonAsStar );**

*Optional behavior of TSQLRestServerAuthentication class*

- by default, saoUserByLogonOrID is set, allowing TSQLRestServerAuthentication.GetUser() to retrieve the TSQLAuthUser by logon name or by ID, if the supplied logon name is an integer

- if `saoHandleUnknownLogonAsStar` is defined, any user successfully authenticated could be logged with the same ID (and authorization) than `TSQLAuthUser.Logon='*'` - of course, this is meaningful only with an external credential check (e.g. via SSPI or Active Directory)

**TSQLRestServerAuthenticationOptions = set of TSQLRestServerAuthenticationOption;**

*Defines the optional behavior of TSQLRestServerAuthentication class*

**TSQLRestServerAuthenticationSignedURIAlgo = ( suaCRC32, suaCRC32C, suaXXHASH, suaMD5, suaSHA1, suaSHA256, suaSHA512 );**

*Algorithms known by TSQLRestServerAuthenticationSignedURI to digitally compute the session\_signature parameter value for a given URI*

- by default, `suaCRC32` will compute fast but not cryptographically secure  
`crc32(crc32(privatesalt,timestamp,8),url,urllen)`
- `suaCRC32C` and `suaXXHASH` will be faster and slightly safer
- but you can select other stronger alternatives, which result will be reduced to 32-bit hexadecimal - `suaMD5` will be the fastest cryptographic hash available on all platforms, for enhanced security, by calling e.g.  
`(aServer.AuthenticationRegister(TSQLRestServerAuthenticationDefault) as TSQLRestServerAuthenticationDefault).Algorithm := suaMD5;`
- `suaSHA1`, `suaSHA256` and `suaSHA512` will be the slowest, to provide additional level of trust, depending on your requirements: note that since the hash is reduced to 32-bit resolution, those may not provide higher security than `suaMD5`
- note that `SynCrossPlatformRest` clients only implements `suaCRC32` yet

**TSQLRestServerAuthenticationSignedURIComputeSignature = function( privatesalt: cardinal; timestamp, url: PAnsiChar; urlen: integer): cardinal of object;**

*Function prototype for TSQLRestServerAuthenticationSignedURI computation of the session\_signature parameter value*

**TSQLRestServerCallBack = procedure(Ctxt: TSQLRestServerURIContext) of object;**

*Method prototype to be used on Server-Side for method-based services*

- will be routed as `ModelRoot/[TableName/TableID/]MethodName` RESTful requests
- this mechanism is able to handle some custom Client/Server request, similar to the `DataSnap` technology, but in a KISS way; it's fully integrated in the Client/Server architecture of our framework
- just add a published method of this type to any `TSQLRestServer` descendant
- when `TSQLRestServer.URI` receive a request for `ModelRoot/MethodName` or `ModelRoot/TableName/TableID/MethodName`, it will check for a published method in its self instance named `MethodName` which MUST be of `TSQLRestServerCallBack` type (not checked neither at compile time neither at runtime: beware!) and call it to handle the request
- important warning: the method implementation MUST be thread-safe
- when `TSQLRestServer.URI` receive a request for `ModelRoot/MethodName`, it calls the corresponding published method with `aRecord` set to nil
- when `TSQLRestServer.URI` receive a request for `ModelRoot/TableName/TableID/MethodName`, it calls the corresponding published method with `aRecord` pointing to a just created instance of the corresponding class, with its field ID set; note that the only set field is ID: other fields of `aRecord` are not set, but must specifically be retrieved on purpose
- for `ModelRoot/TableName/TableID/MethodName`, the just created instance will be freed by `TSQLRestServer.URI` when the method returns
- `Ctxt.Parameters` values are set from incoming URI, and each parameter can be retrieved with a loop like this:

```
if not UrlDecodeNeedParameters(Ctxt.Parameters, 'SORT,COUNT') then
 exit;
while Ctxt.Parameters<>nil do begin
```

```

 UrlDecodeValue(Ctxt.Parameters, 'SORT=', aSortString);
 UrlDecodeValueInteger(Ctxt.Parameters, 'COUNT=', aCountInteger, @Ctxt.Parameters);
end;

```

- Ctxt.Call is set with low-level incoming and outgoing data from client (e.g. Ctxt.Call.InBody contain POST/PUT data message)
- Ctxt.Session\* will identify to the authentication session of the remote client (CONST\_AUTHENTICATION\_NOT\_USED=1 if authentication mode is not enabled or CONST\_AUTHENTICATION\_SESSION\_NOT\_STARTED=0 if the session not started yet) - code may use SessionGetUser() method to retrieve the user details
- Ctxt.Method will indicate the used HTTP verb (e.g. GET/POST/PUT..)
- if process succeeded, implementation shall call Ctxt.Results([]) method to set a JSON response object with one "result" field name or Ctxt>Returns([]) with a JSON object described in Name/Value pairs; if the returned value is not JSON\_CONTENT\_TYPE, use Ctxt>Returns() and its optional CustomHeader parameter can specify a custom header like TEXT\_CONTENT\_TYPE\_HEADER
- if process succeeded, and no data is expected to be returned to the caller, implementation shall call overloaded Ctxt.Success() method with the expected status (i.e. just Ctxt.Success will return HTTP\_SUCCESS)
- if process failed, implementation shall call Ctxt.Error() method to set the corresponding error message and error code number
- a typical implementation may be:

```

procedure TSQLRestServerTest.Sum(Ctxt: TSQLRestServerURIContext);
var a,b: TSynExtended;
begin
 if UrlDecodeNeedParameters(Ctxt.Parameters, 'A,B') then begin
 while Ctxt.Parameters<>nil do begin
 UrlDecodeExtended(Ctxt.Parameters, 'A=', a);
 UrlDecodeExtended(Ctxt.Parameters, 'B=', b, @Ctxt.Parameters);
 end;
 Ctxt.Results([a+b]);
 // same as: Ctxt.Returns(JSONEncode(['result',a+b]));
 // same as: Ctxt.Returns(['result',a+b]);
 end else
 Ctxt.Error('Missing Parameter');
end;

```

- Client-Side can be implemented as you wish. By convention, it could be appropriate to define in either TSQLRestServer (if to be called as ModelRoot/MethodName), either TSQLRecord (if to be called as ModelRoot/TableName[/TableID]/MethodName) a custom public or protected method, calling TSQLRestClientURI.URL with the appropriate parameters, and named (by convention) as MethodName; TSQLRestClientURI has dedicated methods like CallbackGetResult, CallbackGet, CallbackPut and Callback; see also TSQLModel.getURICallback and JSONDecode function

```

function TSQLRecordPeople.Sum(aClient: TSQLRestClientURI; a, b: double): double;
var err: integer;
begin
 val(aClient.CallbackGetResult('sum', ['a',a,'b',b]),result,err);
end;

```

```
TSQLRestServerClass = class of TSQLRestServer;
```

*Class-reference type (metaclass) of a REST server*

```
TSQLRestServerKind = (sMainEngine, sStaticDataTable, sVirtualTable);
```

*Kind of (static) database server implementation available*

- sMainEngine will identify the default main SQLite3 engine
- sStaticDataTable will identify a TSQLRestStorageInMemory - i.e. TSQLRestServer.fStaticData[] which can work without SQLite3
- sVirtualTable will identify virtual TSQLRestStorage classes - i.e. TSQLRestServer.fStaticVirtualTable[]

which points to SQLite3 virtual tables (e.g. TObjectList or external databases)

**TSQLRestServerMethods** = **array of** TSQLRestServerMethod;

*Used to store all method-based services of a TSQLRestServer instance*

**TSQLRestServerMonitorLevels** = **set of** ( m1Tables, m1Methods, m1Interfaces, m1Sessions, m1SQLite3);

*How TSQLRestServer should maintain its statistical information*

- used by TSQLRestServer.StatLevels property

**TSQLRestServerNotifyCallback** = **function**(aSender: TSQLRestServer; **const** aInterfaceDotMethodName, aParams: RawUTF8; aConnectionID: Int64; aFakeCallID: integer; aResult, aErrorMsg: PRawUTF8): **boolean of object**;

*Event signature used to notify a client callback*

- implemented e.g. by TSQLHttpServer.NotifyCallback

**TSQLRestServerOption** = ( rsoNoAJAXJSON, rsoGetAsJsonNotAsString, rsoGetID\_str, rsoRedirectForbiddenToAuth, rsoHttp200WithNoBodyReturns204, rsoAddUpdateReturnsContent, rsoComputeFieldsBeforeWriteOnServerSide, rsoSecureConnectionRequired, rsoCookieIncludeRootPath, rsoCookieHttpOnlyFlagDisable, rsoAuthenticationURIDisable, rsoTimestampInfoURIDisable, rsoHTTPHeaderCheckDisable, rsoGetUserRetrieveNoBlobData, rsoNoInternalState, rsoNoTableURI, rsoMethodUnderscoreAsSlashURI );

*Some options for TSQLRestServer process*

- read-only rsoNoAJAXJSON indicates that JSON data is transmitted in "not expanded" format: you should NEVER change this option by including this property in TSQLRestServer.Options, but always call explicitly TSQLRestServer.NoAJAXJSON := true so that the SetNoAJAXJSON virtual method should be called as expected (e.g. to flush TSQLRestServerDB cache)
- rsoGetAsJsonNotAsString will let ORM GET return to AJAX (non Delphi) clients JSON objects instead of the JSON text stored in database fields
- rsoGetID\_str will add a "ID\_str": string field to circumvent JavaScript limitation of 53-bit for integers
- only for AJAX (non Delphi) clients
- unauthenticated requests from browsers (i.e. not Delphi clients) may be redirected to the TSQLRestServer.Auth() method via rsoRedirectForbiddenToAuth (e.g. for TSQLRestServerAuthenticationHttpBasic popup)
- some REST/AJAX clients may expect to return status code 204 as instead of 200 in case of a successful operation, but with no returned body (e.g. a DELETE with SAPUI5 / OpenUI5 framework): include rsoHttp200WithNoBodyReturns204 so that any HTTP\_SUCCESS (200) with no returned body will return a HTTP\_NOCONTENT (204), as expected by some clients
- by default, Add() or Update() will return HTTP\_CREATED (201) or HTTP\_SUCCESS (200) with no body, unless rsoAddUpdateReturnsContent is set to return as JSON the last inserted/updated record
- TModTime / TCreateTime fields are expected to be filled on client side, unless you set rsoComputeFieldsBeforeWriteOnServerSide so that AJAX requests will set the fields on the server side by calling the TSQLRecord ComputeFieldsBeforeWrite virtual method, before writing to the database
- rsoSecureConnectionRequired will ensure Call is flagged as IfSecured (i.e. in-process, HTTPS, or encrypted WebSockets) - with the only exception of the Timestamp method-based service (for monitoring purposes) - note that this option doesn't make sense behind a proxy, just with a true HTTPS server
- by default, cookies will contain only 'Path=/Model.Root', but '; Path=/' may be also added setting rsoCookieIncludeRootPath
- you can disable the 'HttpOnly' flag via rsoCookieHttpOnlyFlagDisable
- TSQLRestServerURIContext.AuthenticationBearerToken will return the ?authenticationbearer=...

URI parameter value alternatively to the HTTP header unless `rsoAuthenticationURIDisable` is set (for security reasons)

- you can switch off root/timestamp/info URI via `rsoTimestampInfoURIDisable`
- `URI()` header output will be sanitized for any EOL injection, unless `rsoHTTPHeaderCheckDisable` is defined (to gain a few cycles?)
- by default, `TSQLAuthUser.Data` blob is retrieved from the database, unless `rsoGetUserRetrieveNoBlobData` is defined
- `rsoNoInternalState` could be state to avoid transmitting the 'Server-InternalState' header, e.g. if the clients wouldn't need it
- `rsoNoTableURI` will disable any `/root/tablename` URI for safety
- `rsoMethodUnderscoreAsSlashURI` will try to decode `/root/method/name` as 'method\_name' method

**TSQLRestServerOptions = set of TSQLRestServerOption;**

*Allow to customize the TSQLRestServer process via its Options property*

**TSQLRestServerURIContextClass = class of TSQLRestServerURIContext;**

*Class used to define the Client-Server expected routing*

- most of the internal methods are declared as virtual, so it allows any kind of custom routing or execution scheme
- `TSQLRestRoutingREST` and `TSQLRestRoutingJSON_RPC` classes are provided in this unit, to allow RESTful and JSON/RPC protocols

**TSQLRestServerURIContextClientInvoke = set of (csiAsOctetStream);**

*/ used to customize TSQLRestServerURIContext.ClientSideInvoke process*

**TSQLRestServerURIContextClientKind = ( ckUnknown, ckFramework, ckAJAX );**

*Used by TSQLRestServerURIContext.ClientKind to identify the currently connected client*

**TSQLRestServerURIContextCommand = ( execNone, execSOABByMethod, execSOABByInterface, execORMGet, execORMWrite );**

*All commands which may be executed by TSQLRestServer.URI() method*

- `execSOABByMethod` for method-based services
- `execSOABByInterface` for interface-based services
- `execORMGet` for ORM reads i.e. `Retrieve*()` methods
- `execORMWrite` for ORM writes i.e. `Add Update Delete TransactionBegin Commit Rollback` methods

**TSQLRestServerURIDynArray = array of TSQLRestServerURI;**

*Store a list of TSQLRestServer URIs*

**TSQLRestServerURIString = type RawUTF8;**

*A specialized UTF-8 string type, used for TSQLRestServerURI storage*

- URI format is 'address:port/root', but port or root are optional
- you could use `TSQLRestServerURI` record to store and process it

**TSQLRestServerURIStringDynArray = array of TSQLRestServerURIString;**

*A list of UTF-8 strings, used for TSQLRestServerURI storage*

- URI format is 'address:port/root', but port or root are optional
- you could use `TSQLRestServerURI` record to store and process each item

**TSQLRestStorageClass = class of TSQLRestStorage;**

*Class-reference type (metaclass) of our abstract table storage*

- may be e.g. `TSQLRestStorageInMemory`, `TSQLRestStorageInMemoryExternal`, `TSQLRestStorageExternal` or `TSQLRestStorageMongoDB`

**TSQLRestStorageInMemoryClass = class of TSQLRestStorageInMemory;**

*Class-reference type (metaclass) of our TObjectList memory-stored table storage*  
 - may be TSQLRestStorageInMemory or TSQLRestStorageInMemoryExternal

**TSQLRestStorageInMemoryDynArray = array of TSQLRestStorageInMemory;**

*A dynamic array of TSQLRestStorageInMemory instances*  
 - used e.g. by TSQLRestServerFullMemory

**TSQLRestStorageShardClass = class of TSQLRestStorageShard;**

*Class metadata of a Sharding storage engine*

**TSQLRestStorageShardOption = ( ssoNoUpdate, ssoNoUpdateButLastShard, ssoNoDelete, ssoNoDeleteButLastShard, ssoNoBatch, ssoNoList, ssoNoExecute, ssoNoUpdateField, ssoNoConsolidateAtDestroy );**

*Defines how TSQLRestStorageShard will handle its partitioned process*

**TSQLRestStorageShardOptions = set of TSQLRestStorageShardOption;**

*How TSQLRestStorageShard will handle its partitioned process*

**TSQLRestTempStorageItemDynArray = array of TSQLRestTempStorageItem;**

*Used to store the entries in the TSQLRestTempStorage class*

**TSQLRestTempStorageItemKind = set of (itemInsert,itemFakeID);**

*Defines what is stored in a TSQLRestTempStorageItem entry*

**TSQLRestURIParamsLowLevelFlag = ( llfHttps, llfSecured, llfWebsockets );**

*Flags which may be set by the caller to notify low-level context*

- llfHttps will indicates that the communication was made over HTTPS
- llfSecured is set if the transmission is encrypted or in-process, using e.g. HTTPS/SSL/TLS or our proprietary AES/ECDHE algorithms
- llfWebsockets communication was made using WebSockets

**TSQLRestURIParamsLowLevelFlags = set of TSQLRestURIParamsLowLevelFlag;**

*Some flags set by the caller to notify low-level context*

**TSQURIMethod = ( mNone, mGET, mPOST, mPUT, mDELETE, mHEAD, mBEGIN, mEND, mABORT, mLOCK, mUNLOCK, mSTATE, mOPTIONS, mPROPFIND, mPROPPATCH, mTRACE, mCOPY, mMKCOL, mMOVE, mPURGE, mREPORT, mMKACTIVITY, mMKCALENDAR, mCHECKOUT, mMERGE, mNOTIFY, mPATCH, mSEARCH, mCONNECT );**

*The available HTTP methods transmitted between client and server*

- some custom verbs are available in addition to standard REST commands
- most of iana verbs are available see <http://www.iana.org/assignments/http-methods/http-methods.xhtml>
- for basic CRUD operations, we consider Create=mPOST, Read=mGET, Update=mPUT and Delete=mDELETE - even if it is not fully RESTful

**TSQURIMethods = set of TSQURIMethod;**

*Set of available HTTP methods transmitted between client and server*

**TSQVirtualTableClass = class of TSQVirtualTable;**

*Class-reference type (metaclass) of a virtual table implementation*

**TSQVirtualTableCursorClass = class of TSQVirtualTableCursor;**

*Class-reference type (metaclass) of a cursor on an abstract Virtual Table*

**TSQVirtualTableFeature = ( vtWrite, vtTransaction, vtSavePoint, vtWhereIDPrepared );**

### *The possible features of a Virtual Table*

- vtWrite is to be set if the table is not Read/Only
- vtTransaction if handles vttBegin, vttSync, vttCommit, vttRollBack
- vtSavePoint if handles vttSavePoint, vttRelease, vttRollBackTo
- vtWhereIDPrepared if the ID=? WHERE statement will be handled in TSQLVirtualTableCursor.Search()

```
TSQLVirtualTableFeatures = set of TSQLVirtualTableFeature;
```

*A set of features of a Virtual Table*

```
TSQLVirtualTablePreparedCost = (costFullScan, costScanWhere, costSecondaryIndex, costPrimaryIndex);
```

*Abstract planning execution of a query, as set by TSQLVirtualTable.Prepare*

```
TSQLVirtualTableTransaction = (vttBegin, vttSync, vttCommit, vttRollBack, vttSavePoint, vttRelease, vttRollBackTo);
```

*The available transaction levels*

```
TSynMonitorUsageGranularities = set of TSynMonitorUsageGranularity;
```

*Defines one or several time periods for TSynMonitorUsage process*

```
TSynMonitorUsageGranularity = (mugUndefined, mugMinute, mugHour, mugDay, mugMonth, mugYear);
```

*The time periods covered by TSynMonitorUsage process*

- defines the resolution of information computed and stored

```
TURIMapRequest = function(url, method, SendData: PUTF8Char; Resp, Head: PPUTF8Char): Int64Rec; cdecl;
```

*Function prototype for remotely calling a TSQLRestServer*

- use PUTF8Char instead of string: no need to share a memory manager, and can be used with any language (even C or .NET, thanks to the cdecl calling convention)
- you can specify some POST/PUT data in SendData (leave as nil otherwise)
- returns in result.Lo the HTTP STATUS integer error or success code
- returns in result.Hi the server database internal status
- on success, allocate and store the resulting JSON body into Resp^, headers in Head^
- use a GlobalFree() function to release memory for Resp and Head responses

### **Constants implemented in the mORMot unit**

```
ALL_ACCESS_RIGHTS = [0..MAX_SQLTABLES-1];
```

*Supervisor Table access right, i.e. allmighty over all fields*

```
ALL_FIELDS: TSQLFieldBits = [0..MAX_SQLFIELDS-1];
```

*Special TSQLFieldBits value containing all field bits set to 1*

```
AS_UNIQUE = false;
```

*Used as "stored AS\_UNIQUE" published property definition in TSQLRecord*

```
CONST_AUTHENTICATION_NOT_USED = 1;
```

*The used TAuthSession.IDCardinal value if authentication mode is not set*

- i.e. if TSQLRest.HandleAuthentication equals FALSE

```
CONST_AUTHENTICATION_SESSION_NOT_STARTED = 0;
```

*The used TAuthSession.IDCardinal value if the session not started yet*

- i.e. if the session handling is still in its handshaking phase

```
COOKIE_EXPIRED = '; Expires=Sat, 01 Jan 2010 00:00:01 GMT';
```

*You can use this cookie value to delete a cookie on the browser side*

```
COPIABLE_FIELDS: TSQLFieldTypes = [low(TSQLFieldType)..high(TSQLFieldType)] -
[sftUnknown, sftMany];
```

*Kind of fields which can be copied from one TSQLRecord instance to another*

```
DEFAULT_HASH_SYNOPSE =
'67aeea294e1cb515236fd7829c55ec820ef888e8e221814d24d83b3dc4d825dd';
```

*Default hashed password set by TSQLAuthGroup.InitializeTable for all users*

- contains TSQLAuthUser.ComputeHashedPassword('synopse')
- override AuthAdminDefaultPassword, AuthSupervisorDefaultPassword and AuthUserDefaultPassword values to follow your own application expectations

```
FULL_ACCESS_RIGHTS: TSQLAccessRights = (AllowRemoteExecute:
[reSQL, reSQLSelectWithoutTable, reService, reUrlEncodedSQL, reUrlEncodedDelete]; GET:
ALL_ACCESS_RIGHTS; POST: ALL_ACCESS_RIGHTS; PUT: ALL_ACCESS_RIGHTS; DELETE:
ALL_ACCESS_RIGHTS);
```

*Complete Database access right, i.e. allmighty over all Tables*

- WITH the possibility to remotely execute any SQL statement (reSQL right)
- is used by default by TSQLRestClientDB.URI() method, i.e. for direct local/in-process access
- is used as reference to create TSQLAuthUser 'Admin' access policy

```
GUID_FAKETYPEINFO: packed record Kind: TTypeKind; Name: string[5]; Size: cardinal;
Count: integer; end = (Kind: tkRecord; Name: 'TGUID'; Size: SizeOf(TGUID); Count: 0);
```

*Fake TTypeInfo RTTI used for TGUID on older versions of the compiler*

```
HTTP_ACCEPTED = 202;
```

*HTTP Status Code for "Accepted"*

```
HTTP_BADGATEWAY = 502;
```

*HTTP Status Code for "Bad Gateway"*

```
HTTP_BADREQUEST = 400;
```

*HTTP Status Code for "Bad Request"*

```
HTTP_CONFLICT = 409;
```

*HTTP Status Code for "Conflict"*

```
HTTP_CONTINUE = 100;
```

*HTTP Status Code for "Continue"*

```
HTTP_CREATED = 201;
```

*HTTP Status Code for "Created"*

```
HTTP_FORBIDDEN = 403;
```

*HTTP Status Code for "Forbidden"*

```
HTTP_FOUND = 302;
```

*HTTP Status Code for "Found"*

```
HTTP_GATEWAYTIMEOUT = 504;
```

*HTTP Status Code for "Gateway Timeout"*

```
HTTP_HTTPVERSIONNOTSUPPORTED = 505;
```

*HTTP Status Code for "HTTP Version Not Supported"*

HTTP\_MOVEDPERMANENTLY = 301;  
*HTTP Status Code for "Moved Permanently"*

HTTP\_MULTIPLECHOICES = 300;  
*HTTP Status Code for "Multiple Choices"*

HTTP\_NOCONTENT = 204;  
*HTTP Status Code for "No Content"*

HTTP\_NONAUTHORIZEDINFO = 203;  
*HTTP Status Code for "Non-Authoritative Information"*

HTTP\_NONE = 0;  
*Void HTTP Status Code (not a standard value, for internal use only)*

HTTP\_NOTACCEPTABLE = 406;  
*HTTP Status Code for "Not Acceptable"*

HTTP\_NOTALLOWED = 405;  
*HTTP Status Code for "Method Not Allowed"*

HTTP\_NOTFOUND = 404;  
*HTTP Status Code for "Not Found"*

HTTP\_NOTIMPLEMENTED = 501;  
*HTTP Status Code for "Not Implemented"*

HTTP\_NOTMODIFIED = 304;  
*HTTP Status Code for "Not Modified"*

HTTP\_PARTIALCONTENT = 206;  
*HTTP Status Code for "Partial Content"*

HTTP\_PAYLOADTOOLARGE = 413;  
*HTTP Status Code for "Payload Too Large"*

HTTP\_PROXYAUTHREQUIRED = 407;  
*HTTP Status Code for "Proxy Authentication Required"*

HTTP\_RESETCONTENT = 205;  
*HTTP Status Code for "Reset Content"*

HTTP\_SEEOOTHER = 303;  
*HTTP Status Code for "See Other"*

HTTP\_SERVERERROR = 500;  
*HTTP Status Code for "Internal Server Error"*

HTTP\_SUCCESS = 200;  
*HTTP Status Code for "Success"*

HTTP\_SWITCHINGPROTOCOLS = 101;  
*HTTP Status Code for "Switching Protocols"*

HTTP\_TEMPORARYREDIRECT = 307;  
*HTTP Status Code for "Temporary Redirect"*

**HTTP\_TIMEOUT = 408;**

*HTTP Status Code for "Request Time-out"*

**HTTP\_UNAUTHORIZED = 401;**

*HTTP Status Code for "Unauthorized"*

**HTTP\_UNAVAILABLE = 503;**

*HTTP Status Code for "Service Unavailable"*

**HTTP\_USEPROXY = 305;**

*HTTP Status Code for "Use Proxy"*

**INITIALIZETABLE\_NOINDEX: TSQLInitializeTableOptions =**  
**[itoNoIndex4ID..itoNoIndex4RecordVersion];**

*Options to specify no index creation for TSQLRestServer.CreateMissingTables and TSQLRecord.InitializeTable methods*

**INSERT\_WITH\_ID = [rFTS3, rFTS4, rFTS5, rRTree, rRTreeInteger, rCustomForcedID];**

*If the TSQLRecordVirtual table kind expects the ID to be set on INSERT*

**IS\_CUSTOM\_VIRTUAL = [rCustomForcedID, rCustomAutoID];**

*If the TSQLRecordVirtual table kind is not an embedded type*

- can be set for a TSQLRecord after a VirtualTableExternalRegister call

**IS\_FTS = [rFTS3, rFTS4, rFTS5];**

*If the TSQLRecordVirtual table kind is a FTS virtual table*

**JSONSERIALIZEROPTIONS\_AJAX = [jwoAsJsonNotAsString, jwoID\_str];**

*Typical TJSONSerializerSQLRecordOptions values for AJAX clients*

**JSOINTOOBJECT\_TOLERANTOPTIONS = [j2oHandleCustomVariants, j2oIgnoreUnknownEnum,**  
**j2oIgnoreUnknownProperty, j2oIgnoreStringType, j2oAllowInt64Hex];**

*Some open-minded options for JSOINTOObject() parsing*

- won't block JSON unserialization due to some minor class type definitions

- used e.g. by TObjArraySerializer.CustomReader and TInterfacedObjectFake.FakeCall/TServiceMethodExecute.ExecuteJson methods

**MAX\_METHOD\_ARGS = 32;**

*Maximum number of method arguments handled by interfaces*

- if you consider this as a low value, you should better define some records/classes as DTOs instead of multiplying parameters: so don't ask to increase this value, we rather encourage writing clean code

- used e.g. to avoid creating dynamic arrays if not needed, and ease method calls

**MAX\_METHOD\_COUNT = 128;**

*Maximum number of methods handled by interfaces*

- if you think this constant is too low, you are about to break the "Interface Segregation" SOLID principle: so don't ask to increase this value, we won't allow to write un-SOLID code! :)

**MAX\_SQLTABLES = 256;**

*Maximum number of Tables in a Database Model*

- this constant is used internally to optimize memory usage in the generated asm code

- you should not change it to a value lower than expected in an existing database (e.g. as expected by TSQLAccessRights or such)

```
NORESPONSE_CONTENT_TYPE = '!NORESPONSE';
```

*Used to notify e.g. the THttpRequest not to wait for any response from the client*

- is not to be used in normal HTTP process, but may be used e.g. by TWebSocketProtocolRest.ProcessFrame() to avoid to wait for an incoming response from the other endpoint
- should match HTTP\_RESP\_NORESPONSE constant defined in SynCrtSock.pas unit

```
NOT_SIMPLE_FIELDS: TSQLFieldTypes = [sftUnknown, sftBlob, sftMany, sftRecordVersion];
```

*Kind of fields not retrieved during normal query, update or adding*

- by definition, BLOB are excluded to save transmission bandwidth
- by design, TSQLRecordMany properties are stored in an external pivot table
- by convenience, the TRecordVersion number is for internal use only

```
NO_DEFAULT = longint($80000000);
```

*Back to normal alignment*

```
NULLABLE_TYPES = [sftInteger, sftBoolean, sftEnumerate, sftFloat, sftCurrency,
sftDateTime, sftTimeLog, sftUTF8Text];
```

*The SQL field property types with their TNullable\* equivalency*

- those types may be stored in a variant published property, e.g.  
`property Int: TNullableInteger read fInt write fInt;`  
`property Txt: TNullableUTF8Text read fTxt write fTxt;`  
`property Txt: TNullableUTF8Text index 32 read fTxt write fTxt;`

```
PAGINGPARAMETERS_YAHOO: TSQLRestServerURIPagingParameters = (Sort: 'SORT='; Dir:
'DIR='; StartIndex: 'STARTINDEX='; Results: 'RESULTS='; Select: 'SELECT='; Where:
'WHERE='; SendTotalRowsCountFmt: '');
```

*The default URI parameters for query paging*

- those values are the one expected by YUI components

```
RAWTEXT_FIELDS: TSQLFieldTypes = [sftAnsiText, sftUTF8Text];
```

*Kind of fields which will contain pure TEXT values*

- independently from the actual storage level
- i.e. will match RawUTF8, string, UnicodeString, WideString properties

```
RTREE_MAX_DIMENSION = 5;
```

*Maximum handled dimension for TSQLRecordRTree*

- this value is the one used by SQLite3 R-Tree virtual table

```
SERVERDEFAULTMONITORLEVELS: TSQLRestServerMonitorLevels =
[mlTables, mlMethods, mlInterfaces, mlSQLite3];
```

*Default value of TSQLRestServer.StatLevels property*

- i.e. gather all statistics, but mlSessions

```
SERVICE_CONTRACT_NONE_EXPECTED = '*';
```

*Custom contract value to ignore contract validation from client side*

- you could set the aContractExpected parameter to this value for TSQLRestClientURI.ServiceDefine or TSQLRestClientURI.ServiceRegister so that the contract won't be checked with the server
- it will be used e.g. if the remote server is not a mORMot server, but a plain REST/HTTP server - e.g. for public API notifications

```
SERVICE_IMPLEMENTATION_NOID = [sicSingle, sicShared];
```

*The Server-side instance implementation patterns without any ID*

**STATICFILE\_CONTENT\_TYPE = '!STATICFILE';**

*Internal HTTP content-type for efficient static file sending*

- detected e.g. by http.sys' THttpApiServer.Request or via the NGINX X-Accel-Redirect header's THttpServer.Process for direct sending
- the OutCustomHeader should contain the proper 'Content-type: ....' corresponding to the file (e.g. by calling GetMimeContentType() function from SynCommons supplying the file name)
- should match HTTP\_RESP\_STATICFILE constant defined in SynCrtSock.pas unit

**STATICFILE\_CONTENT\_TYPE\_HEADER = HEADER\_CONTENT\_TYPE+STATICFILE\_CONTENT\_TYPE;**

*Internal HTTP content-type Header for efficient static file sending*

**STATICFILE\_CONTENT\_TYPE\_HEADER\_UPPER =  
 HEADER\_CONTENT\_TYPE\_UPPER+STATICFILE\_CONTENT\_TYPE;**

*Uppercase version of HTTP header for static file content serving*

**STRING\_FIELDS: TSQLFieldTypes = [sftAnsiText, sftUTF8Text, sftUTF8Custom,  
 sftDateTime, sftDateTimeMS];**

*Kind of fields which will be stored as TEXT values*

- i.e. RAWTEXT\_FIELDS and TDateTime/TDateTimeMS

**SUPERVISOR\_ACCESS\_RIGHTS: TSQLAccessRights = (AllowRemoteExecute:  
 [reSQLSelectWithoutTable, reService, reUrlEncodedSQL, reUrlEncodedDelete]; GET:  
 ALL\_ACCESS\_RIGHTS; POST: ALL\_ACCESS\_RIGHTS; PUT: ALL\_ACCESS\_RIGHTS; DELETE:  
 ALL\_ACCESS\_RIGHTS);**

*Supervisor Database access right, i.e. allmighty over all Tables*

- but WITHOUT the possibility to remotely execute any SQL statement (reSQL)
- is used as reference to create TSQLAuthUser 'Supervisor' access policy

**SYNMONITORVALUE\_CUMULATIVE = [smvMicroSec, smvBytes, smvCount, smvCount64];**

*Kind of "cumulative" TSynMonitorType stored in TSynMonitor / TSynMonitorUsage*

- those properties will have their values reset for each granularity level
- will recognize TSynMonitorTotalMicroSec, TSynMonitorTotalBytes, TSynMonitorOneBytes, TSynMonitorBytesPerSec, TSynMonitorCount and TSynMonitorCount64 types

**TEXT\_DBFIELDS: TSQLDBFieldTypes = [ftUTF8, ftDate];**

*Kind of DB fields which will contain TEXT content when converted to JSON*

**VIRTUAL\_TABLE\_IGNORE\_COLUMN = -2;**

*If a TSQLVirtualTablePreparedConstraint.Column is to be ignored*

**VIRTUAL\_TABLE\_ROWID\_COLUMN = -1;**

*If a TSQLVirtualTablePreparedConstraint.Column points to the RowID*

**WM\_TIMER\_REFRESH\_REPORT = 2;**

*Timer identifier which indicates we must refresh the Report content*

- used for User Interface generation
- is handled in TSQLRibbon.RefreshClickHandled

**WM\_TIMER\_REFRESH\_SCREEN = 1;**

*Timer identifier which indicates we must refresh the current Page*

- used for User Interface generation
- is associated with the TSQLRibbonTabParameters.AutoRefresh property, and is handled in TSQLRibbon.RefreshClickHandled

## Functions or procedures implemented in the *mORMot* unit

| Functions or procedures                  | Description                                                                                                      | Page |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------|------|
| AddID                                    | Similar to AddInt64() function, but for a TIDDynArray                                                            | 2269 |
| AddID                                    | Similar to AddInt64() function, but for a TIDDynArray                                                            | 2269 |
| AdministrationExecuteGetFiles            | May be used by DatabaseExecute/AdministrationExecute methods to serve a folder content for remote administration | 2269 |
| AuthURI                                  | Computes an URI with optional jwt authentication parameter                                                       | 2269 |
| Base64MagicToBlob                        | Convert a Base64-encoded content into binary hexadecimal ready for SQL                                           | 2269 |
| BlobToBytes                              | Create a TBytes from TEXT-encoded blob data                                                                      | 2269 |
| BlobToStream                             | Create a memory stream from TEXT-encoded blob data                                                               | 2269 |
| BlobToTSQLRawBlob                        | Fill a TSQLRawBlob from TEXT-encoded blob data                                                                   | 2269 |
| BlobToTSQLRawBlob                        | Fill a TSQLRawBlob from TEXT-encoded blob data                                                                   | 2269 |
| BlobToTSQLRawBlob                        | Fill a TSQLRawBlob from TEXT-encoded blob data                                                                   | 2269 |
| ClassFieldAllProps                       | Retrieve the PPropInfo values of all published properties of a class                                             | 2270 |
| ClassFieldCountWithParents               | Retrieve the total number of properties for a class, including its parents                                       | 2270 |
| ClassFieldInstance                       | Retrieve a class Field property instance from a Property class type                                              | 2270 |
| ClassFieldInstance                       | Retrieve a class Field property instance from a Property Name                                                    | 2270 |
| ClassFieldInstances                      | Retrieve all class Field property instances from a Property class type                                           | 2270 |
| ClassFieldInt64                          | Retrieve an integer/Int64 Field property value from a Property Name                                              | 2270 |
| ClassFieldNamesAllProps                  | Retrieve the field names of all published properties of a class                                                  | 2270 |
| ClassFieldNamesAllPropsAsText            | Retrieve the field names of all published properties of a class                                                  | 2270 |
| ClassFieldProp                           | Retrieve a Field property RTTI information from a Property Name                                                  | 2270 |
| ClassFieldPropInstanceMatchingClass      | Retrieve a class instance property value matching a class type                                                   | 2271 |
| ClassFieldPropWithParents                | Retrieve a Field property RTTI information from a Property Name                                                  | 2271 |
| ClassFieldPropWithParentsFromClassOffset | Retrieve a Field property RTTI information searching for an exact Property offset address                        | 2271 |
| ClassFieldPropWithParentsFromClassType   | Retrieve a Field property RTTI information searching for an exact Property class type                            | 2271 |
| ClassFieldPropWithParentsFromUTF8        | Retrieve a Field property RTTI information from a Property Name                                                  | 2271 |

| Functions or procedures                        | Description                                                                                                  | Page |
|------------------------------------------------|--------------------------------------------------------------------------------------------------------------|------|
| ClassFieldPropWithParentsInheritsFromClassType | Retrieve a Field property RTTI information searching for an inherited Property class type                    | 2271 |
| ClassHasPublishedFields                        | Returns TRUE if the class has some published fields, including its parents                                   | 2271 |
| ClassHierarchyWithField                        | Retrieve all class hierarchy types which have some published properties                                      | 2271 |
| ClearObject                                    | Will reset all the object properties to their default                                                        | 2271 |
| CopyCollection                                 | Copy two TCollection instances                                                                               | 2271 |
| CopyObject                                     | Create a new object instance, from an existing one                                                           | 2272 |
| CopyObject                                     | Copy object properties                                                                                       | 2272 |
| CopyStrings                                    | Copy two TString instances                                                                                   | 2272 |
| CurrentServerNonce                             | Returns a safe 256-bit hexadecimal nonce, changing every 5 minutes                                           | 2272 |
| CurrentServiceContext                          | Wrapper function to retrieve the global ServiceContext threadvar value                                       | 2272 |
| CurrentServiceContextServer                    | Wrapper function to retrieve the current REST server instance from the global ServiceContext threadvar value | 2272 |
| DocVariantToObjArray                           | Fill a T*ObjArray variable from a TDocVariant array document values                                          | 2272 |
| DocVariantToObjArray                           | Fill a T*ObjArray variable from a TDocVariant array document values                                          | 2272 |
| DocVariantToObject                             | Fill a class instance from a TDocVariant object document properties                                          | 2272 |
| GetEnumCaption                                 | Retrieve the ready to be displayed text of an enumeration                                                    | 2272 |
| GetEnumNameTrimmed                             | Get the corresponding enumeration name, without the first lowercase chars (otDone -> 'Done')                 | 2273 |
| GetInterfaceFromEntry                          | Execute an instance method from its RTTI per-interface information                                           | 2273 |
| GetJSONObjectAsSQL                             | Decode JSON fields object into an UTF-8 encoded SQL-ready statement                                          | 2273 |
| GetJSONObjectAsSQL                             | Decode JSON fields object into an UTF-8 encoded SQL-ready statement                                          | 2273 |
| GetObjectComponent                             | Retrieve an object's component from its property name and class                                              | 2273 |
| GetSetNameCSV                                  | Get all included values of an enumeration set, as CSV names                                                  | 2273 |
| GetTableNameFromSQLSelect                      | Naive search of '... FROM TableName ...' pattern in the supplied SQL                                         | 2274 |
| GetTableNamesFromSQLSelect                     | Naive search of '... FROM Table1,Table2 ...' pattern in the supplied SQL                                     | 2274 |
| InterfaceArrayDeleteAfterException             | Safe deletion of a T*InterfaceArray dynamic array item                                                       | 2274 |
| InternalClassProp                              | Retrieve the class property RTTI information for a specific class                                            | 2274 |

| Functions or procedures       | Description                                                                                                                      | Page |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------|------|
| InternalClassPropInfo         | Retrieve the class property RTTI information for a specific class                                                                | 2274 |
| InternalMethodInfo            | Retrieve a method RTTI information for a specific class                                                                          | 2274 |
| isBlobHex                     | Return true if the TEXT is encoded as SQLite3 BLOB literals (X'53514C697465' e.g.)                                               | 2274 |
| IsInvalidHTTPHeader           | Check the supplied HTTP header to not contain more than one EOL                                                                  | 2274 |
| IsNotAjaxJSON                 | Returns TRUE if the JSON content is in expanded format                                                                           | 2274 |
| IsObjectDefaultOrVoid         | Returns TRUE on a nil instance or if all its published properties are default/0                                                  | 2274 |
| JSONFileToObject              | Fill the object properties from a JSON file content                                                                              | 2275 |
| JSONGetID                     | Retrieve the ID/RowID field of a JSON object                                                                                     | 2275 |
| JSONGetObject                 | Retrieve a JSON '{"Name":Value,...}' object                                                                                      | 2275 |
| JSONSettingsToObject          | Parse the supplied JSON with some tolerance about Settings format                                                                | 2275 |
| JSONToNewObject               | Create a new object instance, as saved by ObjectToJSON(...,[...,woStoreClassName,...]);                                          | 2275 |
| JSONToObject                  | Read an object properties, as saved by ObjectToJSON function                                                                     | 2276 |
| MonitorPropUsageValue         | Guess the kind of value stored in a TSynMonitor / TSynMonitorUsage property                                                      | 2276 |
| ObjArrayCopy                  | Wrapper to create a new T*ObjArray with copied instances of a source T*ObjArray                                                  | 2276 |
| ObjArrayRecordIDs             | Wrapper to return all TID values of an array of TSQLRecord                                                                       | 2276 |
| ObjArraySearch                | Wrapper to search for a given TSQLRecord by ID in an array of TSQLRecord                                                         | 2276 |
| ObjectDefaultToVariant        | Will convert a blank TObject into a TDocVariant document instance                                                                | 2276 |
| ObjectEquals                  | Is able to compare two objects by value                                                                                          | 2277 |
| ObjectFromInterface           | Low-level function to retrieve the class instance implementing a given interface                                                 | 2277 |
| ObjectFromInterfaceImplements | Low-level function to check if a class instance, retrieved from its interface variable, does in fact implement a given interface | 2277 |
| ObjectLoadJSON                | Read an object properties, as saved by ObjectToJSON function                                                                     | 2277 |
| ObjectLoadVariant             | Read an object properties from a TDocVariant object document                                                                     | 2277 |
| ObjectToJSONDebug             | Will serialize any TObject into its expanded UTF-8 JSON representation                                                           | 2277 |
| ObjectToJSONFile              | Persist a class instance into a JSON file                                                                                        | 2277 |

| Functions or procedures   | Description                                                                                                                                                                                | Page |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| ObjectToVariantDebug      | Will serialize any TObject into a TDocVariant debugging document                                                                                                                           | 2278 |
| ObjectToVariantDebug      | Will serialize any TObject into a TDocVariant debugging document                                                                                                                           | 2278 |
| ReadObject                | Read an object properties, as saved by TINIWriter.WriteObject() method                                                                                                                     | 2278 |
| ReadObject                | Read an object properties, as saved by TINIWriter.WriteObject() method                                                                                                                     | 2278 |
| RecordReference           | Create a TRecordReference with the corresponding parameters                                                                                                                                | 2278 |
| RecordReference           | Create a TRecordReference with the corresponding parameters                                                                                                                                | 2278 |
| RecordRefToID             | Convert a dynamic array of TRecordReference into its corresponding IDs                                                                                                                     | 2278 |
| SelectInClause            | Compute 'PropName in (...)' where clause for a SQL statement                                                                                                                               | 2279 |
| SelectInClause            | Compute 'PropName in (...)' where clause for a SQL statement                                                                                                                               | 2279 |
| SetDefaultValuesObject    | Set any default integer or enumerates (including boolean) published properties values for a TPersistent/TSynPersistent                                                                     | 2279 |
| SetID                     | Set the TID (=64-bit integer) value from the numerical text stored in P^                                                                                                                   | 2279 |
| SetID                     | Set the TID (=64-bit integer) value from the numerical text stored in U                                                                                                                    | 2279 |
| SetWeak                   | Assign a Weak interface reference, to be used for circular references                                                                                                                      | 2279 |
| SetWeakZero               | {ifdef HASINLINE}inline;{endif} raise compilation Internal Error C2170 assign a Weak interface reference, which will be ZEROed (set to nil) when the corresponding object will be released | 2280 |
| SQLFromWhere              | Compute the SQL corresponding to a WHERE clause                                                                                                                                            | 2280 |
| SQLGetOrder               | Get the order table name from a SQL statement                                                                                                                                              | 2280 |
| SQLWhereIsEndClause       | Find out if the supplied WHERE clause starts with one of the ORDER/GROUP/LIMIT/OFFSET/JOIN keywords                                                                                        | 2280 |
| StatusCodeIsSuccess       | Returns true for successful HTTP status codes, i.e. in 200..399 range                                                                                                                      | 2280 |
| StatusCodeToErrorMsg      | Convert any HTTP_* constant to an integer error code and its English text                                                                                                                  | 2280 |
| ToMethod                  | Convert a string HTTP verb into its TSQLURIMethod enumerate                                                                                                                                | 2280 |
| ToText                    | Returns the interface name of a registered GUID, or its hexadecimal value                                                                                                                  | 2280 |
| TSQLRawBlobToBlob         | Creates a TEXT-encoded version of blob data from a memory data                                                                                                                             | 2281 |
| TSQLRawBlobToBlob         | Creates a TEXT-encoded version of blob data from a TSQLRawBlob                                                                                                                             | 2281 |
| TSQLRecordDynArrayCompare | TDynArraySortCompare compatible function, sorting by TSQLRecord.ID                                                                                                                         | 2281 |

| Functions or procedures   | Description                                                                                                                                                                                                | Page |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| TSQlRecordDynArrayHashOne | TDynArrayHashOne compatible function, hashing TSQlRecord.ID                                                                                                                                                | 2281 |
| UnJSONFirstField          | Get the FIRST field value of the FIRST row, from a JSON content                                                                                                                                            | 2281 |
| URIRequest                | This function can be exported from a DLL to remotely access to a TSQlRestServer                                                                                                                            | 2281 |
| UrlDecodeObject           | Decode a specified parameter compatible with URI encoding into its original object contents                                                                                                                | 2281 |
| UTF8CompareBoolean        | Special comparison function for sorting sftBoolean UTF-8 encoded values in the SQLite3 database or JSON content                                                                                            | 2281 |
| UTF8CompareCurr64         | Special comparison function for sorting sftCurrency UTF-8 encoded values in the SQLite3 database or JSON content                                                                                           | 2281 |
| UTF8CompareDouble         | Special comparison function for sorting sftFloat UTF-8 encoded values in the SQLite3 database or JSON content                                                                                              | 2281 |
| UTF8CompareInt64          | Special comparison function for sorting sftInteger, sftTID, sftRecordVersion sftTimeLog/sftModTime/sftCreateTime or sftUnixTime/sftUnixMSTime UTF-8 encoded values in the SQLite3 database or JSON content | 2282 |
| UTF8CompareISO8601        | Special comparison function for sorting sftDateTime or sftDateTimeMS UTF-8 encoded values in the SQLite3 database or JSON content                                                                          | 2282 |
| UTF8CompareRecord         | Special comparison function for sorting ftRecord (TRecordReference/RecordRef) UTF-8 encoded values in the SQLite3 database or JSON content                                                                 | 2282 |
| UTF8CompareUInt32         | Special comparison function for sorting sftEnumerate, sftSet or sftID UTF-8 encoded values in the SQLite3 database or JSON content                                                                         | 2282 |
| UTF8ContentNumberType     | Guess the number type of an UTF-8 encoded field value, as used in TSQlTable.Get()                                                                                                                          | 2282 |
| UTF8ContentType           | Guess the content type of an UTF-8 encoded field value, as used in TSQlTable.Get()                                                                                                                         | 2282 |
| ValueVarToVariant         | Low-level function used to convert a JSON Value into a variant, according to the property type                                                                                                             | 2282 |
| WriteObject               | Write an object properties, as saved by TINIWriter.WriteObject() method                                                                                                                                    | 2283 |
| WriteObject               | Write an object properties, as saved by TINIWriter.WriteObject() method                                                                                                                                    | 2283 |
| _ObjAddProps              | Add the property values of a TObject to a document-based object content                                                                                                                                    | 2283 |

**procedure** AddID(**var** Values: TIDDynArray; Value: TID); overload;

*Similar to AddInt64() function, but for a TIDDynArray*

- some random GPF were identified with AddInt64(TInt64DynArray(Values),...) with the Delphi Win64 compiler

**procedure** AddID(**var** Values: TIDDynArray; **var** ValuesCount: integer; Value: TID); overload;

*Similar to AddInt64() function, but for a TIDDynArray*

- some random GPF were identified with AddInt64(TInt64DynArray(Values),...) with the Delphi Win64 compiler

**procedure** AdministrationExecuteGetFiles(**const** Folder, Mask: TFileName; **const** Param: RawUTF8; **var** Answer: TServiceCustomAnswer);

*May be used by DatabaseExecute/AdministrationExecute methods to serve a folder content for remote administration*

**function** AuthURI(**const** URI, URIAuthenticationBearer: RawUTF8): RawUTF8;

*Computes an URI with optional jwt authentication parameter*

- if AuthenticationBearer is set, will add its values as additional parameter:  
URI?authenticationbearer=URIAuthenticationBearer

**procedure** Base64MagicToBlob(Base64: PUTF8Char; **var** result: RawUTF8);

*Convert a Base64-encoded content into binary hexadecimal ready for SQL*

- returns e.g. X'53514C697465'

**function** BlobToBytes(P: PUTF8Char): TBytes;

*Create a TBytes from TEXT-encoded blob data*

- blob data can be encoded as SQLite3 BLOB literals (X'53514C697465' e.g.) or or Base-64 encoded content ('\uFFF0base64encodedbinary') or plain TEXT

**function** BlobToStream(P: PUTF8Char): TStream;

*Create a memory stream from TEXT-encoded blob data*

- blob data can be encoded as SQLite3 BLOB literals (X'53514C697465' e.g.) or or Base-64 encoded content ('\uFFF0base64encodedbinary') or plain TEXT  
- the caller must free the stream instance after use

**procedure** BlobToTSQRawBlob(P: PUTF8Char; **var** result: TSQRawBlob); overload;

*Fill a TSQRawBlob from TEXT-encoded blob data*

- blob data can be encoded as SQLite3 BLOB literals (X'53514C697465' e.g.) or or Base-64 encoded content ('\uFFF0base64encodedbinary') or plain TEXT

**function** BlobToTSQRawBlob(**const** Blob: RawByteString): TSQRawBlob; overload;

*Fill a TSQRawBlob from TEXT-encoded blob data*

- blob data can be encoded as SQLite3 BLOB literals (X'53514C697465' e.g.) or or Base-64 encoded content ('\uFFF0base64encodedbinary') or plain TEXT

**function** BlobToTSQRawBlob(P: PUTF8Char): TSQRawBlob; overload;

*Fill a TSQRawBlob from TEXT-encoded blob data*

- blob data can be encoded as SQLite3 BLOB literals (X'53514C697465' e.g.) or or Base-64 encoded content ('\uFFF0base64encodedbinary') or plain TEXT

```
function ClassFieldAllProps(ClassType: TClass; Types:
TTypeKinds=[low(TTypeKind)..high(TTypeKind)]): PPropInfoDynArray;
```

*Retrieve the PPropInfo values of all published properties of a class*  
- you could select which property types should be included in the list

```
function ClassFieldCountWithParents(ClassType: TClass; onlyWithoutGetter:
boolean=false): integer;
```

*Retrieve the total number of properties for a class, including its parents*

```
function ClassFieldInstance(Instance: TObject; const PropName: shortstring;
PropClassType: TClass; out PropInstance): boolean; overload;
```

*Retrieve a class Field property instance from a Property Name*  
- this version also search into parent properties  
- returns TRUE and set PropInstance if a matching property was found

```
function ClassFieldInstance(Instance: TObject; PropClassType: TClass; out
PropInstance): boolean; overload;
```

*Retrieve a class Field property instance from a Property class type*  
- this version also search into parent properties  
- returns TRUE and set PropInstance if a matching property was found

```
function ClassFieldInstances(Instance: TObject; PropClassType: TClass):
TObjectDynArray;
```

*Retrieve all class Field property instances from a Property class type*  
- this version also search into parent properties  
- returns all matching property instances found

```
function ClassFieldInt64(Instance: TObject; const PropName: ShortString; out
PropValue: Int64): boolean;
```

*Retrieve an integer/Int64 Field property value from a Property Name*  
- this version also search into parent properties  
- returns TRUE and set PropValue if a matching property was found

```
function ClassFieldNamesAllProps(ClassType: TClass; IncludePropType: boolean=false;
Types: TTypeKinds=[low(TTypeKind)..high(TTypeKind)]): TRawUTF8DynArray;
```

*Retrieve the field names of all published properties of a class*  
- will optionally append the property type to the name, e.g 'Age: integer'  
- you could select which property types should be included in the list

```
function ClassFieldNamesAllPropsAsText(ClassType: TClass; IncludePropType:
boolean=false; Types: TTypeKinds=[low(TTypeKind)..high(TTypeKind)]): RawUTF8;
```

*Retrieve the field names of all published properties of a class*  
- will optionally append the property type to the name, e.g 'Age: integer'  
- you could select which property types should be included in the list

```
function ClassFieldProp(ClassType: TClass; const PropName: shortstring): PPropInfo;
```

*Retrieve a Field property RTTI information from a Property Name*

**function** ClassFieldPropInstanceMatchingClass(aSearchedInstance: TObject;  
aSearchedClassType: TClass): TObject;

*Retrieve a class instance property value matching a class type*  
- if aSearchedInstance is aSearchedClassType, will return aSearchedInstance  
- if aSearchedInstance is not aSearchedClassType, it will try all nested properties of aSearchedInstance for a matching aSearchedClassType: if no exact match is found, will return aSearchedInstance

**function** ClassFieldPropWithParents(aClassType: TClass; **const** aPropName: shortstring;  
aCaseSensitive: boolean=false): PPropInfo;

*Retrieve a Field property RTTI information from a Property Name*  
- this special version also search into parent properties (default is only current)

**function** ClassFieldPropWithParentsFromClassOffset(aClassType: TClass;  
aSearchedOffset: pointer): PPropInfo;

*Retrieve a Field property RTTI information searching for an exact Property offset address*  
- this special version also search into parent properties

**function** ClassFieldPropWithParentsFromClassType(aClassType, aSearchedClassType:  
TClass): PPropInfo;

*Retrieve a Field property RTTI information searching for an exact Property class type*  
- this special version also search into parent properties

**function** ClassFieldPropWithParentsFromUTF8(aClassType: TClass; PropName: PUTF8Char;  
PropNameLen: integer; aCaseSensitive: boolean=false): PPropInfo;

*Retrieve a Field property RTTI information from a Property Name*  
- this special version also search into parent properties (default is only current)

**function**  
ClassFieldPropWithParentsInheritsFromClassType(aClassType, aSearchedClassType:  
TClass): PPropInfo;

*Retrieve a Field property RTTI information searching for an inherited Property class type*  
- this special version also search into parent properties

**function** ClassHasPublishedFields(ClassType: TClass): boolean;

*Returns TRUE if the class has some published fields, including its parents*

**function** ClassHierarchyWithField(ClassType: TClass): TClassDynArray;

*Retrieve all class hierarchy types which have some published properties*

**procedure** ClearObject(Value: TObject; FreeAndNilNestedObjects: boolean=false);

*Will reset all the object properties to their default*  
- strings will be set to '', numbers to 0  
- if FreeAndNilNestedObjects is the default FALSE, will recursively reset all nested class properties values  
- if FreeAndNilNestedObjects is TRUE, will FreeAndNil() all the nested class properties  
- for a TSQLRecord, use its ClearProperties method instead, which will handle the ID property, and any nested JOINed instances

**procedure** CopyCollection(Source, Dest: TCollection);

*Copy two TCollection instances*  
- will call CopyObject() in loop to repopulate the Dest collection, which will work even if Assign() method was not overridden

**procedure** CopyObject(aFrom, aTo: TObject); overload;

*Copy object properties*

- copy Integer, Int64, enumerates (including boolean), variant, records, dynamic arrays, classes and any string properties (excluding shortstring)
- TCollection items can be copied also, if they are of the same exact class
- object properties instances are created in aTo if the objects are not TSQLRecord children (in this case, these are not class instances, but INTEGER reference to records, so only the integer value is copied), that is for regular Delphi classes

**function** CopyObject(aFrom: TObject): TObject; overload;

*Create a new object instance, from an existing one*

- will create a new instance of the same class, then call the overloaded CopyObject() procedure to copy its values

**procedure** CopyStrings(Source, Dest: TStrings);

*Copy two TStrings instances*

- will just call Dest.Assign(Source) in practice

**function** CurrentServerNonce(Previous: boolean=false): RawUTF8;

*Returns a safe 256-bit hexadecimal nonce, changing every 5 minutes*

- as used e.g. by TSQLRestServerAuthenticationDefault.Auth
- this function is very fast, even if cryptographically-level SHA-3 secure

**function** CurrentServiceContext: TServiceRunningContext;

*Wrapper function to retrieve the global ServiceContext threadvar value*

- to be used when accessing the value from a package, to circumvent a Delphi RTL/compiler restriction (bug?)
- for a cleaner SOA/DI approach, consider using TInjectableObjectRest

**function** CurrentServiceContextServer: TSQLRestServer;

*Wrapper function to retrieve the current REST server instance from the global ServiceContext threadvar value*

- may return nil if ServiceContext.Request is nil: in this case, you should better implement your service by inheriting the implementation class from TInjectableObjectRest

**procedure** DocVariantToObjArray(var arr: TDocVariantData; var objArray; objClass: TClass); overload;

*Fill a T\*ObjArray variable from a TDocVariant array document values*

- will always erase the T\*ObjArray instance, and fill it from arr values

**procedure** DocVariantToObjArray(var arr: TDocVariantData; var objArray; objClass: PClassInstance); overload;

*Fill a T\*ObjArray variable from a TDocVariant array document values*

- will always erase the T\*ObjArray instance, and fill it from arr values

**function** DocVariantToObject(var doc: TDocVariantData; obj: TObject): boolean;

*Fill a class instance from a TDocVariant object document properties*

- returns FALSE if the variant is not a dvObject, TRUE otherwise

**function** GetEnumCaption(aTypeInfo: PTypeInfo; const aIndex): string;

*Retrieve the ready to be displayed text of an enumeration*

- will "uncamel" then translate into a generic VCL string
- aIndex will be converted to the matching ordinal value (byte or word)

**function** GetEnumNameTrimed(aTypeInfo: PTypeInfo; **const** aIndex): RawUTF8;

*Get the corresponding enumeration name, without the first lowercase chars (otDone -> 'Done')*  
 - aIndex will be converted to the matching ordinal value (byte or word)  
 - this will return the code-based English text; use GetEnumCaption() to retrieve the enumeration display text

**function** GetInterfaceFromEntry(Instance: TObject; Entry: PInterfaceEntry; **out** Obj): boolean;

*Execute an instance method from its RTTI per-interface information*  
 - calling this function with a pre-computed PInterfaceEntry value is faster than calling the TObject.GetInterface() method, especially when the class implements several interfaces, since it avoid a slow GUID lookup

**function** GetJSONObjectAsSQL(**var** P: PUTF8Char; **const** Fields: TRawUTF8DynArray; Update, InlinedParams: boolean; RowID: TID=0; ReplaceRowIDWithID: Boolean=false): RawUTF8; **overload;**

*Decode JSON fields object into an UTF-8 encoded SQL-ready statement*  
 - this function decodes in the P^ buffer memory itself (no memory allocation or copy), for faster process - so take care that it is an unique string  
 - P should be after the initial '{' or '[' character, i.e. at first field  
 - P contains the next object start or nil on unexpected end of input  
 - if Fields is void, expects expanded "COL1"="VAL1" pairs in P^, stopping at '}' or ']'  
 - otherwise, Fields[] contains the column names and expects "VAL1","VAL2".. in P^  
 - returns 'COL1="VAL1", COL2=VAL2' if UPDATE is true (UPDATE SET format)  
 - returns '(COL1, COL2) VALUES ("VAL1", VAL2)' otherwise (INSERT format)  
 - escape SQL strings, according to the official SQLite3 documentation (i.e. ' inside a string is stored as '')  
 - if InlinedParams is set, will create prepared parameters like 'COL1=:("VAL1");, COL2=: (VAL2):'  
 - if RowID is set, a RowID column will be added within the returned content

*Used for DI-2.1.2 (page 2555).*

**function** GetJSONObjectAsSQL(**const** JSON: RawUTF8; Update, InlinedParams: boolean; RowID: TID=0; ReplaceRowIDWithID: Boolean=false): RawUTF8; **overload;**

*Decode JSON fields object into an UTF-8 encoded SQL-ready statement*  
 - is used e.g. by TSQLRestServerDB.EngineAdd/EngineUpdate methods  
 - expect a regular JSON expanded object as "COL1"="VAL1",...} pairs  
 - make its own temporary copy of JSON data before calling GetJSONObjectAsSQL() above  
 - returns 'COL1="VAL1", COL2=VAL2' if UPDATE is true (UPDATE SET format)  
 - returns '(COL1, COL2) VALUES ("VAL1", VAL2)' otherwise (INSERT format)  
 - if InlinedParams is set, will create prepared parameters like 'COL2=: (VAL2):'  
 - if RowID is set, a RowID column will be added within the returned content

*Used for DI-2.1.2 (page 2555).*

**function** GetObjectComponent(Obj: TPersistent; **const** ComponentName: shortstring; ComponentClass: TClass): pointer;

*Retrieve an object's component from its property name and class*  
 - useful to set User Interface component, e.g.

**function** GetSetNameCSV(aTypeInfo: PTypeInfo; **const** aValue): RawUTF8;

*Get all included values of an enumeration set, as CSV names*

```
function GetTableNameFromSQLSelect(const SQL: RawUTF8; EnsureUniqueTableInFrom: boolean): RawUTF8;
```

*Naive search of '... FROM TableName ...' pattern in the supplied SQL*

```
function GetTableNamesFromSQLSelect(const SQL: RawUTF8): TRawUTF8DynArray;
```

*Naive search of '... FROM Table1,Table2 ...' pattern in the supplied SQL*

```
procedure InterfaceArrayDeleteAfterException(var aInterfaceArray; const aItemIndex: integer; aLog: TSynLogFamily; const aLogMsg: RawUTF8; aInstance: TObject);
```

*Safe deletion of a T\*InterfaceArray dynamic array item*

- similar to InterfaceArrayDelete, but with a safe try .. except block during the entry deletion (since the system may be unstable)
- will also log a warning with the Interface name (from aLogMsg) and aInstance

```
function InternalClassProp(ClassType: TClass): PClassProp;
```

*Retrieve the class property RTTI information for a specific class*

```
function InternalClassPropInfo(ClassType: TClass; out PropInfo: PPropInfo): integer;
```

*Retrieve the class property RTTI information for a specific class*

- will return the number of published properties
- and set the PropInfo variable to point to the first property
- typical use to enumerate all published properties could be:

```
var i: integer;
 CT: TClass;
 P: PPropInfo;
begin
 CT := ..;
 repeat
 for i := 1 to InternalClassPropInfo(CT,P) do begin
 // use P^
 P := P^.Next;
 end;
 CT := GetClassParent(CT);
 until CT=nil;
end;
```

such a loop is much faster than using the RTL's TypeInfo or RTTI units

```
function InternalMethodInfo(aClassType: TClass; const aMethodName: ShortString): PMethodInfo;
```

*Retrieve a method RTTI information for a specific class*

```
function isBlobHex(P: PUTF8Char): boolean;
```

*Return true if the TEXT is encoded as SQLite3 BLOB literals (X'53514C697465' e.g.)*

```
function IsInvalidHTTPHeader(head: PUTF8Char; headlen: PtrInt): boolean;
```

*Check the supplied HTTP header to not contain more than one EOL*

- to avoid unexpected HTTP body injection, e.g. from unsafe business code

```
function IsNotAjaxJSON(P: PUTF8Char): Boolean;
```

*Returns TRUE if the JSON content is in expanded format*

- i.e. as plain [{"ID":10,"FirstName":"John","LastName":"Smith"}...]
- i.e. not as '{"fieldCount":3,"values":["ID","FirstName","LastName",...']}'

```
function IsObjectDefaultOrVoid(Value: TObject): boolean;
```

*Returns TRUE on a nil instance or if all its published properties are default/0*

- calls internally TPropInfo.IsDefaultOrVoid()

```
function JSONFileToObject(const JSONFile: TFileName; var ObjectInstance;
TObjectListItemClass: TClass=nil; Options: TJSONToObjectOptions=[]): boolean;
```

*Fill the object properties from a JSON file content*

- ObjectInstance must be an existing TObject instance
- this function will call RemoveCommentsFromJSON() before process

```
function JSONGetID(P: PUTF8Char; out ID: TID): Boolean;
```

*Retrieve the ID/RowID field of a JSON object*

- this function expects this "ID" property to be the FIRST in the "Name":Value pairs, as generated by TSQLRecord.GetJSONValues(W)
- returns TRUE if a ID/RowID>0 has been found, and set ID with the value

```
function JSONGetObject(var P: PUTF8Char; ExtractID: PID; var EndOfObject: AnsiChar;
KeepIDField: boolean): RawUTF8;
```

*Retrieve a JSON '{"Name":Value,...}' object*

- P is nil in return in case of an invalid object
- returns the UTF-8 encoded JSON object, including first '{' and last '}'
- if ExtractID is set, it will contain the "ID":203 field value, and this field won't be included in the resulting UTF-8 encoded JSON object unless KeepIDField is true
- this function expects this "ID" property to be the FIRST in the "Name":Value pairs, as generated by TSQLRecord.GetJSONValues(W)

```
function JSONSettingsToObject(var InitialJsonContent: RawUTF8; Instance: TObject):
boolean;
```

*Parse the supplied JSON with some tolerance about Settings format*

- will make a TSynTempBuffer copy for parsing, and un-comment it
- returns true if the supplied JSON was successfully retrieved
- returns false and set InitialJsonContent := " on error

```
function JSONTToNewObject(var From: PUTF8Char; var Valid: boolean; Options:
TJSONToOptions=[]): TObject;
```

*Create a new object instance, as saved by ObjectToJSON(...,[...,woStoreClassName,...]);*

- JSON input should be either 'null', either '{"ClassName":"TMyClass",...}'
- woStoreClassName option shall have been used at ObjectToJSON() call
- and the corresponding class shall have been previously registered by TJSONSerializer.RegisterClassForJSON(), in order to retrieve the class type from it name - or, at least, by a Classes.RegisterClass() function call
- the data inside From^ is modified in-place (unescaped and transformed): don't call JSNTToJSON(pointer(JSONRawUTF8)) but makes a temporary copy of the JSON text buffer before calling this function, if want to reuse it later

```
function JSONToObject(var ObjectInstance; From: PUTF8Char; out Valid: boolean;
TObjectListItemClass: TClass=nil; Options: TJSONToJSONObjectOptions=[]): PUTF8Char;
```

*Read an object properties, as saved by ObjectToJSON function*

- ObjectInstance must be an existing TObject instance
- the data inside From^ is modified in-place (unescaped and transformed): calling JSONToObject(pointer(JSONRawUTF8)) will change the JSONRawUTF8 variable content, which may not be what you expect - consider using the ObjectLoadJSON() function instead
- handle Integer, Int64, enumerate (including boolean), set, floating point, TDateTime, TCollection, TString, TRawUTF8List, variant, and string properties (excluding ShortString, but including WideString and UnicodeString under Delphi 2009+)
- TList won't be handled since it may leak memory when calling TList.Clear
- won't handle TObjectList (even if ObjectToJSON is able to serialize them) since has no way of knowing the object type to add (TCollection.Add is missing), unless: 1. you set the TObjectListItemClass property as expected, and provide a TObjectList object, or 2. woStoreClassName option has been used at ObjectToJSON() call and the corresponding classes have been previously registered by TJSONSerializer.RegisterClassForJSON() (or Classes.RegisterClass)
- will clear any previous TCollection objects, and convert any null JSON basic type into nil - e.g. if From='null', will call FreeAndNil(Value)
- you can add some custom (un)serializers for ANY Delphi class, via the TJSONSerializer.RegisterCustomSerializer() class method
- set Valid=TRUE on success, Valid=FALSE on error, and the main function will point in From at the syntax error place (e.g. on any unknown property name)
- caller should explicitly perform a SetDefaultValuesObject(Value) if the default values are expected to be set before JSON parsing

```
function MonitorPropUsageValue(info: PPropInfo): TSynMonitorType;
```

*Guess the kind of value stored in a TSynMonitor / TSynMonitorUsage property*

- will recognize TSynMonitorTotalMicroSec, TSynMonitorOneMicroSec, TSynMonitorTotalBytes, TSynMonitorOneBytes, TSynMonitorBytesPerSec, TSynMonitorCount and TSynMonitorCount64 types from supplied RTTI

```
procedure ObjArrayCopy(const aSourceObjArray; var aDestObjArray; aDestObjArrayClear:
boolean=true);
```

*Wrapper to create a new T\*ObjArray with copied instances of a source T\*ObjArray*

- use internally CopyObject() over aSourceObjArray[] instances
- will clear aDestObjArray before items copy, if aDestObjArrayClear = TRUE

```
procedure ObjArrayRecordIDs(const aSQLRecordObjArray; out result: TInt64DynArray);
```

*Wrapper to return all TID values of an array of TSQLRecord*

```
function ObjArraySearch(const aSQLRecordObjArray; aID: TID): TSQLRecord;
```

*Wrapper to search for a given TSQLRecord by ID in an array of TSQLRecord*

```
function ObjectDefaultToVariant(aClass: TClass; aOptions: TDocVariantOptions):
variant; overload;
```

*Will convert a blank TObject into a TDocVariant document instance*

**function** ObjectEquals(Value1,Value2: TObject; ignoreGetterFields: boolean=false): boolean;

*Is able to compare two objects by value*

- both instances may or may not be of the same class, but properties should match
- will use direct RTTI access of property values, or TSQLRecord.SameValues() if available to make the comparison as fast and accurate as possible
- if you want only to compare the plain fields with no getter function, e.g. if they are just some conversion of the same information, you can set ignoreGetterFields=TRUE

**function** ObjectFromInterface(const aValue: IInterface): TObject;

*Low-level function to retrieve the class instance implementing a given interface*

- this will work with interfaces stubs generated by the compiler, but also with TInterfaceFactory.CreateFakeInstance kind of classes
- returns nil if aValue is nil or not recognized

**function** ObjectFromInterfaceImplements(const aValue: IInterface; const aInterface: TGUID): boolean;

*Low-level function to check if a class instance, retrieved from its interface variable, does in fact implement a given interface*

- this will call ObjectFromInterface(), so will work with interfaces stubs generated by the compiler, but also with TInterfaceFactory.CreateFakeInstance kind of classes

**function** ObjectLoadJSON(var ObjectInstance; const JSON: RawUTF8; TObjectListItemClass: TClass=nil; Options: TJSONToJSONObjectOptions=[]): boolean;

*Read an object properties, as saved by ObjectToJSON function*

- ObjectInstance must be an existing TObject instance
- this overloaded version will make a private copy of the supplied JSON content (via TSynTempBuffer), to ensure the original buffer won't be modified during process, before calling safely JSONToObject()
- will return TRUE on success, or FALSE if the supplied JSON was invalid

**function** ObjectLoadVariant(var ObjectInstance; const aDocVariant: variant; TObjectListItemClass: TClass=nil; Options: TJSONToJSONObjectOptions=[]): boolean;

*Read an object properties from a TDocVariant object document*

- ObjectInstance must be an existing TObject instance
- will return TRUE on success, or FALSE if the supplied aDocVariant was not a TDocVariant object

**function** ObjectToJSONDebug(Value: TObject; Options: TTextWriterWriteObjectOptions=[woDontStoreDefault,woHumanReadable,woStoreClassName,woStorePointer]): RawUTF8;

*Will serialize any TObject into its expanded UTF-8 JSON representation*

- includes debugger-friendly information, similar to TSynLog, i.e. class name and sets/enumerates as text
- could be used to create a TDocVariant object with full information
- wrapper around ObjectToJSON(Value,[woDontStoreDefault,woFullExpand]) also able to serialize plain Exception as a simple '{"Exception":"Message"}', and append .map/.mab source code line number for ESynException

**function** ObjectToJSONFile(Value: TObject; const JSONFile: TFileName; Options: TTextWriterWriteObjectOptions=[woHumanReadable]): boolean;

*Persist a class instance into a JSON file*

- returns TRUE on success, false on error (e.g. the file name is invalid or the file is existing and could not be overwritten)

```
function ObjectToVariantDebug(Value: TObject; const ContextFormat: RawUTF8; const ContextArgs: array of const; const ContextName: RawUTF8='context'): variant; overload;
```

*Will serialize any TObject into a TDocVariant debugging document*

- just a wrapper around \_JsonFast(ObjectToJSONDebug()) with an optional "Context":"..." text message
- if the supplied context format matches '{....}' then it will be added as a corresponding TDocVariant JSON object

```
function ObjectToVariantDebug(Value: TObject): variant; overload;
```

*Will serialize any TObject into a TDocVariant debugging document*

- just a wrapper around \_JsonFast(ObjectToJSONDebug())

```
procedure ReadObject(Value: TObject; const FromContent: RawUTF8; const SubCompName: RawUTF8=''); overload;
```

*Read an object properties, as saved by TINIWriter.WriteObject() method*

- i.e. only Integer, Int64, enumerates (including boolean), floating point values and (Ansi/Wide/Unicode)String properties (excluding shortstring)
- read only the published properties of the current class level (do NOT read the properties content published in the parent classes)
- for integers, if no value is stored in FromContent, the default value is set
- this version gets the appropriate section from [Value.ClassName]
- this version doesn't handle embedded objects

```
procedure ReadObject(Value: TObject; From: PUTF8Char; const SubCompName: RawUTF8=''); overload;
```

*Read an object properties, as saved by TINIWriter.WriteObject() method*

- i.e. only Integer, Int64, enumerates (including boolean), floating point, variant and (Ansi/Wide/Unicode)String properties (excluding shortstring)
- read only the published properties of the current class level (do NOT read the properties content published in the parent classes)
- "From" must point to the [section] containing the object properties
- for integers and enumerates, if no value is stored in From (or From is ""), the default value from the property definition is set

```
function RecordReference(aTableIndex: cardinal; aID: TID): TRecordReference; overload;
```

*Create a TRecordReference with the corresponding parameters*

```
function RecordReference(Model: TSQLModel; aTable: TSQLRecordClass; aID: TID): TRecordReference; overload;
```

*Create a TRecordReference with the corresponding parameters*

```
procedure RecordRefToID(var aArray: TInt64DynArray);
```

*Convert a dynamic array of TRecordReference into its corresponding IDs*

**function** SelectInClause(**const** PropName: RawUTF8; **const** Values: **array of** Int64; **const** Suffix: RawUTF8=''; ValuesInlinedMax: integer=0): RawUTF8; overload;

*Compute 'PropName in (...)' where clause for a SQL statement*

- if Values has no value, returns ''
- if Values has a single value, returns 'PropName=Values0' or inlined 'PropName=:(Values0):' if ValuesInlined is bigger than 1
- if Values has more than one value, returns 'PropName in (Values0,Values1,...)' or 'PropName in (:(Values0):,(Values1):,...)' if length(Values)<ValuesInlinedMax
- PropName can be used as a prefix to the 'in ()' clause, in conjunction with optional Suffix value

**function** SelectInClause(**const** PropName: RawUTF8; **const** Values: **array of** RawUTF8; **const** Suffix: RawUTF8=''; ValuesInlinedMax: integer=0): RawUTF8; overload;

*Compute 'PropName in (...)' where clause for a SQL statement*

- if Values has no value, returns ''
- if Values has a single value, returns 'PropName="Values0"' or inlined 'PropName=:("Values0"): ' if ValuesInlined is true
- if Values has more than one value, returns 'PropName in ("Values0","Values1",...)' or 'PropName in (:("Values0");:("Values1");:,...)' if length(Values)<ValuesInlinedMax
- PropName can be used as a prefix to the 'in ()' clause, in conjunction with optional Suffix value

**procedure** SetDefaultValuesObject(Value: TObject);

*Set any default integer or enumerates (including boolean) published properties values for a TPersistent/TSynPersistent*

- set only the values set as "property ... default ..." at class type level
- will also reset the published properties of the nested classes

**procedure** SetID(**const** U: RawByteString; **var** result: TID); overload;

*Set the TID (=64-bit integer) value from the numerical text stored in U*

- just a redirection to SynCommons.SetInt64()

**procedure** SetID(P: PUTF8Char; **var** result: TID); overload;

*Set the TID (=64-bit integer) value from the numerical text stored in P^*

- just a redirection to SynCommons.SetInt64()

**procedure** SetWeak(aInterfaceField: PIInterface; **const** aValue: IInterface);

*Assign a Weak interface reference, to be used for circular references*

- by default setting aInterface.Field := aValue will increment the internal reference count of the implementation object: when underlying objects reference each other via interfaces (e.g. as parent and children), what causes the reference count to never reach zero, therefore resulting in memory links
- to avoid this issue, use this procedure instead

**procedure** SetWeakZero(aObject: TObject; aObjectInterfaceField: PIInterface; **const** aValue: IInterface);

*{\$ifdef HASINLINE}inline;{\$endif} raise compilation Internal Error C2170 assign a Weak interface reference, which will be ZEROed (set to nil) when the corresponding object will be released*

- this function is bit slower than SetWeak, but will avoid any GPF, by maintaining a list of per-instance weak interface field reference, and hook the FreeInstance virtual method in order to reset any reference to nil: FreeInstance will be overridden for this given class VMT only (to avoid unnecessary slowdown of other classes), calling the previous method afterward (so will work even with custom FreeInstance implementations)
- for faster possible retrieval, it will assign the unused vmtAutoTable VMT entry trick (just like TSQLRecord.RecordProps) - note that it will be compatible also with interfaces implemented via TSQLRecord children
- thread-safe implementation, using a per-class fast lock

**function** SQLFromWhere(**const** Where: RawUTF8): RawUTF8;

*Compute the SQL corresponding to a WHERE clause*

- returns directly the Where value if it starts with one the ORDER/GROUP/LIMIT/OFFSET/JOIN keywords
- otherwise, append ' WHERE '+Where

**function** SQLGetOrder(**const** SQL: RawUTF8): RawUTF8;

*Get the order table name from a SQL statement*

- return the word following any 'ORDER BY' statement
- return 'RowID' if none found

**function** SQLWhereIsEndClause(**const** Where: RawUTF8): boolean;

*Find out if the supplied WHERE clause starts with one of the ORDER/GROUP/LIMIT/OFFSET/JOIN keywords*

**function** StatusCodeIsSuccess(Code: integer): boolean;

*Returns true for successful HTTP status codes, i.e. in 200..399 range*

- will map mainly SUCCESS (200), CREATED (201), NOCONTENT (204), PARTIALCONTENT (206), NOTMODIFIED (304) or TEMPORARYREDIRECT (307) codes
- any HTTP status not part of this range will be identified as erroneous request in the internal server statistics

**function** StatusCodeToErrorMsg(Code: integer): shortstring;

*Convert any HTTP\_\* constant to an integer error code and its English text*

- see @<http://www.w3.org/Protocols/rfc2616/rfc2616-sec10.html>
- will call StatusCodeToErrorMessage()

**function** ToMethod(**const** method: RawUTF8): TSQLURIMethod;

*Convert a string HTTP verb into its TSQLURIMethod enumerate*

**function** ToText(**const** aGUID: TGUID): TGUIDShortString; overload;

*Returns the interface name of a registered GUID, or its hexadecimal value*

**function** TSQLRawBlobToBlob(**const** RawBlob: TSQLRawBlob): RawUTF8; overload;

*Creates a TEXT-encoded version of blob data from a TSQLRawBlob*

- TEXT will be encoded as SQLite3 BLOB literals (X'53514C697465' e.g.)

**function** TSQLRawBlobToBlob(RawBlob: pointer; RawBlobLength: integer): RawUTF8;  
 overload;

*Creates a TEXT-encoded version of blob data from a memory data*

- same as TSQLRawBlob, but with direct memory access via a pointer/byte size pair
- TEXT will be encoded as SQLite3 BLOB literals (X'53514C697465' e.g.)

**function** TSQLRecordDynArrayCompare(const Item1,Item2): integer;

*TDynArraySortCompare compatible function, sorting by TSQLRecord.ID*

**function** TSQLRecordDynArrayHashOne(const Elem; Hasher: THasher): cardinal;

*TDynArrayHashOne compatible function, hashing TSQLRecord.ID*

**function** UnJSONFirstField(var P: PUTF8Char): RawUTF8;

*Get the FIRST field value of the FIRST row, from a JSON content*

- e.g. useful to get an ID without converting a JSON content into a TSQLTableJSON

*Used for DI-2.1.2 (page 2555).*

**function** URIRequest(url, method, SendData: PUTF8Char; Resp, Head: PPUTF8Char):  
 Int64Rec; cdecl;

*This function can be exported from a DLL to remotely access to a TSQLRestServer*

- use TSQLRestServer.ExportServer to assign a server to this function
- return 501 HTTP\_NOTIMPLEMENTED if no TSQLRestServer.ExportServer has been assigned
- memory for Resp and Head are allocated with GlobalAlloc(): client must release this pointers with GlobalFree() after having retrieved their content
- simply use TSQLRestClientURIDll to access to an exported URIRequest() function

*Used for DI-2.1.1.2.1 (page 2554).*

**function** UrlDecodeObject(U: PUTF8Char; Upper: PAnsiChar; var ObjectInstance; Next:  
 PPUTF8Char=nil; Options: TJSONToJSONObjectOptions=[]): boolean;

*Decode a specified parameter compatible with URI encoding into its original object contents*

- ObjectInstance must be an existing TObject instance
- will call internally JSONToObject() function to unserialize its content
- 

*UrlDecodeExtended('price=20.45&where=LastName%3D%27M%C3%B4net%27','PRICE=',P,@Next ) will return Next^='where=...' and P=20.45*

- if Upper is not found, Value is not modified, and result is FALSE
- if Upper is found, Value is modified with the supplied content, and result is TRUE

**function** UTF8CompareBoolean(P1,P2: PUTF8Char): PtrInt;

*Special comparison function for sorting sftBoolean UTF-8 encoded values in the SQLite3 database or JSON content*

**function** UTF8CompareCurr64(P1,P2: PUTF8Char): PtrInt;

*Special comparison function for sorting sftCurrency UTF-8 encoded values in the SQLite3 database or JSON content*

**function** UTF8CompareDouble(P1,P2: PUTF8Char): PtrInt;

*Special comparison function for sorting sftFloat UTF-8 encoded values in the SQLite3 database or JSON content*

**function** UTF8CompareInt64(P1,P2: PUTF8Char): PtrInt;

*Special comparison function for sorting sftInteger, sftTID, sftRecordVersion  
 sftTimeLog/sftModTime/sftCreateTime or sftUnixTime/sftUnixMSTime UTF-8 encoded values in  
 the SQLite3 database or JSON content*

**function** UTF8CompareISO8601(P1,P2: PUTF8Char): PtrInt;

*Special comparison function for sorting sftDateTime or sftDateTimeMS UTF-8 encoded values in  
 the SQLite3 database or JSON content*

**function** UTF8CompareRecord(P1,P2: PUTF8Char): PtrInt;

*Special comparison function for sorting ftRecord (TRecordReference/RecordRef) UTF-8 encoded  
 values in the SQLite3 database or JSON content*

**function** UTF8CompareUInt32(P1,P2: PUTF8Char): PtrInt;

*Special comparison function for sorting sftEnumerate, sftSet or sftID UTF-8 encoded values in the  
 SQLite3 database or JSON content*

**function** UTF8ContentNumberType(P: PUTF8Char): TSQLFieldType;

*Guess the number type of an UTF-8 encoded field value, as used in TSQLTable.Get()*

- if P is nil or 'null', return sftUnknown
- will return sftInteger or sftFloat if the supplied text is a number
- will return sftUTF8Text for any non numerical content

**function** UTF8ContentType(P: PUTF8Char): TSQLFieldType;

*Guess the content type of an UTF-8 encoded field value, as used in TSQLTable.Get()*

- if P is nil or 'null', return sftUnknown
- otherwise, guess its type from its value characters
- sftBlob is returned if the field is encoded as SQLite3 BLOB literals (X'53514C697465' e.g.) or with  
 '\uFFFF0' magic code
- since P is PUTF8Char, string type is sftUTF8Text only
- sftFloat is returned for any floating point value, even if it was declared as sftCurrency type
- sftInteger is returned for any INTEGER stored value, even if it was declared as sftEnumerate,  
 sftSet, sftID, sftTID, sftRecord, sftRecordVersion, sftSessionUserID, sftBoolean,  
 sftModTime/sftCreateTime/sftTimeLog or sftUnixTime/sftUnixMSTime type

**procedure** ValueVarToVariant(Value: PUTF8Char; ValueLen: integer; fieldType:  
 TSQLFieldType; var result: TVarData; createValueTempCopy: boolean; typeInfo: pointer;  
 options: TDocVariantOptions=JSON\_OPTIONS\_FAST);

*Low-level function used to convert a JSON Value into a variant, according to the property type*

- for sftObject, sftVariant, sftBlobDynArray and sftUTF8Custom, the JSON buffer may be an array  
 or an object, so createValueTempCopy can create a temporary copy before parsing it in-place, to  
 preserve the buffer
- sftUnknown and sftMany will set a varEmpty (Unassigned) value
- typeInfo may be used for sftBlobDynArray conversion to a TDocVariant array

```
procedure WriteObject(Value: TObject; var IniContent: RawUTF8; const Section: RawUTF8; const SubCompName: RawUTF8=''); overload;
```

*Write an object properties, as saved by TINIWriter.WriteObject() method*

- i.e. only Integer, Int64, enumerates (including boolean), floating point values and (Ansi/Wide/Unicode)String properties (excluding shortstring)
- write only the published properties of the current class level (do NOT write the properties content published in the parent classes)
- direct update of INI-like content
- for integers, value is always written, even if matches the default value

```
function WriteObject(Value: TObject): RawUTF8; overload;
```

*Write an object properties, as saved by TINIWriter.WriteObject() method*

- i.e. only Integer, Int64, enumerates (including boolean), floating point values and (Ansi/Wide/Unicode)String properties (excluding shortstring)
- write only the published properties of the current class level (do NOT write the properties content published in the parent classes)
- return the properties as text Name=Values pairs, with no section
- for integers, if the value matches the default value, it is not added to the result

```
procedure _ObjAddProps(Value: TObject; var Obj: variant); overload;
```

*Add the property values of a TObject to a document-based object content*

- if Obj is a TDocVariant object, then all Values's published properties will be added at the root level of Obj

## Variables implemented in the mORMot unit

```
AlgoDeflate: TAlgoCompress;
```

*Access to Zip Deflate compression in level 6 as a TAlgoCompress class*

```
AlgoDeflateFast: TAlgoCompress;
```

*Access to Zip Deflate compression in level 1 as a TAlgoCompress class*

```
AuthAdminDefaultPassword: RawUTF8 = DEFAULT_HASH_SYNOPSE;
```

*Default hashed password set by TSQLAuthGroup.InitializeTable for 'Admin' user*

- you can override this value to follow your own application expectations

```
AuthAdminGroupDefaultTimeout: integer = 10;
```

*Default timeout period set by TSQLAuthGroup.InitializeTable for 'Admin' group*

- you can override this value to follow your own application expectations

```
AuthGuestGroupDefaultTimeout: integer = 60;
```

*Default timeout period set by TSQLAuthGroup.InitializeTable for 'Guest' group*

- you can override this value to follow your own application expectations
- note that clients will maintain the session alive using CacheFlush/\_ping\_

```
AuthSupervisorDefaultPassword: RawUTF8 = DEFAULT_HASH_SYNOPSE;
```

*Default hashed password set by TSQLAuthGroup.InitializeTable for 'Supervisor' user*

- you can override this value to follow your own application expectations

```
AuthSupervisorGroupDefaultTimeout: integer = 60;
```

*Default timeout period set by TSQLAuthGroup.InitializeTable for 'Supervisor' group*

- you can override this value to follow your own application expectations
- note that clients will maintain the session alive using CacheFlush/\_ping\_

```
AuthUserDefaultPassword: RawUTF8 = DEFAULT_HASH_SYNOPOSE;
```

*Default hashed password set by TSQLAuthGroup.InitializeTable for 'User' user*  
 - you can override this value to follow your own application expectations

```
AuthUserGroupDefaultTimeout: integer = 60;
```

*Default timeout period set by TSQLAuthGroup.InitializeTable for 'User' group*  
 - you can override this value to follow your own application expectations  
 - note that clients will maintain the session alive using CacheFlush/\_ping\_

```
DEFAULT_WRITEOPTIONS: array[boolean] of TTextWriterWriteObjectOptions = (
[woDontStoreDefault, woSQLRawBlobAsBase64], [woDontStoreDefault,
woDontStoreEmptyString, woDontStore0, woSQLRawBlobAsBase64]);
```

*The options used by TObjArraySerializer, TInterfacedObjectFake and TServiceMethodExecute when serializing values as JSON*  
 - used as DEFAULT\_WRITEOPTIONS[DontStoreVoidJSON]  
 - you can modify this global variable to customize the whole process

```
ObjArraySerializers: TPointerClassHash;
```

*A shared list of T\*ObjArray registered serializers*  
 - you should not access this variable, but via inline methods

```
ServiceContext: TServiceRunningContext;
```

*This thread-specific variable will be set with the currently running service context (on the server side)*

- note that in case of direct server side execution of the service, this information won't be filled, so the safest (and slightly faster) access to the TSQLRestServer instance associated with a service is to inherit your implementation class from TInjectableObjectRest, and not use this threadvar  
 - is set by TServiceFactoryServer.ExecuteMethod() just before calling the implementation method of a service, allowing to retrieve the current execution context - Request member is set from a client/server execution: Request.Server is the safe access point to the underlying TSQLRestServer, in such context - also consider the CurrentServiceContextServer function to retrieve directly the running TSQLRestServer (if any)  
 - its content is reset to zero out of the scope of a method execution  
 - when used, a local copy or a PServiceRunningContext pointer should better be created, since accessing a threadvar has a non negligible performance cost - for instance, if you want to use a "with" statement:

```
with PServiceRunningContext(@ServiceContext)^ do
... access TServiceRunningContext members
```

or as a local variable:

```
var context: PServiceRunningContext;
inContentType: RawUTF8;
begin
context := @ServiceContext; // threadvar access once
...
inContentType := context.Request.Call^.InBodyType;
end;
```

- when accessed from a package, use function CurrentServiceContext() instead, to circumvent a Delphi RTL/compiler restriction (bug?)

```
SERVICELOG_WRITEOPTIONS: TTextWriterWriteObjectOptions = [woDontStoreDefault,
woDontStoreEmptyString, woDontStore0, woHideSynPersistentPassword];
```

*The options used by TServiceFactoryServer.OnLogRestExecuteMethod*  
 - you can modify this global variable to customize the whole process

```
SetThreadNameLog: TSynLogClass = TSQLLog;
```

*TSQLLogClass used by overridden SetThreadName() function to name the thread*

```
SETTINGS_WRITEOPTIONS: TTextWriterWriteObjectOptions = [woHumanReadable,
woStoreStoredFalse, woHumanReadableFullSetsAsStar,
woHumanReadableEnumSetAsComment, woInt64AsHex];
```

*The options used by TSynJsonFileSettings.SaveIfNeeded*

- you can modify this global variable to customize the whole process

```
SQLite3Log: TSynLogClass = TSQLLog;
```

*TSQLLog class is used for logging for all our ORM related functions*

- this global variable can be used to customize it for the whole process
- each TSQLRest.LogClass property is set by default to this SQLite3Log
- you can override the TSQLRest.LogClass property value to customize it for a given REST instance

```
StatusCodeToErrorMessage: procedure(Code: integer; var result: RawUTF8);
```

*Convert any HTTP\_\* constant to a short English text*

- see @<http://www.w3.org/Protocols/rfc2616/rfc2616-sec10.html>
- if SynCrtSock is linked (i.e. set mORMotHttpClient or mORMotHttpServer), SynCrtSock.StatusCodeToReason() function will be assigned, which is somewhat faster, and more complete

```
USEFASTMM4ALLOC: boolean = false;
```

*If this variable is TRUE, the URIRequest() function won't use Win32 API GlobalAlloc() function, but fastest native Getmem()*

- can be also useful for debugg

*Used for DI-2.1.1.2.1 (page 2554).*

## 27.53. mORMotDB.pas unit

*Purpose:* Virtual Tables for external DB access for mORMot

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *mORMotDB* unit

| Unit Name         | Description                                                                                                                                                                                             | Page |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>     | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                        | 1907 |
| <i>SynCommons</i> | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                               | 718  |
| <i>SynDB</i>      | Abstract database direct access classes<br>- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                             | 1208 |
| <i>SynLog</i>     | Logging functions used by Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                   | 1368 |
| <i>SynTable</i>   | Filter/database/cache/buffer/security/search/multithread/OS features<br>- as a complement to SynCommons, which tended to increase too much<br>- licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1728 |

*mORMotDB class hierarchy*

### Objects implemented in the *mORMotDB* unit

| Objects                        | Description                                                       | Page |
|--------------------------------|-------------------------------------------------------------------|------|
| TSQLRestStorageExternal        | REST server with direct access to a SynDB-based external database | 2287 |
| TSQLVirtualTableCursorExternal | A Virtual Table cursor for reading a TSQLDBStatement content      | 2289 |
| TSQLVirtualTableExternal       | A SynDB-based virtual table for accessing any external database   | 2290 |

**TSQLRestStorageExternal = class(TSQLRestStorage)**

*REST server with direct access to a SynDB-based external database*

- handle all REST commands, using the external SQL database connection, and prepared statements
- is used by TSQLRestServer.URI for faster RESTful direct access
- for JOINed SQL statements, the external database is also defined as a SQLite3 virtual table, via the TSQLVirtualTableExternal[Cursor] classes

**constructor** Create(aClass: TSQLRecordClass; aServer: TSQLRestServer); **override;**

*Initialize the remote database connection*

- you should not use this, but rather call VirtualTableExternalRegister()
- RecordProps.ExternalDatabase will map the associated TSQLDBConnectionProperties
- RecordProps.ExternalTableName will retrieve the real full table name, e.g. including any database schema prefix

**destructor** Destroy; **override;**

*Finalize the remote database connection*

**function** ComputeSQL(const Prepared: TSQLVirtualTablePrepared): RawUTF8;

- Compute the SQL query corresponding to a prepared request*
- can be used internally e.g. for debugging purposes

**class function** ConnectionProperties(aClass: TSQLRecordClass; aServer: TSQLRestServer): TSQLDBConnectionProperties; **overload;**

*Retrieve the external database connection associated to a TSQLRecord*

- just map aServer.StaticVirtualTable[] and will return nil if not a TSQLRestStorageExternal

**function** CreateSQLMultiIndex(Table: TSQLRecordClass; const FieldNames: array of RawUTF8; Unique: boolean; IndexName: RawUTF8=''): boolean; **override;**

*Create one index for all specific FieldNames at once*

- this method will in fact call the SQLAddIndex method, if the index is not already existing
- for databases which do not support indexes on BLOB fields (i.e. all engine but SQLite3), such FieldNames will be ignored

**function** EngineDelete(TableModelIndex: integer; ID: TID): boolean; **override;**

*Delete a row, calling the external engine with SQL*

- made public since a TSQLRestStorage instance may be created stand-alone, i.e. without any associated Model/TSQLRestServer

**function** EngineUpdateField(TableModelIndex: integer; const SetFieldName, SetValue, WhereFieldName, WhereValue: RawUTF8): boolean; **override;**

*Update a field value of the external database*

**function** EngineUpdateFieldIncrement(TableModelIndex: integer; ID: TID; const FieldName: RawUTF8; Increment: Int64): boolean; **override;**

*Update a field value of the external database*

**class function** Instance(aClass: TSQLRecordClass; aServer: TSQLRestServer): TSQLRestStorageExternal;

*Retrieve the REST server instance corresponding to an external TSQLRecord*

- just map aServer.StaticVirtualTable[] and will return nil if not a TSQLRestStorageExternal
- you can use it e.g. to call MapField() method in a fluent interface

**function** RetrieveBlobFields(Value: TSQLRecord): boolean; **override;**

*Overridden method for direct external database engine call*

**function** SearchField(const FieldName: RawUTF8; FieldValue: Int64; out ResultID: TIDDynArray): boolean; overload; **override;**

*Search for a numerical field value*

- return true on success (i.e. if some values have been added to ResultID)
- store the results into the ResultID dynamic array

**function** SearchField(const FieldName, FieldValue: RawUTF8; out ResultID: TIDDynArray): boolean; overload; **override;**

*Search for a field value, according to its SQL content representation*

- return true on success (i.e. if some values have been added to ResultID)
- store the results into the ResultID dynamic array

**function** TableHasRows(Table: TSQLRecordClass): boolean; **override;**

*Overridden method for direct external database engine call*

**function** TableRowCount(Table: TSQLRecordClass): Int64; **override;**

*Overridden method for direct external database engine call*

**function** TransactionBegin(aTable: TSQLRecordClass; SessionID: cardinal=1): boolean; **override;**

*Begin a transaction (implements REST BEGIN Member)*

- to be used to speed up some SQL statements like Insert/Update/Delete
- must be ended with Commit on success
- must be aborted with Rollback if any SQL statement failed
- return true if no transaction is active, false otherwise

**function** UpdateBlobFields(Value: TSQLRecord): boolean; **override;**

*Overridden method for direct external database engine call*

**procedure** Commit(SessionID: cardinal=1; RaiseException: boolean=false); **override;**

*End a transaction (implements REST END Member)*

- write all pending SQL statements to the external database

**procedure** EndCurrentThread(Sender: TThread); **override;**

*This method is called by TSQLRestServer.EndCurrentThread method just before a thread is finished to ensure that the associated external DB connection will be released for this thread*

- this overridden implementation will clean thread-specific connections, i.e. call TSQLDBConnectionPropertiesThreadSafe.EndCurrentThread method
- this method shall be called directly, nor from the main thread

**procedure** EngineAddForceSelectMaxID;

*Reset the internal cache of external table maximum ID*

- next EngineAdd/BatchAdd will execute SELECT max(ID) FROM externaltable
- is a lighter alternative to EngineAddUseSelectMaxID=TRUE, since this method may be used only once, when some records have been inserted into the external database outside this class scope (e.g. by legacy code)

**procedure** RollBack(SessionID: cardinal=1); **override;**

*Abort a transaction (implements REST ABORT Member)*

- restore the previous state of the database, before the call to TransactionBegin

**property** EngineAddForcedID: TID read fEngineAddForcedID write fEngineAddForcedID;

*Disable internal ID generation for INSERT*

- by default, a new ID will be set (either with 'select max(ID)' or via the OnEngineLockedNextID event)
- if the client supplies a forced ID within its JSON content, it would be used for adding
- define this property to a non 0 value if no such ID is expected to be supplied, but a fixed "fake ID" is returned by the Add() method; at external DB level, no such ID field would be computed nor set at INSERT - this feature may be useful when working with a legacy database - of course any ID-based ORM method would probably fail to work

**property** EngineAddUseSelectMaxID: Boolean read fEngineAddUseSelectMaxID write fEngineAddUseSelectMaxID;

*By default, any INSERT will compute the new ID from an internal variable*

- it is very fast and reliable, unless external IDs can be created outside this engine
- you can set EngineAddUseSelectMaxID=true to execute a slower 'select max(ID) from TableName' SQL statement before each EngineAdd()
- a lighter alternative may be to call EngineAddForceSelectMaxID only when required, i.e. when the external DB has just been modified by a third-party/legacy SQL process

**property** OnEngineAddComputeID: TOnEngineAddComputeID read fOnEngineAddComputeID write fOnEngineAddComputeID;

*Define an alternate method of compute the ID for INSERT*

- by default, a new ID will be with 'select max(ID)', and an internal counter (unless EngineAddUseSelectMaxID is true)
- you can specify a custom callback, which may compute the ID as expected (e.g. using a SQL sequence)

**property** Properties: TSQLDBConnectionProperties read GetConnectionProperties;

*The associated external SynDB database connection properties*

**TSQVirtualTableCursorExternal = class(TSQVirtualTableCursor)**

*A Virtual Table cursor for reading a TSQLDBStatement content*

- this is the cursor class associated to TSQVirtualTableExternal

**destructor** Destroy; **override;**

*Finalize the external cursor by calling ReleaseRows*

**function** Column(aColumn: integer; var aResult: TSQLVar): boolean; **override;**

*Called to retrieve a column value of the current data row*

- if aColumn=VIRTUAL\_TABLE\_ROWID\_COLUMN(-1), will return the row ID as varInt64 into aResult
- will return false in case of an error, true on success

**function** HasData: boolean; **override;**

*Called after Search() to check if there is data to be retrieved*

- should return false if reached the end of matching data

**function** Next: boolean; **override;**

*Called to go to the next row of matching data*

- should return false on low-level database error (but true in case of a valid call, even if HasData will return false, i.e. no data match)

**function** Search(const Prepared: TSQLVirtualTablePrepared): boolean; **override;**

*Called to begin a search in the virtual table, creating a SQL query*

- the TSQLVirtualTablePrepared parameters were set by TSQLVirtualTable.Prepare and will contain both WHERE and ORDER BY statements (retrieved by x\_BestIndex from a TSQLite3IndexInfo structure)
- Prepared will contain all prepared constraints and the corresponding expressions in the Where[].Value field
- will move cursor to first row of matching data
- will return false on low-level database error (but true in case of a valid call, even if HasData will return false, i.e. no data match)
- all WHERE and ORDER BY clauses are able to be translated into a plain SQL statement calling the external DB engine
- will create the internal fStatement from a SQL query, bind the parameters, then execute it, ready to be accessed via HasData/Next

**property** SQL: RawUTF8 read fSQL;

*Read-only access to the SELECT statement*

TSQLVirtualTableExternal = **class**(TSQLVirtualTable)

*A SynDB-based virtual table for accessing any external database*

- for ORM access, you should use VirtualTableExternalRegister method to associate this virtual table module to any TSQLRecord class
- transactions are handled by this module, according to the external database

**function** Delete(aRowID: Int64): boolean; **override;**

*Called to delete a virtual table row*

- returns true on success, false otherwise

**function** Drop: boolean; **override;**

*Called when a DROP TABLE statement is executed against the virtual table*

- returns true on success, false otherwise

**function** Insert(aRowID: Int64; var Values: TSQLVarDynArray; out insertedRowID: Int64): boolean; **override;**

*Called to insert a virtual table row content*

- column order follows the Structure method, i.e. StoredClassProps.Fields[] order
- returns true on success, false otherwise
- returns the just created row ID in insertedRowID on success

**function** Prepare(var Prepared: TSQLVirtualTablePrepared): boolean; **override;**

*Called to determine the best way to access the virtual table*

- will prepare the request for TSQLVirtualTableCursor.Search()
- this overridden method will let the external DB engine perform the search, using a standard SQL "SELECT \* FROM .. WHERE .. ORDER BY .." statement
- in Where[], Expr must be set to not 0 if needed for Search method, and OmitCheck always set to true since double check is not necessary
- OmitOrderBy will be set to true since double sort is not necessary
- EstimatedCost/EstimatedRows will receive the estimated cost, with lowest value if fStatic.fFieldsExternal[].ColumnIndexed is set (i.e. if column has an index)

```
function Update(oldRowID, newRowID: Int64; var Values: TSQLVarDynArray): boolean;
override;
```

*Called to update a virtual table row content*

- column order follows the Structure method, i.e. StoredClassProps.Fields[] order
- returns true on success, false otherwise

```
class procedure GetTableModuleProperties(var aProperties:
TVirtualTableModuleProperties); override;
```

*Returns the main specifications of the associated TSQLVirtualTableModule*

- this is a read/write table, without transaction (yet), associated to the TSQLVirtualTableCursorExternal cursor type, with 'External' as module name and TSQLRestStorageExternal as the related static class
- no particular class is supplied here, since it will depend on the associated Static TSQLRestStorageExternal instance

### Types implemented in the *mORMotDB* unit

```
TOnEngineAddComputeID = function(Sender: TSQLRestStorageExternal; var Handled:
Boolean): TID of object;
```

*Event handler called to customize the computation of a new ID*

- should set Handled=TRUE if a new ID has been computed and returned
- Handled=FALSE would let the default ID computation take place
- note that execution of this method would be protected by a mutex, so it would be thread-safe

```
TVirtualTableExternalRegisterOption = (regDoNotRegisterUserGroupTables,
regMapAutoKeywordFields, regClearPoolOnConnectionIssue);
```

*All possible options for VirtualTableExternalRegisterAll/TSQLRestExternalDBCreate*

- by default, TSQLAuthUser and TSQLAuthGroup tables will be handled via the external DB, but you can avoid it for speed when handling session and security by setting regDoNotRegisterUserGroupTables
- you can set regMapAutoKeywordFields to ensure that the mapped field names won't conflict with a SQL reserved keyword on the external database by mapping a name with a trailing '\_' character for the external column
- regClearPoolOnConnectionIssue will call ClearConnectionPool when a connection-linked exception is discovered

```
TVirtualTableExternalRegisterOptions = set of TVirtualTableExternalRegisterOption;
```

*Set of options for VirtualTableExternalRegisterAll/TSQLRestExternalDBCreate functions*

### Functions or procedures implemented in the *mORMotDB* unit

| Functions or procedures      | Description                                                                                         | Page |
|------------------------------|-----------------------------------------------------------------------------------------------------|------|
| TSQLRestExternalDBCreate     | Create a new TSQLRest instance, and possibly an external database, from its Model and stored values | 2292 |
| VirtualTableExternalMap      | Register one table of the model to be external, with optional mapping                               | 2292 |
| VirtualTableExternalRegister | Register several tables of the model to be external                                                 | 2293 |

| Functions or procedures         | Description                                                        | Page |
|---------------------------------|--------------------------------------------------------------------|------|
| VirtualTableExternalRegister    | Register on the Server-side an external database for an ORM class  | 2293 |
| VirtualTableExternalRegisterAll | Register all tables of the model to be external, with some options | 2294 |
| VirtualTableExternalRegisterAll | Register all tables of the model to be external                    | 2294 |

**function** TSQLRestExternalDBCreate(aModel: TSQLModel; aDefinition: TSynConnectionDefinition; aHandleAuthentication: boolean; aExternalOptions: TVirtualTableExternalRegisterOptions): TSQLRest; overload;

*Create a new TSQLRest instance, and possibly an external database, from its Model and stored values*

- if aDefinition.Kind matches a TSQLRest registered class, one new instance of this kind will be created and returned
- if aDefinition.Kind is a registered TSQLDBConnectionProperties class name, it will instantiate an in-memory TSQLRestServerDB or a TSQLRestServerFullMemory instance, then call VirtualTableExternalRegisterAll() on this connection
- will return nil if the supplied aDefinition does not match any registered TSQLRest or TSQLDBConnectionProperties types

**function** VirtualTableExternalMap(aModel: TSQLModel; aClass: TSQLRecordClass; aExternalDB: TSQLDBConnectionProperties; **const** aExternalTableName: RawUTF8=''; aMapping: TSQLRecordPropertiesMappingOptions=[]): PSQLRecordPropertiesMapping;

*Register one table of the model to be external, with optional mapping*

- this method would allow to chain MapField() or MapAutoKeywordFields definitions, in a fluent interface:

```
function VirtualTableExternalRegister(aModel: TSQLModel; aClass: TSQLRecordClass;
aExternalDB: TSQLDBConnectionProperties; const aExternalTableName: RawUTF8='';
aMappingOptions: TSQLRecordPropertiesMappingOptions=[]): boolean; overload;
```

*Register on the Server-side an external database for an ORM class*

- will associate the supplied class with a TSQLVirtualTableExternal module (calling aModel.VirtualTableRegister method), even if the class does not inherit from TSQLRecordVirtualTableAutoID (it can be any plain TSQLRecord or TSQLRecordMany sub-class for instance)
- note that TSQLModel.Create() will reset all supplied classes to be defined as non virtual (i.e. Kind=rSQLite3)
- this function shall be called BEFORE TSQLRestServer.Create (the server-side ORM must know if the database is to be managed as internal or external)
- this function (and the whole unit) is NOT to be used on the client-side
- the TSQLDBConnectionProperties instance should be shared by all classes, and released globally when the ORM is no longer needed
- the full table name, as expected by the external database, could be provided here (SQLTableName will be used internally as table name when called via the associated SQLite3 Virtual Table) - if no table name is specified (''), will use SQLTableName (e.g. 'Customer' for 'TSQLCustomer')
- typical usage is therefore for instance:
 

```
Props := TOLeDBMSSQLConnectionProperties.Create('.\SQLEXPRESS', 'AdventureWorks2008R2', '', '');
Model := TSQLModel.Create([TSQLCustomer], 'root');
VirtualTableExternalRegister(Model, TSQLCustomer, Props, 'Sales.Customer');
Server := TSQLRestServerDB.Create(aModel, 'application.db'), true)
```
- the supplied aExternalDB parameter is stored within aClass.RecordProps, so the instance must stay alive until all database access to this external table is finished (e.g. use a private/protected property)
- aMappingOptions can be specified now, or customized later
- server-side may omit a call to VirtualTableExternalRegister() if the need of an internal database is expected: it will allow custom database configuration at runtime, depending on the customer's expectations (or license)
- after registration, you can tune the field-name mapping by calling aModel.Props[aClass].ExternalDB.MapField(..)

```
function VirtualTableExternalRegister(aModel: TSQLModel; const aClass: array of
TSQLRecordClass; aExternalDB: TSQLDBConnectionProperties; aMappingOptions:
TSQLRecordPropertiesMappingOptions=[]): boolean; overload;
```

*Register several tables of the model to be external*

- just a wrapper over the overloaded VirtualTableExternalRegister() method

```
function VirtualTableExternalRegisterAll(aModel: TSQLModel; aExternalDB:
TSQLDBConnectionProperties; DoNotRegisterUserGroupTables: boolean=false;
ClearPoolOnConnectionIssue: boolean=false): boolean; overload;
```

*Register all tables of the model to be external*

- mainly for retro-compatibility with existing code
- just a wrapper around the VirtualTableExternalRegisterAll() overloaded function with some boolean flags instead of TVirtualTableExternalRegisterOptions

```
function VirtualTableExternalRegisterAll(aModel: TSQLModel; aExternalDB:
TSQLDBConnectionProperties; aExternalOptions:
TVirtualTableExternalRegisterOptions): boolean; overload;
```

*Register all tables of the model to be external, with some options*

- by default, all tables are handled by the SQLite3 engine, unless they are explicitly declared as external via VirtualTableExternalRegister: this function can be used to register all tables to be handled by an external DBs
- this function shall be called BEFORE TSQLRestServer.Create (the server-side ORM must know if the database is to be managed as internal or external)
- this function (and the whole unit) is NOT to be used on the client-side
- the TSQLDBConnectionProperties instance should be shared by all classes, and released globally when the ORM is no longer needed
- by default, TSQLAuthUser and TSQLAuthGroup tables will be handled via the external DB, but you can avoid it for speed when handling session and security by setting regDoNotRegisterUserGroupTables in aExternalOptions
- other aExternalOptions can be defined to tune the ORM process e.g. about mapping or connection loss detection
- after registration, you can tune the field-name mapping by calling  
aModel.Props[aClass].ExternalDB.MapField(..)

## 27.54. mORMotDDD.pas unit

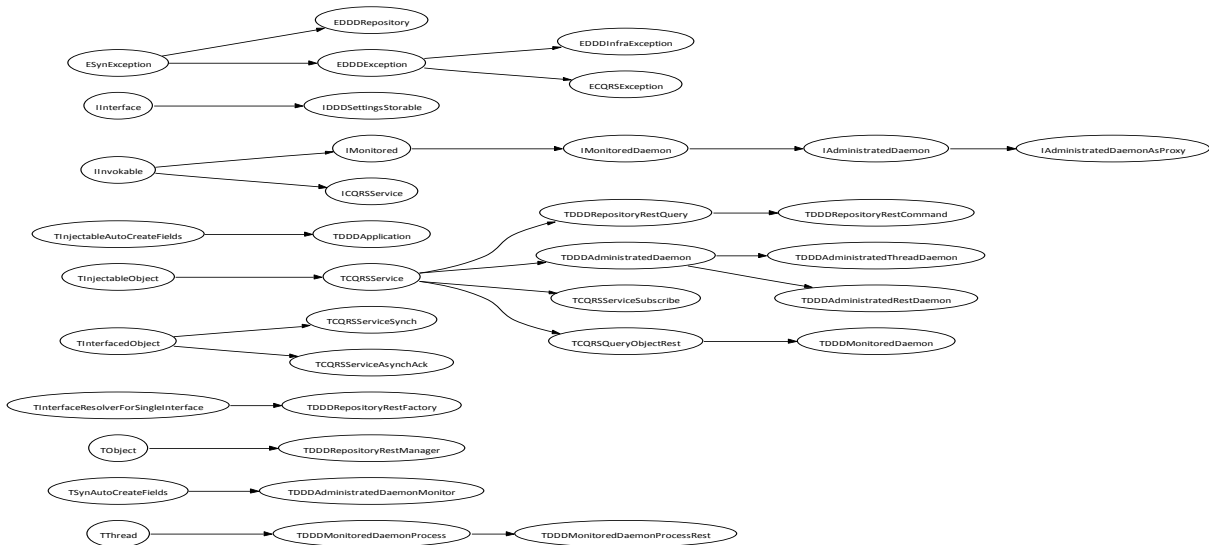

*Purpose:* Domain-Driven-Design toolbox for mORMot

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *mORMotDDD* unit

| Unit Name         | Description                                                                                                                                                                                                                                                                                                                                   | Page |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>     | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                              | 1907 |
| <i>SynCommons</i> | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                     | 718  |
| <i>SynCrtSock</i> | Classes implementing TCP/UDP/HTTP client and server protocol<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                       | 1086 |
| <i>SynCrypto</i>  | Fast cryptographic routines (hashing and cypher)<br>- implements<br>AES,XOR,ADLER32,MD5,RC4,SHA1,SHA256,SHA384,SHA512,SHA3 and JWT<br>- optimized for speed (tuned assembler and SSE3/SSE4/AES-NI/PADLOCK support)<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1143 |
| <i>SynLog</i>     | Logging functions used by Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                         | 1368 |
| <i>SynTable</i>   | Filter/database/cache/buffer/security/search/multithread/OS features<br>- as a complement to SynCommons, which tended to increase too much<br>- licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                       | 1728 |

*mORMotDDD class hierarchy*

## Objects implemented in the *mORMotDDD* unit

| Objects                     | Description                                                                                                                       | Page |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------|------|
| ECQRSEException             | Exception type linked to CQRS repository service methods                                                                          | 2297 |
| EDDException                | Abstract ancestor for all Domain-Driven Design related Exceptions                                                                 | 2297 |
| EDDDInfraException          | Abstract ancestor for any Domain-Driven Design infrastructure Exceptions                                                          | 2297 |
| EDDDRepository              | Abstract ancestor for all persistence/repository related Exceptions                                                               | 2301 |
| IAdministratedDaemon        | Generic interface, to manage a service/daemon instance from an executable                                                         | 2298 |
| IAdministratedDaemonAsProxy | Any service/daemon implementing this interface would be able to redirect all the administration process to another service/daemon | 2299 |
| ICQRSService                | Generic interface, to be used for CQRS I*Query and I*Command types definition                                                     | 2297 |
| IDDDSettingsStorable        | Allow persistence of any TObject settings storage                                                                                 | 2299 |
| IMonitored                  | Generic interface, to be used so that you may retrieve a running state                                                            | 2298 |
| IMonitoredDaemon            | Generic interface, to be used so that you may manage a service/daemon instance                                                    | 2298 |
| TCQRSQueryObjectRest        | Abstract CQRS class tied to a TSQLRest instance for low-level persistence                                                         | 2305 |
| TCQRSService                | To be inherited to implement CQRS I*Query or I*Command services extended error process                                            | 2300 |
| TCQRSServiceAsynchAck       | Used to acknowledge asynchronous CQRS Service calls                                                                               | 2300 |
| TCQRSServiceSubscribe       | A CQRS Service, which maintains an internal list of "Subscribers"                                                                 | 2300 |

| Objects                       | Description                                                                                                             | Page |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------|------|
| TCQRSServiceSynch             | A CQRS Service, ready to implement a set of synchronous (blocking) commands over an asynchronous (non-blocking) service | 2300 |
| TDDAdministratedDaemon        | Abstract class to implement an administrable service/daemon                                                             | 2307 |
| TDDAdministratedDaemonMonitor | Abstract class to monitor an administrable service/daemon                                                               | 2309 |
| TDDAdministratedRestDaemon    | Abstract class to implement a TSQLRest-based administrable service/daemon                                               | 2309 |
| TDDAdministratedThreadDaemon  | Abstract class to implement an TThread-based administrable service/daemon                                               | 2309 |
| TDDApplication                | Abstract class for implementing an Application Layer service                                                            | 2309 |
| TDDMonitoredDaemon            | Abstract class using several process threads and with monitoring abilities                                              | 2306 |
| TDDMonitoredDaemonProcess     | Abstract process thread class with monitoring abilities                                                                 | 2306 |
| TDDMonitoredDaemonProcessRest | Abstract process thread class with monitoring abilities, using the ORM for pending tasks persistence                    | 2306 |
| TDDRepositoryRestCommand      | Abstract class to implement I*Command interface using ORM's TSQLRecord                                                  | 2304 |
| TDDRepositoryRestFactory      | Implement a DDD Entity factory over one ORM's TSQLRecord                                                                | 2301 |
| TDDRepositoryRestManager      | Home repository of several DDD Entity factories using REST storage                                                      | 2301 |
| TDDRepositoryRestQuery        | Abstract repository class to implement I*Query interface using RESTful ORM                                              | 2304 |

**EDDException = class(ESynException)**

*Abstract ancestor for all Domain-Driven Design related Exceptions*

**ECQRSEException = class(EDDException)**

*Exception type linked to CQRS repository service methods*

**EDDDInfraException = class(EDDException)**

*Abstract ancestor for any Domain-Driven Design infrastructure Exceptions*

**ICQRSService = interface(IInvokable)**

*Generic interface, to be used for CQRS I\*Query and I\*Command types definition*

- TCQRSService class will allow to easily implement LastError\* members
- all CQRS services, which may be executed remotely, would favor a function result as TCQRSResult enumeration for error handling, rather than a local Exception, which is not likely to be transferred easily on consumer side

**function** GetLastError: TCQRSResult;

*Should return the last error as an enumerate*

- when stubbed or mocked via TInterfaceStub, any method interface would return 0, i.e. cqrSuccess by default, to let the test pass

**function** GetLastErrorInfo: variant;

*Should return addition information for the last error*

- may be a plain string, or a JSON document stored as TDocVariant

**IMonitored = interface**(IInvokable)

*Generic interface, to be used so that you may retrieve a running state*

**function** RetrieveState(out Status: variant): TCQRSResult;

*Retrieve the current status of the instance*

- the status is returned as a schema-less value (typically a TDocVariant document), which may contain statistics about the current processing numbers, timing and throughput

**IMonitoredDaemon = interface**(IMonitored)

*Generic interface, to be used so that you may manage a service/daemon instance*

**function** Start: TCQRSResult;

*Launch the service/daemon*

- should first stop any previous running instance (so may be used to restart a service on demand)

**function** Stop(out Information: variant): TCQRSResult;

*Abort the service/daemon, returning statistics about the whole execution*

**IAdministeredDaemon = interface**(IMonitoredDaemon)

*Generic interface, to manage a service/daemon instance from an executable*

- in addition to Start/Stop methods, Halt would force the whole executable to abort its execution, SubscribeLog allows log monitoring, and DatabaseList/DatabaseExecute remote SQL/SQL/SQL execution on one or several logical REST servers
- those methods would allow a single administration daemon (installed e.g. as a Windows Service) to be able to launch and monitor child processes as individual executables, or via a custom DDD's ToolsAdmin tool
- since SubscribeLog() uses a callback, this REST server should be published via supported transmission protocol, e.g. WebSockets

**function** DatabaseExecute(const DatabaseName, SQL: RawUTF8): TServiceCustomAnswer;

*Execute a SQL query on an internal database*

- the database name should match one existing in the DatabaseList
- the supplied SQL parameter may be #cmd internal commands: in this case, the database name may not be mandatory
- will return JSON most of the time, but may return binary if needed

**function** DatabaseList: TRawUTF8DynArray;

*Returns a list of internal database names, exposed by this daemon*

- in practice, each database name should identify a TSQLRest instance
- the database name should be supplied to DatabaseExecute() as target

**function** DatabaseTables(const DatabaseName: RawUTF8): TRawUTF8DynArray;

*Returns a list of tables, stored in the internal database names*

- the database name should match one existing in the DatabaseList
- in practice, returns all TSQLRecord table of the TSQLRest instance

**function** Halt(out Information: variant): TCQRSResult;

*Will Stop the service/daemon process, then quit the executable*

- the returned Information and TCQRSResult are passed directly from the Stop() method

**procedure** CallbackReleased(const callback: IInvokable; const interfaceName: RawUTF8);

*Will be called when a callback is released on the client side*

- this method matches IServiceWithCallbackReleased signature
- will be used to unsubscribe any previous ISynLogCallback notification

**procedure** SubscribeLog(const Level: TSynLogInfos; const Callback: ISynLogCallback; ReceiveExistingKB: cardinal);

*Used to subscribe for real-time remote log monitoring*

- allows to track the specified log events, with a callback
- you can specify a number of KB of existing log content to send to the monitoring tool, before the actual real-time process: Callback.Log() would be called first with Level=sllNone and all the existing text

**IAdministratedDaemonAsProxy = interface(IAdministratedDaemon)**

*Any service/daemon implementing this interface would be able to redirect all the administration process to another service/daemon*

- i.e. would work as a safe proxy service, over several networks

**function** StartProxy(const aDDDRestClientSettings: variant): TCQRSResult;

*Allows to connect to another service/daemon IAdministratedDaemon*

- detailed connection definition would be supplied as a TDocVariantData object, serialized from dddInfraApp.pas TDDDRestClientSettings

**IDDDSettingsStorable = interface(IInterface)**

*Allow persistence of any TObject settings storage*

**procedure** StoreIfUpdated;

*Persist the settings if needed*

- will call the virtual InternalPersist method

**TCQRSService = class(TInjectableObject)**

*To be inherited to implement CQRS I\*Query or I\*Command services extended error process*

- you should never assign directly a cQRS\* value to a method result, but rather use the CQRSBeginMethod/CQRSSetResult/CQRSSetResultMsg methods provided by this class:

```
function TMyService.MyMethod: TCQRSResult;
begin
 CQRSBeginMethod(qsNone,result); // reset the error information to cQRSUnspecifiedError
 ... // do some work
 if error then
 CQRSSetResultMsg(cQRSUnspecifiedError,'Oops! For "%",',[name],result) else
 CQRSSetResult(cQRSSuccess,result); // instead of result := cQRSSuccess
end;
```

- the methods are implemented as a simple state machine, following the TCQRSQueryAction and TCQRSQueryState definitions

- warning: by definition, fLastError\* access is NOT thread-safe so the CQRSBeginMethod/CQRSSetResult feature should be used in a single context

**constructor** Create; **override**;

*Initialize the instance*

**destructor** Destroy; **override**;

*Finalize the instance*

**property** Action: TCQRSQueryAction **read** fAction;

*The action currently processing*

**property** LastError: TCQRSResult **read** GetLastError;

*The last error, as an enumerate*

**property** LastErrorInfo: **variant** **read** GetLastErrorInfo;

*The last error extended information, as a string or TDocVariant*

**property** Log: TSynLogFamily **read** fLog **write** fLog;

*Where logging should take place*

**property** State: TCQRSQueryState **read** fState;

*Current step of the TCQRSService state machine*

**TCQRSServiceSubscribe = class(TCQRSService)**

*A CQRS Service, which maintains an internal list of "Subscribers"*

- allow to notify in cascade when a callback is released

**TCQRSServiceSynch = class(TInterfacedObject)**

*A CQRS Service, ready to implement a set of synchronous (blocking) commands over an asynchronous (non-blocking) service*

- you may use this class e.g. at API level, over a blocking REST server, and communicate with the Domain event-driven services via asynchronous calls

- this class won't inherit from TCQRSService, since it would be called from multiple threads at once, so all CQRSSetResult() methods would fail

**TCQRSServiceAsynchAck = class(TInterfacedObject)**

*Used to acknowledge asynchronous CQRS Service calls*

- e.g. to implement TCQRSServiceSynch

**EDDDRepository = class(ESynException)**

*Abstract ancestor for all persistence/repository related Exceptions*

**constructor** CreateUTF8(Caller: TDDDRepositoryRestFactory; **const** Format: RawUTF8;  
**const** Args: array of **const**);

*Constructor like FormatUTF8() which will also serialize the caller info*

**TDDDRepositoryRestManager = class(TObject)**

*Home repository of several DDD Entity factories using REST storage*

- this shared class will be can to manage a service-wide repositories, e.g. manage actual I\*Query/I\*Command implementation classes across a set of TSQLRest instances
- is designed to optimize BATCH or transactional process

**destructor** Destroy; **override**;

*Finalize all factories*

**function** AddFactory( **const** aInterface: TGUID; aImplementation:  
 TDDDRepositoryRestClass; aAggregate: TClass; aRest: TSQLRest; aTable:  
 TSQLRecordClass; **const** TableAggregatePairs: array of RawUTF8):  
 TDDDRepositoryRestFactory;

*Register one DDD Entity repository over an ORM's TSQLRecord*

- will raise an exception if the aggregate has already been defined

**function** GetFactory(**const** aInterface: TGUID): TDDDRepositoryRestFactory;

*Retrieve the registered Factory definition of a given DDD Entity*

- raise an EDDDDRepository exception if the TPersistence class is unknown

**function** GetFactoryIndex(**const** aInterface: TGUID): integer;

*Retrieve the registered definition of a given DDD Entity in Factory[]*

- returns -1 if the TPersistence class is unknown

**property** Factory: TDDDRepositoryRestFactoryObjArray **read** fFactory;

*Read-only access to all defined DDD Entity factories*

**TDDDRepositoryRestFactory = class(TInterfaceResolverForSingleInterface)**

*Implement a DDD Entity factory over one ORM's TSQLRecord*

- it will centralize some helper classes and optimized class mapping
- the Entity class may be defined as any TPersistent or TSynPersistent, with an obvious preference for TSynPersistent and TSynAutoCreateFields classes

**constructor** Create( **const** aInterface: TGUID; aImplementation:  
 TDDDRepositoryRestClass; aAggregate: TClass; aRest: TSQLRest; aTable:  
 TSQLRecordClass; aOwner: TDDDRepositoryRestManager=nil); **reintroduce**; **overload**;

*Initialize the DDD Aggregate factory using a mORMot ORM class*

- this overloaded constructor does not expect any custom fields
- any missing or unexpected field on any side will just be ignored

```
constructor Create(const aInterface: TGUID; aImplementation:
TDDDRepositoryRestClass; aAggregate: TClass; aRest: TSQLRest; aTable:
TSQLRecordClass; const TableAggregatePairs: array of RawUTF8; aOwner:
TDDDRepositoryRestManager=nil); reintroduce; overload;
```

*Initialize the DDD Aggregate factory using a mORMot ORM class*

- by default, field names should match on both sides - but you can specify a custom field mapping as TSQLRecord,Aggregate pairs
- any missing or unexpected field on any side will just be ignored

```
destructor Destroy; override;
```

*Finalize the factory*

```
function AggregateCreate: TObject;
```

*Create a new DDD Aggregate instance*

```
function AggregateFilterAndValidate(aAggregate: TObject; aInvalidFieldIndex:
PInteger=nil; aValidator: PSynValidate=nil): RawUTF8; virtual;
```

*Perform filtering and validation on a supplied DDD Aggregate*

- all logic defined by AddFilterOrValidate() will be processed

```
function AggregateToJSON(aAggregate: TObject; ORMMappedFields: boolean; aID: TID):
RawUTF8; overload;
```

*Serialize a DDD Aggregate as JSON RawUTF8*

```
procedure AddFilterOrValidate(const aFieldNames: array of RawUTF8;
aFilterOrValidate: TSynFilterOrValidate; aFieldNameFlattened: boolean=false);
virtual;
```

*Register a custom filter or validator to some Aggregate's fields*

- once added, the TSynFilterOrValidate instance will be owned to this factory, until it is released
- the field names should be named from their full path (e.g. 'Email' or 'Address.Country.Iso') unless aFieldNameFlattened is TRUE, which will expect ORM-like naming (e.g. 'Address\_Country')

- if '\*' is specified as field name, it will be applied to all text fields, so the following will ensure that all text fields will be trimmed for spaces:

```
AddFilterOrValidate(['*'],TSynFilterTrim.Create);
```

- filters and validators will be applied to a specified aggregate using AggregateFilterAndValidate() method

- the same filtering classes as with the ORM can be applied to DDD's aggregates, e.g.

TSynFilterUpperCase, TSynFilterLowerCase or TSynFilterTrim

- the same validation classes as with the ORM can be applied to DDD's aggregates, e.g.

TSynValidateText.Create for a void field, TSynValidateText.Create('{MinLength:5}') for a more complex test (including custom password strength validation if TSynValidatePassWord is not enough), TSynValidateIPAddress.Create or TSynValidateEmail.Create for some network settings, or TSynValidatePattern.Create()

- you should not define TSynValidateUniqueField here, which could't be checked at DDD level, but rather set a "stored AS\_UNIQUE" attribute in the corresponding property of the TSQLRecord type definition

```
procedure AggregateClear(aAggregate: TObject);
```

*Clear all properties of a given DDD Aggregate*

```
procedure AggregateFromTable(aSource: TSQLRecord; aAggregate: TObject);
```

*Convert a ORM TSQLRecord instance into a DDD Aggregate*

```
procedure AggregatesFromTableFill(aSource: TSQLRecord; var aAggregateObjArray);
 Convert ORM TSQLRecord.FillPrepare instances into a DDD Aggregate ObjArray
```

```
procedure AggregateToJSON(aAggregate: TObject; W: TJSONSerializer;
ORMMappedFields: boolean; aID: TID); overload;
 Serialize a DDD Aggregate as JSON
 - you can optionally force the generated JSON to match the mapped TSQLRecord fields, so that it
 would be compatible with ORM's JSON
```

```
procedure AggregateToTable(aAggregate: TObject; aID: TID; aDest: TSQLRecord);
 Convert a DDD Aggregate into an ORM TSQLRecord instance
```

```
class procedure ComputeSQLRecord(const aAggregate: array of TClass;
DestinationSourceCodeFile: TFileName='');
```

*Will compute the ORM TSQLRecord\* source code type definitions corresponding to DDD aggregate objects into a supplied file name*

- will generate one TSQLRecord\* per aggregate class level, following the inheritance hierarchy
- dedicated DDD types will be translated into native ORM types (e.g. RawUTF8)
- if no file name is supplied, it will generate a dddsqlrecord.inc file in the executable folder
- could be used as such:

```
TDDDRepositoryRestFactory.ComputeSQLRecord([TPersonContactable, TAuthInfo]);
```

- once created, you may refine the ORM definition, by adding

```
... read f.... write f... stored AS_UNIQUE;
```

for fields which should be unique, and/or

```
... read f... write f... index #;
```

to specify an optional textual field width (VARCHAR n) for SQL storage

- most advanced ORM-level filters/validators, or low-level implementation details (like the Sqlite3 collation) may be added by overriding this method:

```
protected
 class procedure InternalDefineModel(Props: TSQLRecordProperties); override;
 ...
class procedure TSQLRecordMyAggregate.InternalDefineModel(
 Props: TSQLRecordProperties);
begin
 AddFilterNotVoidText(['HashedPassword']);
 Props.SetCustomCollation('Field', 'BINARY');
 Props.AddFilterOrValidate('Email', TSynValidateEmail.Create);
end;
```

```
property Aggregate: TClass read fAggregate.ItemClass;
```

*The DDD's Entity class handled by this factory*

- may be any TPersistent, but very likely a TSynAutoCreateFields class

```
property AggregateClass: string read GetAggregateName;
```

*The DDD's Entity class name handled by this factory*

```
property FieldMapping: TSQLRecordPropertiesMapping read fPropsMapping;
```

*Access to the Aggregate / ORM field mapping*

```
property Owner: TDDDRepositoryRestManager read fOwner;
```

*The home repository owning this factory*

```
property Props: TSQLPropInfoList read fAggregateRTTI;
```

*The mapped DDD's Entity class published properties RTTI*

**property** Repository: TInterfaceFactory read fInterface;

*The associated I\*Query / I\*Command repository interface*

**property** Rest: TSQLRest read fRest;

*The associated TSQLRest instance*

**property** Table: TSQLRecordClass read fTable;

*The ORM's TSQLRecord used for actual storage*

**property** TableClass: string read GetTableName;

*The ORM's TSQLRecord class name used for actual storage*

**TDDDRepositoryRestQuery = class(TCQRSservice)**

*Abstract repository class to implement I\*Query interface using RESTful ORM*

- actual repository implementation will just call the ORM\*() protected method from the published Aggregate-oriented CQRS service interface

**constructor** Create(aFactory: TDDDRepositoryRestFactory); reintroduce; virtual;

*You should not have to use this constructor, since the instances would be injected by TDDDRepositoryRestFactory.TryResolve()*

**destructor** Destroy; override;

*Finalize the used memory*

**function** GetCount: integer; virtual;

*Return the number all currently selected aggregates*

- returns 0 if no select was available, 1 if it was a ORMGetSelectOne(), or the number of items after a ORMGetSelectAll()  
 - this is a generic operation which would work for any class  
 - if you do not need this method, just do not declare it in I\*Command

**class function** GetRest(const Service: ICQRSservice): TSQLRest;

*Returns the associated TSQLRest instance used in the associated factory*

- this method is able to extract it from a I\*Query/I\*Command instance, if it is implemented by a TDDDRepositoryRestQuery class  
 - returns nil if the supplied Service is not recognized

**property** CurrentORMInstance: TSQLRecord read fCurrentORMInstance;

*Access to the current state of the underlying mapped TSQLRecord*

- is nil if no query was run yet  
 - contains the queried object after a successful Select\*() method  
 - is either a single object, or a list of objects, via its internal CurrentORMInstance.FillTable cursor

**property** Factory: TDDDRepositoryRestFactory read fFactory;

*Access to the associated factory*

**TDDDRepositoryRestCommand = class(TDDDRepositoryRestQuery)**

*Abstract class to implement I\*Command interface using ORM's TSQLRecord*

- it will use an internal TSQLRestBatch for dual-phase commit, therefore implementing a generic Unit Of Work / Transaction pattern

**constructor** Create(aFactory: TDDDRepositoryRestFactory); **override;**

*This constructor will set default fBatch options*

**destructor** Destroy; **override;**

*Finalize the Unit Of Work context*  
- any uncommitted change will be lost

**function** Commit: TCQRSResult; **virtual;**

*Write all pending changes prepared by Add/Update/Delete methods*  
- this is the only mandatory method, to be declared in your I\*Command  
- in practice, will send the current internal BATCH to the REST instance

**function** Delete: TCQRSResult; **virtual;**

*Perform a deletion on the currently selected aggregate*  
- this is a generic operation which would work for any class  
- if you do not need this method, just do not declare it in I\*Command

**function** DeleteAll: TCQRSResult; **virtual;**

*Perform a deletion on all currently selected aggregates*  
- this is a generic operation which would work for any class  
- if you do not need this method, just do not declare it in I\*Command

**function** Rollback: TCQRSResult; **virtual;**

*Flush any pending changes prepared by Add/Update/Delete methods*  
- if you do not need this method, just do not publish it in I\*Command  
- the easiest to perform a roll-back would be to release the I\*Command instance - but you may explicitly reset the pending changes by calling this method  
- in practice, will release the internal BATCH instance

**property** Batch: TSQLRestBatch **read** fBatch;

*Access to the low-level BATCH instance, used for dual-phase commit*  
- you should not need to access it directly, but rely on Commit and Rollback methods to

**TCQRSQueryObjectRest = class(TCQRSService)**

*Abstract CQRS class tied to a TSQLRest instance for low-level persistence*  
- not used directly by the DDD repositories (since they will rely on a TDDDRepositoryRestFactory for the actual ORM process), but may be the root class for any Rest-based infrastructure cross-cutting features

**constructor** Create(aRest: TSQLRest); **reintroduce; virtual;**

*Reintroduced constructor, allowing to specify the associated REST instance*

**constructor** CreateInjected(aRest: TSQLRest; **const** aStubsByGUID: **array of** TGUID; **const** aOtherResolvers: **array of** TInterfaceResolver; **const** aDependencies: **array of** TInterfacedObject); **reintroduce;**

*Reintroduced constructor, associating a REST instance with the supplied IoC resolvers (may be stubs/mocks, resolver classes or single instances)*

**constructor** CreateWithResolver(aRest: TSQLRest; aResolver: TInterfaceResolver; aRaiseEServiceExceptionIfNotFound: boolean=true); **reintroduce; overload;**

*Reintroduced constructor, associating a REST instance with the supplied IoC resolvers*

**constructor** CreateWithResolver(aResolver: TInterfaceResolver;  
 aRaiseEServiceExceptionIfNotFound: boolean); overload; **override**;

*This constructor would identify a TServiceContainer SOA resolver and set the Rest property*  
 - when called e.g. by TServiceFactoryServer.CreateInstance()

**property** Rest: TSQLRest **read** FRest;

*Access to the associated REST instance*

**TDDDMonitoredDaemonProcess = class**(TThread)

*Abstract process thread class with monitoring abilities*

**constructor** Create(aDaemon: TDDDMonitoredDaemon; aIndexInDaemon: integer);  
**virtual**;

*Initialize the process thread for a given Service/Daemon instance*

**destructor** Destroy; **override**;

*Finalize the process thread*

**property** IdleDelay: cardinal **read** fProcessIdleDelay;

*Milliseconds delay defined before getting the next pending tasks*

- equals TDDDMonitoredDaemon.ProcessIdleDelay, unless a fatal exception occurred during  
 TDDDMonitoredDaemonProcess.ExecutIdle method: in this case, the delay would be  
 increased to 500 ms

**TDDDMonitoredDaemonProcessRest = class**(TDDDMonitoredDaemonProcess)

*Abstract process thread class with monitoring abilities, using the ORM for pending tasks  
 persistence*

- a protected TSQLRecord instance will be maintained to store the processing task and its current  
 state

**TDDDMonitoredDaemon = class**(TCQRSQueryObjectRest)

*Abstract class using several process threads and with monitoring abilities*

- able to implement any DDD Daemon/Service, with proper statistics gathering  
 - each TDDDMonitoredDaemon will own its TDDDMonitoredDaemonProcess

**constructor** Create(aRest: TSQLRest; aProcessThreadCount: integer); **reintroduce**;  
**overload**;

*You should override this constructor to set the actual process*  
 - i.e. define the fProcessClass protected property

**constructor** Create(aRest: TSQLRest); **overload**; **override**;

*Abstract constructor, which should not be called by itself*

**destructor** Destroy; **override**;

*Finalize the Daemon*

**function** RetrieveState(out Status: variant): TCQRSResult;

*Monitor the Daemon/Service by returning some information as a TDocVariant*

- its Status.stats sub object will contain global processing statistics, and Status.threadstats  
 similar information, detailed by running thread

**function** Start: TCQRSResult; **virtual**;

*Launch all processing threads*

- any previous running threads are first stopped

**function** Stop(out Information: **variant**): TCQRSResult; **virtual**;

*Finalize all processing threads*

- and returns updated statistics as a TDocVariant

**property** ProcessIdleDelay: integer **read** fProcessIdleDelay **write** fProcessIdleDelay;

*How many milliseconds each process thread should wait before checking for pending tasks*

- default value is 50 ms, which seems good enough in practice

**property** ProcessThreadCount: integer **read** fProcessThreadCount;

*How many process threads should be created by this Daemon/Service*

**TDDAdministratedDaemon = class**(TCQRSService)

*Abstract class to implement an administrable service/daemon*

- a single administration daemon (running e.g. as a Windows Service) would be able to launch and administrate such process, via a remote REST link
- inherited class should override the Internal\* virtual abstract protected methods to supply the actual process (e.g. set a background thread)

**constructor** Create(const aUserName, aHashedPassword: RawUTF8; const aRoot: RawUTF8='admin'; const aServerNamedPipe: TFileName=''); **reintroduce**; **overload**;

*Initialize the administrable service/daemon with its own TSQLRestServer*

- will initialize and own its dedicated TSQLRestServerFullMemory
- if aUserName is specified, authentication will be enabled, and a single TSQLAuthUser will be created, with the supplied credentials (the password matching TSQLAuthUser.PasswordHashHexa expectations)
- under Windows, you can export the administration server as named pipe, if the optional aServerNamedPipe parameter is set

**constructor** Create(aAdministrationServer: TSQLRestServer); **reintroduce**; **overload**; **virtual**;

*Initialize the administrable service/daemon*

- aAdministrationServer.ServiceDefine(IAdministratedDaemon) will be called to publish the needed methods over it, to allow remote administration from a single administration daemon (installed e.g. as a Windows Service)
- this constructor won't start the associated process, which would be idle until the Start method is called

**destructor** Destroy; **override**;

*Finalize the service/daemon*

- will call Halt() if the associated process is still running

**function** DaemonName: RawUTF8; **virtual**;

*Returns the daemon name*

- e.g. TMyOwnDaemon would return 'MyOwn' text

**function** DatabaseExecute(**const** DatabaseName, SQL: RawUTF8): TServiceCustomAnswer;  
**virtual**;

*AdministratedDaemon command to execute a SQL query on an internal database*  
 - you may override this method to implement addition "pseudo-SQL" commands

**function** DatabaseList: TRawUTF8DynArray; **virtual**;

*AdministratedDaemon command to retrieve all internal databases names*  
 - will return fInternalDatabases[].Model.Root values

**function** DatabaseTables(**const** DatabaseName: RawUTF8): TRawUTF8DynArray; **virtual**;

*AdministratedDaemon command to return the table names of an internal database*

**function** Halt(**out** Information: **variant**): TCQRSResult; **virtual**;

*AdministratedDaemon command to Stop the associated process, then quit the executable*  
 - returning the same output information than Stop()

**function** RetrieveState(**out** Status: **variant**): TCQRSResult; **virtual**;

*Monitor the Daemon/Service by returning some information as a TDocVariant*

**function** Start: TCQRSResult; **virtual**;

*AdministratedDaemon command to launch the associated process*  
 - if the process was already running, returns cqsAlreadyExists

**function** Stop(**out** Information: **variant**): TCQRSResult; **virtual**;

*AdministratedDaemon command to finalize the associated process*  
 - and returns updated statistics as a TDocVariant

**procedure** CallbackReleased(**const** callback: IInvokable; **const** interfaceName: RawUTF8);

*AdministratedDaemon command called when a callback is released on the client side*

**procedure** Execute(RemotelyAdministrated: boolean);

*Run the daemon, until it is halted*  
 - if RemotelyAdministrated is FALSE, it will Start the process, then wait until the [Enter] key is pressed (to be used in pure console mode)  
 - if RemotelyAdministrated is TRUE, it will follow remote activation from its administration server  
 - both modes will log some minimal message on the console (if any)

**procedure** SubscribeLog(**const** Levels: TSynLogInfos; **const** Callback: ISynLogCallback; ReceiveExistingKB: cardinal); **virtual**;

*AdministratedDaemon command to subscribe to a set of events for real-time remote monitoring of the specified log events*

**procedure** WaitUntilHalted; **virtual**;

*This method will wait until Halt() is executed*  
 - i.e. protected fFinished TEvent is notified

**property** AdministrationHTTPServer: TObject **read** fAdministrationHTTPServer **write** fAdministrationHTTPServer;

*Reference to the WebSockets/HTTP server publishing AdministrationServer*  
 - is defined as an opaque TObject instance, to avoid unneeded dependencies

**property** AdministrationServer: TSQLRestServer read fAdministrationServer;

*Reference to the REST server publishing IAdministratedDaemon service*  
 - e.g. from named pipe local communication on Windows

**property** InternalSettings: TObject read fInternalSettings write SetInternalSettings;

*Access to the associated internal settings*  
 - is defined as an opaque TObject instance, to avoid unneeded dependencies

**property** InternalSettingsFolder: TFileName read fInternalSettingsFolder write fInternalSettingsFolder;

*Access to the associated internal settings storage folder*

**property** Log: TSynLogFamily read fLog;

*Access to the associated logging class*

**property** Status: TDDAdministratedDaemonStatus read fStatus;

*The current status of the service/daemon*

TDDAdministratedThreadDaemon = **class**(TDDAdministratedDaemon)

*Abstract class to implement an TThread-based administrable service/daemon*  
 - inherited class should override InternalStart and InternalRetrieveState abstract methods, and set the protected fThread with the processing thread

TDDAdministratedRestDaemon = **class**(TDDAdministratedDaemon)

*Abstract class to implement a TSQLRest-based administrable service/daemon*  
 - inherited class should override InternalStart and InternalRetrieveState abstract methods, and set the protected fRest with the processing TSQLRest

**property** Rest: TSQLRestServer read fRest;

*Read-only access to the associated REST instance*  
 - is assigned only between daemon Start/Stop

TDDAdministratedDaemonMonitor = **class**(TSynAutoCreateFields)

*Abstract class to monitor an administrable service/daemon*  
 - including Input/Output statistics and connected Clients count  
 - including OS Memory information

**property** Server: TSynMonitorServer read fServer;

*Information about the REST server process*

**property** SystemMemory: variant read GetMemory;

*Information about the main System memory, as returned by the OS*

TDDApplication = **class**(TInjectableAutoCreateFields)

*Abstract class for implementing an Application Layer service*  
 - is defined as an TInjectableAutoCreateFields, so that any published properties defined as interfaces would be resolved at creation, and published properties defined as TPersistent/TSynPersistent will be managed by this instance, i.e. created and released with it

## Types implemented in the mORMotDDD unit

```
TCQRSQueryAction = (qaNone, qaSelect, qaGet, qaCommandDirect, qaCommandOnSelect,
qaCommit);
```

*Which kind of process is about to take place after an CqrsBeginMethod()*

```
TCQRSQueryActions = set of TCQRSQueryAction;
```

*Define one or several process to take place after an CqrsBeginMethod()*

```
TCQRSQueryState = (qsNone, qsQuery, qsCommand);
```

*The current step of a TCQRSQuery state machine*

- basic state diagram is defined by the methods execution:
- qsNone refers to the default state, with no currently selected values, nor any pending write request
- qsQuery corresponds to a successful I\*Query.Select\*(), expecting either a I\*Query.Get\*(), or a I\*Command.Add/Update/Delete
- qsCommand corresponds to a successful I\*Command.Add/Update/Delete, expected a I\*Command.Commit

```
TCQRSResult = (cqrsSuccess, cqrsSuccessWithMoreData, cqrsUnspecifiedError,
cqrsBadRequest, cqrsNotFound, cqrsNoMoreData, cqrsDataLayerError,
cqrsInvalidCallback, cqrsInternalError, cqrsDDDValidationFailed, cqrsInvalidContent,
cqrsAlreadyExists, cqrsNoPriorQuery, cqrsNoPriorCommand, cqrsNoMatch,
cqrsNotImplemented, cqrsBusy, cqrsTimeout);
```

*Result enumerate for I\*Query/I\*Command CQRS repository service methods*

- cqrsSuccess will map the default TInterfaceStub returned value
- cqrsSuccessWithMoreData would be used e.g. for versioned publish/ subscribe to notify the caller that there are still data available, and the call should be reiterated until cqrsSuccess is returned
- cqrsBadRequest would indicate that the method was not called in the expected workflow sequence
- cqrsNotFound appear after a I\*Query.SelectBy\*() method with no match
- cqrsNoMoreData indicates a GetNext\*() method has no more matching data
- cqrsDataLayerError indicates a low-level error at database level
- cqrsInvalidCallback is returned if a callback is required for this method
- cqrsInternalError for an unexpected issue, like an Exception raised
- cqrsDDDValidationFailed will be triggered when
- cqrsInvalidContent for any I\*Command method with invalid aggregate input value (e.g. a missing field)
- cqrsAlreadyExists for a I\*Command.Add method with a primary key conflict
- cqrsNoPriorQuery for a I\*Command.Update/Delete method with no prior call to SelectBy\*()
- cqrsNoPriorCommand for a I\*Command.Commit with no prior Add/Update/Delete
- cqrsNoMatch will notify that a command did not have any match
- cqrsNotImplemented may be returned when there is no code yet for a method
- cqrsBusy is returned if the command could not be executed, since it is currently processing a request
- cqrsTimeout indicates that the method didn't succeed in the expected time
- otherwise, cqrsUnspecifiedError will be used for any other kind of error

```
TCQRSServiceClass = class of TCQRSService;
```

*Class-reference type (metaclass) of TCQRSService*

```
TDDDAdministratedDaemonClass = class of TDDDAdministratedDaemon;
```

*Type used to define a class kind of TDDDAdministratedDaemon*

```
TDDDAdministratedDaemonStatus = (dsUnknown, dsCreated, dsStarted, dsStopped, dsHalted
);
```

*Current status of an administrable service/daemon*

**TDDDMonitoredDaemonProcessClass = class of TDDDMonitoredDaemonProcess;**

*Class-reference type (metaclass) to determine which actual thread class will implement the monitored process*

**TDDDMonitoredDaemonProcessState = ( dpsPending, dpsProcessing, dpsProcessed, dpsFailed );**

*The current state of a process thread*

**TDDRepositoryRestClass = class of TDDRepositoryRestQuery;**

*Class-reference type (metaclass) to implement I\*Query or I\*Command interface definitions using our RESTful ORM*

**TDDRepositoryRestFactoryObjArray = array of TDDRepositoryRestFactory;**

*Store reference of several factories, each with one mapping definition*

### Constants implemented in the mORMotDDD unit

**CQRSRESULT\_SUCCESS = [ cqrsSuccess, cqrsSuccessWithData, cqrsNoMoreData, cqrsNotFound];**

*Successful result enumerates for I\*Query/I\*Command CQRS*

- those items would generate no log entry
- i.e. any command not included in CQRSRESULT\_SUCCESS nor CQRSRESULT\_WARNING would trigger a slDDDError log entry

**CQRSRESULT\_WARNING = [ cqrsNotFound, cqrsNoMatch];**

*Dubious result enumerates for I\*Query/I\*Command CQRS*

- those items would generate a slDDDDInfo log entry
- i.e. any command not included in CQRSRESULT\_SUCCESS nor CQRSRESULT\_WARNING would trigger a slDDDError log entry

### Functions or procedures implemented in the mORMotDDD unit

| Functions or procedures | Description                                               | Page |
|-------------------------|-----------------------------------------------------------|------|
| ToText                  | Returns the text equivalency of a CQRS result enumeration | 2311 |
| ToText                  | Returns the text equivalency of a CQRS state enumeration  | 2311 |

**function ToText(res: TCQRSQueryState): PShortString; overload;**

*Returns the text equivalency of a CQRS state enumeration*

**function ToText(res: TCQRSResult): PShortString; overload;**

*Returns the text equivalency of a CQRS result enumeration*

## 27.55. mORMotFastCgiServer.pas unit

*Purpose:* FastCGI HTTP/1.1 Server implementation for mORMot

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *mORMotFastCgiServer* unit

| Unit Name         | Description                                                                                                                                                                             | Page |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>     | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                        | 1907 |
| <i>SynCommons</i> | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18               | 718  |
| <i>SynCrtSock</i> | Classes implementing TCP/UDP/HTTP client and server protocol<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1086 |
| <i>SynWinSock</i> | Low level access to network Sockets for the Win32 platform<br>- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18          | 1851 |

*mORMotFastCgiServer class hierarchy*

### Objects implemented in the *mORMotFastCgiServer* unit

| Objects           | Description           | Page |
|-------------------|-----------------------|------|
| TFastCGIServer    | Handle Fast CGI       | 2313 |
| TFCGIBeginRequest | RtBeginRequest record | 2313 |
| TFCGIHeader       | FastCGI header        | 2312 |

**TFCGIHeader = packed record**

*FastCGI header*

**Filler:** byte;

*Pad field*

**ID:** word;

*Identifies the FastCGI request to which the record belongs*

- equals zero for a management request request

- non zero for an application record Used also to determine if the session is being multiplexed

**Len:** word;

*FastCGI record length*

- will send up to 64 KB of data per block

**PadLen:** byte;

*Pad length to complete 8 bytes alignment boundary in FastCGI protocol*

**RecType:** TFCGIRecType;

*FastCGI record type*

**Version:** byte;

*FastCGI protocol version, ever constant 1*

**TFCGIBeginRequest = packed record**

*RtBeginRequest record*

**Filler:** byte;

*Pad field*

**Filler2:** array[1..5] of byte;

*Pad field*

**Header:** TFCGIHeader;

*FastCGI header*

**KeepConn:** boolean;

*Keep connection*

**Role:** TFCGIRole;

*FastCGI role*

**TFastCGIServer = class(TObject)**

*Handle Fast CGI*

- implements the official Fast CGI Specification available at

@<http://www.fastcgi.com/devkit/doc/fcgi-spec.html>

- this base type has virtual public methods ReadPacked and SendPacket, implementing the named pipe or socket defined by the single file descriptor sent by the web server which can be overridden by its children for proper socket/pipe handling

**constructor** Create(aServer: TSQLRestServer);

*Create the object instance to run with the specified RESTful Server*

**destructor** Destroy; **override;**

*Release the associated memory and handles*

**function** ReadPacked: RawUTF8; **virtual;**

*Virtual method used to read a packet from the remote server*

- must return "" on error

- by default, use the single file descriptor sent by the web server, and expect to read data from the corresponding named pipe or TCP/IP socket

**function** Run: boolean; virtual;

*The main loop of the FastCGI application*

- loop until application is terminated
- use the associated RESTful Server to calculate the answer
- call the virtual methods ReadPacked and SendPacket to handle the response
- the FastCGI server must have been successfully connected before calling it
- return true if communication was made successfully

**function** SendPacket(Buffer: pointer; BufferLen: integer): boolean; virtual;

*Virtual method used to send a packed to the remote server*

- must return FALSE on error
- by default, use the single file descriptor sent by the web server, and expect to write data to the corresponding named pipe or TCP/IP socket

**procedure** LogOut; virtual;

*Method triggered when the Web server wants to abort the request*

- do nothing by default - only to be implemented for Multiplex connection which are not enabled with this class

**procedure** ProcessRequest; virtual;

*Method triggered to calculate the response*

- expect fRequestHeaders, fRequestMethod, fRequestBody and fRequestURL properties as input
- update fResponseHeaders and fResponseContent properties as output

**property** Server: TSQLRestServer read fServer;

*Associated RESTful Server*

## Types implemented in the mORMotFastCgiServer unit

TFCGIListenType = ( ltUnused, ltSocketSync, ltPipeSync );

*FastCGI connection modes*

TFCGIProtocolStatus = ( psRequestComplete, psCantMultiplexConnections, psOverloaded, psUnknownRole );

*FastCGI level status (and error) code for END\_REQUEST record*

TFCGIRecType = ( rtBeginRequest, rtAbortRequest, rtEndRequest, rtParams, rtStdIn, rtStdOut, rtStdErr, rtData, rtGetValues, rtGetValuesResult, rtUnknown );

*FastCGI record types, i.e. the general function that the record performs*

TFCGIRole = ( rUnknown, rResponder, rAuthorizer, rFilter );

*FastCGI roles, only Responder role is supported in this unit version*

## Functions or procedures implemented in the mORMotFastCgiServer unit

| Functions or procedures | Description                                                                                              | Page |
|-------------------------|----------------------------------------------------------------------------------------------------------|------|
| mORMotFastCGIMainProc   | The pascal version use our Synapse socket publishes a HTTP/1.1 RESTFUL JSON mORMot Server, using FASTCGI | 2315 |

**procedure** mORMotFastCGIMainProc(Server: TSQLRestServer);

*The pascal version use our Synopse socket publishes a HTTP/1.1 RESTFUL JSON mORMot Server, using FASTCGI*

- will raise an exception if the executable was not used as a FastCGI process, but a normal CGI process
- call this procedure in your main block of your program: it is up to the HTTP server to implement the request handling

## 27.56. mORMotHttpClient.pas unit

*Purpose:* HTTP/1.1 RESTful JSON Client classes for mORMot

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

**The *mORMotHttpClient* unit is quoted in the following items**

| SWRS #       | Description       | Page |
|--------------|-------------------|------|
| DI-2.1.1.2.4 | HTTP/1.1 protocol | 2555 |

### Units used in the *mORMotHttpClient* unit

| Unit Name           | Description                                                                                                                                                                                                                                                                                                                                   | Page |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>       | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                              | 1907 |
| <i>SynBidirSock</i> | Implements bidirectional client and server protocol, e.g. WebSockets<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                               | 681  |
| <i>SynCommons</i>   | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                     | 718  |
| <i>SynCrtSock</i>   | Classes implementing TCP/UDP/HTTP client and server protocol<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                       | 1086 |
| <i>SynCrypto</i>    | Fast cryptographic routines (hashing and cypher)<br>- implements<br>AES,XOR,ADLER32,MD5,RC4,SHA1,SHA256,SHA384,SHA512,SHA3 and JWT<br>- optimized for speed (tuned assembler and SSE3/SSE4/AES-NI/PADLOCK support)<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1143 |
| <i>SynLog</i>       | Logging functions used by Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                         | 1368 |
| <i>SynLZ</i>        | SynLZ Compression routines<br>- licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                                                                                                       | 1399 |
| <i>SynTable</i>     | Filter/database/cache/buffer/security/search/multithread/OS features<br>- as a complement to SynCommons, which tended to increase too much<br>- licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                       | 1728 |
| <i>SynZip</i>       | Low-level access to ZLib compression (1.2.5 engine version)<br>- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                               | 1853 |

*mORMotHttpClient class hierarchy*

## Objects implemented in the *mORMotHttpClient* unit

| Objects                  | Description                                                                                     | Page |
|--------------------------|-------------------------------------------------------------------------------------------------|------|
| TSQLHttpClientGeneric    | Abstract HTTP/1.1 RESTful JSON mORMot Client class                                              | 2317 |
| TSQLHttpClientRequest    | HTTP/1.1 RESTful JSON mORMot Client abstract class using either WinINet, WinHTTP or libcurl API | 2320 |
| TSQLHttpClientWebsockets | HTTP/1.1 RESTful JSON mORMot Client able to upgrade to WebSockets                               | 2319 |
| TSQLHttpClientWinHTTP    | HTTP/1.1 RESTful JSON Client class using WinHTTP API                                            | 2321 |
| TSQLHttpClientWinINet    | HTTP/1.1 RESTful JSON mORMot Client class using WinINet API                                     | 2321 |
| TSQLHttpClientWinSock    | HTTP/1.1 RESTful JSON mORMot Client class using SynCrtSock's Sockets                            | 2319 |

**TSQLHttpClientGeneric** = **class**(TSQLRestClientURI)

*Abstract HTTP/1.1 RESTful JSON mORMot Client class*

- this class, and other inherited classes defined in this unit, are thread-safe, since each of their URI() method is protected by a giant lock

**constructor** Create(const aServer: TSQLRestServerURIString; aModel: TSQLModel; aDefaultPort: integer; aHttps: boolean=false); **reintroduce**; overload;

*Connect to TSQLHttpServer via 'address:port/root' URI format*

- if port is not specified, aDefaultPort is used  
- if root is not specified, aModel.Root is used

**constructor** Create(const aServer, aPort: AnsiString; aModel: TSQLModel; aHttps: boolean=false; const aProxyName: AnsiString=''; const aProxyByPass: AnsiString=''; aSendTimeout: DWORD=0; aReceiveTimeout: DWORD=0; aConnectTimeout: DWORD=0); **reintroduce**; overload; **virtual**;

*Connect to TSQLHttpServer on aServer:aPort*

- optional aProxyName may contain the name of the proxy server to use, and aProxyByPass an optional semicolon delimited list of host names or IP addresses, or both, that should not be routed through the proxy - note that proxy parameters are currently not available for TSQLHttpClientWinSock  
- you can customize the default client timeouts by setting appropriate ConnectTimeout, SendTimeout and ReceiveTimeout parameters (in ms) - if you left the 0 default parameters, it would use global HTTP\_DEFAULT\_CONNECTTIMEOUT, HTTP\_DEFAULT\_SENDDTIMEOUT and HTTP\_DEFAULT\_RECEIVETIMEOUT variable values

**constructor** CreateForRemoteLogging(const aServer: AnsiString; aLogClass: TSynLogClass; aPort: Integer=8091; const aRoot: RawUTF8='LogService');

*Connect to a LogView HTTP Server for remote logging*

- will associate the EchoCustom callback of the log class to this server
- the aLogClass.Family will manage this TSQLHttpClientGeneric instance life time, until application is closed or Family.EchoRemoteStop is called

**function** HostName: AnsiString;

*Returns 'Server:Port' current value*

**procedure** DefinitionTo(Definition: TSynConnectionDefinition); **override**;

*Save the TSQLHttpClientGeneric properties into a persistent storage object*

- CreateFrom() will expect Definition.ServerName to store the URI as 'server:port' or 'https://server:port', Definition.User/Password to store the TSQLRestClientURI.SetUser() information, and Definition.DatabaseName to store the extended options as an URL-encoded string

**property** Compression: TSQLHttpCompressions **read** fCompression **write** SetCompression;

*The compression algorithms usable with this client*

- equals [hcSynLZ] by default, since our SynLZ algorithm provides a good compression, with very low CPU use on server side
- you may include hcDeflate, which will have a better compression ratio, be recognized by all browsers and libraries, but would consume much more CPU resources than hcSynLZ
- if you include hcSynShaAes, it will use SHA-256/AES-256-CFB to encrypt the content (after SynLZ compression), if it is enabled on the server side:

```
MyServer := TSQLHttpServer.Create('888',[DataBase], '+', useHttpApi, 32, secSynShaAes);
```

- for fast and safe communication between stable mORMot nodes, consider using TSQLHttpClientWebSockets, leaving hcDeflate for AJAX or non mORMot clients, and hcSynLZ if you expect to have mORMot client(s)

**property** ConnectRetrySeconds: integer **read** fConnectRetrySeconds **write** fConnectRetrySeconds;

*How many seconds the client may try to connect after open socket failure*

- is disabled to 0 by default, but you may set some seconds here e.g. to let the server start properly, and let the client handle exceptions to wait and retry until the specified timeout is reached
- this property is used only once at startup, then flushed to 0 once connected

**property** KeepAliveMS: cardinal **read** fKeepAliveMS **write** SetKeepAliveMS;

*The time (in milliseconds) to keep the connection alive with the TSQLHttpServer*

- default is 20000, i.e. 20 seconds

**property** Port: AnsiString **read** fPort;

*The Server IP port*

**property** Server: AnsiString **read** fServer;

*The Server IP address*

**property** UserAgent: SockString **read** fExtendedOptions.UserAgent **write** fExtendedOptions.UserAgent;

*Optional custom HTTP "User Agent:" header value*

**TSQLHttpClientWinSock = class(TSQLHttpClientGeneric)**

*HTTP/1.1 RESTful JSON mORMot Client class using SynCrtSock's Sockets*

- will give the best performance on a local computer, but has been found out to be slower over a network
- is not able to use secure HTTPS protocol
- note that, in its current implementation, this class is not thread-safe: you need either to lock its access via a critical section, or initialize one client instance per thread

**property** Socket: THttpClientSocket **read** fSocket;

*Internal HTTP/1.1 compatible client*

- can be used e.g. to access SendTimeout and ReceiveTimeout properties

**TSQLHttpClientWebsockets = class(TSQLHttpClientWinSock)**

*HTTP/1.1 RESTful JSON mORMot Client able to upgrade to WebSockets*

- in addition to TSQLHttpClientWinSock, this client class is able to upgrade its HTTP connection to the WebSockets protocol, so that the server may be able to notify the client via a callback
- the internal Socket class will be in fact a THttpClientWebSockets instance, as defined in the SynBidirSock unit

**constructor** Create(**const** aServer, aPort: AnsiString; aModel: TSQLModel; aHttps: boolean=false; **const** aProxyName: AnsiString=''; **const** aProxyByPass: AnsiString=''; aSendTimeout: DWORD=0; aReceiveTimeout: DWORD=0; aConnectTimeout: DWORD=0);  
**override;**

*Connect to TSQLHttpServer on aServer:aPort*

- this overridden method will handle properly WebSockets settings

**function** DefaultWebSocketProcessSettings: PWebSocketProcessSettings;

*Returns a reference to default settings for every new WebSocket process*

**function** WebSockets: THttpClientWebSockets;

*Internal HTTP/1.1 and WebSockets compatible client*

- you could use its properties after upgrading the connection to WebSockets

**function** WebSocketsConnect(**const** aWebSocketsEncryptionKey: RawUTF8; aWebSocketsAJAX: boolean=false; aWebSocketsCompression: boolean=true): RawUTF8;

*Connect using a specified WebSockets protocol*

- this method would call WebSocketsUpgrade, then ServerTimestampSynchronize
- it therefore expects SetUser() to have been previously called

**function** WebSocketsConnected: boolean;

*Returns true if the connection is a running WebSockets*

- may be false even if fSocket<>nil, e.g. when gracefully disconnected

**function** WebSocketsUpgrade(**const** aWebSocketsEncryptionKey: RawUTF8;  
aWebSocketsAJAX: boolean=false; aWebSocketsCompression: boolean=true): RawUTF8;

*Upgrade the HTTP client connection to a specified WebSockets protocol*

- the Model.Root URI will be used for upgrade
- if aWebSocketsAJAX equals default FALSE, it will use 'synopsebinary' i.e. TWebSocketProtocolBinaryprotocol, with AES-CFB 256 bits encryption if the encryption key text is not "" and optional SynLZ compression
- if aWebSocketsAJAX is TRUE, it will register the slower and less secure 'synopsejson' mode, i.e. TWebSocketProtocolJSON (to be used for AJAX debugging/test purposes only) and aWebSocketsEncryptionKey/aWebSocketsCompression parameters won't be used
- once upgraded, the client would automatically re-upgrade any new HTTP client link on automatic reconnection, so that use of this class should be not tied to a particular TCP/IP socket
- use OnWebsocketsUpgraded event to perform any needed initialization set, e.g. SOA real-time callbacks registration
- will return "" on success, or an error message on failure

**procedure** CallbackNonBlockingSetHeader(**out** Header: RawUTF8); **override**;

*Will set the HTTP header as expected by THttpClientWebSockets.Request to perform the Callback() query in wscNonBlockWithoutAnswer mode*

**property** OnWebSocketsClosed: TNotifyEvent **read** fOnWebSocketsClosed **write** fOnWebSocketsClosed;

*This event handler will be executed when the WebSocket link is destroyed*

- may happen e.g. after graceful close from the server side, or after DisconnectAfterInvalidHeartbeatCount is reached

**property** OnWebSocketsUpgraded: TOnRestClientNotify **read** fOnWebSocketsUpgraded **write** fOnWebSocketsUpgraded;

*This event will be executed just after the HTTP client has been upgraded to the expected WebSockets protocol*

- supplied Sender parameter will be this TSQLHttpClientWebsockets instance
- it will be executed the first time, and also on each reconnection occurring when the HTTP-TCP/IP link is re-created, and user re-authenticated
- this event handler is the right place to setup link-driven connection, e.g. SOA real-time callbacks registration (using Sender.Services)

**property** WebSocketLoopDelay: integer **read** fWebSocketLoopDelay **write** fWebSocketLoopDelay;

*Customize the internal REST loop delay*

- to be defined before WebSocketsUpdate/WebSocketsConnect
- will set TWebSocketProcessSettings.LoopDelay value at WebSocketsUpgrade
- will override LoopDelay from DefaultWebSocketProcessSettings

TSQLHttpClientRequest = **class**(TSQLHttpClientGeneric)

*HTTP/1.1 RESTful JSON mORMot Client abstract class using either WinINet, WinHTTP or libcurl API*

- not to be called directly, but via TSQLHttpClientWinINet or (even better)

TSQLHttpClientWinHTTP overridden classes under Windows

**property** AuthPassword: SynUnicode **read** fExtendedOptions.Auth.Password **write** fExtendedOptions.Auth.Password;

*Optional Password for Authentication*

**property** AuthScheme: THttpRequestAuthentication **read** fExtendedOptions.Auth.Scheme  
**write** fExtendedOptions.Auth.Scheme;

*Optional Authentication Scheme*

**property** AuthUserName: SynUnicode **read** fExtendedOptions.Auth.UserName **write** fExtendedOptions.Auth.UserName;

*Optional User Name for Authentication*

**property** IgnoreSSLCertificateErrors: boolean **read** fExtendedOptions.IgnoreSSLCertificateErrors **write** fExtendedOptions.IgnoreSSLCertificateErrors;

*Allows to ignore untrusted SSL certificates*

- similar to adding a security exception for a domain in the browser

**property** Request: THttpRequest **read** fRequest;

*Internal class instance used for the connection*

- will return either a TWinINet, a TWinHTTP or a TCurlHTTP class instance

**TSQLHttpClientWinINet = class(TSQLHttpClientRequest)**

*HTTP/1.1 RESTful JSON mORMot Client class using WinINet API*

- this class is 15/20 times slower than TSQLHttpClient using SynCrtSock on a local machine, but was found to be faster throughout local networks
- this class is able to connect via the secure HTTPS protocol
- it will retrieve by default the Internet Explorer proxy settings, and display some error messages or authentication dialog on screen
- you can optionally specify manual Proxy settings at constructor level
- by design, the WinINet API should not be used from a service
- is implemented by creating a TWinINet internal class instance

**TSQLHttpClientWinHTTP = class(TSQLHttpClientRequest)**

*HTTP/1.1 RESTful JSON Client class using WinHTTP API*

- has a common behavior as THttpClientSocket() but seems to be faster over a network and is able to retrieve the current proxy settings (if available) and handle secure HTTPS connection - so it seems to be used in your client programs: TSQLHttpClient will therefore map to this class
- WinHTTP does not share directly any proxy settings with Internet Explorer. The default WinHTTP proxy configuration is set by either proxycfg.exe on Windows XP and Windows Server 2003 or earlier, either netsh.exe on Windows Vista and Windows Server 2008 or later; for instance, you can run "proxycfg -u" or "netsh winhttp import proxy source=ie" to use the current user's proxy settings for Internet Explorer (under 64 bit Vista/Seven, to configure applications using the 32 bit WinHttp settings, call netsh or proxycfg bits from %SystemRoot%\SysWOW64 folder explicitly)
- you can optionally specify manual Proxy settings at constructor level
- by design, the WinHTTP API can be used from a service or a server
- is implemented by creating a TWinHTTP internal class instance

## Types implemented in the mORMotHttpClient unit

**TSQLHttpClient = TSQLHttpClientWinHTTP;**

*HTTP/1.1 RESTful JSON default mORMot Client class*

- under Windows, maps the TSQLHttpClientWinHTTP class

*Used for DI-2.1.1.2.4 (page 2555).*

**TSQLHttpClientRequestClass = class of TSQLHttpClientRequest;**

### *Meta-class of TSQLHttpClientRequest types*

```
TSQLHttpCompression = (hcSynLZ, hcDeflate, hcSynShaAes);
```

*For WebSockets for hcSynShaAes available compression algorithms for transmission*

- SynLZ is faster than Deflate, but not standard: use hcSynLZ for Delphi clients, but hcDeflate for AJAX or any HTTP clients
- with hcSynLZ, the 440 KB JSON for TTestClientServerAccess.\_TSQLHttpClient is compressed into 106 KB with no speed penalty (it's even a bit faster) whereas hcDeflate with its level set to 1 (fastest), is 25 % slower
- hcSynShaAes will use SHA-256/AES-256-CFB to encrypt the content (after SynLZ compression), via SynCrypto.CompressShaAes() function
- here hcDeflate will use in fact gzip content encoding, since deflate is inconsistent between browsers: <http://stackoverflow.com/a/9186091>
- TSQLHttpClientGeneric.Compression default property is [hcSynLZ]

```
TSQLHttpCompressions = set of TSQLHttpCompression;
```

*Set of available compressions schemes*

```
TSQLHttpsClient = TSQLHttpClientWinHTTP;
```

*HTTP/HTTPS RESTful JSON default mORMot Client class*

- under Windows, maps the TSQLHttpClientWinHTTP class, or TSQLHttpClientCurl under Linux

### **Variables implemented in the mORMotHttpClient unit**

```
HttpClientFullWebSocketsLog: Boolean;
```

*A global hook variable, able to set WebSockets logging to full verbose*

- checked by TSQLHttpClientWebsockets.WebSocketsConnect()

## 27.57. mORMotHttpServer.pas unit

*Purpose:* HTTP/1.1 RESTFUL JSON Server classes for mORMot

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

The *mORMotHttpServer* unit is quoted in the following items

| SWRS #       | Description       | Page |
|--------------|-------------------|------|
| DI-2.1.1.2.4 | HTTP/1.1 protocol | 2555 |

### Units used in the *mORMotHttpServer* unit

| Unit Name           | Description                                                                                                                                                                                                                                                                                                                                   | Page |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>       | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                              | 1907 |
| <i>SynBidirSock</i> | Implements bidirectional client and server protocol, e.g. WebSockets<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                               | 681  |
| <i>SynCommons</i>   | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                     | 718  |
| <i>SynCrtSock</i>   | Classes implementing TCP/UDP/HTTP client and server protocol<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                       | 1086 |
| <i>SynCrypto</i>    | Fast cryptographic routines (hashing and cypher)<br>- implements<br>AES,XOR,ADLER32,MD5,RC4,SHA1,SHA256,SHA384,SHA512,SHA3 and JWT<br>- optimized for speed (tuned assembler and SSE3/SSE4/AES-NI/PADLOCK support)<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1143 |
| <i>SynLog</i>       | Logging functions used by Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                         | 1368 |
| <i>SynLZ</i>        | SynLZ Compression routines<br>- licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                                                                                                       | 1399 |
| <i>SynTable</i>     | Filter/database/cache/buffer/security/search/multithread/OS features<br>- as a complement to SynCommons, which tended to increase too much<br>- licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                       | 1728 |
| <i>SynZip</i>       | Low-level access to ZLib compression (1.2.5 engine version)<br>- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                               | 1853 |

*mORMotHttpServer class hierarchy*

## Objects implemented in the *mORMotHttpServer* unit

| Objects                 | Description                                                                         | Page |
|-------------------------|-------------------------------------------------------------------------------------|------|
| EHttpServerException    | For WebSockets for CompressShaAes() exception raised in case of a HTTP Server error | 2324 |
| TSQLHTTPRemoteLogServer | Limited HTTP server which is will receive remote log notifications                  | 2330 |
| TSQLHttpServer          | HTTP/1.1 RESTFUL JSON mORMot Server class                                           | 2324 |

**EHttpServerException** = **class**(ECommunicationException)

*For WebSockets for CompressShaAes() exception raised in case of a HTTP Server error*

**TSQLHttpServer** = **class**(TSynPersistentLock)

*HTTP/1.1 RESTFUL JSON mORMot Server class*

- this server is multi-threaded and not blocking
- under Windows, it will first try to use fastest http.sys kernel-mode server (i.e. create a THttpApiServer instance); it should work OK under XP or WS 2K3 - but you need to have administrator rights under Vista or Seven: if http.sys fails to initialize, it will use the socket-based THttpServer; a solution is to call the THttpApiServer.AddUrlAuthorize class method during program setup for the desired port, or define a useHttpApiRegisteringURI kind of server, in order to allow it for every user
- under Linux, only THttpServer is available
- you can specify useBidirSocket kind of server (i.e. TWebSocketServerRest) if you want the HTTP protocol connection to be upgraded to a WebSockets mode, to allow immediate callbacks from the server to the client
- just create it and it will serve SQL statements as UTF-8 JSON
- for a true AJAX server, expanded data is preferred - your code may contain:  
DBServer.NoAJAXJSON := false;

*Used for DI-2.1.1.2.4 (page 2555).*

```
constructor Create(aServer: TSQLRestServer; aDefinition: TSQLHttpServerDefinition;
aForcedKind: TSQLHttpServerOptions=HTTP_DEFAULT_MODE; aWebSocketsLoopDelay:
integer=0); reintroduce; overload;
```

*Create a Server instance, binded and listening on a TCP port to HTTP requests*

- raise a EHttpServer exception if binding failed
- specify one TSQLRestServer instance to be published, and the associated transmission definition; other parameters would be the standard one
- only the supplied aDefinition.Authentication will be defined
- under Windows, will use http.sys with automatic URI registration, unless aDefinition.WebSocketPassword is set and binary WebSockets would be expected with the corresponding encryption, or aForcedKind is overridden
- optional aWebSocketsLoopDelay parameter could be set for tuning WebSockets responsiveness

*Used for DI-2.1.1.2.4 (page 2555).*

```
constructor Create(const aPort: AnsiString; aServer: TSQLRestServer; const
aDomainName: AnsiString='+'; aHttpServerKind:
TSQLHttpServerOptions=HTTP_DEFAULT_MODE; aRestAccessRights: PSQLAccessRights=nil;
ServerThreadPoolCount: Integer=32; aHttpServerSecurity:
TSQLHttpServerSecurity=secNone; const aAdditionalURL: AnsiString=''; const
aQueueName: SynUnicode=''); reintroduce; overload;
```

*Create a Server instance, binded and listening on a TCP port to HTTP requests*

- raise a EHttpServer exception if binding failed
- specify one TSQLRestServer server class to be used
- port is an AnsiString, as expected by the WinSock API - in case of useHttpSocket or useBidirSocket kind of server, you can specify the public server address to bind to: e.g. '1.2.3.4:1234' - even for http.sys, the public address could be used e.g. for TSQLRestServer.SetPublicURI()
- aDomainName is the URLprefix to be used for HttpAddUrl API call
- the aHttpServerSecurity can be set to secSSL to initialize a HTTPS instance (after proper certificate installation as explained in the SAD pdf), or to secSynShaAes if you want our proprietary SHA-256 / AES-256-CTR encryption identified as "ACCEPT-ENCODING: synshaaes"
- optional aAdditionalURL parameter can be used e.g. to registry an URI to server static file content, by overriding TSQLHttpServer.Request
- for THttpApiServer, you can specify an optional name for the HTTP queue

*Used for DI-2.1.1.2.4 (page 2555).*

```
constructor Create(const aPort: AnsiString; const aServers: array of TSQLRestServer;

const aDomainName: AnsiString='+'; aHttpServerKind: TSQLHttpServerOptions=HTTP_DEFAULT_MODE; ServerThreadPoolCount: Integer=32;

aHttpServerSecurity: TSQLHttpServerSecurity=secNone; const aAdditionalURL:

AnsiString=''; const aQueueName: SynUnicode=''; aHeadersUnFiltered:

boolean=false); reintroduce; overload;
```

*Create a Server instance, binded and listening on a TCP port to HTTP requests*

- raise a EHttpServer exception if binding failed
- specify one or more TSQLRestServer server class to be used: each class must have an unique Model.Root value, to identify which TSQLRestServer instance must handle a particular request from its URI
- port is an AnsiString, as expected by the WinSock API - in case of useHttpSocket or useBidirSocket kind of server, you should specify the public server address to bind to: e.g. '1.2.3.4:1234' - even for http.sys, the public address could be used e.g. for TSQLRestServer.SetPublicURI()
- aDomainName is the URLprefix to be used for HttpAddUrl API call: it could be either a fully qualified case-insensitive domain name an IPv4 or IPv6 literal string, or a wildcard ('+' will bound to all domain names for the specified port, '\*' will accept the request when no other listening hostnames match the request for that port) - this parameter is ignored by the TSQLHttpApiServer instance
- aHttpServerKind defines how the HTTP server itself will be implemented: it will use by default optimized kernel-based http.sys server (useHttpApi), optionally registering the URI (useHttpApiRegisteringURI) if needed, or using the standard Sockets library (useHttpSocket), possibly in its WebSockets-friendly version (useBidirSocket - you should call the WebSocketsEnable method to initialize the available protocols)
- by default, the PSQLAccessRights will be set to nil
- the ServerThreadPoolCount parameter will set the number of threads to be initialized to handle incoming connections (default is 32, which may be sufficient for most cases, maximum is 256)
- the aHttpServerSecurity can be set to secSSL to initialize a HTTPS instance (after proper certificate installation as explained in the SAD pdf), or to secSynShaAes if you want our proprietary SHA-256 / AES-256-CTR encryption identified as "ACCEPT-ENCODING: synshaaes"
- optional aAdditionalURL parameter can be used e.g. to registry an URI to server static file content, by overriding TSQLHttpServer.Request
- for THttpApiServer, you can specify an optional name for the HTTP queue
- for THttpServer, you can force aHeadersUnFiltered flag

*Used for DI-2.1.1.2.4 (page 2555).*

```
destructor Destroy; override;
```

*Release all memory, internal mORMot server and HTTP handlers*

**function** AddServer(aServer: TSQLRestServer; aRestAccessRights: PSQLAccessRights=nil; aHttpServerSecurity: TSQLHttpServerSecurity=secNone): boolean;

*Try to register another TSQLRestServer instance to the HTTP server*

- each TSQLRestServer class must have an unique Model.Root value, to identify which instance must handle a particular request from its URI
- an optional aRestAccessRights parameter is available to override the default HTTP\_DEFAULT\_ACCESS\_RIGHTS access right setting - but you shall better rely on the authentication feature included in the framework
- the aHttpServerSecurity can be set to secSSL to initialize a HTTPS instance (after proper certificate installation as explained in the SAD pdf), or to secSynShaAes if you want our proprietary SHA-256 / AES-256-CTR encryption identified as "ACCEPT-ENCODING: synshaes"
- return true on success, false on error (e.g. duplicated Root value)

*Used for DI-2.1.1.2.4 (page 2555).*

**function** DBServerFind(aServer: TSQLRestServer): integer;

*Find the first instance of a registered REST server*

- note that the same REST server may appear several times in this HTTP server instance, e.g. with diverse security options

**function** RemoveServer(aServer: TSQLRestServer): boolean;

*Un-register a TSQLRestServer from the HTTP server*

- each TSQLRestServer class must have an unique Model.Root value, to identify which instance must handle a particular request from its URI
- return true on success, false on error (e.g. specified server not found)

**function** WebSocketsEnable(aServer: TSQLRestServer; const aWebSocketsEncryptionKey: RawUTF8; aWebSocketsAJAX: boolean=false; aWebSocketsCompressed: boolean=true): TWebSocketServerRest; overload;

*Defines the useBidirSocket WebSockets protocol to be used for a REST server*

- same as the overloaded WebSocketsEnable() method, but the URI will be forced to match the aServer.Model.Root value, as expected on the client side by TSQLHttpClientWebsockets.WebSocketsUpgrade()

**function** WebSocketsEnable(const aWebSocketsURI, aWebSocketsEncryptionKey: RawUTF8; aWebSocketsAJAX: boolean=false; aWebSocketsCompressed: boolean=true): TWebSocketServerRest; overload;

*Defines the WebSockets protocols to be used for useBidirSocket*

- i.e. 'synapsebinary' and optionally 'synapsejson' protocols
- if aWebSocketsURI is "", any URI would potentially upgrade; you can specify an URI to limit the protocol upgrade to a single REST server
- TWebSocketProtocolBinary will always be registered by this method
- if the encryption key text is not "", TWebSocketProtocolBinary will use AES-CFB 256 bits encryption
- if aWebSocketsAJAX is TRUE, it will also register TWebSocketProtocolJSON so that AJAX applications would be able to connect to this server
- this method does nothing if the associated HttpServer class is not a TWebSocketServerRest (i.e. this instance was not created as useBidirSocket)

**procedure** DomainHostRedirect(**const** aDomain, aURI: RawUTF8);

*Register a domain name to be redirected to a given Model.Root*

- i.e. can be used to support some kind of virtual hosting
- by default, the URI would be used to identify which TSQLRestServer instance to use, and the incoming HOST value would just be ignored
- you can specify here domain names which would be checked against the incoming HOST header, to redirect to a given URI, as such:

```
DomainHostRedirect('project1.com', 'root1');
DomainHostRedirect('project2.com', 'root2');
DomainHostRedirect('blog.project2.com', 'root2/blog');
```

for the last entry, you may have for instance initialized a MVC web server on the 'blog' sub-URI of the 'root2' TSQLRestServer via:

```
constructor TMyMVCApplication.Create(aRestModel: TSQLRest; aInterface: PTypeInfo);
...
fMainRunner := TMVCRunOnRestServer.Create(self, nil, 'blog');
...
```

- if aURI="" is given, the corresponding host redirection will be disabled
- note: by design, 'something.localhost' is likely to be not recognized as aDomain, since 'localhost' can not be part of proper DNS resolution

**procedure** RootRedirectToURI(**const** aRedirectedURI: RawUTF8; aRegisterURI: boolean=true; aHttps: boolean=false);

*Allow to temporarily redirect ip:port root URI to a given sub-URI*

- by default, only sub-URI, as defined by TSQLRestServer.Model.Root, are registered - you can define here a sub-URI to reach when the main server is directly accessed from a browser, e.g. localhost:port will redirect to localhost:port/RedirectedURI
- for http.sys server, would try to register '/' if aRegisterURI is TRUE
- by default, will redirect http://localhost:port unless you set aHttpServerSecurity=secSSL so that it would redirect https://localhost:port

**procedure** Shutdown(noRestServerShutdown: boolean=false);

*You can call this method to prepare the HTTP server for shutting down*

- it will call all associated TSQLRestServer.Shutdown methods, unless noRestServerShutdown is true
- note that Destroy won't call this method on its own, since the TSQLRestServer instances may have a life-time uncoupled from HTTP process

**property** AccessControlAllowCredential: boolean **read** fAccessControlAllowCredential **write** fAccessControlAllowCredential;

*Enable cookies, authorization headers or TLS client certificates CORS exposition*

- this option works with the AJAX XMLHttpRequest.withCredentials property on client/JavaScript side, as stated by

@<https://developer.mozilla.org/en-US/docs/Web/API/XMLHttpRequest/withCredentials>

- see

@<https://developer.mozilla.org/en-US/docs/Web/HTTP/Headers/Access-Control-Allow-Credentials>

**property** AccessControlAllowOrigin: RawUTF8 **read** fAccessControlAllowOrigin **write** SetAccessControlAllowOrigin;

*Enable cross-origin resource sharing (CORS) for proper AJAX process*

- see @[https://developer.mozilla.org/en-US/docs/HTTP/Access\\_control\\_CORS](https://developer.mozilla.org/en-US/docs/HTTP/Access_control_CORS)
- can be set e.g. to '\*' to allow requests from any site/domain; or specify an CSV white-list of URI to be allowed as origin e.g. as 'https://foo.example1,https://foo.example2' or 'https://\*.foo.example1' or (faster) '\*.foo.example1,\*.foo.example2' following the TMatch syntax
- see also AccessControlAllowCredential property

**property** DBServer[Index: integer]: TSQLRestServer **read** GetDBServer;

*Read-only access to all internal servers*

*Used for DI-2.1.1.2.4 (page 2555).*

**property** DBServerAccessRight[Index: integer]: PSQLAccessRights **write** SetDBServerAccessRight;

*Write-only access to all internal servers access right*

- can be used to override the default HTTP\_DEFAULT\_ACCESS\_RIGHTS setting

**property** DBServerCount: integer **read** GetDBServerCount;

*Read-only access to the number of registered internal servers*

**property** DomainName: AnsiString **read** fDomainName;

*The URLprefix used for internal HttpAddUrl API call*

**property** HttpServer: THttpServerGeneric **read** fHttpServer;

*The associated running HTTP server instance*

- either THttpApiServer (available only under Windows), THttpServer or TWebSocketServerRest (on any system)

**property** OnlyJSONRequests: boolean **read** fOnlyJSONRequests **write** fOnlyJSONRequests;

*Set this property to TRUE if the server must only respond to request of MIME type APPLICATION/JSON*

- the default is false, in order to allow direct view of JSON from any browser

**property** Port: AnsiString **read** fPort;

*The TCP/IP (address and) port on which this server is listening to*

- may contain the public server address to bind to: e.g. '1.2.3.4:1234'
- see PublicAddress and PublicPort properties if you want to get the true IP port or address

**property** PublicAddress: RawUTF8 **read** fPublicAddress;

*The TCP/IP public address on which this server is listening to*

- equals e.g. '1.2.3.4' if Port = '1.2.3.4:1234'
- if Port does not contain an explicit address (e.g. '1234'), the current computer host name would be assigned as PublicAddress

**property** PublicPort: RawUTF8 **read** fPublicPort;

*The TCP/IP public port on which this server is listening to*

- equals e.g. '1234' if Port = '1.2.3.4:1234'

**property** RedirectServerRootUriForExactCase: boolean **read**  
 fRedirectServerRootUriForExactCase **write** fRedirectServerRootUriForExactCase;

*Enable redirect to fix any URI for a case-sensitive match of Model.Root*  
 - by default, TSQLRestServer.Model.Root would be accepted with case insensitivity; but it may induce errors for HTTP cookies, since they are bound with '; Path=/ModelRoot', which is case-sensitive on the browser side  
 - set this property to TRUE so that only exact case URI would be handled by TSQLRestServer.URI(), and any case-sensitive URIs (e.g. /Root/... or /ROOT/...) would be temporary redirected to Model.Root (e.g. /root/...) via a HTTP 307 command

**TSQLHTTPRemoteLogServer = class(TSQLHttpServer)**

*Limited HTTP server which will receive remote log notifications*  
 - this will create a simple in-memory mORMot server, which will trigger a supplied callback when a remote log is received  
 - see TSQLHttpClientWinGeneric.CreateForRemoteLogging() for the client side  
 - used e.g. by the LogView tool

**constructor** Create(const aRoot: RawUTF8; aPort: integer; const aEvent: TRemoteLogReceivedOne); **reintroduce**;

*Initialize the HTTP server and an internal mORMot server*  
 - you can share several HTTP log servers on the same port, if you use a dedicated root URI and use the http.sys server (which is the default)

**destructor** Destroy; **override**;

*Release the HTTP server and its internal mORMot server*

**procedure** RemoteLog(Ctxt: TSQLRestServerURIContext);

*This HTTP server will publish a 'RemoteLog' method-based service*  
 - expecting PUT with text as body, at http://server/root/RemoteLog

**property** Server: TSQLRestServerFullMemory **read** fServer;

*The associated mORMot server instance running with this HTTP server*

## Types implemented in the mORMotHttpServer unit

TRemoteLogReceivedOne = **procedure**(const Text: RawUTF8) **of object**;

*Callback expected by TSQLHTTPRemoteLogServer to notify about a received log*

TSQLHttpServerOptions = ( useHttpApi, useHttpApiRegisteringURI, useHttpSocket, useBidirSocket );

*Available running options for TSQLHttpServer.Create() constructor*

- useHttpApi to use kernel-mode HTTP.SYS server (THttpApiServer) with an already registered URI (default way, similar to IIS/WCF security policy as specified by Microsoft) - you would need to register the URI by hand, e.g. in the Setup program, via code similar to this one:

```
THttpApiServer.AddUrlAuthorize('root', '888', false, '+')
```

- useHttpApiRegisteringURI will first registry the given URI, then use kernel-mode HTTP.SYS server (THttpApiServer) - will need Administrator execution rights at least one time (e.g. during setup); note that if the URI is already registered, the server will still be launched, even if the program does not run as Administrator - it is therefore sufficient to run such a program once as Administrator to register the URI, when this useHttpApiRegisteringURI option is set

- useHttpSocket will use the standard Sockets library (i.e. socket-based THttpServer) - it will trigger

the Windows firewall popup UAC window at first execution

- useBidirSocket will use the standard Sockets library but via the TWebSocketServerRest class, allowing HTTP connection upgrade to the WebSockets protocol, allowing immediate event callbacks in addition to the standard RESTful mode
- the first item should be the preferred one (see HTTP\_DEFAULT\_MODE)

```
TSQLHttpServerSecurity = (secNone, secSSL, secSynShaAes);
```

*Available security options for TSQLHttpServer.Create() constructor*

- default secNone will use plain HTTP connection
- secSSL will use HTTPS secure connection
- secSynShaAes will use our proprietary SHA-256 / AES-256-CTR encryption identified as 'synshaaes' as ACCEPT-ENCODING: header parameter

### Constants implemented in the *mORMotHttpServer* unit

```
HTTP_DEFAULT_ACCESS_RIGHTS: PSQLAccessRights = @SUPERVISOR_ACCESS_RIGHTS;
```

*The default access rights used by the HTTP server if none is specified*

```
HTTP_DEFAULT_MODE = useHttpApiRegisteringURI;
```

*The kind of HTTP server to be used by default*

- will define the best available server class, depending on the platform

### Variables implemented in the *mORMotHttpServer* unit

```
HttpServerFullWebSocketsLog: Boolean;
```

*A global hook variable, able to enhance WebSockets logging*

- when a TSQLHttpServer is created from a TSQLHttpServerDefinition

## 27.58. mORMoti18n.pas unit

*Purpose:* Internationalization (i18n) routines and classes for mORMot

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

The *mORMoti18n* unit is quoted in the following items

| SWRS #     | Description    | Page |
|------------|----------------|------|
| DI-2.3.1.3 | Automated i18n | 2560 |

Units used in the *mORMoti18n* unit

| Unit Name         | Description                                                                                                                                                               | Page |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>     | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18          | 1907 |
| <i>SynCommons</i> | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 718  |

*mORMoti18n class hierarchy*

Objects implemented in the *mORMoti18n* unit

| Objects       | Description                                                                | Page |
|---------------|----------------------------------------------------------------------------|------|
| TLanguage     | A common record to identify a language                                     | 2332 |
| TLanguageFile | Class to load and handle translation files (fr.msg, de.msg, ja.msg.. e.g.) | 2334 |

**TLanguage = object(TObject)**

*A common record to identify a language*

*Used for DI-2.3.1.3 (page 2560).*

**CharSet: integer;**

*The corresponding Char Set*

**CodePage: cardinal;**

*The corresponding Code Page*

**Index: TLanguages;**

*As in LanguageAbr[index], LANGUAGE\_NONE before first SetLanguageLocal()*

**LCID:** cardinal;

*The corresponding Windows LCID*

**function** Abr: RawByteString;

*Returns two-chars long language abbreviation ('HE' e.g.)*

**function** Name: string;

*Returns fully qualified language name ('Hebrew' e.g.), using current UI language*

*- return "string" type, i.e. UnicodeString for Delphi 2009 and up*

**procedure** Fill(Language: TLanguages);

*Initializes all TLanguage object fields for a specific language*

## **TLanguageFile = class(TObject)**

*Class to load and handle translation files (fr.msg, de.msg, ja.msg.. e.g.)*

- This standard .msg text file contains all the program resources translated into any language.
- Unicode characters (Chinese or Japanese) can be used.
- The most important part of this file is the [Messages] section, which contain all the text to be displayed in NumericValue=Text pairs. The numeric value is a hash (i.e. unique identifier) of the Text. To make a new translation, the "Text" part of these pairs must be translated, but the NumericValue must remain the same.
- In the "Text" part, translator must be aware of some important characters, which must NOT be modified, and appears in exactly the same place inside the translated text:
  1. | indicates a CR (carriage return) character;
  2. ~ indicates a LF (line feed) character;
  3. , sometimes is a comma inside a sentence, but is also used some other times as a delimiter between sentences;
  4. %s will be replaced by a textual value before display;
  5. %d will be replaced by a numerical value before display;
 some HTML code may appear (e.g. <br><font color="clnavy">...) and all text between < and > must NOT be modified;
- 6. no line feed or word wrap is to be used inside the "Text" part; the whole NumericValue=Text pair must be contained in an unique line, even if it is huge.
- Some other sections appears before the [Messages] part, and does apply to windows as they are displayed on screen. By default, the text is replaced by a \_ with a numerical value pointing to a text inside the [Messages] section. On some rare occasion, this default translation may be customized: in such cases, the exact new text to be displayed can be used instead of the \_1928321 part. At the end of every line, the original text (never used, only put there for translator convenience) was added.
- In order to add a new language, the steps are to be performed:
  0. Extract all english message into a .txt ansi file, by calling the ExtractAllResources() procedure in the main program
  1. Use the latest .txt original file, containing the original English messages
  2. Open this file into a text editor (not Microsoft Word, but a real text editor, like the Windows notepad)
  3. Translate the English text into a new language; some Unicode characters may be used
  4. Save this new file, with the ISO two chars corresponding to the new language as file name, and .msg as file extension (e.g. FR.msg for French or RU.msg for Russian).
  5. By adding this .msg file into the Phd.exe folder, the PC User software will automatically find and use it to translate the User Interface on the fly. Each user is able to select its own preferred translation.
  6. The translator can perform the steps 3 to 5 more than once, to see in real time its modifications: he/she just has to restart the PC software to reload the updated translations.

*Used for DI-2.3.1.3 (page 2560).*

**Language: TLanguage;**

*Identify the current language*

**constructor Create(aLanguageLocale: TLanguages); overload;**

*Load corresponding \*.msg translation text file from the current exe directory*

*Used for DI-2.3.1.3 (page 2560).*

**constructor** Create(const aFileName: TFileName; aLanguageLocale: TLanguages);  
overload;

*Specify a text file containing the translation messages for a language*

*Used for DI-2.3.1.3 (page 2560).*

**destructor** Destroy; **override**;

*Free translation tables memory*

**function** BooleanToString(Value: boolean): string;

*Convert the supplied boolean constant into ready to be displayed text*

*- by default, returns 'No' for false, and 'Yes' for true*

*- returns the text as generic string type, ready to be used in the VCL*

**function** DateTimeToText(const DateTime: TDateTime): string; overload;

*Convert a date and time into a ready to be displayed text on the screen*

*Used for DI-2.3.1.3 (page 2560).*

**function** DateTimeToText(const Time: TTimeLog): string; overload;

*Convert a date and time into a ready to be displayed text on the screen*

*Used for DI-2.3.1.3 (page 2560).*

**function** DateTimeToText(const Time: TTimeLogBits): string; overload;

*Convert a date and time into a ready to be displayed text on the screen*

*Used for DI-2.3.1.3 (page 2560).*

**function** DateToText(const DateTime: TDateTime): string; overload;

*Convert a date into a ready to be displayed text on the screen*

*Used for DI-2.3.1.3 (page 2560).*

**function** DateToText(const Time: TTimeLogBits): string; overload;

*Convert a date into a ready to be displayed text on the screen*

*Used for DI-2.3.1.3 (page 2560).*

**function** DateToText(const Time: TTimeLog): string; overload;

*Convert a date into a ready to be displayed text on the screen*

*Used for DI-2.3.1.3 (page 2560).*

**function** PropToString(Prop: TSQLPropInfo; Instance: TSQLRecord; Client: TSQLRest): string;

*Convert a TSQLRecord published property value into ready to be displayed text*

- will convert any sftUTF8Text/sftAnsiText into ready to be displayed text
- will convert any sftInteger/sftFloat/sftCurrency into its textual value
- will convert any sftBoolean, sftEnumerate, sftDateTime, sftUnixTime or sftTimeLog/sftModTime/sftCreateTime into the corresponding text, depending on the current language
- will convert a sftSet property value to a list of all set enumerates, separated by #13#10
- will convert any sftID to 'Record Name', i.e. the value of the main property (mostly 'Name') of the referenced record
- will convert any sftRecord to 'Table Name: Record Name'
- will ignore sftBlob field
- returns the text as generic string type, ready to be used in the VCL

**function** ReadParam(const ParamName: RawUTF8): string;

*Read a parameter, stored in the .msg file before any [Section]*

**function** TimeToText(const DateTime: TDateTime): string; overload;

*Convert a time into a ready to be displayed text on the screen*

*Used for DI-2.3.1.3 (page 2560).*

**function** TimeToText(const Time: TTimeLogBits): string; overload;

*Convert a time into a ready to be displayed text on the screen*

*Used for DI-2.3.1.3 (page 2560).*

**function** TimeToText(const Time: TTimeLog): string; overload;

*Convert a time into a ready to be displayed text on the screen*

*Used for DI-2.3.1.3 (page 2560).*

**procedure** FormTranslateOne(aForm: TComponent);

*Translate the english captions of a TForm into the current UI language*

- must be called once with english captions
- call automatically if conditional USEFORMCREATEHOOK is defined

**procedure** LoadFromFile(const aFileName: TFileName);

*Fill translation tables from text file containing the translation messages*

- handle on the fly UTF-8 and UNICODE decode into the corresponding ANSI CHARSET, or into UnicodeString for Delphi 2009 and up (checking UTF-8 or Unicode BOM marker is available)

**procedure** Translate(var English: string);

*Translate an English string into a localized string*

- English is case-sensitive (same as standard gettext)
- translations are stored in Messages[] and Text properties
- expect parameter as generic VCL string (i.e. UnicodeString for Delphi 2009 and up)

*Used for DI-2.3.1.3 (page 2560).*

## Types implemented in the mORMoti18n unit

TCompareFunction = function(const S1, S2: AnsiString): Integer;

*Function prototype for comparing two Ansi strings*

- used for comparison within the current selected language

```
TLanguages = (lngHebrew, lngGreek, lngLatin, lngDari, lngBosnian, lngCatalan,
lngCorsican, lngCzech, lngCoptic, lngSlavic, lngWelsh, lngDanish, lngGerman, lngArabic,
lngEnglish, lngSpanish, lngFarsi, lngFinnish, lngFrench, lngIrish, lngGaelic,
lngAramaic, lngCroatian, lngHungarian, lngArmenian, lngIndonesian, lngInterlingue,
lngIcelandic, lngItalian, lngJapanese, lngKorean, lngTibetan, lngLithuanian,
lngMalgash, lngNorwegian, lngOccitan, lngPortuguese, lngPolish, lngRomanian,
lngRussian, lngSanskrit, lngSlovak, lngSlovenian, lngAlbanian, lngSerbian, lngSwedish,
lngSyriac, lngTurkish, lngTahitian, lngUkrainian, lngVietnamese, lngChinese, lngDutch,
lngThai, lngBulgarian, lngBelarusian, lngEstonian, lngLatvian, lngMacedonian,
lngPashtol);
```

*Some basic types and functions need extended RTTI information languages handled by this mORMoti18n unit*

- include all languages known by WinXP SP2 without some unicode-only very rare languages; total count is 60
- some languages (Japanese, Chinese, Arabic) may need specific language pack installed on western/latin version of windows
- lngEnglish is the default language of the executable, used as reference for all other translation, and included into executable (no EN.msg file will never be loaded)

#### Constants implemented in the mORMoti18n unit

```
LanguageAbr: packed array[TLanguages] of RawByteString =
('he','gr','la','ad','bs','ca','co','cs','cp','cu','cy','da','de','ar',
'en','es','fa','fi','fr','ga','gd','am','hr','hu','hy','id','ie','is',
'it','ja','ko','bo','lt','mg','no','oc','pt','pl','ro','ru','sa','sk',
'sl','sq','sr','sv','sy','tr','ty','uk','vi','zh','nl',
'th','bg','be','et','lv','mk','ap');
```

*ISO 639-1 compatible abbreviations (not to be translated):*

```
LanguageAlpha: packed array[TLanguages] of byte = (3, 21, 59, 13, 55, 54, 31, 4, 5, 6,
8, 7, 9, 10, 11, 12, 14, 15, 56, 16, 17, 18, 19, 20, 1, 0, 22, 23, 24, 25, 26, 27, 28,
29, 30, 2, 32, 57, 33, 58, 52, 34, 35, 37, 36, 38, 39, 40, 41, 42, 43, 44, 45, 46, 53,
47, 48, 49, 50, 51);
```

*To sort in alphabetic order : LanguageAbr[TLanguages(LanguageAlpha[lng])]*

- recreate these table with ModifiedLanguageAbr if LanguageAbr[] changed

```
LANGUAGE_NONE = TLanguages(255);
```

*Value stored into a TLanguages enumerate to mark no language selected yet*

```
LCID_US = $0409;
```

*US English Windows LCID, i.e. standard international settings*

```
RegistryCompanyName = '';
```

*Language is read from registry once at startup: the sub-entry used to store the i18n settings in the registry; change this value to your company's name, with a trailing backslash ('WorldCompany\' e.g.). the key is HKEY\_CURRENT\_USER\Software\[RegistryCompanyName]i18n\programname*

#### Functions or procedures implemented in the mORMoti18n unit

| Functions or procedures | Description                                        | Page |
|-------------------------|----------------------------------------------------|------|
| DateTime2S              | Convert a custom date/time into a VCL-ready string | 2338 |

| Functions or procedures | Description                                                                      | Page |
|-------------------------|----------------------------------------------------------------------------------|------|
| DateTimeToIso           | Generic US/English date/time to VCL text conversion                              | 2338 |
| GetText                 | Translate the 'Text' term into current language, with no    nor \$\$[\$[\$]]     | 2338 |
| i18nAddLanguageCombo    | Add combo-box items, for all available languages on disk                         | 2339 |
| i18nAddLanguageItems    | Add strings items, for all available languages on disk                           | 2339 |
| i18nAddLanguageMenu     | Add sub-menu items to the Menu, for all available languages on disk              | 2339 |
| i18nLanguageToRegistry  | Save the default language to the registry                                        | 2339 |
| i18nRegistryToLanguage  | Get the default language from the registry                                       | 2339 |
| Iso2S                   | Convert a custom date/time into a VCL-ready string                               | 2339 |
| LanguageAbrToIndex      | LanguageAbrToIndex('GR')=1, e.g.                                                 | 2339 |
| LanguageAbrToIndex      | LanguageAbrToIndex('GR')=1, e.g.                                                 | 2339 |
| LanguageName            | Return the language text, ready to be displayed (after translation if necessary) | 2339 |
| LanguageToLCID          | Convert a i18n language index into a Windows LCID                                | 2339 |
| LCIDToLanguage          | Convert a Windows LCID into a i18n language                                      | 2340 |
| LoadResString           | Our hooked procedure for reading a string resource                               | 2340 |
| S2U                     | Convert any generic VCL Text into an UTF-8 encoded String                        | 2340 |
| U2S                     | Convert an UTF-8 encoded text into a VCL-ready string                            | 2340 |
| –                       | Translate the 'English' term into current language                               | 2340 |

**function** DateTime2S(const DateTime: TDateTime): string;

*Convert a custom date/time into a VCL-ready string*

- this function must be assigned to i18nDateTimeText global var of SynCommons.pas
- wrapper to Language.DateTimeToText(DateTime) method

**function** DateTimeToIso(const DateTime: TDateTime; DateOnly: boolean): string;

*Generic US/English date/time to VCL text conversion*

- not to be used in your programs: it's just here to allow inlining of TLanguageFile.DateTimeToText/DateToText/TimeToText

**procedure** GetText(var Text: string);

*Translate the 'Text' term into current language, with no || nor \$\$[\$[\$]]*

- LoadResStringTranslate of our customized system.pas points to this procedure
- therefore, direct use of LoadResStringTranslate() is better in apps
- expect "string" type, i.e. UnicodeString for Delphi 2009 and up

**procedure** i18nAddLanguageCombo(**const** MsgPath: TFileName; Combo: TComboBox);

*Add combo-box items, for all available languages on disk*

- uses internally i18nAddLanguageItems() function above
- current language is selected by default
- the OnClick event will launch Language.LanguageClick to change the current language in the registry

**function** i18nAddLanguageItems(MsgPath: TFileName; List: TStrings): integer;

*Add strings items, for all available languages on disk*

- it will search in MsgPath for all \*.msg available
- if MsgPath is not set, the current executable directory will be used for searching
- new items are added to List: Strings[] will contain a caption text, ready to be displayed, and PtrInt(Objects[]) will be the corresponding language ID
- return the current language index in List.Items[]

**procedure** i18nAddLanguageMenu(**const** MsgPath: TFileName; Menu: TMenuItem);

*Add sub-menu items to the Menu, for all available languages on disk*

- uses internally i18nAddLanguageItems() function above
- current language is checked
- all created MenuItem.OnClick event will launch Language.LanguageClick to change the current language in the registry

**function** i18nLanguageToRegistry(**const** Language: TLanguages): **string**;

*Save the default language to the registry*

- language will be changed at next startup
- return a message ready to be displayed on the screen
- return "string" type, i.e. UnicodeString for Delphi 2009 and up

**function** i18nRegistryToLanguage: TLanguages;

*Get the default language from the registry*

**function** Iso2S(**const** Iso: TTimeLog): **string**;

*Convert a custom date/time into a VCL-ready string*

- this function must be assigned to i18nDateText global var of SynCommons.pas
- wrapper to Language.DateTimeToText(Iso) method

**function** LanguageAbrToIndex(**const** value: RawUTF8): TLanguages; overload;

*LanguageAbrToIndex('GR')=1, e.g.*

- return LANGUAGE\_NONE if not found

**function** LanguageAbrToIndex(p: pAnsiChar): TLanguages; overload;

*LanguageAbrToIndex('GR')=1, e.g.*

- return LANGUAGE\_NONE if not found

**function** LanguageName(aLanguage: TLanguages): **string**;

*Return the language text, ready to be displayed (after translation if necessary)*

- e.g. LanguageName(IngEnglish)='English'
- return "string" type, i.e. UnicodeString for Delphi 2009 and up

**function** LanguageToLCID(Language: TLanguages): integer;

*Convert a i18n language index into a Windows LCID*

**function** LCIDToLanguage(LCID: integer): TLanguages;

*Convert a Windows LCID into a i18n language*

**function** LoadResString(ResStringRec: PResStringRec): string;

*Our hooked procedure for reading a string resource*

- the default one in System.pas unit is replaced by this one
- this function add caching and on the fly translation (if LoadResStringTranslate is defined in SynCommons.pas unit)
- use "string" type, i.e. UnicodeString for Delphi 2009 and up

**function** S2U(const Text: string): RawUTF8;

*Convert any generic VCL Text into an UTF-8 encoded String*

- same as SynCommons.StringToUTF8()

*Used for DI-2.3.1.3 (page 2560).*

**function** U2S(const Text: RawUTF8): string;

*Convert an UTF-8 encoded text into a VCL-ready string*

- same as SynCommons.UTF8ToString()

*Used for DI-2.3.1.3 (page 2560).*

**function** \_(const English: WinAnsiString): string;

*Translate the 'English' term into current language*

- you should use resourcestring instead of this function
- call interenaly GetText() procedure, i.e. LoadResStringTranslate()

*Used for DI-2.3.1.3 (page 2560).*

## Variables implemented in the mORMoti18n unit

CurrentLanguage: TLanguage = ( Index: LANGUAGE\_NONE; CharSet: DEFAULT\_CHARSET;  
 CodePage: CODEPAGE\_US; LCID: LCID\_US );

*The global Language used by the User Interface, as updated by the last SetCurrentLanguage() call*

i18nCompareStr: TCompareFunction = nil;

*Use this function to compare string with case sensitivity for the UI*

- use current language for comparison
- can be used for MBCS strings (with such code pages, it will use windows slow but accurate API)

i18nCompareText: TCompareFunction = nil;

*Use this function to compare string with no case sensitivity for the UI*

- use current language for comparison
- can be used for MBCS strings (with such code pages, it will use windows slow but accurate API)

i18nToLower: TNormTable;

*A table used for fast conversion to lowercase, according to the current language*

- can NOT be used for MBCS strings (with such code pages, you should use windows slow but accurate API)

i18nToLowerByte: TNormTableByte absolute i18nToLower;

*A table used for fast conversion to lowercase, according to the current language*

- can NOT be used for MBCS strings (with such code pages, you should use windows slow but accurate API)

**i18nToUpper: TNormTable;**

*A table used for fast conversion to uppercase, according to the current language*

- can NOT be used for MBCS strings (with such code pages, you should use windows slow but accurate API)

**i18nToUpperByte: TNormTableByte absolute i18nToUpper;**

*A table used for fast conversion to uppercase, according to the current language*

- can NOT be used for MBCS strings (with such code pages, you should use windows slow but accurate API)

**isVista: boolean = false;**

*True if this program is running on Windows Vista (tm)*

- used to customize on the fly any TTreeView component, to meet Vista and Seven expectations

**Language: TLanguageFile = nil;**

*Global variable set by SetCurrentLanguage(), used for translation*

- use this object, and its Language property, to retrieve current UI settings

**OnTranslateComponent: function(C: TComponent): boolean of object = nil;**

*Global event to be assigned for component translation override*

- the method implementing this event must return true if the translation was handled, or false if the translation must be done by the framework

**SettingsUS: TFormatSettings;**

*International settings from US English \$0409*

- useful in any software, if you want to save some content with the default english encoding (e.g. floating point values with '.')

## 27.59. mORMotMidasVCL.pas unit

*Purpose:* Fill a VCL TClientDataSet from TSQLTable/TSQLTableJSON data

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *mORMotMidasVCL* unit

| Unit Name         | Description                                                                                                                                                                  | Page |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>     | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18             | 1907 |
| <i>mORMotVCL</i>  | DB VCL dataset using TSQLTable/TSQLTableJSON data access<br>- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 2436 |
| <i>SynCommons</i> | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18    | 718  |

### Types implemented in the *mORMotMidasVCL* unit

`TClientDataSetMode = ( cdsNew, cdsAppend, cdsReplace );`

*How ToClientDataSet/JSONToClientDataSet functions will fill the TClientDataSet instance*

### Functions or procedures implemented in the *mORMotMidasVCL* unit

| Functions or procedures | Description                                                               | Page |
|-------------------------|---------------------------------------------------------------------------|------|
| JSONToClientDataSet     | Convert a JSON result into a new VCL TClientDataSet                       | 2343 |
| JSONToClientDataSet     | Convert a JSON result into an existing VCL TClientDataSet                 | 2343 |
| JSONToClientDataSet     | Convert a JSON result into a new VCL TClientDataSet                       | 2343 |
| ToClientDataSet         | Convert a TSQLTable result into an existing VCL TClientDataSet            | 2343 |
| ToClientDataSet         | For GetDBField() convert a TSQLTable result into a new VCL TClientDataSet | 2343 |

**function** JSONToClientDataSet(aOwner: TComponent; **const** aJSON: RawUTF8; **const** Tables: array of TSQLRecordClass; aClient: TSQLRest=nil ; aForceWideString: boolean=false): TClientDataSet; overload;

*Convert a JSON result into a new VCL TClientDataSet*

- this overloaded method allows to specify the TSQLRecord class types associated with the supplied JSON

```
function JSONToClientDataSet(aDataSet: TClientDataSet; const aJSON: RawUTF8;
aClient: TSQLRest=nil; aMode: TClientDataSetMode=cdsReplace; aLogChange:
boolean=false ; aForceWideString: boolean=false): boolean; overload;
```

*Convert a JSON result into an existing VCL TClientDataSet*

- current implementation will return a TClientDataSet instance, created from the supplied TSQLTable content (a more optimized version may appear later)
- with non-Unicode version of Delphi, you can set aForceWideString to force the use of WideString fields instead of AnsiString, if needed
- with Unicode version of Delphi (2009+), UnicodeString will be used
- for better speed with Delphi older than Delphi 2009 Update 3, it is recommended to use <http://andy.jgknet.de/blog/bugfix-units/midas-speed-fix-12>

```
function JSONToClientDataSet(aOwner: TComponent; const aJSON: RawUTF8; aClient:
TSQLRest=nil ; aForceWideString: boolean=false): TClientDataSet; overload;
```

*Convert a JSON result into a new VCL TClientDataSet*

- current implementation will return a TClientDataSet instance, created from the supplied TSQLTable content - see mORMotVCL.pas if you need a more efficient, but read-only version
- with non-Unicode version of Delphi, you can set aForceWideString to force the use of WideString fields instead of AnsiString, if needed
- with Unicode version of Delphi (2009+), UnicodeString will be used
- for better speed with Delphi older than Delphi 2009 Update 3, it is recommended to use <http://andy.jgknet.de/blog/bugfix-units/midas-speed-fix-12>

```
function ToClientDataSet(aOwner: TComponent; aTable: TSQLTable; aClient:
TSQLRest=nil ; aForceWideString: boolean=false): TClientDataSet; overload;
```

*For GetDBField() convert a TSQLTable result into a new VCL TClientDataSet*

- current implementation will return a TClientDataSet instance, created from the supplied TSQLTable content (a more optimized version may appear later)
- with non-Unicode version of Delphi, you can set aForceWideString to force the use of WideString fields instead of AnsiString, if needed
- for better speed with Delphi older than Delphi 2009 Update 3, it is recommended to use <http://andy.jgknet.de/blog/bugfix-units/midas-speed-fix-12>

```
function ToClientDataSet(aDataSet: TClientDataSet; aTable: TSQLTable; aClient:
TSQLRest=nil; aMode: TClientDataSetMode=cdsReplace; aLogChange: boolean=false ;
aForceWideString: boolean=false): boolean; overload;
```

*Convert a TSQLTable result into an existing VCL TClientDataSet*

- current implementation will return a TClientDataSet instance, created from the supplied TSQLTable content (a more optimized version may appear later)
- with non-Unicode version of Delphi, you can set aForceWideString to force the use of WideString fields instead of AnsiString, if needed
- for better speed with Delphi older than Delphi 2009 Update 3, it is recommended to use <http://andy.jgknet.de/blog/bugfix-units/midas-speed-fix-12>

## 27.60. mORMotMongoDB.pas unit

*Purpose:* Direct optimized MongoDB access for mORMot's ORM

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *mORMotMongoDB* unit

| Unit Name         | Description                                                                                                                                                                                             | Page |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>     | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                        | 1907 |
| <i>SynCommons</i> | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                               | 718  |
| <i>SynLog</i>     | Logging functions used by Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                   | 1368 |
| <i>SynMongoDB</i> | MongoDB document-oriented database direct access classes<br>- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                            | 1402 |
| <i>SynTable</i>   | Filter/database/cache/buffer/security/search/multithread/OS features<br>- as a complement to SynCommons, which tended to increase too much<br>- licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1728 |

*mORMotMongoDB class hierarchy*

### Objects implemented in the *mORMotMongoDB* unit

| Objects                | Description                                                   | Page |
|------------------------|---------------------------------------------------------------|------|
| EORMMongoDBException   | For TSynTableStatement exception class raised by this units   | 2344 |
| TSQLRestStorageMongoDB | REST server with direct access to a MongoDB external database | 2345 |

```
EORMMongoDBException = class(EORMException)
```

*For TSynTableStatement exception class raised by this units*

**TSQLRestStorageMongoDB = class(TSQLRestStorage)**

*REST server with direct access to a MongoDB external database*

- handle all REST commands via direct SynMongoDB call
- is used by TSQLRestServer.URI for faster RESTful direct access
- JOINed SQL statements are not handled yet

**constructor** Create(aClass: TSQLRecordClass; aServer: TSQLRestServer); **override;**

*Initialize the direct access to the MongoDB collection*

- in practice, you should not have to call this constructor, but rather StaticMongoDBRegister() with a TMongoDatabase instance

**destructor** Destroy; **override;**

*Release used memory*

**function** CreateSQLMultiIndex(Table: TSQLRecordClass; **const** FieldNames: array of RawUTF8; Unique: boolean; IndexName: RawUTF8=''): boolean; **override;**

*Create one index for all specific FieldNames at once*

**function** EngineDelete(TableModelIndex: integer; ID: TID): boolean; **override;**

*Delete a row, calling the current MongoDB server*

- made public since a TSQLRestStorage instance may be created stand-alone, i.e. without any associated Model/TSQLRestServer

**function** RetrieveBlobFields(Value: TSQLRecord): boolean; **override;**

*Overridden method for one single read call to the MongoDB server*

**function** SearchField(**const** FieldName, FieldValue: RawUTF8; **out** ResultID: TIDDynArray): boolean; **override;**

*Search for a field value, according to its SQL content representation*

- return true on success (i.e. if some values have been added to ResultID)
- store the results into the ResultID dynamic array
- faster than OneFieldValues method, which creates a temporary JSON content

**function** TableHasRows(Table: TSQLRecordClass): boolean; **override;**

*Check if there is some data rows in a specified table*

**function** TableRowCount(Table: TSQLRecordClass): Int64; **override;**

*Get the row count of a specified table*

- return -1 on error
- return the row count of the table on success

**function** UpdateBlobFields(Value: TSQLRecord): boolean; **override;**

*Overridden method for one single update call to the MongoDB server*

**procedure** Drop;

*Drop the whole table content*

- in practice, dropping the whole MongoDB database would be faster
- but you can still add items to it - whereas Collection.Drop would trigger GPF issues

**procedure** SetEngineAddComputeIdentifier(aIdentifier: word);

*Initialize an internal time-based unique ID generator, linked to a genuine process identifier*

- will allocate a local TSynUniqueIdentifierGenerator
- EngineAddCompute would be set to eacSynUniqueIdentifier

**property** Collection: TMongoCollection **read** fCollection;

*The associated MongoDB collection instance*

**property** EngineAddCompute: TSQLRestStorageMongoDBEngineAddComputeID **read** fEngineAddCompute **write** fEngineAddCompute;

*How the next ID would be compute at each insertion*

- default eacLastIDOnce may be the fastest, but other options are available, and may be used in some special cases
- consider using SetEngineAddComputeIdentifier() which is both safe and fast, with a cloud of servers sharing the same MongoDB collection

### Types implemented in the *mORMotMongoDB* unit

TSQLRestStorageMongoDBEngineAddComputeID = ( eacLastIDOnce, eacLastIDEachTime, eacMaxIDOnce, eacMaxIDEachTime, eacSynUniqueIdentifier );

*How TSQLRestStorageMongoDB would compute the next ID to be inserted*

- you may choose to retrieve the last inserted ID via  
 {\$query:{},\$orderby:{\_id:-1}}

or search for the current maximum ID in the collection via

{\$group:{\_id:null,max:{\$max:"\$\_id"}}

- eacLastIDOnce and eacMaxIDOnce would execute the request once when the storage instance is first started, whereas eacLastIDEachTime and eacMaxIDEachTime would be execute before each insertion
- with big amount of data, retrieving the maximum ID (eacMaxID\*) performs a full scan, which would be very slow: the last inserted ID (eacLastID\*) would definitively be faster
- in all cases, to ensure that a centralized MongoDB server has unique ID, you should better pre-compute the ID using your own algorithm depending on your nodes topology, and not rely on the ORM, e.g. using SetEngineAddComputeIdentifier() method, which would allocate a TSynUniqueIdentifierGenerator and associate eacSynUniqueIdentifier

TStaticMongoDBRegisterOption = ( mrDoNotRegisterUserGroupTables, mrMapAutoFieldsIntoSmallerLength );

*All possible options for StaticMongoDBRegisterAll/TSQLRestMongoDBCreate functions*

- by default, TSQLAuthUser and TSQLAuthGroup tables will be handled via the external DB, but you can avoid it for speed when handling session and security by setting mrDoNotRegisterUserGroupTables
- you can set mrMapAutoFieldsIntoSmallerLength to compute a field name mapping with minimal length, so that the stored BSON would be smaller: by definition, ID/RowID will be mapped as 'id', but other fields will use their first letter, and another other letter if needed (after a '\_', or in uppercase, or the next one) e.g. FirstName -> 'f', LastName -> 'l', LockedAccount: 'la'... - WARNING: not yet implemented

TStaticMongoDBRegisterOptions = set of TStaticMongoDBRegisterOption;

*Set of options for StaticMongoDBRegisterAll/TSQLRestMongoDBCreate functions*

### Functions or procedures implemented in the *mORMotMongoDB* unit

| Functions or procedures  | Description                                                                                                          | Page |
|--------------------------|----------------------------------------------------------------------------------------------------------------------|------|
| StaticMongoDBRegister    | Creates and register a static class on the Server-side to let a given ORM class be stored on a remote MongoDB server | 2347 |
| StaticMongoDBRegisterAll | Create and register ALL classes of a given model to access a MongoDB server                                          | 2347 |
| TSQLRestMongoDBCreate    | Create a new TSQLRest instance, possibly using MongoDB for its ORM process                                           | 2348 |

**function** StaticMongoDBRegister(aClass: TSQLRecordClass; aServer: TSQLRestServer; aMongoDatabase: TMongoDatabase; aMongoCollectionName: RawUTF8=''; aMapAutoFieldsIntoSmallerLength: boolean=false): TSQLRestStorageMongoDB;

*Creates and register a static class on the Server-side to let a given ORM class be stored on a remote MongoDB server*

- will associate the supplied class with a MongoDB collection for a specified MongoDB database
- to be called before Server.CreateMissingTables
- by default, the collection name will match TSQLRecord.SQLTableName, but you can customize it with the corresponding parameter
- the TSQLRecord.ID (RowID) field is always mapped to MongoDB's \_id field
- will call create needed indexes
- you can later call aServer.InitializeTables to create any missing index and initialize the void tables (e.g. default TSQLAuthGroup and TSQLAuthUser records)
- after registration, you can tune the field-name mapping by calling  
aModel.Props[aClass].ExternalDB.MapField(..)

(just a regular external DB as defined in mORMotDB.pas unit) - it may be a good idea to use short field names on MongoDB side, to reduce the space used for storage (since they will be embedded within the document data)

- it will return the corresponding TSQLRestStorageMongoDB instance - you can access later to it and its associated collection e.g. via:

```
(aServer.StaticDataServer[TSQLMyTable] as TSQLRestStorageMongoDB)
```

- you can set aMapAutoFieldsIntoSmallerLength to compute a field name mapping with minimal length, so that the stored BSON would be smaller: by definition, ID/RowID will be mapped as 'id', but other fields will use their first letter, and another other letter if needed (after a '\_', or in uppercase, or the next one) e.g. FirstName -> 'f', LastName -> 'l', LockedAccount: 'la'...

**function** StaticMongoDBRegisterAll(aServer: TSQLRestServer; aMongoDatabase: TMongoDatabase; aOptions: TStaticMongoDBRegisterOptions=[]; aMongoDBIdentifier: word=0): boolean;

*Create and register ALL classes of a given model to access a MongoDB server*

- the collection names will follow the class names
- this function will call aServer.InitializeTables to create any missing index or populate default collection content
- if aMongoDBIdentifier is not 0, then SetEngineAddComputeIdentifier() would be called

```
function TSQLRestMongoDBCreate(aModel: TSQLModel; aDefinition:
TSynConnectionDefinition; aHandleAuthentication: boolean; aOptions:
TStaticMongoDBRegisterOptions; aMongoDBIdentifier: word=0): TSQLRest; overload;
```

*Create a new TSQLRest instance, possibly using MongoDB for its ORM process*

- if aDefinition.Kind matches a TSQLRest registered class, one new instance of this kind will be created and returned
- if aDefinition.Kind is 'MongoDB' or 'MongoDBS', it will instantiate an in-memory TSQLRestServerDB or a TSQLRestServerFullMemory instance (calling TSQLRestServer.CreateInMemoryForAllVirtualTables), then call StaticMongoDBRegisterAll() with a TMongoClient initialized from aDefinition.ServerName ('server' or 'server:port') - optionally with TLS enabled if Kind equals 'MongoDBS' - and a TMongoDatabase created from aDefinition.DatabaseName, using authentication if aDefinition.User/Password credentials are set
- it will return nil if the supplied aDefinition is invalid
- if aMongoDBIdentifier is not 0, then SetEngineAddComputeIdentifier() would be called for all created TSQLRestStorageMongoDB

## 27.61. mORMotMVC.pas unit

*Purpose:* Implements MVC patterns over mORMot's ORM/SOA and SynMustache

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *mORMotMVC* unit

| Unit Name             | Description                                                                                                                                                                                                                                                                                                                                   | Page |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>         | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                              | 1907 |
| <i>mORMotWrappers</i> | Generate cross-platform clients code and documentation from a mORMot server<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                        | 2440 |
| <i>SynCommons</i>     | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                     | 718  |
| <i>SynCrypto</i>      | Fast cryptographic routines (hashing and cypher)<br>- implements<br>AES,XOR,ADLER32,MD5,RC4,SHA1,SHA256,SHA384,SHA512,SHA3 and JWT<br>- optimized for speed (tuned assembler and SSE3/SSE4/AES-NI/PADLOCK support)<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1143 |
| <i>SynLog</i>         | Logging functions used by Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                         | 1368 |
| <i>SynMustache</i>    | Logic-less mustache template rendering<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                             | 1456 |

*mORMotMVC class hierarchy*

## Objects implemented in the *mORMotMVC* unit

| Objects                   | Description                                                               | Page |
|---------------------------|---------------------------------------------------------------------------|------|
| EMVCApplication           | Exception class triggered by mORMot MVC/MVVM applications externally      | 2359 |
| EMVCException             | Exception class triggered by mORMot MVC/MVVM applications internally      | 2359 |
| IMVCApplication           | Defines the main and error pages for the ViewModel of one application     | 2360 |
| TMVCAction                | Record type to define commands e.g. to redirect to another URI            | 2356 |
| TMVCApplication           | Parent class to implement a MVC/MVVM application                          | 2360 |
| TMVCRendererAbstract      | Abstract MVC rendering execution context                                  | 2356 |
| TMVCRendererFromViews     | MVC rendering execution context, returning some rendered View content     | 2357 |
| TMVCRendererJson          | MVC rendering execution context, returning some un-rendered JSON content  | 2357 |
| TMVCRendererReturningData | Abstract MVC rendering execution context, returning some content          | 2357 |
| TMVCRun                   | Abstract class used by TMVCApplication to run                             | 2357 |
| TMVCRunOnRestServer       | Run TMVCApplication directly within a TSQLRestServer method-based service | 2358 |
| TMVCRunWithViews          | Abstract class used by TMVCApplication to run TMVCViews-based process     | 2358 |
| TMVCSessionAbstract       | An abstract class able to implement ViewModel/Controller sessions         | 2353 |

| Objects                       | Description                                                            | Page |
|-------------------------------|------------------------------------------------------------------------|------|
| TMVCSessionSingle             | Implement a single ViewModel/Controller in-memory session              | 2356 |
| TMVCSessionWithCookies        | A class able to implement ViewModel/Controller sessions with cookies   | 2355 |
| TMVCSessionWithCookiesContext | Information used by TMVCSessionWithCookies for cookie generation       | 2354 |
| TMVCSessionWithRestServer     | Implement a ViewModel/Controller sessions in a TSQLRestServer instance | 2356 |
| TMVCView                      | Define a particular rendered View                                      | 2351 |
| TMVCViewsAbstract             | An abstract class able to implement Views                              | 2351 |
| TMVCViewsMustache             | A class able to implement Views using Mustache templates               | 2352 |
| TMVCViewsMustacheParameters   | General parameters defining the Mustache Views process                 | 2352 |

#### TMVCView = record

*Define a particular rendered View*  
- as rendered by TMVCViewsAbstract.Render() method

**Content:** RawByteString;  
*The low-level content of this View*

**ContentType:** RawUTF8;  
*The MIME content type of this View*

**Flags:** TMVCViewFlags;  
*Some additional rendering information about this View*

#### TMVCViewsAbstract = class(TObject)

*An abstract class able to implement Views*

**constructor** Create(aInterface: PTypeInfo; aLogClass: TSynLogClass);  
*Initialize the class*

**property** Factory: TInterfaceFactory **read** fFactory;  
*Read-only access to the associated factory for the implementation class*

**property** ViewGenerationTimeTag: RawUTF8 **read** fViewGenerationTimeTag **write** fViewGenerationTimeTag;  
*Any occurrence of this tag in a rendered view will be converted into the rendering time in microseconds*  
- equals '[[GENERATION\_TIME\_TAG]]' by default

**property** ViewStaticFolder: TFileName **read** fViewStaticFolder;  
*Retrieve the .static local folder name*

```
property ViewTemplateFolder: TFileName read fViewTemplateFolder write
SetViewTemplateFolder;
```

*Read-only access to the local folder containing the Mustache views*

```
TMVCViewsMustacheParameters = record
```

*General parameters defining the Mustache Views process*

- used as a separate value so that we would be able to store the settings in a file, e.g. encoded as a JSON object

```
CSVExtensions: TFileName;
```

*The file extensions to search in the given Folder, specified as CSV*

- if not set, will search for 'html,json,css'

```
ExtensionForNotExistingTemplate: TFileName;
```

*File extension (e.g. '.html') to be used to create void templates*

- default '' will create no void template file in the given Folder

```
FileTimestampMonitorAfterSeconds: cardinal;
```

*Defines if the view files should be checked for modification*

- any value would automatically update the rendering template, if the file changed after a given number of seconds - default is 5 seconds

- setting 0 would be slightly faster, since content would never be checked

```
Folder: TFileName;
```

*Where the mustache template files are stored*

- if not set, will search in a 'Views' folder under the current executable

```
Helpers: TSynMustacheHelpers;
```

*Set of block helpers to be registered to TSynMustache*

- default will use TSynMustache.HelpersGetStandardList definition

```
TMVCViewsMustache = class(TMVCViewsAbstract)
```

*A class able to implement Views using Mustache templates*

```
constructor Create(aInterface: PTypeInfo; aLogClass: TSynLogClass=nil;
aExtensionForNotExistingTemplate: TFileName=''); overload;
```

*Create an instance of this ViewModel implementation class*

- this overloaded version will use default parameters (i.e. search for html+json+css in the "Views" sub-folder under the executable)

- will search and parse the matching views (and associated \*.partial), optionally creating void templates for any missing view

```
constructor Create(aInterface: PTypeInfo; const aParameters:
TMVCViewsMustacheParameters; aLogClass: TSynLogClass=nil); reintroduce; overload;
virtual;
```

*Create an instance of this ViewModel implementation class*

- define the associated REST instance, the interface definition and the local folder where the mustache template files are stored

- will search and parse the matching views (and associated \*.partial)

**destructor** Destroy; **override**;

*Finalize the instance*

**function** RegisterExpressionHelpers(**const** aNames: **array of** RawUTF8; **const** aEvents: **array of** TSynMustacheHelperEvent): TMVCViewsMustache;

*Define the supplied Expression Helpers definition*

- returns self so that may be called in a fluent interface

**function** RegisterExpressionHelpersForCrypto: TMVCViewsMustache;

*Define some Expression Helpers for hashing*

- i.e. md5, sha1 and sha256 hashing

- would allow e.g. to compute a Gravatar URI via:

```

```

- returns self so that may be called in a fluent interface

**function** RegisterExpressionHelpersForTables(aRest: TSQLRest; **const** aTables: **array of** TSQLRecordClass): TMVCViewsMustache; **overload**;

*Define Expression Helpers for some ORM tables*

- e.g. to read a TSQLMyRecord from its ID value and put its fields in the current rendering data context, you can write:

```
aView.RegisterExpressionHelpersForTables(aServer, [TSQLMyRecord]);
```

then use the following Mustache tag

```
{{#TSQLMyRecord MyRecordID}} ... {{/TSQLMyRecord MyRecordID}}
```

- returns self so that may be called in a fluent interface

**function** RegisterExpressionHelpersForTables( aRest: TSQLRest): TMVCViewsMustache; **overload**;

*Define Expression Helpers for all ORM tables of the supplied model*

- e.g. to read a TSQLMyRecord from its ID value and put its fields in the current rendering data context, you can write:

```
aView.RegisterExpressionHelpersForTables(aServer);
```

then use the following Mustache tag

```
{{#TSQLMyRecord MyRecordID}} ... {{/TSQLMyRecord MyRecordID}}
```

- returns self so that may be called in a fluent interface

**TMVCSessionAbstract** = **class**(TObject)

*An abstract class able to implement ViewModel/Controller sessions*

- see TMVCSessionWithCookies to implement cookie-based sessions

- this kind of ViewModel will implement client side storage of sessions, storing any (simple) record content on the browser client side

- at login, a record containing session-related information (session ID, display and login name, preferences, rights...) can be computed only once on the server side from the Model, then stored on the client side (typically in a cookie): later on, session information can be retrieved by the server logic (via CheckAndRetrieve - note that any security attribute should be verified against the Model), then the renderer (CheckAndRetrieveInfo returning the record as TDocVariant in the data context "Session" field) - such a pattern is very efficient and allows good scaling

- session are expected to be tied to the TMVCSessionAbstract instance lifetime, so are lost after server restart, unless they are persisted via LoadContext/SaveContext methods

**constructor** Create; **virtual**;

*Create an instance of this ViewModel implementation class*

**function** CheckAndRetrieve(PRecordData: pointer=nil; PRecordTypeInfo: pointer=nil; PExpires: PCardinal=nil): integer; **virtual**; **abstract**;

*Retrieve the current session ID*

- can optionally retrieve the associated record Data parameter

**function** CheckAndRetrieveInfo(PRecordDataTypeInfo: pointer): **variant**; **virtual**;

*Retrieve the session information as a JSON object*

- returned as a TDocVariant, including any associated record Data

- will call CheckAndRetrieve() then RecordSaveJSON() and \_JsonFast()

**function** Exists: boolean; **virtual**; **abstract**;

*Fast check if there is a session associated to the current context*

**function** Initialize(PRecordData: pointer=nil; PRecordTypeInfo: pointer=nil; SessionTimeoutMinutes: cardinal=60): integer; **virtual**; **abstract**;

*Will create a new session*

- setting an optional record data, and returning the internal session ID

- you can supply a time period, after which the session will expire - default is 1 hour - note that overridden methods may not implement it

**function** LoadContext(const Saved: RawUTF8): boolean; **virtual**; **abstract**;

*Restore session generation information from SaveContext format*

- returns TRUE on success

**function** SaveContext: RawUTF8; **virtual**; **abstract**;

*Return all session generation information as ready-to-be stored string*

- to be retrieved via LoadContext, e.g. after restart

**procedure** Finalize; **virtual**; **abstract**;

*Clear the session*

**TMVCSessionWithCookiesContext** = **packed record**

*Information used by TMVCSessionWithCookies for cookie generation*

- i.e. the session ID, cookie name, encryption and HMAC secret keys

- this data can be persisted so that the very same cookie information are available after server restart

**CookieName**: RawUTF8;

*The cookie name, used for storage on the client side*

**Crypt**: array[byte] of byte;

*Secret information, used for encryption of the cookie content*

**CryptNonce**: Cardinal;

*Random IV used as CTR on Crypt[] secret key*

**Secret**: THMAC\_CRC32C;

*Secret information, used for HMAC digital signature of cookie content*

**SessionSequence: integer;**

*An increasing counter, to implement unique session ID*

**TMVCSessionWithCookies = class(TMVCSessionAbstract)**

*A class able to implement ViewModel/Controller sessions with cookies*

- this kind of ViewModel will implement cookie-based sessions, able to store any (simple) record content in the cookie, on the browser client side
- those cookies have the same feature set than JWT, but with a lower payload (thanks to binary serialization), and cookie safety (not accessible from JavaScript): they are digitally signed (with HMAC-CRC32C and a temporary secret key), they include an unique session identifier (like "jti" claim), issue and expiration dates (like "iat" and "exp" claims), and they are encrypted with a temporary key - this secret keys is tied to the TMVCSessionWithCookies instance lifetime, so new cookies are generated after server restart, unless they are persisted via LoadContext/SaveContext
- signature and encryption are weak, but very fast, to avoid DDOS attacks

**constructor Create; override;**

*Create an instance of this ViewModel implementation class*

**function CheckAndRetrieve(PRecordData: pointer=nil; PRecordTypeInfo: pointer=nil; PExpires: PCardinal=nil): integer; override;**

*Retrieve the session ID from the current cookie*

- can optionally retrieve the record Data parameter stored in the cookie
- will return the 32-bit internal session ID, or 0 if the cookie is invalid

**function Exists: boolean; override;**

*Fast check if there is a cookie session associated to the current context*

**function Initialize(PRecordData: pointer=nil; PRecordTypeInfo: pointer=nil; SessionTimeoutMinutes: cardinal=60): integer; override;**

*Will initialize the session cookie*

- setting an optional record data, which will be stored Base64-encoded
- will return the 32-bit internal session ID
- you can supply a time period, after which the session will expire - default is 1 hour, and could go up to

**function LoadContext(const Saved: RawUTF8): boolean; override;**

*Restore cookie generation information from SaveContext text format*

- returns TRUE after checking the crc and unserializing the supplied data
- WARNING: if the unerlying record type structure changed (i.e. any field is modified or added), restoration will lead to data corruption of low-level binary content, then trigger unexpected GPF: if you change the record type definition, do NOT use LoadContext - and reset all cookies

**function SaveContext: RawUTF8; override;**

*Return all cookie generation information as base64 encoded text*

- to be retrieved via LoadContext

**procedure Finalize; override;**

*Clear the session*

- by deleting the cookie on the client side

**property** Context: TMVCSessionWithCookiesContext **read** fContext **write** fContext;

*Direct access to the low-level information used for cookies generation*

- use SaveContext and LoadContext methods to persist this information before server shutdown, so that the cookies can be re-used after restart

**property** CookieName: RawUTF8 **read** fContext.CookieName **write** fContext.CookieName;

*You can customize the cookie name*

- default is 'mORMot', and cookie is restricted to Path=/RestRoot

TMVCSessionWithRestServer = **class**(TMVCSessionWithCookies)

*Implement a ViewModel/Controller sessions in a TSQLRestServer instance*

- will use ServiceContext.Request threadvar to access the client cookies

TMVCSessionSingle = **class**(TMVCSessionWithCookies)

*Implement a single ViewModel/Controller in-memory session*

- this kind of session could be used in-process, e.g. for a VCL/FMX GUI

- do NOT use it with multiple clients, e.g. from HTTP remote access

TMVCAction = **record**

*Record type to define commands e.g. to redirect to another URI*

- do NOT access those record property directly, but rather use

TMVCApplication.GotoView/GotoError/GotoDefault methods, e.g.

```
function TBlogApplication.Logout: TMVCAction;
begin
 CurrentSession.Finalize;
 GotoDefault(result);
end;
```

- this record type should match exactly TServiceCustomAnswer layout, so that TServiceMethod.InternalExecute() would handle it directly

RedirectToMethodName: RawUTF8;

*The method name to be executed*

RedirectToMethodParameters: RawUTF8;

*May contain a JSON object which will be used to specify parameters to the specified method*

ReturnedStatus: cardinal;

*Which HTTP Status code should be returned*

- if RedirectToMethodName is set, will return 307 HTTP\_TEMPORARYREDIRECT by default, but you can set here the expected HTTP Status code, e.g. 201 HTTP\_CREATED or 404 HTTP\_NOTFOUND

TMVCRendererAbstract = **class**(TObject)

*Abstract MVC rendering execution context*

- you should not execute this abstract class, but any of the inherited class

- one instance inherited from this class would be allocated for each event

- may return some data (when inheriting from TMVCRendererReturningData), or even simply display the value in a VCL/FMX GUI, without any output

**constructor** Create(aApplication: TMVCApplication); **reintroduce**;

*Initialize a rendering process for a given MVC Application/ViewModel*

**procedure** ExecuteCommand(aMethodIndex: integer); **virtual**;

*Main execution method of the rendering process*

- Input should have been set with the incoming execution context

**property** Input: RawUTF8 **read** fInput **write** fInput;

*Incoming execution context, to be processed via ExecuteCommand() method*

- should be specified as a raw JSON object

**TMVCRendererReturningData** = **class**(TMVCRendererAbstract)

*Abstract MVC rendering execution context, returning some content*

- the Output property would contain the content to be returned
- can be used to return e.g. some rendered HTML or some raw JSON, or even some server-side generated report as PDF, using our mORMotReport.pas

**constructor** Create(aRun: TMVCRunWithViews); **reintroduce**; **virtual**;

*Initialize a rendering process for a given MVC Application/ViewModel*

- you need to specify a MVC Views engine, e.g. TMVCViewsMustache instance

**procedure** ExecuteCommand(aMethodIndex: integer); **override**;

*Main execution method of the rendering process*

- this overridden method would handle proper caching as defined by TMVCRunWithViews.SetCache()

**property** Output: TServiceCustomAnswer **read** fOutput;

*Caller should retrieve this value after ExecuteCommand method execution*

**TMVCRendererFromViews** = **class**(TMVCRendererReturningData)

*MVC rendering execution context, returning some rendered View content*

- will use an associated Views templates system, e.g. a Mustache renderer

**constructor** Create(aRun: TMVCRunWithViews); **override**;

*Initialize a rendering process for a given MVC Application/ViewModel*

- this overridden constructor will ensure that cache is enabled

**TMVCRendererJson** = **class**(TMVCRendererReturningData)

*MVC rendering execution context, returning some un-rendered JSON content*

- may be used e.g. for debugging purpose
- for instance, TMVCRunOnRestServer will return such context with the supplied URI ends with '/json' (e.g. for any /root/method/json request)

**TMVCRun** = **class**(TObject)

*Abstract class used by TMVCAApplication to run*

- a single TMVCAApplication logic may handle several TMVCRun instances

**constructor** Create(aApplication: TMVCAApplication); **reintroduce**;

*Link this runner class to a specified MVC application*

- will also reset the associated Application.Session instance

**procedure** NotifyContentChanged; **virtual**;

*Method called to flush the caching mechanism for all MVC commands*

**procedure** NotifyContentChangedForMethod(const aMethodName: RawUTF8); **overload**;

*You may call this method to flush any caching mechanism for a MVC command*

**procedure** NotifyContentChangedForMethod(aMethodIndex: integer); **overload**; **virtual**;

*You may call this method to flush any caching mechanism for a MVC command*

**property** Application: TMVCAApplication **read** fApplication **write** fApplication;

*Read-write access to the associated MVC Application/ViewModel instance*

TMVCRunWithViews = **class**(TMVCRun)

*Abstract class used by TMVCAApplication to run TMVCViews-based process*

- this inherited class will host a MVC Views instance, and handle an optional simple in-memory cache

**constructor** Create(aApplication: TMVCAApplication; aViews: TMVCViewsAbstract=nil);  
**reintroduce**;

*FCache[MethodIndex] link this runner class to a specified MVC application*

**destructor** Destroy; **override**;

*Finalize this instance*

**function** SetCache(const aMethodName: RawUTF8; aPolicy: TMVCRendererCachePolicy;  
 aTimeOutSeconds: cardinal=0): TMVCRunWithViews; **virtual**;

*Defines the caching policy for a given MVC command*

- a time expiration period (up to 5 minutes) can also be defined per MVC command - leaving default 0 will set to 5 minutes expiration delay

- function calls can be chained to create some fluent definition interface like in

TAnyBLogapplication.Create:

fMainRunner := TMVCRunWithViews.Create(self).SetCache('default', cacheRoot);

**procedure** NotifyContentChangedForMethod(aMethodIndex: integer); **override**;

*Method called to flush the caching mechanism for a MVC command*

**property** Views: TMVCViewsAbstract **read** fViews;

*Read-write access to the associated MVC Views instance*

TMVCRunOnRestServer = **class**(TMVCRunWithViews)

*Run TMVCAApplication directly within a TSQLRestServer method-based service*

- this is the easiest way to host and publish a MVC Application, optionally in conjunction with REST/AJAX client access

**constructor** Create(aApplication: TMVCAApplication; aRestServer: TSQLRestServer=nil;  
**const** aSubURI: RawUTF8=''; aViews: TMVCViewsAbstract=nil; aPublishOptions:  
 TMVCPublishOptions= [low(TMVCPublishOption)..high(TMVCPublishOption)]);  
**reintroduce**;

*This constructor will publish some views to a TSQLRestServer instance*

- the associated RestModel can match the supplied TSQLRestServer, or be another instance (if the data model is not part of the publishing server)
- all TMVCAApplication methods would be registered to the TSQLRestServer, as /root/methodName if aSubURI is "", or as /root/aSubURI/methodName
- if aApplication has no Views instance associated, this constructor will initialize a Mustache renderer in its default folder, with '.html' void template generation
- will also create a TMVCSessionWithRestServer for simple cookie sessions
- aPublishOptions could be used to specify integration with the server

**function** AddStaticCache(**const** aFileName: TFileName; **const** aFileContent:  
 RawByteString): RawByteString;

*Define some content for a static file*

- only used if cacheStatic has been defined

**property** PublishOptions: TMVCPublishOptions **read** fPublishOptions **write**  
 fPublishOptions;

*Current publishing options, as specify to the constructor*

**property** StaticCacheControlMaxAge: integer **read** fStaticCacheControlMaxAge **write**  
 fStaticCacheControlMaxAge;

*Optional "Cache-Control: max-age=###" header value for static content*

EMVCEXception = **class**(ESynException)

*Exception class triggered by mORMot MVC/MVVM applications internally*

- those error are internal fatal errors of the server side process

EMVCAApplication = **class**(ESynException)

*Exception class triggered by mORMot MVC/MVVM applications externally*

- those error are external errors which should be notified to the client
- can be used to change the default view, e.g. on application error

**constructor** CreateDefault(aStatus: cardinal=HTTP\_TEMPORARYREDIRECT);

*Same as calling TMVCAApplication.GotoDefault*

- HTTP\_TEMPORARYREDIRECT will change the URI, but HTTP\_SUCCESS won't

**constructor** CreateGotoError(aHtmlErrorCode: integer); overload;

*Same as calling TMVCAApplication.GotoError()*

**constructor** CreateGotoError(**const** aErrorMessage: **string**; aErrorCode:  
 integer=HTTP\_BADREQUEST); overload;

*Same as calling TMVCAApplication.GotoError()*

**constructor** CreateGotoView(**const** aMethod: RawUTF8; **const**  
 aParametersNameValuePair: **array of const**; aStatus:  
 cardinal=HTTP\_TEMPORARYREDIRECT);

*Same as calling TMVCAApplication.GotoView()*

- HTTP\_TEMPORARYREDIRECT will change the URI, but HTTP\_SUCCESS won't

**IMVCApplication = interface(IInvokable)**

*Defines the main and error pages for the ViewModel of one application*

**procedure Default(var Scope: variant);**

*The default main page*

- whole data context is retrieved and returned as a TDocVariant

**procedure Error(var Msg: RawUTF8; var Scope: variant);**

*The error page*

- in addition to the error message, a whole data context is retrieved and returned as a TDocVariant

**TMVCApplication = class(TInjectableObject)**

*Parent class to implement a MVC/MVVM application*

- you should inherit from this class, then implement an interface inheriting from IMVCApplication to define the various commands of the application  
- here the Model would be a TSQLRest instance, Views will be defined by TMVCViewsAbstract (e.g. TMVCViewsMustache), and the ViewModel/Controller will be implemented with IMVCApplication methods of the inherited class  
- inherits from TInjectableObject, so that you could resolve dependencies via services or stubs, following the IoC pattern

**destructor Destroy; override;**

*Finalize the application*

- and release any associated CurrentSession, Views, and fMainRunner

**procedure Start(aRestModel: TSQLRest; aInterface: PTypeInfo); virtual;**

*Initialize the instance of the MVC/MVVM application*

- define the associated REST instance, and the interface definition for application commands  
- is not defined as constructor, since this TInjectableObject may expect injection using the CreateInjected() constructor

**property CurrentSession: TMVCSessionAbstract read fSession write SetSession;**

*Read-write access to the associated Session instance*

**property Factory: TInterfaceFactory read fFactory;**

*Read-only access to the associated factory for IMVCApplication interface*

**property Locker: IAutoLocker read fLocker;**

*Global mutex which may be used to protect ViewModel/Controller code*

- you may call Locker.ProtectMethod in any implementation method to ensure that no other thread would access the same data  
- for store some cache data among methods, you may consider defining a ILockedDocVariant private field, and use it to store values safely  
- note that regular RestModel CRUD operations are already thread safe, so it is not necessary to use this Locker with ORM or SOA methods

**property** MainRunner: TMVCRun **read** fMainRunner;

*Read-write access to the main associated TMVCRun instance*

- if any TMVCRun instance is stored here, will be freed by Destroy
- but note that a single TMVCApplication logic may handle several TMVCRun

**property** RestModel: TSQLRest **read** fRestModel;

*Read-only access to the associated mORMot REST instance implementing the MVC data Model of the application*

- is a TSQLRestServer instance e.g. for TMVCRunOnRestServer

### Types implemented in the *mORMotMVC* unit

TMVCPublishOption = ( publishMvcInfo, publishStatic, cacheStatic, registerORMTableAsExpressions, bypassAuthentication );

*The kinds of optional content which may be published*

- publishMvcInfo will define a /root/[aSubURI/]mvc-info HTML page, which is pretty convenient when working with views
- publishStatic will define a /root/[aSubURI/].static sub-folder, ready to serve any file available in the Views\static local folder, via an in-memory cache (if cacheStatic is also defined)
- cacheStatic enables an in-memory cache of publishStatic files; if not set, TSQLRestServerURIContext.ReturnFile is called to avoid buffering, which may be a better solution on http.sys or if NGINX's X-Accel-Redirect header is set
- registerORMTableAsExpressions will register Mustache Expression Helpers for every TSQLRecord table of the Server data model
- by default, TSQLRestServer authentication would be by-passed for all MVC routes, unless bypassAuthentication option is undefined

TMVCPublishOptions = **set of** TMVCPublishOption;

*Which kind of optional content should be publish*

TMVCRendererCachePolicy = ( cacheNone, cacheRootIgnoringSession, cacheRootIfSession, cacheRootIfNoSession, cacheRootWithSession, cacheWithParametersIgnoringSession, cacheWithParametersIfSession, cacheWithParametersIfNoSession );

*How TMVCRendererReturningData should cache its content*

TMVCViewFlags = **set of** (viewHasGenerationTimeTag);

*TMVCView.Flags rendering context*

### Constants implemented in the *mORMotMVC* unit

MVCINFO\_URI = 'mvc-info';

*The pseudo-method name for the MVC information html page*

STATIC\_URI = '.static';

*The pseudo-method name for any static content for Views*

## 27.62. mORMotReport.pas unit

*Purpose:* Reporting unit

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

The *mORMotReport* unit is quoted in the following items

| SWRS #   | Description                                                                                | Page |
|----------|--------------------------------------------------------------------------------------------|------|
| DI-2.3.2 | A reporting feature, with full preview and export as PDF or TXT files, shall be integrated | 2560 |

### Units used in the *mORMotReport* unit

| Unit Name         | Description                                                                                                                                                                                                                                                                                                                                    | Page |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>SynCommons</i> | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                      | 718  |
| <i>SynGdiPlus</i> | GDI+ library API access<br>- adds GIF, TIF, PNG and JPG pictures read/write support as standard TGraphic<br>- make available most useful GDI+ drawing methods<br>- allows Antialiased rendering of any EMF file using GDI+<br>- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1355 |
| <i>SynLZ</i>      | SynLZ Compression routines<br>- licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                                                                                                        | 1399 |
| <i>SynPdf</i>     | PDF file generation<br>- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                                                        | 1479 |

*mORMotReport class hierarchy*

### Objects implemented in the *mORMotReport* unit

| Objects | Description                      | Page |
|---------|----------------------------------|------|
| TColRec | Internal format of a text column | 2363 |

| Objects           | Description                                                             | Page |
|-------------------|-------------------------------------------------------------------------|------|
| TGDIPageContent   | Contains one page                                                       | 2364 |
| TGDIPagereference | Internal structure used to store bookmarks or links                     | 2363 |
| TGDIPages         | Report class for generating documents from code                         | 2364 |
| THeaderFooter     | Internal format of the header or footer text                            | 2363 |
| TPagePaintBox     | Hack the TPaintBox to allow custom background erase                     | 2363 |
| TSavedState       | A report layout state, as used by SaveLayout/RestoreSavedLayout methods | 2363 |

**TSavedState = record**

*A report layout state, as used by SaveLayout/RestoreSavedLayout methods*

**THeaderFooter = class(TObject)**

*Internal format of the header or footer text*

**constructor** Create(Report: TGDIPages; doubleline: boolean; **const** aText: SynUnicode=''; IsText: boolean=false);

*Initialize the header or footer parameters with current report state*

**TColRec = record**

*Internal format of a text column*

**TPagePaintBox = class(TPaintBox)**

*Hack the TPaintBox to allow custom background erase*

**TGDIPagereference = class(TObject)**

*Internal structure used to store bookmarks or links*

**Page: Integer;**

*The associated page number (starting at 1)*

**Preview: TRect;**

*Coordinates on screen of the hot zone*

**Rect: TRect;**

*Graphical coordinates of the hot zone*

- for bookmarks, Top is the Y position
- for links, the TRect will describe the hot region
- for Outline, Top is the Y position and Bottom the outline tree level

**constructor** Create(PageNumber: integer; Left, Top, Right, Bottom: integer);

*Initialize the structure with the current page*

**procedure** ToPreview(Pages: TGDIPages);

*Compute the coordinates on screen into Preview*

**TGDIPageContent = record**

*Contains one page*

**MarginPx: TRect;**

*Margin of the page*

**MetaFileCompressed: RawByteString;**

*SynLZ-compressed content of the page*

**OffsetPx: TPoint;**

*Non printable offset of the page*

**SizePx: TPoint;**

*The physical page size*

**Text: string;**

*Text equivalent of the page*

**TGDIPages = class(TScrollBox)**

*Report class for generating documents from code*

- data is drawn in memory, they displayed or printed as desired
- allow preview and printing, and direct pdf export
- handle bookmark, outlines and links inside the document
- page coordinates are in mm's

*Used for DI-2.3.2 (page 2560).*

**Caption: string;**

*The title of the report*

- used for the preview caption form
- used for the printing document name

**ForceCopyTextAsWholeContent: boolean;**

*If true, the headers are copied only once to the text*

**ForceInternalAntiAliased: boolean;**

*If true, drawing will NOT to use native GDI+ 1.1 conversion*

- we found out that GDI+ 1.1 was not as good as our internal conversion function written in Delphi, e.g. for underlined fonts
- so this property is set to true by default for proper display on screen
- will only be used if ForceNoAntiAliased is false, of course

**ForceInternalAntiAliasedFontFallBack: boolean;**

*If true, internal text drawing will use a font-fallback mechanism for characters not existing within the current font (just as with GDI)*

- is disabled by default, but could be set to TRUE to force enabling TGDIPPlusFull.ForceUseDrawString property

**ForceNoAntiAliased: boolean;**

*If true the preview will not use GDI+ library to draw anti-aliased graphics*

- this may be slow on old computers, so caller can disable it on demand

**ForcePrintAsBitmap:** boolean;

*If true, the PrintPages() method will use a temporary bitmap for printing*

- some printer device drivers have problems with printing metafiles which contains other metafiles; should have been fixed
- not useful, since slows the printing a lot and makes huge memory usage

**GroupsMustBeOnSamePage:** boolean;

*Set group page fill method*

- if set to true, the groups will be forced to be placed on the same page (this was the original default "Pages" component behavior, but this is not usual in page composition, so is disabled by default in TGDIPages)
- if set to false, the groups will force a page feed if there is not enough place for 20 lines on the current page (default behavior)

**OnPopupMenuClick:** TNotifyEvent;

*Event triggered when a ReportPopupMenu item is selected*

- default handling (i.e. leave this field nil) is for Page navigation
- you can override this method for handling additional items to the menu
- the Tag component of the custom TMenuItem should be 0 or greater than Report pages count: use 1000 as a start for custom TMenuItem.Tag values

**OnPopupMenuPopup:** TNotifyEvent;

*Event triggered when the ReportPopupMenu is displayed*

- default handling (i.e. leave this field nil) is to add Page navigation
- you can override this method for adding items to the ReportPopupMenu

**OnStringToUnicode:** TOnStringToUnicodeEvent;

*Customize text conversion before drawing*

- Text content can be modified by this event handler to customize some characters (e.g. '>=' can be converted to its Unicode glyph)

**PopupMenuClass:** TPopupMenuClass;

*User can customize this class to create an advanced popup menu instance*

**PreviewSurfaceBitmap:** TBitmap;

*The bitmap used to draw the page*

**constructor** Create(AOwner: TComponent); **override;**

*Creates the reporting component*

**destructor** Destroy; **override;**

*Finalize the component, releasing all used memory*

**function** AddBookMark(const aBookmarkName: string; aYPosition: integer=0): Boolean;  
**virtual;**

*Create a bookmark entry at the current position of the current page*

- return false if this bookmark name was already existing, true on success
- if aYPosition is not 0, the current Y position will be used

**function** CreatePictureMetaFile(Width, Height: integer; **out** MetaCanvas: TCanvas):  
TMetaFile;

*Create a meta file and its associated canvas for displaying a picture*

- you must release manually both Objects after usage

**function** CurrentGroupPosStart: integer;

*Distance (in mm's) from the top of the page to the top of the current group*  
- returns CurrentYPos if no group is in use

**function** ExportPDF(aPdfFileName: TFileName; ShowErrorOnScreen: boolean;  
LaunchAfter: boolean=true): boolean;

*Export the current report as PDF file*  
- uses internal PDF code, from Synopse PDF engine (handle bookmarks, outline and twin bitmaps) - in this case, a file name can be set

**function** ExportPDFStream(aDest: TStream): boolean;

*Export the current report as PDF in a specified stream*  
- uses internal PDF code, from Synopse PDF engine (handle bookmarks, outline and twin bitmaps) - in this case, a file name can be set

**function** GetColumnInfo(index: integer): TColRec;

*Retrieve the attributes of a specified column*

**function** GotoBookmark(const aBookmarkName: string): Boolean; **virtual**;

*Go to the specified bookmark*  
- returns true if the bookmark name was existing and reached

**function** HasSpaceFor(mm: integer): boolean;

*Returns true if there is enough space in the current Report for a vertical size, specified in mm*

**function** HasSpaceForLines(Count: integer): boolean;

*Returns true if there is enough space in the current Report for Count lines*  
- Used to check if there's sufficient vertical space remaining on the page for the specified number of lines based on the current Y position

**function** MmToPrinter(const R: TRect): TRect;

*Convert a rect of mm into pixel canvas units*

**function** MmToPrinterPxX(mm: integer): integer;

*Convert a mm X position into pixel canvas units*

**function** MmToPrinterPxY(mm: integer): integer;

*Convert a mm Y position into pixel canvas units*

**function** NewPopupMenuItem(const aCaption: string; Tag: integer=0; SubMenu:  
TMenuItem=nil; OnClick: TNotifyEvent=nil; ImageIndex: integer=-1): TMenuItem;

*Add an item to the popup menu*  
- used mostly internally to add page browsing  
- default OnClick event is to go to page set by the Tag property

**function** PrinterPxToMmX(px: integer): integer;

*Convert a pixel canvas X position into mm*

**function** PrinterPxToMmY(px: integer): integer;

*Convert a pixel canvas Y position into mm*

**function** PrinterToMM(const R: TRect): TRect;

*Convert a rect of pixel canvas units into mm*

**function** PrintPages(PrintFrom, PrintTo: integer): boolean;

*Print the selected pages to the default printer of Printer unit*

- if PrintFrom=0 and PrintTo=0, then all pages are printed
- if PrintFrom=-1 or PrintTo=-1, then a printer dialog is displayed

**function** TextWidth(const Text: SynUnicode): integer;

*Return the width of the specified text, in mm*

**function** TitleFlags: integer;

*Get the forming flags associated to a Title*

**procedure** AddColumn(left, right: integer; align: TColAlign; bold: boolean);

*Register a column, with proper alignment*

**procedure** AddColumnHeaders(const headers: array of SynUnicode; WithBottomGrayLine: boolean=false; BoldFont: boolean=false; RowLineHeight: integer=0; flags: integer=0);

*Register some column headers, with the current font forming*

- Column headers will appear just above the first text output in columns on each page
- you can call this method several times in order to have diverse font formats across the column headers

**procedure** AddColumnHeadersFromCSV(var CSV: PWideChar; WithBottomGrayLine: boolean; BoldFont: boolean=false; RowLineHeight: integer=0);

*Register some column headers, with the current font forming*

- Column headers will appear just above the first text output in columns on each page
- call this method once with all columns text as CSV

**procedure** AddColumns(const PercentWidth: array of integer; align: TColAlign=caLeft);

*Register same alignment columns, with percentage of page column width*

- sum of all percent width should be 100, but can be of any value
- negative widths are converted into absolute values, but corresponding alignment is set to right
- if a column need to be right aligned or currency aligned, use SetColumnAlign() method below
- individual column may be printed in bold with SetColumnBold() method

**procedure** AddLineToFooter(doubleline: boolean);

*Adds either a single line or a double line (drawn between the left & right page margins) to the page footer*

**procedure** AddLineToHeader(doubleline: boolean);

*Adds either a single line or a double line (drawn between the left & right page margins) to the page header*

**procedure** AddLink(const aBookmarkName: string; aRect: TRect; aPageNumber: integer=0; aNoBorder: boolean=false); **virtual**;

*Create a link entry at the specified coordinates of the current page*

- coordinates are specified in mm
- the bookmark name is not checked by this method: a bookmark can be linked before being marked in the document

```
procedure AddOutline(const aTitle: string; aLevel: Integer; aYPosition: integer=0;
aPageNumber: integer=0); virtual;
```

*Create an outline entry at the current position of the current page*  
- if aYPosition is not 0, the current Y position will be used

```
procedure AddPagesToFooterAt(const PageText: string; XPos: integer; YPosMultiplier:
integer=1);
```

*Will add the current 'Page n/n' text at the specified position*  
- PageText must be of format 'Page %d/%d', in the desired language  
- if XPos=-1, will put the text at the current right margin  
- if the vertical position does not fit your need, you could set YPosMultiplier to a value which will be multiplied by fFooterHeight to compute the YPos

```
procedure AddTextToFooter(const s: SynUnicode);
```

*Adds text using to current font and alignment to the page footer*

```
procedure AddTextToFooterAt(const s: SynUnicode; XPos: integer);
```

*Adds text to the page footer at the specified horizontal position and using to current font. No Line feed will be triggered.*  
- if XPos=-1, will put the text at the current right margin

```
procedure AddTextToHeader(const s: SynUnicode);
```

*Adds text using to current font and alignment to the page header*

```
procedure AddTextToHeaderAt(const s: SynUnicode; XPos: integer);
```

*Adds text to the page header at the specified horizontal position and using to current font.*  
- No Line feed will be triggered: this method doesn't increment the YPos, so can be used to add multiple text on the same line  
- if XPos=-1, will put the text at the current right margin

```
procedure AppendRichEdit(RichEditHandle: HWND; EndOfPagePositions:
PIntegerDynArray=nil);
```

*Append a Rich Edit content to the current report*  
- note that if you want the TRichEdit component to handle more than 64 KB of RTF content, you have to set its MaxLength property as expected (this is a limitation of the VCL, not of this method)  
- you can specify optionally a pointer to a TIntegerDynArray variable, which will be filled with the position of each page last char: it may be handy e.g. to add some cross-reference table about the rendered content

```
procedure BeginDoc;
```

*Begin a Report document*  
- Every report must start with BeginDoc and end with EndDoc  
- note that Printers.SetPrinter() should be set BEFORE calling BeginDoc, otherwise you may have a "canvas does not allow drawing" error

```
procedure BeginGroup;
```

*Begin a Group: stops the contents from being split across pages*  
- BeginGroup-EndGroup text blocks can't be nested

```
procedure Clear; virtual;
```

*Clear the current Report document*

**procedure** ClearColumnHeaders;

*Clear the Headers associated to the Columns*

**procedure** ClearColumns;

*Erase all columns and the associated headers*

**procedure** ClearFooters;

*Clear all already predefined Footers*

**procedure** ClearHeaders;

*Clear all already predefined Headers*

**procedure** ColumnHeadersNeeded;

*ColumnHeadersNeeded will force column headers to be drawn again just prior to printing the next row of columned text*

- Usually column headers are drawn once per page just above the first column.

ColumnHeadersNeeded is useful where columns of text have been separated by a number of lines of non-columned text

**procedure** DrawAngledTextAt(const s: SynUnicode; XPos, Angle: integer);

*Draw one line of text, with a specified Angle and X Position*

**procedure** DrawArrow(Point1, Point2: TPoint; HeadSize: integer; SolidHead: boolean);

*Draw an Arrow*

**procedure** DrawBMP(rec: TRect; bmp: TBitmap); overload;

*Stretch draws a bitmap image at the specified page coordinates in mm's*

**procedure** DrawBMP(bmp: TBitmap; bLeft, bWidth: integer; const Legend: string='');  
overload;

*Add the bitmap at the specified X position*

- if there is not enough place to draw the bitmap, go to next page

- then the current Y position is updated

- bLeft (in mm) is calculated in reference to the LeftMargin position

- if bLeft is maxInt, the bitmap is centered to the page width

- bitmap is stretched (keeping aspect ratio) for the resulting width to match the bWidth parameter (in mm)

**procedure** DrawBox(left,top,right,bottom: integer);

*Draw a square box at the given coordinates*

**procedure** DrawBoxFilled(left,top,right,bottom: integer; Color: TColor);

*Draw a filled square box at the given coordinates*

**procedure** DrawColumnLine(ColIndex: integer; aAtTop: boolean; aDoDoubleLine: boolean);

*Draw a Line, following a column layout*

**procedure** DrawDashedLine;

*Draw a Dashed Line between the left & right margins*

```
procedure DrawGraphic(graph: TGraphic; bLeft, bWidth: integer; const Legend: SynUnicode='');
```

*Add the graphic (bitmap or metafile) at the specified X position*

- handle only TBitmap and TMetafile kind of TGraphic
- if there is not enough place to draw the bitmap, go to next page
- then the current Y position is updated
- bLeft (in mm) is calculated in reference to the LeftMargin position
- if bLeft is maxInt, the bitmap is centered to the page width
- bitmap is stretched (keeping aspect ratio) for the resulting width to match the bWidth parameter (in mm)

```
procedure DrawLine(doubleline: boolean=false);
```

*Draw a Line, either simple or double, between the left & right margins*

```
procedure DrawLinesInCurrencyCols(doublelines: boolean);
```

*Draw (double if specified) lines at the bottom of all currency columns*

```
procedure DrawMeta(rec: TRect; meta: TMetafile);
```

*Stretch draws a metafile image at the specified page coordinates in mm's*

```
procedure DrawText(const s: string; withNewLine: boolean=true);
```

*Draw some text as a paragraph, with the current alignment*

- this method does all word-wrapping and formatting if necessary
- this method handle multiple paragraphs inside s (separated by newlines - i.e. #13)
- by default, will write a paragraph, unless withNewLine is set to FALSE, so that the next DrawText() will continue drawing at the current position

```
procedure DrawTextAcrossCols(const StringArray, LinkArray: array of SynUnicode; BackgroundColor: TColor=clNone); overload;
```

*Draw some text, split across every columns*

- you can specify an optional bookmark name to be used to link a column content via a AddLink() call
- if BackgroundColor is not clNone (i.e. clRed or clNavy or clBlack), the row is printed on white with this background color (e.g. to highlight errors)

```
procedure DrawTextAcrossCols(const StringArray: array of SynUnicode; BackgroundColor: TColor=clNone); overload;
```

*Draw some text, split across every columns*

- if BackgroundColor is not clNone (i.e. clRed or clNavy or clBlack), the row is printed on white with this background color (e.g. to highlight errors)

```
procedure DrawTextAcrossColsFromCSV(var CSV: PWideChar; BackgroundColor: TColor=clNone);
```

*Draw some text, split across every columns*

- this method expect the text to be separated by commas
- if BackgroundColor is not clNone (i.e. clRed or clNavy or clBlack), the row is printed on white with this background color (e.g. to highlight errors)

```
procedure DrawTextAt(s: SynUnicode; XPos: integer; const aLink: string=''; CheckPageNumber: boolean=false; aLinkNoBorder: boolean=false);
```

*Draw one line of text, with the current alignment*

**procedure** DrawTextFmt(**const** s: **string**; **const** Args: **array of const**; withNewLine: **boolean**=true);

*Draw some text as a paragraph, with the current alignment*  
- this method use format() like parameterss

**procedure** DrawTextU(**const** s: RawUTF8; withNewLine: **boolean**=true);

*Draw some UTF-8 text as a paragraph, with the current alignment*  
- this method does all word-wrapping and formatting if necessary  
- this method handle multiple paragraphs inside s (separated by newlines - i.e. #13)  
- by default, will write a paragraph, unless withNewLine is set to FALSE, so that the next DrawText() will continue drawing at the current position

**procedure** DrawTextW(**const** s: SynUnicode; withNewLine: **boolean**=true);

*Draw some Unicode text as a paragraph, with the current alignment*  
- this method does all word-wrapping and formatting if necessary  
- this method handle multiple paragraphs inside s (separated by newlines - i.e. #13)  
- by default, will write a paragraph, unless withNewLine is set to FALSE, so that the next DrawText() will continue drawing at the current position

**procedure** DrawTitle(**const** s: SynUnicode; DrawBottomLine: **boolean**=false; OutlineLevel: **Integer**=0; **const** aBookmark: **string**=''; **const** aLink: **string**=''; aLinkNoBorder: **boolean**=false);

*Draw some text as a paragraph title*  
- the outline level can be specified, if UseOutline property is enabled  
- if aBookmark is set, a bookmark is created at this position  
- if aLink is set, a link to the specified bookmark name (in aLink) is made

**procedure** EndDoc;

*End the Report document*  
- Every report must start with BeginDoc and end with EndDoc

**procedure** EndGroup;

*End a previously defined Group*  
- BeginGroup-EndGroup text blocks can't be nested

**procedure** GotoPosition(aPage: **integer**; aYPos: **integer**);

*Go to the specified Y position on a given page*  
- used e.g. by GotoBookmark() method

**procedure** Invalidate; **override**;

*Customized invalidate*

**procedure** NewHalfLine;

*Jump some half line space between paragraphs*  
- Increments the current Y Position the equivalent of an half single line relative to the current font height and line spacing

**procedure** NewLine;

*Jump some line space between paragraphs*  
- Increments the current Y Position the equivalent of a single line relative to the current font height and line spacing

**procedure** NewLines(count: integer);

*Jump some line space between paragraphs*

- Increments the current Y Position the equivalent of 'count' lines relative to the current font height and line spacing

**procedure** NewPage(ForceEndGroup: boolean=false);

*Jump to next page, i.e. force a page break*

**procedure** NewPageIfAnyContent;

*Jump to next page, but only if some content is pending*

**procedure** NewPageLayout(paperSize: TGdiPagePaperSize; orientation: TPrinterOrientation=poPortrait; nonPrintableWidthMM: integer=-1; nonPrintableHeightMM: integer=-1); overload;

*Change the page layout for the upcoming page*

- will then force a page break by a call to NewPage(true) method  
- can change the default margin if margin\*>=0  
- can change the default non-printable printer margin if nonPrintable\*>=0

**procedure** NewPageLayout(sizeWidthMM, sizeHeightMM: integer; nonPrintableWidthMM: integer=-1; nonPrintableHeightMM: integer=-1); overload;

*Change the page layout for the upcoming page*

- will then force a page break by a call to NewPage(true) method  
- can change the default margin if margin\*>=0  
- can change the default non-printable printer margin if nonPrintable\*>=0

**procedure** PopupMenuItemClick(Sender: TObject);

*This is the main popup menu item click event*

**procedure** RestoreSavedLayout; **virtual**;

*Restore last saved font and alignment*

**procedure** SaveLayout; **virtual**;

*Save the current font and alignment*

**procedure** SetColumnAlign(index: integer; align: TColAlign);

*Individually set column alignment*

- useful after habing used AddColumns([]) method e.g.

**procedure** SetColumnBold(index: integer);

*Individually set column bold state*

- useful after habing used AddColumns([]) method e.g.

**procedure** SetTabStops(const tabs: array of integer);

*Set the Tabs stops on every line*

- if one value is provided, it will set the Tabs as every multiple of it  
- if more than one value are provided, they will be the exact Tabs positions

**procedure** ShowPreviewForm(VisibleButtons: TGdiPagePreviewButtons = [rNextPage..High(TGdiPagePreviewButton)]);

*Show a form with the preview, allowing the user to browse pages and print the report*

- you can customize the buttons and popup menu actions displayed on the screen - by default, all buttons are visible

**property** BiDiMode: TBiDiMode **read** fBiDiMode **write** fBiDiMode;

*Specifies the reading order (bidirectional mode) of the box*

- only bdLeftToRight and bdRightToLeft are handled
- this will be used by DrawText[At], DrawTitle, AddTextToHeader/Footer[At], DrawTextAcrossCols, SaveLayout/RestoreSavedLayout methods

**property** Canvas: TMetaFileCanvas **read** fCanvas;

*Can be used to draw directly using GDI commands*

- The Canvas property should be rarely needed

**property** ColumnCount: integer **read** GetColumnCount;

*Retrieve the current Column count*

**property** CurrentYPos: integer **read** GetYPos **write** SetYPos;

*Distance (in mm's) from the top of the page to the top of the next line*

**property** ExportPDFa1: Boolean **read** fExportPDFa1 **write** fExportPDFa1;

*If set to TRUE, the exported PDF is made compatible with PDF/A-1 requirements*

**property** ExportPDFApplication: string **read** fExportPDFApplication **write** fExportPDFApplication;

*Optional application name used during Export to PDF*

- if not set, global Application.Title will be used

**property** ExportPDFAuthor: string **read** fExportPDFAuthor **write** fExportPDFAuthor;

*Optional Author name used during Export to PDF*

**property** ExportPDFBackground: TGraphic **read** fExportPDFBackground **write** fExportPDFBackground;

*An optional background image, to be exported on every pdf page*

- note that no private copy of the TGraphic instance is made: the caller has to manage it, and free it after the pdf is generated

**property** ExportPDFEmbeddedTTF: boolean **read** fExportPDFEmbeddedTTF **write** fExportPDFEmbeddedTTF;

*If set to TRUE, the used True Type fonts will be embedded to the exported PDF*

- not set by default, to save disk space and produce tiny PDF

**property** ExportPDFEncryptionLevel: TPdfEncryptionLevel **read** fExportPDFEncryptionLevel **write** fExportPDFEncryptionLevel;

*Set encryption level to be used in exporting PDF document*

**property** ExportPDFEncryptionOwnerPassword: string **read** fExportPDFEncryptionOwnerPassword **write** fExportPDFEncryptionOwnerPassword;

*Set encryption owner password to be used in exporting PDF document*

- it is mandatory to set it to a non void value - by default, is set to 'SynopsePDFEngine' by should be overridden for security

- ExportPDFEncryptionLevel = eIRC4\_40/eIRC4\_128 expects only ASCII-7 chars

**property** ExportPDfEncryptionPermissions: TPdfEncryptionPermissions **read** fExportPDfEncryptionPermissions **write** fExportPDfEncryptionPermissions;

*Set encryption Permissions to be used in exporting PDF document*

- can be either one of the PDF\_PERMISSION\_ALL / PDF\_PERMISSION\_NOMODIF / PDF\_PERMISSION\_NOPRINT / PDF\_PERMISSION\_NOCOPY / PDF\_PERMISSION\_NOCOPYNOPRINT set of options
- default value is PDF\_PERMISSION\_ALL (i.e. no restriction)

**property** ExportPDfEncryptionUserPassword: **string read** fExportPDfEncryptionUserPassword **write** fExportPDfEncryptionUserPassword;

*Set encryption user password to be used in exporting PDF document*

- leave it to "" unless you want the user to be asked for this password at document opening
- ExportPDfEncryptionLevel = eIRC4\_40/eIRC4\_128 expects only ASCII-7 chars

**property** ExportPDfFontFallBackName: **string read** fExportPDfFontFallBackName **write** fExportPDfFontFallBackName;

*Set the font name to be used for missing characters in exported PDF document*

- used only if UseFontFallBack is TRUE
- default value is 'Arial Unicode MS', if existing

**property** ExportPDfForceJPEGCompression: **integer read** fForceJPEGCompression **write** fForceJPEGCompression;

*This property can force saving all bitmaps as JPEG in exported PDF*

- by default, this property is set to 0 by the constructor of this class, meaning that the JPEG compression is not forced, and the engine will use the native resolution of the bitmap - in this case, the resulting PDF file content will be bigger in size (e.g. use this for printing)
- 60 is the preferred way e.g. for publishing PDF over the internet
- 80/90 is a good ration if you want to have a nice PDF to see on screen
- of course, this doesn't affect vectorial (i.e. emf) pictures

**property** ExportPDfGeneratePDF15File: **Boolean read** fExportPDfGeneratePDF15File **write** fExportPDfGeneratePDF15File;

*Set to TRUE to export in PDF 1.5 format, which may produce smaller files*

**property** ExportPDfKeywords: **string read** fExportPDfKeywords **write** fExportPDfKeywords;

*Optional Keywords name used during Export to PDF*

**property** ExportPDfSubject: **string read** fExportPDfSubject **write** fExportPDfSubject;

*Optional Subject text used during Export to PDF*

**property** ExportPDfUseFontFallBack: **boolean read** fExportPDfUseFontFallBack **write** fExportPDfUseFontFallBack;

*Used to define if the exported PDF document will handle "font fallback" for characters not existing in the current font: it will avoid rendering block/square symbols instead of the correct characters (e.g. for Chinese text)*

- will use the font specified by FontFallBackName property to add any Unicode glyph not existing in the currently selected font
- default value is TRUE

**property** ExportPDFUseUniscribe: boolean **read** fExportPDFUseUniscribe **write** fExportPDFUseUniscribe;

*Set if the exporting PDF engine must use the Windows Uniscribe API to render Ordering and/or Shaping of the text*

- useful for Hebrew, Arabic and some Asiatic languages handling
- set to FALSE by default, for faster content generation

**property** ForceScreenResolution: boolean **read** fForceScreenResolution **write** fForceScreenResolution;

*If set to true, we reduce the precision for better screen display*

**property** HangIndent: integer **read** fHangIndent **write** fHangIndent;

*Left justification hang indentation*

**property** HeaderDone: boolean **read** fHeaderDone;

*True if any header as been drawn, that is if something is to be printed*

**property** LeftMargin: integer **read** GetLeftMargin **write** SetLeftMargin;

*Size of the left margin relative to its corresponding edge in mm's*

**property** LineHeight: integer **read** GetLineHeightMm;

*Get current line height (mm)*

**property** LineSpacing: TLineSpacing **read** fLineSpacing **write** fLineSpacing;

*Line spacing: can be lsSingle, lsOneAndHalf or lsDouble*

**property** NegsToParenthesesInCurrCols: boolean **read** fNegsToParenthesesInCurrCols **write** fNegsToParenthesesInCurrCols;

*Accounting standard layout for caCurrency columns:*

- convert all negative sign into parentheses
- using parentheses instead of negative numbers is used in financial statement reporting (see e.g. [http://en.wikipedia.org/wiki/Income\\_statement](http://en.wikipedia.org/wiki/Income_statement))
- align numbers on digits, not parentheses

**property** OnDocumentProduced: TNotifyEvent **read** fOnDocumentProducedEvent **write** fOnDocumentProducedEvent;

*Event triggered whenever the report document generation is done  
- i.e. when the EndDoc method has just been called*

**property** OnEndColumnHeader: TNotifyEvent **read** fEndColumnHeader **write** fEndColumnHeader;

*Event triggered when each column was drawn*

**property** OnEndPageFooter: TNotifyEvent **read** fEndPageFooter **write** fEndPageFooter;

*Event triggered when each footer was drawn*

**property** OnEndPageHeader: TNotifyEvent **read** fEndPageHeader **write** fEndPageHeader;

*Event triggered when each header was drawn*

**property** OnNewPage: TNewPageEvent **read** fStartNewPage **write** fStartNewPage;

*Event triggered when each new page is created*

**property** OnPreviewPageChanged: TNotifyEvent **read** fPreviewPageChangedEvent **write** fPreviewPageChangedEvent;

*Event triggered whenever the current preview page is changed*

**property** OnStartColumnHeader: TNotifyEvent read fStartColumnHeader write fStartColumnHeader;

*Event triggered when each new column is about to be drawn*

**property** OnStartPageFooter: TNotifyEvent read fStartPageFooter write fStartPageFooter;

*Event triggered when each new footer is about to be drawn*

**property** OnStartPageHeader: TNotifyEvent read fStartPageHeader write fStartPageHeader;

*Event triggered when each new header is about to be drawn*

**property** OnZoomChanged: TZoomChangedEvent read fZoomChangedEvent write fZoomChangedEvent;

*Event triggered whenever the preview page is zoomed in or out*

**property** Orientation: TPrinterOrientation read GetOrientation write SetOrientation;

*The paper orientation*

**property** Page: integer read fCurrPreviewPage write SetPage;

*The index of the previewed page*

- please note that the first page is 1 (not 0)

**property** PageCount: integer read GetPageCount;

*Total number of pages*

**property** PageMargins: TRect read GetPageMargins write SetPageMargins;

*Size of each margin relative to its corresponding edge in mm's*

**property** Pages: TGDIPageContentDynArray read fPages;

*Access to all pages content*

- numerotation begin with Pages[0] for page 1

- the Pages[] property should be rarely needed

**property** PaperSize: TSize read GetPaperSize;

*Get the current selected paper size, in mm's*

**property** PrinterName: string read fCurrentPrinter;

*The name of the current selected printer*

- note that Printers.SetPrinter() should be set BEFORE calling BeginDoc, otherwise you may have a "canvas does not allow drawing" error

**property** PrinterPxPerInch: TPoint read fPrinterPxPerInch;

*Number of pixel per inch, for X and Y directions*

**property** RightMarginPos: integer read GetRightMarginPos;

*Position of the right margin, in mm*

**property** TextAlign: TTextAlign read fAlign write SetTextAlign;

*The current Text Alignment, during text adding*

**property** UseOutlines: boolean read fUseOutlines write fUseOutlines;

*If set, any DrawTitle() call will create an Outline entry*

- used e.g. for PDF generation

- this is enabled by default

**property** VirtualPageNum: integer **read** fVirtualPageNum **write** fVirtualPageNum;

*The current page number, during text adding*  
- Page is used during preview, after text adding

**property** WordWrapLeftCols: boolean **read** fWordWrapLeftCols **write** fWordWrapLeftCols;

*Word wrap (caLeft) left-aligned columns into multiple lines*  
- if the text is wider than the column width, its content is wrapped to the next line  
- if the text contains some #13/#10 characters, it will be splitted into individual lines  
- this is disabled by default

**property** Zoom: integer **read** fZoom **write** SetZoom;

*The current Zoom value, according to the zoom status*  
- you can use PAGE\_WIDTH and PAGE\_FIT constants to force the corresponding zooming mode (similar to ZoomStatus property setter)  
- set this property will work only when the report is already shown in preview mode, not before ShowPreviewForm method call

**property** ZoomStatus: TZoomStatus **read** fZoomStatus **write** SetZoomStatus;

*The current Zoom procedure, i.e. zsPercent, zsPageFit or zsPageWidth*  
- set this property will define the Zoom at PAGE\_WIDTH or PAGE\_FIT special constant, if needed  
- set this property will work only when the report is already shown in preview mode, not before ShowPreviewForm method call

### Types implemented in the mORMotReport unit

TColAlign = ( caLeft, caRight, caCenter, caCurrency );

*Text column alignment*

TGDIPageContentDynArray = **array of** TGDIPageContent;

*Used to store all pages of the report*

TGdiPagePaperSize = ( psA4, psA5, psA3, psLetter, psLegal );

*Available known paper size for NewPageLayout() method*

TGdiPagePreviewButton = ( rNone, rNextPage, rPreviousPage, rGotoPage, rZoom, rBookmarks, rPageAsText, rPrint, rExportPDF, rClose );

*The available menu items*

TGdiPagePreviewButtons = **set of** TGdiPagePreviewButton;

*Set of menu items*

TLineSpacing = ( lsSingle, lsOneAndHalf, lsDouble );

*Text line spacing*

TNewPageEvent = **procedure**(Sender: TObject; PageNumber: integer) **of object**;

*Event triggered when a new page is added*

TOnStringToUnicodeEvent = **function**(const Text: SynUnicode): SynUnicode **of object**;

*Event triggered to allow custom unicode character display on the screen*

- called for all text, whatever the alignment is  
- Text content can be modified by this event handler to customize some characters (e.g. '>=' can be converted to the one Unicode glyph)

TTextAlign = ( taLeft, taRight, taCenter, taJustified );

### *Text paragraph alignment*

**TZoomChangedEvent** = **procedure**(Sender: TObject; Zoom: integer; ZoomStatus: TZoomStatus)  
**of object**;

*Event triggered when the Zoom was changed*

**TZoomStatus** = ( zsPercent, zsPageFit, zsPageWidth );

*Available zoom mode*

- zsPercent is used with a zoom percentage (e.g. 100% or 50%)
- zsPageFit fits the page to the report
- zsPageWidth zooms the page to fit the report width on screen

### **Constants implemented in the *mORMotReport* unit**

**FORMAT\_ALIGN\_MASK** = **\$300**;

*Alignment bits 8-9*

**FORMAT\_BOLD** = **\$400**;

*Fontstyle bits 10-12*

**FORMAT\_DEFAULT** = **\$0**;

*TEXT FORMAT FLAGS...*

**FORMAT\_SINGLELINE** = **\$8000**;

*Line flags bits 14-15*

**FORMAT\_SIZE\_MASK** = **\$FF**;

*Fontsize bits 0-7    .'. max = 255*

**FORMAT\_UNDEFINED** = **\$2000**;

*Undefined bit 13*

**FORMAT\_XPOS\_MASK** = **\$FFFF0000**;

*DrawTextAt XPos 16-30 bits    (max value = ~64000)*

**GRAY\_MARGIN** = **10**;

*Minimum gray border with around preview page*

**PAGENUMBER** = '**<<pagenumber>>**';

*This constant can be used to be replaced by the page number in the middle of any text*

**PAGE\_FIT** = **-2**;

*TGdiPages.Zoom property value for "Page fit" layout during preview*

**PAGE\_WIDTH** = **-1**;

*TGdiPages.Zoom property value for "Page width" layout during preview*

## 27.63. mORMotSelfTests.pas unit

*Purpose:* Automated tests for common units of the Synopse mORMot Framework

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *mORMotSelfTests* unit

| Unit Name           | Description                                                                                                                                                                                     | Page |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>       | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                | 1907 |
| <i>SynBidirSock</i> | Implements bidirectional client and server protocol, e.g. WebSockets<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 681  |
| <i>SynBigTable</i>  | Class used to store huge amount of data with fast retrieval<br>- licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                        | 705  |
| <i>SynCommons</i>   | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                       | 718  |
| <i>SynLog</i>       | Logging functions used by Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                           | 1368 |
| <i>SynSelfTests</i> | Automated tests for common units of the Synopse mORMot Framework<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18     | 1535 |
| <i>SynSQLite3</i>   | SQLite3 Database engine direct access<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                | 1653 |
| <i>SynTests</i>     | Unit test functions used by Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                         | 1840 |

### Functions or procedures implemented in the *mORMotSelfTests* unit

| Functions or procedures | Description | Page |
|-------------------------|-------------|------|
| SQLite3ConsoleTests     |             | 2379 |

**procedure** SQLite3ConsoleTests;

*This is the main entry point of the tests*

- this procedure will create a console, then run all available tests

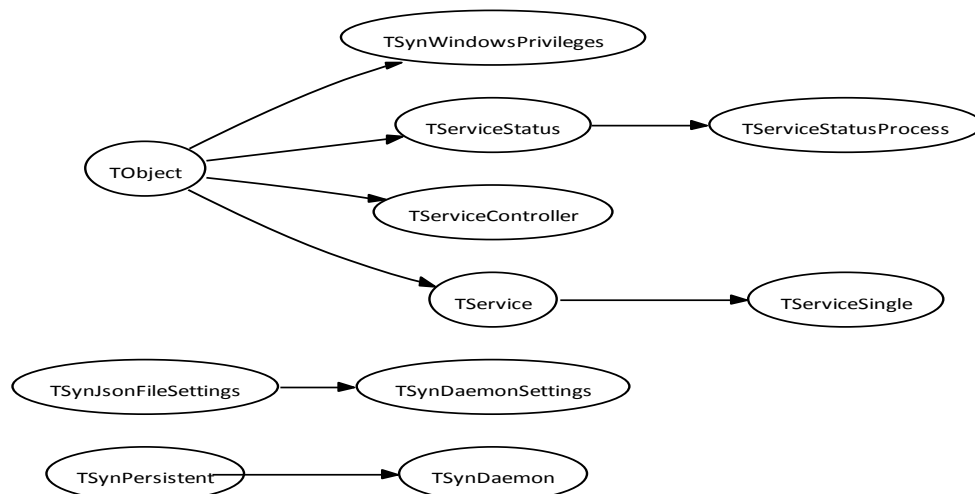

## 27.64. mORMotService.pas unit

*Purpose:* Daemon management classes for mORMot, including low-level Win NT Service

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *mORMotService* unit

| Unit Name         | Description                                                                                                                                                                                                                                                                                                                                   | Page |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>     | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                              | 1907 |
| <i>SynCommons</i> | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                     | 718  |
| <i>SynCrypto</i>  | Fast cryptographic routines (hashing and cypher)<br>- implements<br>AES,XOR,ADLER32,MD5,RC4,SHA1,SHA256,SHA384,SHA512,SHA3 and JWT<br>- optimized for speed (tuned assembler and SSE3/SSE4/AES-NI/PADLOCK support)<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1143 |
| <i>SynLog</i>     | Logging functions used by Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                         | 1368 |
| <i>SynTable</i>   | Filter/database/cache/buffer/security/search/multithread/OS features<br>- as a complement to SynCommons, which tended to increase too much<br>- licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                       | 1728 |

*mORMotService class hierarchy*

### Objects implemented in the *mORMotService* unit

| Objects               | Description                                                                                                                                     | Page |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|------|
| TService              | TService is the class used to implement a service provided by an application                                                                    | 2384 |
| TServiceController    | TServiceControler class is intended to create a new service instance or to maintain (that is start, stop, pause, resume...) an existing service | 2381 |
| TServiceSingle        | Inherit from this service if your application has a single service                                                                              | 2386 |
| TSynDaemon            | Abstract parent to implements a daemon/service                                                                                                  | 2387 |
| TSynDaemonSettings    | Abstract parent containing information able to initialize a TSynDaemon class                                                                    | 2387 |
| TSynWindowsPrivileges | Object dedicated to management of available privileges for Windows platform                                                                     | 2388 |

**TServiceController = class(TObject)**

*TServiceControler class is intended to create a new service instance or to maintain (that is start, stop, pause, resume...) an existing service*

- to provide the service itself, use the TService class

```
constructor CreateNewService(const TargetComputer, DatabaseName, Name,
DisplayName, Path: string; const OrderGroup: string = ''; const Dependencies: string
= ''; const Username: string = ''; const Password: string = ''; DesiredAccess: DWORD
= SERVICE_ALL_ACCESS; ServiceType: DWORD = SERVICE_WIN32_OWN_PROCESS or
SERVICE_INTERACTIVE_PROCESS; StartType: DWORD = SERVICE_DEMAND_START;
ErrorControl: DWORD = SERVICE_ERROR_NORMAL);
```

*Creates a new service and allows to control it and/or its configuration*

- TargetComputer - set it to empty string if local computer is the target.
- DatabaseName - set it to empty string if the default database is supposed ('ServicesActive').
- Name - name of a service.
- DisplayName - display name of a service.
- Path - a path to binary (executable) of the service created.
- OrderGroup - an order group name (unnecessary)
- Dependencies - string containing a list with names of services, which must start before (every name should be separated with #0, entire list should be separated with #0#0. Or, an empty string can be passed if there is no dependancy).
- Username - login name. For service type SERVICE\_WIN32\_OWN\_PROCESS, the account name in the form of "DomainName\Username"; If the account belongs to the built-in domain, ".\Username" can be specified; Services of type SERVICE\_WIN32\_SHARE\_PROCESS are not allowed to specify an account other than LocalSystem. If "" is specified, the service will be logged on as the 'LocalSystem' account, in which case, the Password parameter must be empty too.
- Password - a password for login name. If the service type is SERVICE\_KERNEL\_DRIVER or SERVICE\_FILE\_SYSTEM\_DRIVER, this parameter is ignored.
- DesiredAccess - a combination of following flags: SERVICE\_ALL\_ACCESS (default value), SERVICE\_CHANGE\_CONFIG, SERVICE\_ENUMERATE\_DEPENDENTS, SERVICE\_INTERROGATE, SERVICE\_PAUSE\_CONTINUE, SERVICE\_QUERY\_CONFIG, SERVICE\_QUERY\_STATUS, SERVICE\_START, SERVICE\_STOP, SERVICE\_USER\_DEFINED\_CONTROL
- ServiceType - a set of following flags: SERVICE\_WIN32\_OWN\_PROCESS (default value, which specifies a Win32 service that runs in its own process), SERVICE\_WIN32\_SHARE\_PROCESS, SERVICE\_KERNEL\_DRIVER, SERVICE\_FILE\_SYSTEM\_DRIVER, SERVICE\_INTERACTIVE\_PROCESS (default value, which enables a Win32 service process to interact with the desktop)
- StartType - one of following values: SERVICE\_BOOT\_START, SERVICE\_SYSTEM\_START, SERVICE\_AUTO\_START (which specifies a device driver or service started by the service control manager automatically during system startup), SERVICE\_DEMAND\_START (default value, which specifies a service started by a service control manager when a process calls the StartService function, that is the TServiceController.Start method), SERVICE\_DISABLED
- ErrorControl - one of following: SERVICE\_ERROR\_IGNORE, SERVICE\_ERROR\_NORMAL (default value, by which the startup program logs the error and displays a message but continues the startup operation), SERVICE\_ERROR\_SEVERE, SERVICE\_ERROR\_CRITICAL

**constructor** CreateOpenService(**const** TargetComputer, DataBaseName, Name: **String**;  
DesiredAccess: **DWORD** = SERVICE\_ALL\_ACCESS);

*Opens an existing service, in order to control it or its configuration from your application.*

*Parameters (strings are unicode-ready since Delphi 2009):*

- TargetComputer - set it to empty string if local computer is the target.
- DataBaseName - set it to empty string if the default database is supposed ('ServicesActive').
- Name - name of a service.
- DesiredAccess - a combination of following flags: SERVICE\_ALL\_ACCESS, SERVICE\_CHANGE\_CONFIG, SERVICE\_ENUMERATE\_DEPENDENTS, SERVICE\_INTERROGATE, SERVICE\_PAUSE\_CONTINUE, SERVICE\_QUERY\_CONFIG, SERVICE\_QUERY\_STATUS, SERVICE\_START, SERVICE\_STOP, SERVICE\_USER\_DEFINED\_CONTROL

**destructor** Destroy; **override**;

*Release memory and handles*

**function** Delete: **boolean**;

*Removes service from the system, i.e. close the Service*

**class function** Install(**const** Name, DisplayName, Description: **string**; AutoStart: **boolean**; ExeName: **TFileName**=''; Dependencies: **string**=''): **TServiceState**;

*Wrapper around CreateNewService() to install the current executable as service*

**function** Pause: **boolean**;

*Requests the service to pause*

**function** Refresh: **boolean**;

*Requests the service to update immediately its current status information to the service control manager*

**function** Resume: **boolean**;

*Requests the paused service to resume*

**function** Shutdown: **boolean**;

*Request the service to shutdown*

- this function always return false

**function** Start(**const** Args: **array of PChar**): **boolean**;

*Starts the execution of a service with some specified arguments*

- this version expect PChar pointers, either AnsiString (for FPC and old Delphi compiler), either UnicodeString (till Delphi 2009)

**function** Stop: **boolean**;

*Requests the service to stop*

```
class procedure CheckParameters(const ExeFileName: TFileName; const
ServiceName, DisplayName, Description: string; const Dependencies: string='');
```

*This class method will check the command line parameters, and will let control the service according to it*

- MyServiceSetup.exe /install will install the service
- MyServiceSetup.exe /start will start the service
- MyServiceSetup.exe /stop will stop the service
- MyServiceSetup.exe /uninstall will uninstall the service
- so that you can write in the main block of your .dpr:  
CheckParameters('MyService.exe', HTTPSERVICENAME, HTTPSERVICEDISPLAYNAME);
- if ExeFileName="", it will install the current executable
- optional Description and Dependencies text may be specified

```
procedure SetDescription(const Description: string);
```

*Try to define the description text of this service*

```
property Handle: THandle read FHandle;
```

*Handle of service opened or created*

- its value is 0 if something failed in any Create\*() method

```
property SCHandle: THandle read FSCHandle;
```

*Handle of SC manager*

```
property State: TServiceState read GetState;
```

*Retrieve the Current state of the service*

```
property Status: TServiceStatus read GetStatus;
```

*Retrieve the Current status of the service*

```
TService = class(TObject)
```

*TService is the class used to implement a service provided by an application*

```
constructor Create(const aServiceName, aDisplayName: String); reintroduce; virtual;
```

*Creates the service*

- the service is added to the internal registered services
- main application must call the global ServicesRun procedure to actually start the services
- caller must free the TService instance when it's no longer used

```
destructor Destroy; override;
```

*Free memory and release handles*

```
function Install(const Params: string=''): boolean;
```

*Installs the service in the database*

- return true on success
- create a local TServiceController with the current executable file, with the supplied command line parameters

```
function ReportStatus(dwState, dwExitCode, dwWait: DWORD): BOOL;
```

*Reports new status to the system*

**procedure** DoCtrlHandle(Code: DWORD); **virtual**;

*This method is the main service entrance, from the OS point of view*

- it will call OnControl/OnStop/OnPause/OnResume/OnShutdown events
- and report the service status to the system (via ReportStatus method)

**procedure** Execute; **virtual**;

*This is the main method, in which the Service should implement its run*

**procedure** Remove;

*Removes the service from database*

- uses a local TServiceController with the current Service Name

**procedure** Start;

*Starts the service*

- uses a local TServiceController with the current Service Name

**procedure** Stop;

*Stops the service*

- uses a local TServiceController with the current Service Name

**property** ArgCount: Integer **read** GetArgCount;

*Number of arguments passed to the service by the service controller*

**property** Args[Idx: Integer]: String **read** GetArgs;

*List of arguments passed to the service by the service controller*

**property** ControlHandler: TServiceControlHandler **read** GetControlHandler **write** SetControlHandler;

*Callback handler for Windows Service Controller*

- if handler is not set, then auto generated handler calls DoCtrlHandle (note that this auto-generated stub is... not working yet - so you should either set your own procedure to this property, or use TServiceSingle)
- a typical control handler may be defined as such:

```
var MyGlobalService: TService;

procedure MyServiceControlHandler(Opcode: LongWord); stdcall;
begin
 if MyGlobalService<>nil then
 MyGlobalService.DoCtrlHandle(Opcode);
end;

...
MyGlobalService := TService.Create(...
MyGlobalService.ControlHandler := MyServiceControlHandler;
```

**property** Data: DWORD **read** FData **write** FData;

*Any data You wish to associate with the service object*

**property** DisplayName: String **read** fDName **write** fDName;

*Display name of the service*

**property** Installed: boolean **read** GetInstalled;

*Whether service is installed in DataBase*

- uses a local TServiceController to check if the current Service Name exists

**property** OnControl: TServiceControlEvents read fOnControl write fOnControl;

*Custom event triggered when a Control Code is received from Windows*

**property** OnExecute: TServiceEvent read fOnExecute write fOnExecute;

*Custom Execute event*

- launched in the main service thread (i.e. in the Execute method)

**property** OnInterrogate: TServiceEvent read fOnInterrogate write fOnInterrogate;

*Custom event triggered when the service receive an Interrogate*

**property** OnPause: TServiceEvent read fOnPause write fOnPause;

*Custom event triggered when the service is paused*

**property** OnResume: TServiceEvent read fOnResume write fOnResume;

*Custom event triggered when the service is resumed*

**property** OnShutdown: TServiceEvent read fOnShutdown write fOnShutdown;

*Custom event triggered when the service is shut down*

**property** OnStart: TServiceEvent read fOnStart write fOnStart;

*Start event is executed before the main service thread (i.e. in the Execute method)*

**property** OnStop: TServiceEvent read fOnStop write fOnStop;

*Custom event triggered when the service is stopped*

**property** ServiceName: String read fSName;

*Name of the service. Must be unique*

**property** ServiceType: DWORD read fServiceType write fServiceType;

*Type of service*

**property** StartType: DWORD read fStartType write fStartType;

*Type of start of service*

**property** Status: TServiceStatus read fStatusRec write SetStatus;

*Current service status*

- To report new status to the system, assign another value to this record, or use ReportStatus method (preferred)

**TServiceSingle = class(TService)**

*Inherit from this service if your application has a single service*

- note that TService jumper does not work well - so use this instead

**constructor** Create(const aServiceName, aDisplayName: String); override;

*Will set a global function as service controller*

**destructor** Destroy; override;

*Will release the global service controller*

**TSynDaemonSettings = class(TSynJsonFileSettings)**

*Abstract parent containing information able to initialize a TSynDaemon class*

- will handle persistence as JSON local files
- you may consider using TDDAppSettingsAbstract from dddInfraSettings

**constructor** Create; **override**;

*Initialize and set the default settings*

**function** ServiceDescription: **string**;

*Returns user-friendly description of the service, including version information and company copyright (if available)*

**procedure** SetLog(aLogClass: TSynLogClass);

*Define the log information into the supplied TSynLog class*

- if you don't call this method, the logging won't be initiated
- is to be called typically in the overridden Create constructor of the associated TSynDaemon class, just after "inherited Create"

**property** Log: TSynLogInfos **read** fLog **write** fLog;

*If not void, will enable the logs (default is LOG\_STACKTRACE)*

**property** LogClass: TSynLogClass **read** fLogClass;

*Read-only access to the TSynLog class, if SetLog() has been called*

**property** LogPath: TFileName **read** fLogPath **write** fLogPath;

*Allow to customize where the logs should be written*

**property** LogRotateFileCount: integer **read** fLogRotateFileCount **write** fLogRotateFileCount;

*How many files will be rotated (default is 2)*

**property** ServiceDependencies: **string** **read** fServiceDependencies **write** fServiceDependencies;

*Optional service dependencies*

- not published by default: could be defined if needed, or e.g. set in overridden constructor
- several depending services may be set by appending #0 between names

**property** ServiceDisplayName: **string** **read** fServiceDisplayName **write** fServiceDisplayName;

*The service name, as displayed by Windows or at the console level*

- default is the executable name

**property** ServiceName: **string** **read** fServiceName **write** fServiceName;

*The service name, as used internally by Windows or the TSynDaemon class*

- default is the executable name

**TSynDaemon = class(TSynPersistent)**

*Abstract parent to implements a daemon/service*

- inherit from this abstract class and override Start and Stop methods
- you may consider using TDDAdministratedDaemon from dddInfraApps

**constructor** Create(aSettingsClass: TSynDaemonSettingsClass; **const** aWorkFolder, aSettingsFolder, aLogFolder: TFileName; **const** aSettingsExt: TFileName = **'settings'**; **const** aSettingsName: TFileName = **''**); **reintroduce**;

*Initialize the daemon, creating the associated settings*

- TSynDaemonSettings instance will be owned and freed by the daemon
- any non supplied folder name will be replaced by a default value (executable folder under Windows, or /etc /var/log on Linux)

**destructor** Destroy; **override**;

*Call Stop, finalize the instance, and its settings*

**procedure** CommandLine(aAutoStart: boolean=true);

*Main entry point of the daemon, to process the command line switches*

- aAutoStart is used only under Windows

**procedure** Start; **virtual**; **abstract**;

*Inherited class should override this abstract method with proper process*

**procedure** Stop; **virtual**; **abstract**;

*Inherited class should override this abstract method with proper process*

- should do nothing if the daemon was already stopped

**property** ConsoleMode: boolean **read** fConsoleMode;

*If this instance was run as /console or /verb*

**property** Settings: TSynDaemonSettings **read** fSettings;

*The settings associated with this daemon*

- will be allocated in Create constructor, and released in Destroy

**TSynWindowsPrivileges = object(TObject)**

*Object dedicated to management of available privileges for Windows platform*

- not all available privileges are active for process
- for usage of more advanced WinAPI, explicit enabling of privilege is sometimes needed

**Token**: THandle;

*Handle to privileges token*

**function** Disable(aPrivilege: TWinSystemPrivilege): boolean;

*Disable privilege*

- if aPrivilege is already disabled return true, if operation is not possible (required privilege doesn't exist or API error) return false

**function** Enable(aPrivilege: TWinSystemPrivilege): boolean;

*Enable privilege*

- if aPrivilege is already enabled return true, if operation is not possible (required privilege doesn't exist or API error) return false

**procedure** Done(aRestoreInitiallyEnabled: boolean = true);

*Finalize the object and release Token handle*

- aRestoreInitiallyEnabled parameter can be used to restore initially state of enabled privileges

**procedure** Init(aTokenPrivilege: TPrivilegeTokenType = pttProcess);

*Initialize the object dedicated to management of available privileges*  
- aTokenPrivilege can be used for current process or current thread

**property** Available: TWinSystemPrivileges **read** fAvailable;

*Set of available privileges for current process/thread*

**property** Enabled: TWinSystemPrivileges **read** fEnabled;

*Set of enabled privileges for current process/thread*

### Types implemented in the *mORMotService* unit

TParseCommand = ( pcHasRedirection, pcHasSubCommand, pcHasParenthesis, pcHasJobControl, pcHasWildcard, pcHasShellVariable, pcUnbalancedSingleQuote, pcUnbalancedDoubleQuote, pcTooManyArguments, pcInvalidCommand, pcHasEndingBackSlash );

*Command line patterns recognized by ParseCommandArgs()*

TParseCommandsArgs = **array**[0..31] **of** PAnsiChar;

*Used to store references of arguments recognized by ParseCommandArgs()*

TServiceControlEvents = **procedure**(Sender: TService; Code: DWORD) **of** object;

*Event triggered for Control handler*

TServiceControlHandler = **procedure**(CtrlCode: DWORD); **stdcall**;

*Callback procedure for Windows Service Controller*

TServiceEvent = **procedure**(Sender: TService) **of** object;

*Event triggered to implement the Service functionality*

TServiceState = ( ssNotInstalled, ssStopped, ssStarting, ssStopping, ssRunning, ssResuming, ssPausing, ssPaused, ssErrorRetrievingState );

*All possible states of the service*

TSynDaemonSettingsClass = **class** **of** TSynDaemonSettings;

*Meta-class of TSynDaemon settings information*

TWinSystemPrivilege = ( wspCreateToken, wspAssignPrimaryToken, wspLockMemory, wspIncreaseQuota, wspUnsolicitedInput, wspMachineAccount, wspTCP, wspSecurity, wspTakeOwnership, wspLoadDriver, wspSystemProfile, wspSystemTime, wspProfSingleProcess, wspIncBasePriority, wspCreatePageFile, wspCreatePermanent, wspBackup, wspRestore, wspShutdown, wspDebug, wspAudit, wspSystemEnvironment, wspChangeNotify, wspRemoteShutdown, wspUndock, wspSyncAgent, wspEnableDelegation, wspManageVolume, wspImpersonate, wspCreateGlobal, wspTrustedCredmanAccess, wspRelabel, wspIncWorkingSet, wspTimeZone, wspCreateSymbolicLink );

*Enum synchronized with WinAPI*

- see <https://docs.microsoft.com/en-us/windows/desktop/secauthz/privilege-constants>

### Constants implemented in the *mORMotService* unit

CMDLINESWITCH = **'/'**;

*Text identifier typically used before command line switches*

- equals '/' on Windows, and '--' on POSIX systems

PARSECOMMAND\_BASH = [pcHasRedirection .. pcHasShellVariable];

*Identifies some bash-specific processing*

```
PARSECOMMAND_ERROR = [pcUnbalancedSingleQuote .. pcHasEndingBackSlash];
```

*Identifies obvious invalid content*

## Functions or procedures implemented in the *mORMotService* unit

| Functions or procedures    | Description                                                                           | Page |
|----------------------------|---------------------------------------------------------------------------------------|------|
| CurrentStateToServiceState | Convert the Control Code retrieved from Windows into a service state enumeration item | 2390 |
| GetServicePid              | Return service PID                                                                    | 2390 |
| KillProcess                | Kill Windows process                                                                  | 2390 |
| ParseCommandArgs           | Low-level parsing of a RunCommand() execution command                                 | 2390 |
| RunCommand                 | Like fpSystem, but cross-platform                                                     | 2390 |
| RunProcess                 | Like SysUtils.ExecuteProcess, but allowing not to wait for the process to finish      | 2391 |
| ServicesRun                | Launch the registered Services execution                                              | 2391 |
| ServiceStateText           | Return the ready to be displayed text of a TServiceState value                        | 2391 |

```
function CurrentStateToServiceState(CurrentState: DWORD): TServiceState;
```

*Convert the Control Code retrieved from Windows into a service state enumeration item*

```
function GetServicePid(const aServiceName: string): DWORD;
```

*Return service PID*

```
function KillProcess(pid: DWORD; waitseconds: integer = 30): boolean;
```

*Kill Windows process*

```
function ParseCommandArgs(const cmd: RawUTF8; argv: PParseCommandArgs = nil; argc: PInteger = nil; temp: PRawUTF8 = nil; posix: boolean = false): TParseCommands;
```

*Low-level parsing of a RunCommand() execution command*

- parse and fills argv^[0..argc-1] with corresponding arguments, after un-escaping and un-quoting if applicable, using temp^ to store the content
- if argv=nil, do only the parsing, not the argument extraction - could be used for fast validation of the command line syntax
- you can force arguments OS flavor using the posix parameter - note that Windows parsing is not consistent by itself (e.g. double quoting or escaping depends on the actual executable called) so returned flags should be considered as indicative only with posix=false

```
function RunCommand(const cmd: TFileName; waitfor: boolean; const env: TFileName=''; envaddexisting: boolean=false; parsed: PParseCommands=nil): integer;
```

*Like fpSystem, but cross-platform*

- under POSIX, calls bash only if needed, after ParseCommandArgs() analysis
- under Windows (especially Windows 10), creating a process can be dead slow  
<https://randomascii.wordpress.com/2019/04/21/on2-in-createprocess>

```
function RunProcess(const path, arg1: TFileName; waitfor: boolean; const arg2:
TFileName=''; const arg3: TFileName=''; const arg4: TFileName=''; const arg5:
TFileName=''; const env: TFileName=''; envaddexisting: boolean=false): integer;
```

*Like SysUtils.ExecuteProcess, but allowing not to wait for the process to finish*  
- optional env value follows 'n1=v1'#0'n2=v2'#0'n3=v3'#0#0 Windows layout

```
function ServicesRun: boolean;
```

*Launch the registered Services execution*  
- the registered list of service provided by the application is sent to the operating system  
- returns TRUE on success  
- returns FALSE on error (to get extended information, call GetLastError)

```
function ServiceStateText(State: TServiceState): string;
```

*Return the ready to be displayed text of a TServiceState value*

### Variables implemented in the *mORMotService* unit

```
ServiceLog: TSynLogClass;
```

*You can set this global variable to TSynLog or TSQLLog to enable logging*  
- default is nil, i.e. disabling logging, since it may interfere with the logging process of the service itself

```
Services: TSynList = nil;
```

*The internal list of Services handled by this unit*  
- not to be accessed directly: create TService instances, and they will be added/registered to this list  
- then run the global ServicesRun procedure  
- every TService instance is to be freed by the main application, when it's no more used

```
ServiceSingle: TServiceSingle = nil;
```

*The main TService instance running*

## 27.65. mORMotSQLite3.pas unit

*Purpose:* SQLite3 embedded Database engine used as the mORMot SQL kernel

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

The *mORMotSQLite3* unit is quoted in the following items

| SWRS #   | Description                                                  | Page |
|----------|--------------------------------------------------------------|------|
| DI-2.2.1 | The <i>SQLite3</i> engine shall be embedded to the framework | 2558 |

Units used in the *mORMotSQLite3* unit

| Unit Name         | Description                                                                                                                                                                                             | Page |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>     | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                        | 1907 |

Objects implemented in the *mORMotSQLite3* unit

| Objects                        | Description                                                                            | Page |
|--------------------------------|----------------------------------------------------------------------------------------|------|
| TSQLRestClientDB               | REST client with direct access to a SQLite3 database                                   | 2397 |
| TSQLRestServerDB               | REST server with direct access to a SQLite3 database                                   | 2393 |
| TSQLRestStorageShardDB         | REST storage sharded over several SQLite3 instances                                    | 2398 |
| TSQLTableDB                    | Execute a SQL statement in the local SQLite3 database engine, and get result in memory | 2393 |
| TSQLVirtualTableModuleServerDB | Define a Virtual Table module for a TSQLRestServerDB SQLite3 engine                    | 2398 |
| TSQLVirtualTableModuleSQLite3  | Define a Virtual Table module for a stand-alone SQLite3 engine                         | 2398 |

#### **TSQLTableDB = class(TSQLTableJSON)**

*Execute a SQL statement in the local SQLite3 database engine, and get result in memory*

- all DATA (even the BLOB fields) is converted into UTF-8 TEXT
- uses a TSQLTableJSON internally: faster than sqlite3\_get\_table() (less memory allocation/fragmentation) and allows efficient caching

**constructor** Create(aDB: TSQLDatabase; **const** Tables: **array of** TSQLRecordClass; **const** aSQL: RawUTF8; Expand: boolean); **reintroduce**;

*Execute a SQL statement, and init TSQLTable fields*

- FieldCount=0 if no result is returned
- the BLOB data is converted into TEXT: you have to retrieve it with a special request explicitly (note that JSON format returns BLOB data)
- uses a TSQLTableJSON internally: all currency is transformed to its floating point TEXT representation, and allows efficient caching
- if the SQL statement is in the DB cache, it's retrieved from its cached value: our JSON parsing is a lot faster than SQLite3 engine itself, and uses less memory
- will raise an ESQLException on any error

#### **TSQLRestServerDB = class(TSQLRestServer)**

*REST server with direct access to a SQLite3 database*

- caching is handled at TSQLDatabase level
- SQL statements for record retrieval from ID are prepared for speed

*Used for DI-2.2.1 (page 2558).*

**constructor** Create(aModel: TSQLModel; **const** aDBFileName: TFileName; aHandleUserAuthentication: boolean=false; **const** aPassword: RawUTF8=''; aDefaultCacheSize: integer=10000; aDefaultPageSize: integer=4096); **reintroduce**; overload;

*Initialize a REST server with a database, by specifying its filename*

- TSQLRestServerDB will initialize a owned TSQLDataBase, and free it on Destroy
- if specified, the password will be used to cypher this file on disk (the main SQLite3 database file is encrypted, not the wal file during run)
- it will then call the other overloaded constructor to initialize the server

**constructor** Create(aModel: TSQLModel; aDB: TSQLDataBase; aHandleUserAuthentication: boolean=false; aOwnDB: boolean=false); reintroduce; overload; **virtual**;

*Initialize a REST server with a SQLite3 database*

- any needed TSQLVirtualTable class should have been already registered via the RegisterVirtualTableModule() method

**constructor** Create(aModel: TSQLModel; aHandleUserAuthentication: boolean=false); overload; **override**;

*Initialize a REST server with an in-memory SQLite3 database*

- could be used for test purposes

**constructor** CreateWithOwnModel(const aTables: array of TSQLRecordClass; aHandleUserAuthentication: boolean=false); overload;

*Initialize a REST server with an in-memory SQLite3 database and a temporary Database Model*

- could be used for test purposes

**constructor** CreateWithOwnModel(const aTables: array of TSQLRecordClass; const aDBFileName: TFileName; aHandleUserAuthentication: boolean=false; const aRoot: RawUTF8='root'; const aPassword: RawUTF8=''; aDefaultCacheSize: integer=10000; aDefaultPageSize: integer=4096); overload;

*Initialize a REST server with a database, and a temporary Database Model*

- a Model will be created with supplied tables, and owned by the server
- if you instantiate a TSQLRestServerFullMemory or TSQLRestServerDB with this constructor, an in-memory engine will be created, with enough abilities to run regression tests, for instance

**destructor** Destroy; **override**;

*Close database and free used memory*

**function** Backup(Dest: TStream): boolean; deprecated;

*Backup of the opened Database into an external stream (e.g. a file, compressed or not)*

- DEPRECATED: use DB.BackupBackground() instead
- this method doesn't use the SQLite Online Backup API, but low-level database file copy which may lock the database process if the data is consistent - consider using DB.BackupBackground() method instead
- database is closed, VACCUUMed, copied, then reopened

**function** BackupGZ(const DestFileName: TFileName; CompressionLevel: integer=2): boolean; deprecated;

*Backup of the opened Database into a .gz compressed file*

- DEPRECATED: use DB.BackupBackground() instead
- this method doesn't use the SQLite Online Backup API, but low-level database file copy which may lock the database process if the data is consistent - consider using DB.BackupBackground() method instead
- database is closed, VACCUUMed, compressed into .gz file, then reopened
- default compression level is 2, which is very fast, and good enough for a database file content: you may change it into the default 6 level

**function** ComputeDBStats: variant; overload;

*Retrieves the per-statement detailed timing, as a TDocVariantData*

**function** Restore(const ContentToRestore: RawByteString): boolean;

*Restore a database content on the fly*

- database is closed, source DB file is replaced by the supplied content, then reopened
- there are cases where this method will fail and return FALSE: consider shutting down the server, replace the file, then relaunch the server instead

**function** RestoreGZ(const BackupFileName: TFileName): boolean;

*Restore a database content on the fly, from a .gz compressed file*

- database is closed, source DB file is replaced by the supplied content, then reopened
- there are cases where this method will fail and return FALSE: consider shutting down the server, replace the file, then relaunch the server instead

**function** RetrieveBlobFields(Value: TSQLRecord): boolean; **override;**

*Overridden method for direct SQLite3 database engine call*

- it will retrieve all BLOB fields at once, in one SQL statement

**function** StoredProcExecute(const aSQL: RawUTF8; StoredProc: TOnSQLStoredProc): boolean;

*Execute one SQL statement, and apply an Event to every record*

- lock the database during the run
- call a fast "stored procedure"-like method for each row of the request; this method must use low-level DB access in any attempt to modify the database (e.g. a prepared TSQLRequest with Reset+Bind+Step), and not the TSQLRestServerDB.Engine\*() methods which include a Lock(): this Lock() is performed by the main loop in EngineExecute() and any attempt to such high-level call will fail into an endless loop
- caller may use a transaction in order to speed up StoredProc() writing
- intercept any DB exception and return false on error, true on success

**function** TableMaxID(Table: TSQLRecordClass): TID; **override;**

*Search for the last inserted ID in a table*

- will execute not default select max(rowid) from Table, but faster  
 select rowid from Table order by rowid desc limit 1

**function** TransactionBegin(aTable: TSQLRecordClass; SessionID: cardinal=1): boolean; **override;**

*Begin a transaction (implements REST BEGIN Member)*

- to be used to speed up some SQL statements like Insert/Update/Delete
- must be ended with Commit on success
- must be aborted with Rollback if any SQL statement failed
- return true if no transaction is active, false otherwise

**function** UpdateBlobFields(Value: TSQLRecord): boolean; **override;**

*Overridden method for direct SQLite3 database engine call*

- it will update all BLOB fields at once, in one SQL statement

**procedure** AdministrationExecute(const DatabaseName, SQL: RawUTF8; var result: TServiceCustomAnswer); **override;**

*Used e.g. by IAdministratedDaemon to implement "pseudo-SQL" commands*

**procedure** Commit(SessionID: cardinal=1; RaiseException: boolean=false); **override;**

*End a transaction (implements REST END Member)*

- write all pending SQL statements to the disk

**procedure** ComputeDBStats(out result: variant); overload;

*Retrieves the per-statement detailed timing, as a TDocVariantData*

**procedure** CreateMissingTables(user\_version: cardinal=0; Options: TSQLInitializeTableOptions=[]); **override**;

*Missing tables are created if they don't exist yet for every TSQLRecord class of the Database Model*

- you must call explicitly this before having called StaticDataCreate()
- all table description (even Unique feature) is retrieved from the Model
- this method also create additional fields, if the TSQLRecord definition has been modified; only field adding is available, field renaming or field deleting are not allowed in the Framework (in such cases, you must create a new TSQLRecord type)

**procedure** DefinitionTo(Definition: TSynConnectionDefinition); **override**;

*Save the TSQLRestServerDB properties into a persistent storage object*

- RegisteredClassCreateFrom() will expect Definition.DatabaseName to store the DBFileName, and optionally encrypt the file using Definition.Password

**procedure** FlushInternalDBCach; **override**;

*Call this method when the internal DB content is known to be invalid*

- by default, all REST/CRUD requests and direct SQL statements are scanned and identified as potentially able to change the internal SQL/JSON cache used at SQLite3 database level; but some virtual tables (e.g. TSQLRestStorageExternal classes defined in SQLite3DB) could flush the database content without proper notification
- this overridden implementation will call TSQLDataBase.CacheFlush method

**procedure** FlushStatementCache;

*Call this method to flush the internal SQL prepared statements cache*

- you should not have to flush the cache, only e.g. before a DROP TABLE
- in all cases, running this method would never harm, nor be slow

**procedure** InitializeEngine; **virtual**;

*Initialize the associated DB connection*

- called by Create and on Backup/Restore just after DB.DBOpen
- will register all \*\_in() functions for available TSQLRecordRTree
- will register all modules for available TSQLRecordVirtualTable\*ID with already registered modules via RegisterVirtualTableModule()
- you can override this method to call e.g. DB.RegisterSQLFunction()

**procedure** RollBack(SessionID: cardinal=1); **override**;

*Abort a transaction (implements REST ABORT Member)*

- restore the previous state of the database, before the call to TransactionBegin

**property** DB: TSQLDataBase **read** fDB;

*Associated database*

**property** StatementLastException: RawUTF8 **read** fStatementLastException;

*Contains some textual information about the latest Exception raised during SQL statement execution*

**property** StatementPreparedSelectQueryPlan: boolean **read** fStatementPreparedSelectQueryPlan **write** fStatementPreparedSelectQueryPlan;

*Executes (therefore log) the QUERY PLAN for each prepared statement*

**property** StatementTruncateSQLLogLen: integer **read** fStatementTruncateSQLLogLen  
**write** fStatementTruncateSQLLogLen;

*After how many bytes a SQLite statement log entry should be truncated*

- default is 0, meaning no truncation
- typical value is 2048 (2KB), which will avoid any heap allocation

**TSQLRestClientDB = class(TSQLRestClientURI)**

*REST client with direct access to a SQLite3 database*

- a hidden TSQLRestServerDB server is created and called internally

*Used for DI-2.2.1 (page 2558).*

**constructor** Create(aRunningServer: TSQLRestServerDB); **reintroduce**; **override**;

*Initialize the class, for an existing TSQLRestServerDB*

- the client TSQLModel will be cloned from the server's one
- the TSQLRestServerDB and TSQLDatabase instances won't be managed by the client, but will access directly to the server

**constructor** Create(aClientModel, aServerModel: TSQLModel; **const** aDBFileName: TFileName; aServerClass: TSQLRestServerDBClass; aHandleUserAuthentication: boolean=false; **const** aPassword: RawUTF8=''; aDefaultCacheSize: integer=10000); **reintroduce**; **override**;

*Same as above, from a SQLite3 filename specified*

- an internal TSQLDataBase will be created internally and freed on Destroy
- aServerClass could be TSQLRestServerDB by default
- if specified, the password will be used to cypher this file on disk (the main SQLite3 database file is encrypted, not the wal file during run)

**constructor** Create(aClientModel, aServerModel: TSQLModel; aDB: TSQLDataBase; aServerClass: TSQLRestServerDBClass; aHandleUserAuthentication: boolean=false); **reintroduce**; **override**;

*Initializes the class, and creates an internal TSQLRestServerDB to internally answer to the REST queries*

- aServerClass could be TSQLRestServerDB by default

**destructor** Destroy; **override**;

*Release the server*

**function** List(**const** Tables: array of TSQLRecordClass; **const** SQLSelect: RawUTF8='ID'; **const** SQLWhere: RawUTF8=''); TSQLTableJSON; **override**;

*Retrieve a list of members as a TSQLTable (implements REST GET Collection)*

- this overridden method call directly the database to get its result, without any URI() call, but with use of DB JSON cache if available
- other TSQLRestClientDB methods use URI() function and JSON conversion of only one record properties values, which is very fast

**property** DB: TSQLDataBase **read** getDB;

*Associated database*

**property** Server: TSQLRestServerDB **read** fServer;

*Associated Server*

**TSQVirtualTableModuleSQLite3 = class(TSQVirtualTableModule)**

*Define a Virtual Table module for a stand-alone SQLite3 engine*

- it's not needed to free this instance: it will be destroyed by the SQLite3 engine together with the DB connection

**function** FileName(**const** aTableName: RawUTF8): TFileName; **override;**

*Retrieve the file name to be used for a specific Virtual Table*

- overridden method returning a file located in the DB file folder, and "" if the main DB was created as SQLITE\_MEMORY\_DATABASE\_NAME (i.e. ':memory:' so that no file should be written)

- of course, if a custom FilePath property value is specified, it will be used, even if the DB is created as SQLITE\_MEMORY\_DATABASE\_NAME

**procedure** Attach(aDB: TSQDataBase);

*Initialize the module for a given DB connection*

- internally set fModule and call sqlite3\_create\_module\_v2(fModule)

- will raise EBusinessLayerException if aDB is incorrect, or SetDB() has already been called for this module

- will call sqlite3\_check() to raise the corresponding ESQlite3Exception

- in case of success (no exception), the SQLite3 engine will release the module by itself; but in case of error (an exception is raised), it is up to the caller to intercept it via a try..except and free the TSQVirtualTableModuleSQLite3 instance

**property** DB: TSQDataBase **read** fDB;

*The associated SQLite3 database connection*

**TSQVirtualTableModuleServerDB = class(TSQVirtualTableModuleSQLite3)**

*Define a Virtual Table module for a TSQLRestServerDB SQLite3 engine*

**constructor** Create(aClass: TSQVirtualTableClass; aServer: TSQLRestServer);  
**override;**

*Register the Virtual Table to the database connection of a TSQLRestServerDB server*

- in case of an error, an exception will be raised

**TSQRestStorageShardDB = class(TSQRestStorageShard)**

*REST storage sharded over several SQLite3 instances*

- numerotated '\*0000.dbs' SQLite3 files would contain the sharded data

- here \*.dbs is used as extension, to avoid any confusion with regular SQLite3 database files (\*.db or \*.db3)

- when the server is off (e.g. on periodic version upgrade), you may safely delete/archive some oldest \*.dbs files, for easy and immediate purge of your database content: such process would be much faster and cleaner than regular "DELETE FROM TABLE WHERE ID < ?" + "VACUUM" commands

```
constructor Create(aClass: TSQLRecordClass; aServer: TSQLRestServer; aShardRange:
TID; aOptions: TSQLRestStorageShardOptions=[]; const aShardRootFileName:
TFileName=''; aMaxShardCount: integer=100; aSynchronous:
TSQLSynchronousMode=smOff; aCacheSizePrevious: integer=250; aCacheSizeLast:
integer=500); reintroduce; virtual;
```

*Initialize the table storage redirection for sharding over SQLite3 DB*

- if no aShardRootFileName is set, the executable folder and stored class table name would be used

- typical use may be:

```
Server.StaticDataAdd(TSQLRestStorageShardDB.Create(TSQLRecordSharded, Server, 500000))
```

- you may define some low-level tuning of SQLite3 process via aSynchronous / aCacheSizePrevious / aCacheSizeLast / aMaxShardCount parameters, if the default smOff / 1MB / 2MB / 100 values are not enough

```
property ShardRootFileName: TFileName read fShardRootFileName;
```

*Associated file name for the SQLite3 database files*

- contains the folder, and root file name for the storage
- each shard would end with its 4 digits index: actual file name would append '0000.dbs' to this ShardRootFileName

## Types implemented in the *mORMotSQLite3* unit

```
TSQLRestServerDBClass = class of TSQLRestServerDB;
```

*Class-reference type (metaclass) of a REST server using SQLite3 as main engine*

## Functions or procedures implemented in the *mORMotSQLite3* unit

| Functions or procedures    | Description                                                | Page |
|----------------------------|------------------------------------------------------------|------|
| RegisterVirtualTableModule | Initialize a Virtual Table Module for a specified database | 2399 |

```
function RegisterVirtualTableModule(aModule: TSQLVirtualTableClass; aDatabase:
TSQLDataBase): TSQLVirtualTableModule;
```

*Initialize a Virtual Table Module for a specified database*

- to be used for low-level access to a virtual module, e.g. with TSQLVirtualTableLog
- when using our ORM, you should call TSQLModel.VirtualTableRegister() instead to associate a TSQLRecordVirtual class to a module
- returns the created TSQLVirtualTableModule instance (which will be a TSQLVirtualTableModuleSQLite3 instance in fact)
- will raise an exception of failure

## 27.66. mORMotToolBar.pas unit

*Purpose:* ORM-driven Office 2007 Toolbar for mORMot

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

**The *mORMotToolBar* unit is quoted in the following items**

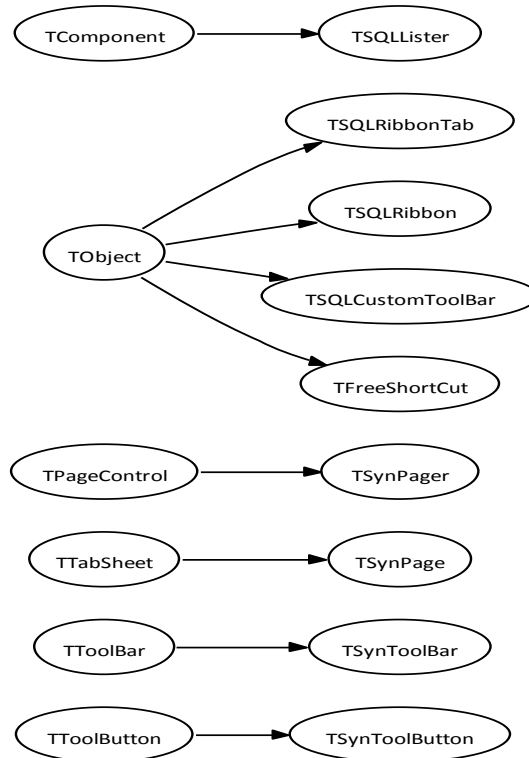

| SWRS #     | Description             | Page |
|------------|-------------------------|------|
| DI-2.3.1.1 | Database Grid Display   | 2559 |
| DI-2.3.1.2 | RTTI generated Toolbars | 2559 |

**Units used in the *mORMotToolBar* unit**

| Unit Name            | Description                                                                                                                                                                                                                                                                                                                                    | Page |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>        | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                               | 1907 |
| <i>mORMoti18n</i>    | Internationalization (i18n) routines and classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                         | 2332 |
| <i>mORMotReport</i>  | Reporting unit<br>- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                                                             | 2362 |
| <i>mORMotUI</i>      | Grid to display database content for mORMot<br>- this unit is a part of the freeware mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                                 | 2414 |
| <i>mORMotUILogin</i> | Some common User Interface functions and dialogs for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                         | 2428 |

*mORMotToolBar class hierarchy*

### Objects implemented in the *mORMotToolBar* unit

| Objects           | Description                                                                                                | Page |
|-------------------|------------------------------------------------------------------------------------------------------------|------|
| TFreeShortCut     | A simple object to get one char shortcuts from caption value                                               | 2402 |
| TSQLCustomToolBar | Create one or more toolbars in a ribbon page, according to an enumeration of actions                       | 2406 |
| TSQLLister        | A hidden component, used for handling toolbar buttons of actions to be performed on a TSQLRecordClass list | 2404 |
| TSQLRibbon        | Store some variables common to all pages, i.e. for the whole ribbon                                        | 2408 |
| TSQLRibbonTab     | Store the UI elements and data, one per each Table                                                         | 2406 |
| TSynPage          | A Ribbon page, which will contain some toolbars for a TSQLRecord class                                     | 2402 |
| TSynPager         | The ribbon pager, which will contain one page per TSQLRecord class                                         | 2403 |

| Objects        | Description                                                  | Page |
|----------------|--------------------------------------------------------------|------|
| TSynToolBar    | A toolbar on a Ribbon page                                   | 2402 |
| TSynToolButton | A button on the Ribbon toolbars, corresponding to one action | 2402 |

**TFreeShortCut = object(TObject)**

*A simple object to get one char shortcuts from caption value*

**Values:** TFreeShortCutSet;

*Bit set for already used short cut, from 'A' to 'Z'*

**function** FindFreeShortCut(const aCaption: string): string;

*Attempt to create free shortcut of one char length, from a Caption: try every character of aCaption, from left to right*

- returns "" if no shortcut calculation was possible

**TSynToolButton = class(TToolButton)**

*A button on the Ribbon toolbars, corresponding to one action*

**constructor** Create(aOwner: TComponent); **override;**

*This class will have AutoSize set to true*

**function** Images: TCustomImageList;

*The associated image list, i.e. TToolBar(Owner).Images*

**procedure** DoDropDown;

*Display drop down menu*

**TSynToolBar = class(TToolBar)**

*A toolbar on a Ribbon page*

**function** CreateToolButton(ButtonClick: TNotifyEvent; iAction, ImageListFirstIndex: integer; const ActionName, ActionHints: string; var ShortCutUsed: TFreeShortCut; ButtonWidth: integer; Images: TCustomImageList): TSynToolButton;

*Create a button on the toolbar*

**TSynPage = class(TTabSheet)**

*A Ribbon page, which will contain some toolbars for a TSQLRecord class*

**function** CreateToolBar(AddToList: boolean=true): TSynToolBar;

*Add a TSynToolBar to the page list*

- then call TSynToolBar.CreateToolButton to add some buttons

**procedure** ToolBarCreated;

*Call this event when all toolbars have been created*

- it will create the captions under the toolbars

- can be call multiple times, when a toolbar has been added and filled with all its buttons

**property** ToolBarCount: integer **read** GetToolBarCount;

*Number of TSynToolBar in the page list*

**property** ToolBars[aIndex: integer]: TSynToolBar **read** GetToolBar;

*Access to the TSynToolBar list of this page*

**TSynPager = class**(TPageControl)

*The ribbon pager, which will contain one page per TSQLRecord class*

**function** AddPage(const aCaption: string): integer; overload;

*Create a new page with the specified caption*

**function** AddPage(aPage: TSynPage): integer; overload;

*Add a page instance*

**class function** CreatePager(aOwner: TCustomForm; NoTabVisible: boolean=false): TSynPager;

*Create the ribbon pager on a form*

- reserve some above space for groups, caption and min/max/close buttons, so that FormNoCaption method can be called later

**function** TabGroupsAdd(TabIndexStart, TabIndexEnd: integer; const aCaption: string): TLabel;

*Create a group label starting for the given page indexes*

**procedure** FormNoCaption;

*Hide TSynForm caption bar and put caption and buttons at groups right*

**property** ActivePageIndex: integer **read** GetActivePageIndex **write** SetActivePageIndex;

*Force OnChange event to be triggered*

**property** Caption: TLabel **read** GetCaption;

*The label on TopMostPanel, i.e. the TSynForm(Owner).NoCaption*

**property** HelpButton: TSynToolButton **read** GetHelpButton;

*The help button to be available on the ribbon*

**property** OnDbClick;

*Publish this property, e.g. to close a tab by a double click*

**property** Pages[aIndex: Integer]: TSynPage **read** GetSynPage;

*Mimic TTabSheet.Pages property*

**property** TopMostPanel: TPanel **read** fTopMostPanel;

*The panel added above the pager, containing groups, caption and buttons*

**property** TopPanel: TPanel **read** fTopPanel;

*The panel containing this TSynPager*

## **TSQLLister = class(TComponent)**

*A hidden component, used for handling toolbar buttons of actions to be performed on a TSQLRecordClass list*

*Used for DI-2.3.1.1 (page 2559), DI-2.3.1.2 (page 2559).*

**constructor** Create(aOwner: TComponent; aClient: TSQLRestClientURI; aClass: TSQLRecordClass; aGrid: TDrawGrid; aIDColumnHide: boolean; aPager: TSynPager; aImageList32, aImageList16: TImageList; aOnClick: TSQLListerEvent; aOnValueText: TValueTextEvent; **const** aGridSelect: RawUTF8= '\*'; aHideDisabledButtons: boolean=false; aHeaderCheckboxSelectsInsteadOfSort: Boolean=false); **reintroduce; overload;**

*Initialize the lister for a specified Client and Class*

- the possible actions are retrieved from the Client TSQLModel
- a single page is used for a list of records, specified by their unique class
- a single page can share multiple toolbars
- both TImageList will be used to display some images in Action buttons (32 pixels wide) and Popup Menu (16 pixels wide)
- if aGrid has no associated TSQLTableToGrid, a default one is created retrieving a list of records with aGridSelect about the aClass Table from aClient, with the ID column hidden (no TSQLTableToGrid will be created if aGridSelect is "")
- aOnClick is called with a specified action if a button is clicked, or with ActionValue=0 each time a row is selected

*Used for DI-2.3.1.1 (page 2559).*

**constructor** Create(aOwner: TComponent; aClient: TSQLRestClientURI; aClass: TSQLRecordClass; aGrid: TDrawGrid; aIDColumnHide: boolean; aPager: TSynPager; aImageList32, aImageList16: TImageList; aOnClick: TSQLListerEvent; aOnValueText: TValueTextEvent; aTable: TSQLTable; aHideDisabledButtons, aHeaderCheckboxSelectsInsteadOfSort: boolean); **reintroduce; overload;**

*Same as above, but with a specified TSQLTable*

*Used for DI-2.3.1.1 (page 2559).*

**function** ActionHint(**const** Action): **string;**

*Retrieve a ready to be displayed hint for a specified action*

- returns the Hint caption of the corresponding button, or "" if not existing

**class function** AddPage(aOwner: TSynPager; aClass: TSQLRecordClass; **const** CustomCaption: **string;** CustomCaptionTranslate: boolean): TSynPage;

*Add a page (if not already) for a corresponding TSQLRecordClass*

- the TSynPage tag property will contain integer(aClass)
- the TSynPage caption is expanded and translated from aClass with LoadResStringTranslate(aClass.SQLTableName) or taken directly from CustomCaption if a value is specified (with translation if CustomCaptionTranslate is set)

**function** FindButton(ActionIndex: integer): TSynToolButton;

*Find associate Button for an action*

**function** FindMenuItem(ActionIndex: integer): TMenuItem;

*Find associate popup Menu item for an action*

**class function** FindPage(aOwner: TSynPager; aClass: TSQLRecordClass): integer;

*Retrieve the page index from a TSQLRecordClass*  
 - the TSynPage tag property contains integer(aClass)

**function** NewMenuItem(Menu: TPopupMenu; **const** aCaption: **string**; ImageIndex: integer=-1; SubMenu: TMenuItem=nil; OnClick: TNotifyEvent=nil; itemEnabled: boolean=true): TMenuItem;

*Create a menu item, and add it to a menu*

**function** SetToolBar(**const** aToolBarName: **string**; **const** aActions; ActionIsNotButton: pointer): TSynToolBar;

*Add or update a ToolBar with a specific actions set*  
 - a single page can share multiple toolbars, which caption name must be identical between calls for genuine buttons  
 - if the ToolBar is already existing, the status of its Action buttons is enabled or disabled according to the actions set  
 - aActions must point to a set of enumerates, as defined by Client.Model.SetActions(TypeInfo(..))  
 - first call once this procedure to create the toolbar buttons, then call it again to update the enable/disable status of the buttons

**procedure** CreateSubMenuItem(**const** aCaption: **string**; ActionIndex: integer; OnClick: TNotifyEvent; ImageIndex: integer=-1; Tag: integer=0; itemEnabled: boolean=true);

*Create a sub menu item to both button and menu item for an action*  
 - if aCaption is "", erase any previous menu

**procedure** OnDrawCellBackground(Sender: TObject; ACol, ARow: Longint; Rect: TRect; State: TGridDrawState);

*Can be used by any TSQLTableToGrid*  
 - to draw marked rows with a highlighted color  
 - with respect to the Toolbar theming

**property** ActionHints: **string** **read** fActionHints **write** fActionHints;

*The Hints captions to be displayed on the screen*  
 - must be set before SetToolBar() method call  
 - one action (starting with actMark) each line

**property** Client: TSQLRestClient **read** fClient;

*The associated Client*

**property** Grid: TDrawGrid **read** fGrid;

*The associated Grid display*

**property** ImageList16: TImageList **read** fImageList16;

*TImageList used to display some images in Action buttons*

**property** ImageList32: TImageList **read** fImageList32;

*TImageList used to display some images in Action buttons*

**property** Menu: TSynPopupMenu **read** fMenu;

*The Popup Menu, displayed with the Grid*

**property** OnMarkAction: TMarkActionEvent **read** fOnMarkAction **write** fOnMarkAction;

*A callback event, triggered after actMark\*/actUnmarkAll has been executed*

**property** Page: TSynPage **read** fPage;

*The associated Page on the Office 2007 menu*

**property** RecordClass: TSQLRecordClass **read** fClass;

*The associated record class*

**property** ReportDetailedIndex: integer **read** fReportDetailedIndex;

*Set to to a "Details" level, according to the bsCheck button pushed  
 - set to the Action index which is currently available*

**property** TableToGrid: TSQLTableToGrid **read** fTableToGrid;

*The associated TSQLTableToGrid hidden component*

**TSQLCustomToolBar = object(TObject)**

*Create one or more toolbars in a ribbon page, according to an enumeration of actions*

- use a similar layout and logic as TSQLLister.SetToolBar() method above
- to be used for custom forms (e.g. preview or edit) or to add some custom buttons to a previously created one by TSQLLister.SetToolBar()
- simply set the associated objects via the Init() method, then call AddToolBar() for every toolbar which need to be created

*Used for DI-2.3.1.2 (page 2559).*

**function** AddToolBar(const ToolBarName: string; ActionsBits: pointer=nil;  
 ButtonWidth: integer=60): TSynToolBar;

*Call this method for every toolbar, with appropriate bits set for its buttons*

**function** CreateSubMenuItem(aButtonIndex: integer; const aCaption: string; aOnClick:  
 TNotifyEvent; aTag: integer=0): TMenuItem;

*Create a popup menu item for a button  
 - call with aCaption void to clear the menu first  
 - then call it for every menu entry*

**procedure** Init(aToolBarOrPage: TControl; aEnum: PTypeInfo; aButtonClick:  
 TNotifyEvent; aImageList: TImageList; const aActionHints: string;  
 aImageListFirstIndex: integer=0);

*Call this method first to initialize the ribbon  
 - if aToolBarOrPage is a TCustomForm, this form will become a  
 - if aToolBarOrPage is a TSynPager descendant, a new page is created and added to this TSynPager, and used for toolbars adding  
 - if aToolBarOrPage is a TSynPage descendant, the toolbar is added to this specified Page*

*Used for DI-2.3.1.2 (page 2559).*

**TSQLRibbonTab = class(TObject)**

*Store the UI elements and data, one per each Table*

*Used for DI-2.3.1.2 (page 2559).*

**CurrentRecord: TSQLRecord;**

*A current record value*

**FrameLeft: TFrame;**

*The frame containing associated the List, left side of the Page*

**FrameRight: TFrame;**

*The frame containing associated Details, right side to the list*

**FrameSplit: TSplitter;**

*Allows List resizing*

**List: TDrawGrid;**

*Associated table list*

**Lister: TSQLLister;**

*To associate Class, Actions, Ribbon and Toolbars*

**Page: TSynBodyPage;**

*Associate Client Body Page*

**Parameters: PSQLRibbonTabParameters;**

*Associated Tab settings used to create this Ribbon Tab*

**Report: TGDIPages;**

*The associated Report, to display the page*

*- exists if aTabParameters.Layout is not IIClient, and if aTabParameters.NoReport is false*

**Tab: TSynPage;**

*Associate Tab in the Ribbon*

**Table: TSQLRecordClass;**

*Associated TSQLRecord*

**TableIndex: integer;**

*Associated TSQLRecord index in database Model*

**TableToGrid: TSQLTableToGrid;**

*To provide the List with data from Client*

**ViewToolBar: TSynToolBar;**

*The "View" toolbar on the associated Ribbon Tab*

**constructor** Create(ToolBar: TSynPager; Body: TSynBodyPager;  
 aImageList32,aImageList16: TImageList; **var** aPagesShortCuts: TFreeShortCut; **const**  
 aTabParameters: TSQLRibbonTabParameters; Client: TSQLRestClientURI; aUserRights:  
 TSQLFieldBits; aOnValueText: TValueTextEvent; SetAction: TSQLRibbonSetActionEvent;  
**const** ActionsTBCaptionCSV, ActionsHintCaption: **string**; ActionIsNotButton: pointer;  
 aOnActionClick: TSQLListerEvent; ViewToolBarIndex: integer; aHideDisabledButtons,  
 aHeaderCheckboxSelectsInsteadOfSort: boolean);

*Create all the UI elements for a specific Table/Class*

- create a new page for this Table/Class
- populate this page with available Toolbars
- populate all Toolbars with action Buttons

**destructor** Destroy; **override;**

*Release associated memory*

**function** AskForAction(**const** ActionCaption, aTitle: **string**; Client: TSQLRest; DontAskIfOneRow, ReturnMarkedIfSomeMarked: **boolean**): **integer**;

*Ask the User where to perform an Action*

- return 100 if "Apply to Selected" was choosen
- return 101 if "Apply to Marked" was choosen
- return any other value if Cancel or No was choosen

**function** Retrieve(Client: TSQLRestClient; ARow: **integer**; ForUpdate: **boolean**=false): **boolean**;

*Retrieve CurrentRecord from server*

**procedure** AddReportPopupMenuOptions(Menu: TPopupMenu; OnClick: TNotifyEvent);

*Add the report options to the specified menu*

**procedure** CustomReportPopupMenu(OnClick: TNotifyEvent; ParamsEnum: PTypeInfo; ParamsEnabled: **pointer**; **const** Values: **array of** PBoolean);

*Used to customize the popup menu of the associated Report*

- this method expect two standard handlers, and a custom enumeration type together with its (bit-oriented) values for the current Ribbon Tab
- caller must supply an array of boolean pointers to reflect the checked state of every popup menu item entry

**procedure** ReportClick(Sender: TObject);

*Triggered when a report popup menu item is clicked*

**property** CurrentID: TID **read** GetCurrentID;

*Retrieve the current selected ID of the grid*

- returns 0 if no row is selected

**property** ReportPopupParamsEnabled: **pointer** **read** FReportPopupParamsEnabled;

*Pointer to the set of available popup menu parameters for this report*

**property** ReportPopupValues: TPBooleanDynArray **read** FReportPopupValues;

*Pointers to every popup menu items data*

**TSQLRibbon = class(TObject)**

*Store some variables common to all pages, i.e. for the whole ribbon*

*Used for DI-2.3.1.2 (page 2559).*

**Page: array of** TSQLRibbonTab;

*The pages array*

**ShortCuts: TFreeShortCut;**

*Store the keyboard shortcuts for the whole ribbon*

```
constructor Create(Owner: TCustomForm; ToolBar: TSynPager; Body: TSynBodyPager;
aImageList32,aImageList16: TImageList; Client: TSQLRestClientURI; aUserRights:
TSQLFieldBits; aOnValueText: TValueTextEvent; SetAction: TSQLRibbonSetActionEvent;
const ActionsTBCaptionCSV, ActionsHintCaption: string; ActionIsNotButton: pointer;
aOnActionClick: TSQLListerEvent; RefreshActionIndex, ViewToolBarIndex: integer;
aHideDisabledButtons: boolean; PagesCount: integer; TabParameters:
PSQLRibbonTabParameters; TabParametersSize: integer; const GroupCSV: string; const
BackgroundPictureResourceNameCSV: string=''; aHeaderCheckboxSelectsInsteadOfSort:
boolean=false); reintroduce; virtual;
```

*Initialize the Pages properties for this ribbon*

- this constructor must be called in the Owner.OnCreate handler (not in OnShow)
- most parameters are sent back to the SQLRibbonTab.Create constructor
- if BackgroundPictureResourceNameCSV is set, the corresponding background pictures will be extracted from resources and displayed behind the ribbon toolbar, according to the group

*Used for DI-2.3.1.2 (page 2559).*

```
destructor Destroy; override;
```

*Release associated memory*

```
function AddToReport(aReport: TGDIPages; aRecord: TSQLRecord; WithTitle: Boolean;
CSVFieldNames: PUTF8Char=nil; CSVFieldNameToHide: PUTF8Char=nil; OnCaptionName:
TOnCaptionName=nil; ColWidthName: Integer=40; ColWidthValue: integer=60): string;
overload;
```

*Add the specified fields content to the report*

- by default, all main fields are displayed, but caller can specify custom field names as Comma-Separated-Values
- retrieve the main Caption of this record (e.g. the "Name" field value)

```
function DeleteMarkedEntries(aTable: TSQLRecordClass; const ActionHint: string):
Boolean;
```

*Generic method which delete either the current selected entry, either all marked entries*

- returns TRUE if deletion was successful, or FALSE if any error occurred

```
function ExportRecord(aTable: TSQLRecordClass; aID: TID; const ActionHint: string;
OpenAfterCreation: boolean=true): TFileName;
```

*Generic method which export the supplied record*

- display the save dialog before
- only two formats are available here: Acrobat (.pdf) and plain text (.txt)
- returns the exported file name if export was successful, or "" if any error occurred
- by default, the report is created by using the CreateReport method

```
function FindButton(aTable: TSQLRecordClass; aActionIndex: integer):
TSynToolButton;
```

*Retrieve the reference of a given button of the ribbon*

- useful to customize the Ribbon layout, if automatic generation from RTTI don't fit exactly your needs, or even worse marketing's know-how ;)
- called by SetButtonHint method

```
function GetActivePage: TSQLRibbonTab;
```

*Retrieve the current TSQLRibbonTab instance on the screen*

- returns nil if no page is currently selected

**function** GetPage(aRecordClass: TSQLRecordClass): integer;

*Retrieve the index of a given Pages[]*  
- returns -1 if this page was not found

**function** GetParameter(aPageIndex: Integer): PSQLRibbonTabParameters; overload;

*Retrieve the TSQLRibbonTabParameters associated to a Ribbon tab, from its index*  
- returns nil if the specified page index is not valid

**function** GetParameter(aTable: TSQLRecordClass): PSQLRibbonTabParameters; overload;

*Get the the TSQLRibbonTabParameters associated to a Ribbon tab, from its table*  
- returns nil if the specified table is not valid

**function** MarkedEntriesToReport(aTable: TSQLRecordClass; **const** ColWidths: array of integer; aRep: TGDIPages=nil): TGDIPages;

*Generic method which print the all marked entries of the supplied table*

**function** RefreshClickHandled(Sender: TObject; RecordClass: TSQLRecordClass; ActionValue: integer; **out** Tab: TSQLRibbonTab): boolean;

*Handle a ribbon button press*  
- returns TRUE if a Refresh command has been processed (caller should exit) and a refresh timer command has been set  
- returns FALSE if the caller must handle the action

**procedure** AddToReport(aReport: TGDIPages; Table: TSQLTable; **const** ColWidths: array of integer); overload;

*Add the specified database Table Content to the report*  
- if ColWidths are not specified (that is set to []), their values are caculated from the Table content columns

**procedure** BodyResize(Sender: TObject);

*Resize the lists according to the body size*

**procedure** CreateReport(aPageIndex: Integer); overload;

*Create a report for the specified page index*  
- the report must be created from the Page[aPageIndex].CurrentRecord record content  
- call the CreateReport virtual method

**procedure** CreateReport(aTable: TSQLRecordClass; aID: TID; aReport: TGDIPages; AlreadyBegan: boolean=false); overload; **virtual**;

*Create a report for the specified page index*  
- this default method create a report with the content of all fields, except those listed in the corresponding TSQLRibbonTabParameters.EditFieldNameToHideCSV value

**procedure** GotoRecord(aRecord: TSQLRecord; ActionToPerform: integer=0); overload;

*Make a specified record available to the UI*  
- select tab and record index  
- if ActionToPerform is set, the corresponding action is launched

**procedure** GotoRecord(aTable: TSQLRecordClass; aID: TID; ActionToPerform: integer=0); overload;

*Make a specified record available to the UI*  
- select tab and record index  
- if ActionToPerform is set, the corresponding action is launched

**procedure** Refresh(aTable: TSQLRecordClass=nil);

*Refresh the specified page content*

- by default, refresh the current page content
- calls internally RefreshClickHandled method

**procedure** SetButtonHint(aTable: TSQLRecordClass; aActionIndex: integer; const aHint: string);

*Customize the Hint property of any button*

- will test the button is available (avoid any GPF error)

**procedure** ToolBarChange(Sender: TObject);

*Trigger this event when a page changed on screen*

- will free GDI resources and unneeded memory

**procedure** WMRefreshTimer(var Msg: TWMTimer);

*Must be called by the main form to handle any WM\_TIMER message*

- will refresh the screen as necessary

**property** Body: TSynBodyPager read fBody;

*The main Pager component used to display the main data (i.e. records list and report) on the Form*

**property** Client: TSQLRestClientURI read fClient write fClient;

*The associated Client connection*

**property** Form: TCustomForm read fForm;

*The associated Form on screen*

**property** ReportAutoFocus: boolean read fReportAutoFocus write fReportAutoFocus;

*If set to TRUE, the right-sided report is focused instead of the left-sided records list*

**property** ToolBar: TSynPager read fToolBar;

*The Toolbar component used to display the Ribbon on the Form*

### Types implemented in the mORMotToolBar unit

TFreeShortCutSet = **set of** ord('A')..ord('Z');

*Used to mark which shortcut keys have already been affected*

TMarkActionEvent = **procedure**(Sender: TObject; RecordClass: TSQLRecordClass; MarkAction: TSQLAction) **of** object;

*This event is called after actMark\*/actUnmarkAll has been executed*

TOnCaptionName = **function**(const Action: RawUTF8; Obj: TObject=nil; Index: integer=-1): **string of** object;

*Event used to customize screen text of property names*

TPBooleanDynArray = **array of** PBoolean;

*Used to store the options status*

TSQLListerEvent = **procedure**(Sender: TObject; RecordClass: TSQLRecordClass; ActionValue: integer) **of** object;

*This event is called when a button is pressed*

- here ActionValue contains the ordinal value of the custom button

TSQLRibbonSetActionEvent = **function**(TabIndex, ToolbarIndex: integer; TestEnabled:

**boolean; var A): string of object;**

*This event provide the action values for a specified toolbar*

- first call is to test the action presence, with TestEnabled=false
- a special call is made with ToolBarIndex=-1, in which A should be filled with the marking actions
- second call is to test the action enable/disable state, with TestEnabled=true
- in all cases, should return any customized toolbar caption name, or "

**TSynBodyPage = TSynPage;**

*Body page used to display the list and the report on the client screen*

**TSynBodyPager = TSynPager;**

*Body pager used to display the list and the report on the client screen*

**TSynForm = TVistaForm;**

*A Vista-enabled TForm descendant*

- this form will have a button in the TaskBar
- this form will hide the default Delphi application virtual form

**TSynPopupMenu = TPopupMenu;**

*A popup menu to be displayed*

### Functions or procedures implemented in the *mORMotToolBar* unit

| Functions or procedures      | Description                                                                    | Page |
|------------------------------|--------------------------------------------------------------------------------|------|
| AddIconToImageList           | Add an Icon to the supplied TImageList                                         | 2412 |
| CaptionName                  | Retrieve the ready to be displayed text of the given property                  | 2412 |
| CreateReportWithIcons        | Create a report containing all icons for a given action enumeration            | 2413 |
| ImageListStretch             | Fill a TImageList from the content of another TImageList                       | 2413 |
| LoadBitmapFromResource       | Load a bitmap from a .png/.jpg file embedded as a resource to the executable   | 2413 |
| LoadImageListFromBitmap      | Load TImageList bitmaps from a TBitmap                                         | 2413 |
| LoadImageListFromEmbeddedZip | Load TImageList bitmaps from an .zip archive embedded as a ZIP resource        | 2413 |
| NewDrawCellBackground        | Draw the cell of a TDrawGrid according to the current Theming of TabAppearance | 2413 |

**function** AddIconToImageList(ImgList: TCustomImageList; Icon: HIcon): integer;

*Add an Icon to the supplied TImageList*

- return the newly created index in the image list
- the HIcon handle is destroyed before returning

**function** CaptionName(OnCaptionName: TOnCaptionName; const Action: RawUTF8; Obj: TObject=nil; Index: integer=-1): string;

*Retrieve the ready to be displayed text of the given property*

**procedure** CreateReportWithIcons(ParamsEnum: PTypeInfo; ImgList: TImageList; **const** Title, Hints: **string**; StartIndexAt: integer);

*Create a report containing all icons for a given action enumeration*  
- useful e.g. for marketing or User Interface review purposes

**procedure** ImageListStretch(ImgListSource, ImgListDest: TImageList; BkColor: TColor=clSilver);

*Fill a TImageList from the content of another TImageList*  
- stretching use GDI+ so is smooth enough for popup menu display

**function** LoadBitmapFromResource(**const** ResName: **string**; Instance: THandle=0): TBitmap;

*Load a bitmap from a .png/.jpg file embedded as a resource to the executable*  
- you can specify a library (dll) resource instance handle, if needed

**procedure** LoadImageListFromBitmap(ImgList: TCustomImageList; Bmp: TBitmap);

*Load TImageList bitmaps from a TBitmap*  
- warning Bmp content can be modified: it could be converted from multi-line (e.g. IDE export format) into one-line (as expected by TImageList.AddMasked)

**procedure** LoadImageListFromEmbeddedZip(ImgList: TCustomImageList; **const** ZipName: TFileName);

*Load TImageList bitmaps from an .zip archive embedded as a ZIP resource*

**procedure** NewDrawCellBackground(Sender: TObject; ACol, ARow: Integer; Rect: TRect; State: TGridDrawState; Marked: boolean);

*Draw the cell of a TDrawGrid according to the current Theming of TabAppearance*

## 27.67. mORMotUI.pas unit

*Purpose:* Grid to display database content for mORMot

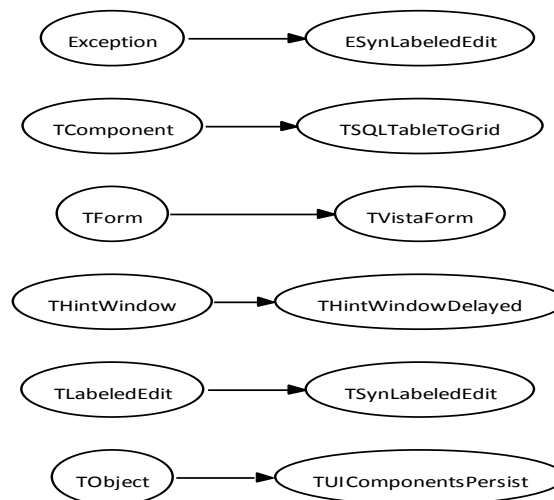

- this unit is a part of the freeware mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

The *mORMotUI* unit is quoted in the following items

| SWRS #     | Description           | Page |
|------------|-----------------------|------|
| DI-2.3.1.1 | Database Grid Display | 2559 |

### Units used in the *mORMotUI* unit

| Unit Name         | Description                                                                                                                                                               | Page |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>     | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18          | 1907 |
| <i>SynCommons</i> | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 718  |

*mORMotUI class hierarchy*

### Objects implemented in the *mORMotUI* unit

| Objects            | Description                                                        | Page |
|--------------------|--------------------------------------------------------------------|------|
| ESynLabeledEdit    | Exception class raised by TSynIntegerLabeledEdit                   | 2420 |
| THintWindowDelayed | A THintWindow descendant, with an internal delay to auto-hide      | 2415 |
| TSQLTableToGrid    | A hidden component, used for displaying a TSQLTable in a TDrawGrid | 2416 |
| TSynLabeledEdit    | TLabeledEdit with optional boundaries check of a Variant value     | 2420 |

| Objects              | Description                                        | Page |
|----------------------|----------------------------------------------------|------|
| TUIComponentsPersist | Allow to track and load/save UI components as JSON | 2421 |
| TVistaForm           | Vista-enabled TForm descendant                     | 2421 |

**THintWindowDelayed** = **class**(THintWindow)

*A THintWindow descendant, with an internal delay to auto-hide*

- this component can be used directly with the hint text to be displayed (companion to the controls Hint properties and Application.ShowHint)
- you can specify a time interval for the popup window to be hidden
- this component expects UTF-8 encoded text, and displays it as Unicode

**constructor** Create(aOwner: TComponent); **override**;

*Initializes the component*

**destructor** Destroy; **override**;

*Releases component resources and memory*

**function** CalcHintRect(MaxWidth: Integer; **const** AHint: RawUTF8; AData: Pointer): TRect; **reintroduce**;

*Overridden method, Unicode ready*

**procedure** ShowDelayedString(**const** Text: **string**; X,Y,Time: integer; FontColor: TColor; AlignLeft: boolean=false); **overload**;

*Displays the appropriate Hint Text at a specified screen position*

- if string is AnsiString (i.e. for Delphi 2 to 2007), Text is decoded into Unicode (using the current i18n code page) before display
- Time is the maximum text display delay, in milliseconds

**procedure** ShowDelayedString(**const** Text: **string**; Origin: TControl; X,Y,Time: integer; FontColor: TColor; AlignLeft: boolean=false); **overload**;

*Displays the appropriate Hint Text at a position relative to a control*

- Text is decoded from Ansi to Unicode (using the current i18n code page) before display
- Time is the maximum text display delay, in milliseconds

**procedure** ShowDelayedUTF8(**const** Text: RawUTF8; X,Y,Time: integer; FontColor: TColor; AlignLeft: boolean=false); **overload**;

*Displays the appropriate Hint Text at a specified screen position*

- Text is decoded from UTF-8 to Unicode before display
- Time is the maximum text display delay, in milliseconds

**procedure** ShowDelayedUTF8(**const** Text: RawUTF8; Origin: TControl; X,Y,Time: integer; FontColor: TColor; AlignLeft: boolean=false); **overload**;

*Displays the appropriate Hint Text at a position relative to a control*

- Text is decoded from UTF-8 to Unicode before display
- Time is the maximum text display delay, in milliseconds

**property** Col: integer **read** fCol;

*The column number when the hint is displayed*

**property** Row: integer **read** fRow;

*The row number when the hint is displayed*

### **TSQLTableToGrid = class(TComponent)**

*A hidden component, used for displaying a TSQLTable in a TDrawGrid*

- just call TSQLTableToGrid.Create(Grid,Table) to initiate the association
- the Table will be released when no longer necessary
- any former association by TSQLTableToGrid.Create() will be overridden
- handle unicode, column size, field sort, incremental key lookup, hide ID
- Ctrl + click on a cell to display its full unicode content

*Used for DI-2.3.1.1 (page 2559).*

### **constructor** Create(aOwner: TDrawGrid; aTable: TSQLTable; aClient: TSQLRestClientURI); **reintroduce;**

*Fill a TDrawGrid with the results contained in a TSQLTable*

*Used for DI-2.3.1.1 (page 2559).*

### **destructor** Destroy; **override;**

*Release the hidden object*

- will be called by the parent Grid when it is destroyed
- will be called by any future TSQLTableToGrid.Create() association
- free the associated TSQLTable and its memory content
- will reset the Grid overridden events to avoid GPF

### **function** ExpandRowAsString(Row: integer; Client: TObject): **string;**

*Read-only access to a particular row values, as VCL text*

- Model is one TSQLModel instance (used to display TRecordReference)
- returns the text as generic string, ready to be displayed via the VCL after translation, for sftEnumerate, sftTimeLog, sftRecord and all other properties
- uses OnValueText property Event if defined by caller

### **class function** From(Grid: TDrawGrid): TSQLTableToGrid;

*Retrieve the associated TSQLTableToGrid from a specific TDrawGrid*

### **function** GetMarkedBits: pointer;

*Retrieve the Marked[] bits array*

### **function** Refresh(ForceRefresh: Boolean=false; AutoResizeColumns: Boolean=true): boolean;

*Force refresh paint of Grid from Table data*

- return true if Table data has been successfully retrieved from Client and if data was refreshed because changed since last time
- if ForceRefresh is TRUE, the Client is not used to retrieve the data, which must be already refreshed before this call
- if AutoResizeColumns is TRUE, the column visual width will be re-computed from the actual content - set it to FALSE to avoid it

### **function** SelectedID: TID;

*Get the ID of the first selected row, 0 on error (no ID field e.g.)*

- useful even if ID column was hidden with IDCColumnHide

**function** SelectedRecordCreate: TSQLRecord;

*Retrieve the record content of the first selected row, nil on error*

- record type is retrieved via Table.QueryTables[0] (if defined)
- warning: it's up to the caller to Free the created instance after use (you should e.g. embedd the process in a try...finally block):

```
Rec := Grid.SelectedRecordCreate;
if Rec<>nil then
try
 DoSomethingWith(Rec);
finally
 Rec.Free;
end;
```

- useful even if ID column was hidden with IDColumnHide

**procedure** AfterRefresh(const aID: TID; AutoResizeColumns: boolean);

*Call this procedure after a refresh of the data*

- current Row will be set back to aID
- called internal by Refresh function above

**procedure** DrawCell(Sender: TObject; ACol, ARow: Longint; Rect: TRect; State: TGridDrawState);

*Called by the owner TDrawGrid to draw a Cell from the TSQLTable data*

- the cell is drawn using direct Win32 Unicode API
- the first row (fixed) is drawn as field name (centered bold text with sorting order displayed with a triangular arrow)

**procedure** DrawGridKeyDown(Sender: TObject; var Key: Word; Shift: TShiftState);

*Called by the owner TDrawGrid when the user presses a key*

- used for LEFT/RIGHT ARROW column order change

**procedure** DrawGridKeyPress(Sender: TObject; var Key: Char);

*Called by the owner TDrawGrid when the user presses a key*

- used for incremental key lookup

**procedure** DrawGridMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y: Integer);

*Called by the owner TDrawGrid when a Cell is clicked by the mouse*

- check if the first (fixed) row is clicked: then change sort order
- Ctrl + click to display its full unicode content (see HintText to customize it)

**procedure** DrawGridMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);

*Called by the owner TDrawGrid when the mouse is over a Cell*

**procedure** DrawGridMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y: Integer);

*Called by the owner TDrawGrid when the mouse is unclicked over a Cell*

**procedure** DrawGridSelectCell(Sender: TObject; ACol, ARow: Integer; var CanSelect: Boolean);

*Called by the owner TDrawGrid when a Cell is selected*

**procedure** IDColumnHide;

*If the ID column is available, hides it from the grid*

**procedure** OnTableUpdate(State: TOnTableUpdateState);

*Used by TSQLRestClientURI.UpdateFromServer() to let the client perform the rows update (for Marked[])*

**procedure** PageChanged;

*You can call this method when the list is no more on the screen  
 - it will hide any pending popup Hint windows, for example*

**procedure** Resize(Sender: TObject);

*Call this procedure to automatically resize the TDrawString columns  
 - can be used as TSQLTableToGrid.From(DrawGrid).Resize();*

**procedure** SetAligned(const aCols: array of cardinal; aAlign: TSQLTableToGridAlign);

*Set columns number which must be aligned to non default left layout  
 - a faster overload to Aligned[] property*

**procedure** SetAlignedByType(aFieldType: TSQLFieldType; aAlign: TSQLTableToGridAlign);

*Set column alignment for a given type  
 - a faster overload to Aligned[] property*

**procedure** SetCustomFormatByType(aFieldType: TSQLFieldType; const aCustomFormat: string);

*Set a custom format for all columns of a given type  
 - a faster overload to CustomFormat[] property  
 - only support the field types and formats handled by CustomFormat[] property*

**procedure** SetFieldFixedWidth(aColumnWidth: integer);

*Force all columns to have a specified width, in pixels*

**procedure** SetFieldLengthMean(const Lengths: RawUTF8; aMarkAllowed: boolean);

*Force the mean of characters length for every field  
 - supply a string with every character value is proportionate to the corresponding column width  
 - if the character is lowercase, the column is set as centered  
 - if aMarkAllowed is set, a first checkbox column is added, for reflecting and updating the Marked[] field values e.g.  
 - if Lengths="", will set some uniform width, left aligned*

**procedure** SetMark(aAction: TSQLAction);

*Perform the corresponding Mark/Unmark[All] Action*

**procedure** ShowHintString(const Text: string; ACol, ARow, Time: integer; FontColor: TColor=clBlack);

*Display a popup Hint window at a specified Cell position  
 - expect generic string Text, i.e. UnicodeString for Delphi 2009/2010, ready to be used with the VCL for all Delphi compiler versions*

**procedure** SortChange(ACol: integer);

*Toggle the sort order of a specified column*

**procedure** SortForce(ACol: integer; Ascending: boolean; ARow: integer=-1);

*Set a specified column for sorting  
 - if ACol=-1, then the Marked[] rows are shown first, in current sort*

**property** Aligned[aCol: cardinal]: TSQLTableToGridAlign **read** GetAlign **write** SetAlign;

*Set individual column alignment*

**property** Client: TSQLRestClientURI **read** fClient;

*Associated Client used to retrieved the Table data*

**property** CurrentFieldOrder: integer **read** fCurrentFieldOrder;

*Current field number used for current table sorting*

**property** CustomFormat[aCol: cardinal]: string **read** GetCustomFormat **write** SetCustomFormat;

*Set individual column custom format*

- as handled by TSQLTable.ExpandAsString() method, i.e. Format() or FormatFloat()/FormatCurrency() mask for sftFloat or sftCurrency, or FormatDateTime() mask for sftDateTime, sftDateTimeMS, sftTimeLog, sftModTime, sftCreateTime, sftUnixTime, sftUnixMSTime)

**property** DrawGrid: TDrawGrid **read** GetDrawGrid;

*Associated TDrawGrid*

- just typecast the Owner as TDrawGrid

**property** FieldIndexTimeLogForMark: integer **read** GetFieldIndexTimeLogForMark;

*Retrieves the index of the sftTimeLog first field*

- i.e. the field index which can be used for Marked actions

- equals -1 if not such field exists

**property** FieldTitleTruncatedNotShownAsHint: boolean **read** fTruncAsHint **write** fTruncAsHint;

*Set to FALSE to display the column title as hint when truncated on screen*

**property** GridColumnWidths: RawUTF8 **read** GetGridColumnWidths **write** SetGridColumnWidths;

*Retrieve or define the column widths of this grid, as text*

- as a CSV list of the associated DrawGrid.ColWidths[] values

**property** HeaderCheckboxSelectsInsteadOfSort: boolean **read** fHeaderCheckboxSelectsInsteadOfSort **write** fHeaderCheckboxSelectsInsteadOfSort;

*Set to TRUE to let the header check box select/unselect all rows instead of sorting them*

- may be more conventional use of this header check box

**property** Hint: THintWindowDelayed **read** fHint;

*Used to display some hint text*

**property** MarkAllowed: boolean **read** fMarkAllowed;

*True if Marked[] is available (add checkboxes at the left side of every row)*

**property** MarkAvailable: boolean **read** GetMarkAvailable;

*True if any Marked[] is checked*

**property** Marked[RowIndex: integer]: boolean **read** GetMarked **write** SetMarked;

*Retrieves if a row was previously marked*

- first data row index is 1

**property** MarkedIsOnlyCurrent: boolean **read** GetMarkedIsOnlyCurrent;

*True if only one entry is in Marked[], and it is the current one*

**property** MarkedTotalCount: integer **read** GetMarkedTotalCount;

*Returns the number of item marked or selected*

*- if no item is marked, it return 0 even if a row is currently selected*

**property** OnDrawCellBackground: TDrawCellEvent **read** fOnDrawCellBackground **write** fOnDrawCellBackground;

*Assign an event here to customize the background drawing of a cell*

**property** OnHintText: THintTextEvent **read** fOnHintText **write** fOnHintText;

*Override this event to customize the Ctrl+Mouse click popup text*

**property** OnRightClickCell: TRightClickCellEvent **read** fOnRightClickCell **write** fOnRightClickCell;

*Override this event to customize the Mouse right click on a data cell*

**property** OnSelectCell: TSelectCellEvent **read** fOnSelectCell **write** fOnSelectCell;

*Override this event to customize the Mouse click on a data cell*

**property** OnSort: TNotifyEvent **read** fOnsort **write** fOnsort;

*Override this event to be notified when the content is sorted*

**property** OnValueText: TValueTextEvent **read** fOnValueText **write** fOnValueText;

*Override this event to customize the text display in the table*

**property** Table: TSQLTable **read** fTable;

*Associated TSQLTable to be displayed*

**ESynLabeledEdit** = **class**(Exception)

*Exception class raised by TSynIntegerLabeledEdit*

**TSynLabeledEdit** = **class**(TLabeledEdit)

*TLabeledEdit with optional boundaries check of a Variant value*

**RaiseExceptionOnError**: boolean;

*If true, GetValue() will raise an ESynVariantLabeledEdit exception on any Variant value range error, when the Value property is read*

**constructor** Create(AOwner: TComponent); **override**;

*Create the component instance*

**function** ToString(NumberOfDigits: integer): **string**; **reintroduce**;

*Convert the entered Variant value into a textual representation*

**function** ValidateValue: boolean;

*Return TRUE if the entered value is inside the boundaries*

**property** AdditionalHint: **string** **read** FAdditionalHint **write** FAdditionalHint;

*Some additional popup hint to be displayed*

*- by default, the allowed range is displayed: 'Min. Value: #, Max. Value: #'*

*- you can specify here some additional text to be displayed when the mouse is hover the component*

**property** Kind: TSynLabeledEditKind **read** fKind **write** fKind **default** sleInteger;

*The kind of value which is currently edited by this TSynLabeledEdit*

**property** MaxValue: Variant **read** FMaxValue **write** FMaxValue;

*Highest allowed Variant value*

**property** MinValue: Variant **read** FMinValue **write** FMinValue;

*Lowest allowed Variant value*

**property** RangeChecking: boolean **read** fRangeChecking **write** fRangeChecking;

*Set to TRUE if MinValue/MaxValue properties must be checked when reading Value property*

**property** Value: Variant **read** GetValue **write** SetValue;

*The entered value*

- getting this property will check for in range according to the current MinValue/MaxValue boundaries, if RangeChecking is set
- if RangeChecking is not set, could return a NULL variant for no data
- it will sound a beep in case of any out of range
- it will also raise a ESynVariantLabeledEdit exception if RaiseExceptionOnError is set to TRUE (equals FALSE by default)

**TUIComponentsPersist = class(TObject)**

*Allow to track and load/save UI components as JSON*

- may be used to persist TEdit / TCheckBox / TComboBox values on a form when the application leaves

**function** SaveToVariant: variant;

*Save all tracked controls properties as a JSON object*

**procedure** LoadFromFile;

*Fill all tracked controls properties from a local JSON file*

**procedure** LoadFromVariant(const aDoc: variant);

*Fill all tracked controls properties from the supplied JSON object*

**procedure** SaveToFile;

*Save all tracked controls properties as JSON in a local file*

**procedure** TrackControls(const ctrls: array of TComponent);

*Would track .Text and .Checked properties only*

**property** FileName: TFileName **read** GetFileName **write** fFileName;

*The local JSON file used for persistence*

- is set to 'executablename.default' if none is specified

**TVistaForm = class(TForm)**

*Vista-enabled TForm descendant*

- this form will have a button in the TaskBar
- this form will hide the default Delphi application virtual form
- this form can be with no caption bar using SetNoCaption method

**procedure** SetNoCaption(aTopMostPanel: TPanel; aLabelLeft: integer);

*Call this method to hide the Caption bar and replace it with a TPanel*

**property** NoCaptionLabel: TLabel **read** fNoCaptionLabel;

*The TLabel instance created on NoCaptionPanel to replace the Caption bar*

**property** NoCaptionPanel: TPanel **read** fNoCaption;

*The TPanel instance replacing the Caption bar*

## Types implemented in the *mORMotUI* unit

THintTextEvent = **function**(Sender: TSQLTable; FieldIndex, RowIndex: Integer; **var** Text: **string**): **boolean of object**;

*Kind of event used to change some text on the fly for popup hint*

- expect generic string Text, i.e. UnicodeString for Delphi 2009/2010, ready to be used with the VCL for all Delphi compiler versions

TRightClickCellEvent = **procedure**(Sender: TSQLTable; ACol, ARow, MouseX, MouseY: Integer) **of object**;

*Kind of event used to display a menu on a cell right click*

TSQLTableToGridAlign = ( alLeft, alCenter, alRight );

*The available alignments of a TSQLTableToGrid cell*

TSynLabeledEditKind = ( sleInteger, sleInt64, sleCurrency, sleDouble );

*Diverse kind of values which may be edited by a TSynLabeledEdit*

TValueTextEvent = **function**(Sender: TSQLTable; FieldIndex, RowIndex: Integer; **var** Text: **string**): **boolean of object**;

*Kind of event used to change some text on the fly for grid display*

- expect generic string Text, i.e. UnicodeString for Delphi 2009/2010, ready to be used with the VCL for all Delphi compiler versions

- if the cell at FieldIndex/RowIndex is to have a custom content, shall set the Text variable content and return TRUE

- if returns FALSE, the default content will be displayed

## Functions or procedures implemented in the *mORMotUI* unit

| Functions or procedures  | Description                                                                                     | Page |
|--------------------------|-------------------------------------------------------------------------------------------------|------|
| AddApplicationToFirewall | Allow an application to access the network through the Windows firewall                         | 2423 |
| AddPortToFirewall        | Open a firewall port on the current computer                                                    | 2423 |
| ClearTypeEnable          | Enable the ClearType font display                                                               | 2423 |
| CreateAnIcon             | Create an Icon                                                                                  | 2423 |
| DrawCheckBox             | Draw a CheckBox in the Canvas Handle of the Wwindow hWnd, in the middle of the Rect coordinates | 2423 |
| FillStringGrid           | Fill TStringGrid.Cells[] with the supplied data                                                 | 2423 |

| Functions or procedures  | Description                                                                  | Page |
|--------------------------|------------------------------------------------------------------------------|------|
| GetShellFolderPath       | Get the corresponding windows folder, from its ID                            | 2423 |
| HideAppFormTaskBarButton | Low level VCL routine in order to hide the application from Windows task bar | 2424 |
| IsClearTypeEnabled       | Test if the ClearType is enabled for font display                            | 2424 |
| Register                 | Register the TSynIntegerLabeledEdit component in the IDE toolbar             | 2424 |

**procedure** AddApplicationToFirewall(**const** EntryName, ApplicationPathAndExe: **string**);

*Allow an application to access the network through the Windows firewall*

- works on Windows WP, Vista and Seven
- caller process must have the administrator rights (this is the case for a setup program)

**procedure** AddPortToFirewall(**const** EntryName: **string**; PortNumber: cardinal);

*Open a firewall port on the current computer*

- works on Windows XP, Vista and Seven
- caller process must have the administrator rights (this is the case for a setup program)

**procedure** ClearTypeEnable;

*Enable the ClearType font display*

- under Windows 2000, standard font smoothing is forced, since Clear Type was introduced with XP

**function** CreateAnIcon (**const** Name, Description, Path, Parameters, WorkingDir, IconFilename: TFileName; **const** IconIndex: Integer; **const** RunMinimized: Boolean = false): TFileName;

*Create an Icon*

- return the .lnk file name (i.e. Name+'.lnk')

**procedure** DrawCheckBox(hWnd: THandle; Handle: HDC; **const** Rect: TRect; Checked: boolean);

*Draw a CheckBox in the Canvas Handle of the Wwindow hWnd, in the middle of the Rect coordinates*

- use theming under XP, Vista and Seven

**procedure** FillStringGrid(Source: TSQLTable; Dest: TStringGrid; Client: TSQLRest=nil);

*Fill TStringGrid.Cells[] with the supplied data*

- will be slower than the TSQLTableToGrid method, but will work on a non standard TDrawGrid component
- it will display date & time and enumerates as plain text, and handle the header properly (using the current mORMoti18n.pas language settings, if any)
- the Client optional parameter will be used to display any RecordRef column
- all data will be stored within the TStringGrid: you can safely release the Source data after having called this procedure

**function** GetShellFolderPath(**const** FolderID: Integer): **string**;

*Get the corresponding windows folder, from its ID*

**procedure** HideAppFormTaskBarButton;

*Low level VCL routine in order to hide the application from Windows task bar*

- don't use it directly: it's called by TVistaForm.CreateParams()

**function** IsClearTypeEnabled: boolean;

*Test if the ClearType is enabled for font display*

- ClearType is a software technology that improves the readability of text on liquid crystal display (LCD) monitors

**procedure** Register;

*Register the TSynIntegerLabeledEdit component in the IDE toolbar*

- not necessary for the mORMot framework to run: since all User Interface is created from code, and not from the Delphi IDE, you don't have to register anything unless you define your own forms including those components

## 27.68. mORMotUIEdit.pas unit

*Purpose:* Record edition dialog, used to edit record content with mORMot

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *mORMotUIEdit* unit

| Unit Name            | Description                                                                                                                                                                                             | Page |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>        | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                        | 1907 |
| <i>mORMoti18n</i>    | Internationalization (i18n) routines and classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                  | 2332 |
| <i>mORMotToolBar</i> | ORM-driven Office 2007 Toolbar for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                    | 2400 |
| <i>mORMotUI</i>      | Grid to display database content for mORMot<br>- this unit is a part of the freeware mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                          | 2414 |
| <i>mORMotUILogin</i> | Some common User Interface functions and dialogs for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                  | 2428 |

*mORMotUIEdit class hierarchy*

### Objects implemented in the *mORMotUIEdit* unit

| Objects         | Description                                                      | Page |
|-----------------|------------------------------------------------------------------|------|
| TRecordEditForm | Record edition dialog, used to edit record content on the screen | 2426 |
| TRTTIForm       | A common ancestor, used by both TRecordEditForm and TOptionsForm | 2426 |

**TRTTIForm = class(TVistaForm)**

*A common ancestor, used by both TRecordEditForm and TOptionsForm*

**OnCaptionName: TOnCaptionName;**

*This event is used to customize screen text of property names*

**OnComponentCreate: TOnComponentCreate;**

*This event is used to customize the input components creation*

- this event is also triggered once at the creation of the Option window, with Obj=Prop=nil and Parent=TOptionsForm: the event must call method Parent.AddEditors() / Parent.SetRecord() to add fields to the Option (this is not mandatory to the Record Edit window)
- this event is triggered once for every object, with Prop=nil, and should return nil if the object is to be added to the dialog, and something not nil if the object is to be ignored (same as a runtime-level \_Name object)
- this is the only mandatory event of this component, for TOptionsForm
- this event is not mandatory for TRecordEditForm (you can call its SetRecord method directly)

**OnComponentCreated: TOnComponentCreated;**

*This event is used to customize the input components after creation*

- triggered when the component has been created
- can be used to disabled the component if user don't have the right to modify its value; but he/she will still be able to view it

**TRecordEditForm = class(TRTTIForm)**

*Record edition dialog, used to edit record content on the screen*

- the window content is taken from the RTTI of the supplied record; all the User Interface (fields, etc...) is created from the class definition using RTTI: published properties are displayed as editing components
- caller must initialize some events, OnComponentCreate at least, in order to supply the objects to be added on the form
- components creation is fully customizable by some events

```
procedure SetRecord(aClient: TSQLRestClient; aRecord: TSQLRecord; CSVFieldNames:
PUTF8Char=nil; Ribbon: TSQLRibbon=nil; FieldHints: string=''; FieldNamesWidth:
integer=0; aCaption: string='');
```

*Create the corresponding components on the dialog for editing a Record*

- to be used by OnComponentCreate(nil,nil,EditForm) in order to populate the object tree of this Form
- create field on the window for all published properties of the supplied TSQLRecord instance
- properties which name starts by '\_' are not added to the UI window
- user can customize the component creation by setting the OnComponentCreate / OnComponentCreated events
- the supplied aRecord instance must be available during all the dialog window modal apparition on screen
- by default, all published fields are displayed, but you can specify a CSV list in the optional CSVFieldNames parameter
- editor parameters are taken from the optional Ribbon parameter, and its EditFieldHints/EditExpandFieldHints/EditFieldNameWidth properties
- if Ribbon is nil, FieldHints may contain the hints to be displayed on screen (useful if your record is not stored in any TSQLRestClient, but only exists in memory); you can set FieldNamesWidth by hand in this case

```
property Client: TSQLRestClient read fClient;
```

*The associated database Client, used to access remote data*

```
property OnComponentValidate: TOnComponentValidate read fOnComponentValidate write
fOnComponentValidate;
```

*Event called to check if the content of a field on form is correct*

- is checked when the user press the "Save" Button
- if returns false, component is focused and window is not closed

```
property Rec: TSQLRecord read fRec;
```

*The associated Record to be edited*

### Types implemented in the *mORMotUIEdit* unit

```
TOnComponentCreate = function(Obj: TObject; Prop: TSQLPropInfo; Parent: TWinControl):
TWinControl of object;
```

*Event used for the window creation*

```
TOnComponentCreated = procedure(Obj: TObject; Prop: TSQLPropInfo; Comp: TWinControl)
of object;
```

*Event used to customize the input component after creation*

```
TOnComponentValidate = function(EditControl: TWinControl; Prop: TSQLPropInfo): boolean
of object;
```

*Event used for individual field validation*

- must return TRUE if the specified field is correct, FALSE if the content is to be modified
- it's up to the handler to inform the user that this field is not correct, via a popup message for instance
- you should better use the TSQLRecord.AddFilterOrValidate() mechanism, which is separated from the UI (better multi-tier architecture)

## 27.69. mORMotUILogin.pas unit

*Purpose:* Some common User Interface functions and dialogs for mORMot

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *mORMotUILogin* unit

| Unit Name            | Description                                                                                                                                                                                                                                                                                                                                    | Page |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|

| <i>SynGdiPlus</i>    | GDI+ library API access<br>- adds GIF, TIF, PNG and JPG pictures read/write support as standard TGraphic<br>- make available most useful GDI+ drawing methods<br>- allows Antialiased rendering of any EMF file using GDI+<br>- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1355 |
| <i>SynTable</i>      | Filter/database/cache/buffer/security/search/multithread/OS features<br>- as a complement to SynCommons, which tended to increase too much<br>- licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                        | 1728 |
| <i>SynTaskDialog</i> | Implement TaskDialog window (native on Vista/Seven, emulated on XP)<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                 | 1832 |

*mORMotUILogin class hierarchy*

### Objects implemented in the *mORMotUILogin* unit

| Objects    | Description                                  | Page |
|------------|----------------------------------------------|------|
| TLoginForm | Form used to Log User and enter its password | 2428 |

```
TLoginForm = class(TForm)
```

*Form used to Log User and enter its password*

```
class function Login(const aTitle, aText: string; var aUserName, aPassword: string;
AllowUserNameChange: boolean; const CSVComboValues: string): boolean;
```

*Display the Login dialog window*

```
class function Password(const aTitle, aText: string; var aPassword: string):
boolean;
```

*Display the password dialog window*

```
class procedure OnIdleProcess(Sender: TSynBackgroundThreadAbstract; ElapsedMS:
Integer);
```

*TOnIdleSQLRestClient-like event to process Windows Messages*

- to be assigned e.g. to TSQLRestClientURI.OnIdle property
- global OnIdleProcessCursorChangeTimeout variable is used to display the crHourGlass cursor after a given time elapsed

```
class procedure OnIdleProcessForm(Sender: TSynBackgroundThreadAbstract; ElapsedMS:
Integer);
```

*TOnIdleSQLRestClient-like event to process Windows Messages and write a temporary form on screen if it takes too long*

- to be assigned e.g. to TSQLRestClientURI.OnIdle property
- global OnIdleProcessCursorChangeTimeout variable is used to display the crHourGlass cursor after a given time elapsed
- global OnIdleProcessTemporaryFormTimeout variable is used to display a temporary form after a given time elapsed

#### Functions or procedures implemented in the *mORMotUILogin* unit

| Functions or procedures | Description                                                              | Page |
|-------------------------|--------------------------------------------------------------------------|------|
| Choose                  | Ask the User to choose between some Commands                             | 2430 |
| Choose                  | Ask the User to choose between some Commands                             | 2430 |
| CreateTempForm          | Popup a temporary form with a message over all forms                     | 2430 |
| EnsureSingleInstance    | Ensure that the program is launched once                                 | 2430 |
| HtmlEscape              | Convert an error message into html compatible equivalency                | 2430 |
| InputBox                | Ask the User to enter some string value                                  | 2430 |
| InputQuery              | Ask the User to enter some string value                                  | 2430 |
| InputSelect             | Ask the User to select one item from an array of strings                 | 2430 |
| InputSelectEnum         | Ask the User to select one enumerate item                                | 2431 |
| SetStyle                | Set the style for a form and a its buttons                               | 2431 |
| ShowException           | Show an error dialog box, corresponding to a specified exception         | 2431 |
| ShowLastClientError     | Show an error dialog box, with the corresponding Client-Side information | 2431 |
| ShowMessage             | Show an (error) message, using a Vista-Style dialog box                  | 2431 |

| Functions or procedures | Description                                                                   | Page |
|-------------------------|-------------------------------------------------------------------------------|------|
| ShowMessage             | Show an (error) message, using a Vista-Style dialog box                       | 2431 |
| YesNo                   | Ask the User to choose Yes or No [and Cancel], using a Vista-Style dialog box | 2431 |

**function** Choose(const aTitle, aCSVContent: string): integer; overload;

*Ask the User to choose between some Commands*

- return the selected command index, starting numerotation at 100
- this overloaded function expect the Content and the Commands to be supplied as CSV string (Content as first CSV, then commands)

**function** Choose(const aTitle, aContent, aFooter: string; const Commands: array of string; aFooterIcon: TTaskDialogFooterIcon=tfiInformation): integer; overload;

*Ask the User to choose between some Commands*

- return the selected command index, starting numerotation at 100

**function** CreateTempForm(const aCaption: string; aPanelReference: PTPanel=nil; ScreenCursorHourGlass: boolean=false; aCaptionColor: integer=clNavy; aCaptionSize: integer=12): TForm;

*Popup a temporary form with a message over all forms*

- caller should execute result.Free and reset the cursor if needed

**procedure** EnsureSingleInstance;

*Ensure that the program is launched once*

- the main project .dpr source file must contain:

```
begin
 Application.Initialize;
 EnsureSingleInstance; // program is launched once
 Application.CreateForm(TMainForm, MainForm);

```

**function** HtmlEscape(const Msg: string): string;

*Convert an error message into html compatible equivalency*

- allow to display < > & correctly

**function** InputBox(const ACaption, APrompt, ADefault: string; QueryMasked: boolean=false): string;

*Ask the User to enter some string value*

- if QueryMasked=TRUE, will mask the prompt with '\*' chars (e.g. for entering a password)

**function** InputQuery(const ACaption, APrompt: string; var Value: string; QueryMasked: boolean=false): Boolean;

*Ask the User to enter some string value*

- if QueryMasked=TRUE, will mask the prompt with '\*' chars (e.g. for entering a password)

**function** InputSelect(const ACaption, APrompt, AItemsText, ASelectedText: string): integer;

*Ask the User to select one item from an array of strings*

- return the selected index, -1 if Cancel button was pressed

**function** InputSelectEnum(**const** ACaption, APrompt: **string**; EnumTypeInfo: PTypeInfo; **var** Index): **boolean**;

*Ask the User to select one enumerate item*

- use internally TEnumType.GetCaption() to retrieve the text to be displayed
- Index must be an instance of this enumeration type (internally mapped to a PByte)

**procedure** SetStyle(Form: TComponent);

*Set the style for a form and a its buttons*

- set the Default Font for all components, i.e. Calibri if available

**function** ShowException(E: Exception; CommonButtons: TCommonButtons=[cbOk]; **const** ContextMessage: **string**='): **integer**;

*Show an error dialog box, corresponding to a specified exception*

**function** ShowLastClientError(Client: TSQLRestClientURI; **const** ContextMessage: **string**='; CommonButtons: TCommonButtons=[cbOk]): **integer**;

*Show an error dialog box, with the corresponding Client-Side information*

- retrieve last error message from Client.LastError\* values

**procedure** ShowMessage(**const** Msg: **string**; Error: **boolean**=false); **overload**;

*Show an (error) message, using a Vista-Style dialog box*

**procedure** ShowMessage(**const** Msg, Inst: **string**; Error: **boolean**=false); **overload**;

*Show an (error) message, using a Vista-Style dialog box*

**function** YesNo(**const** aQuestion: **string**; **const** aConfirm: **string** ='; withCancel: **boolean**=true; Warning: **boolean**=false): **integer**;

*Ask the User to choose Yes or No [and Cancel], using a Vista-Style dialog box*

## Variables implemented in the mORMotUILogin unit

OnIdleProcessCursorChangeTimeout: **integer** = 100;

*Define when TLoginForm.OnIdleProcess() has to display the crHourGlass cursor after a given time elapsed, in milliseconds*

- default is 100 ms

OnIdleProcessTemporaryFormMessage: **string**;

*Define the message text displayed by TLoginForm.OnIdleProcessForm()*

- default is sOnIdleProcessFormMessage resourcestring, i.e. 'Please wait...'

OnIdleProcessTemporaryFormTimeout: **integer** = 2000;

*Define when TLoginForm.OnIdleProcessForm() has to display the temporary form after a given time elapsed, in milliseconds*

- default is 2000 ms, i.e. 2 seconds

## 27.70. mORMotUIOptions.pas unit

*Purpose:* General Options setting dialog for mORMot

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *mORMotUIOptions* unit

| Unit Name            | Description                                                                                                                                                                                    | Page |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>        | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                               | 1907 |
| <i>mORMoti18n</i>    | Internationalization (i18n) routines and classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18         | 2332 |
| <i>mORMotToolBar</i> | ORM-driven Office 2007 Toolbar for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                           | 2400 |
| <i>mORMotUI</i>      | Grid to display database content for mORMot<br>- this unit is a part of the freeware mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                 | 2414 |
| <i>mORMotUIEdit</i>  | Record edition dialog, used to edit record content with mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18      | 2425 |
| <i>mORMotUILogin</i> | Some common User Interface functions and dialogs for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18         | 2428 |
| <i>SynCommons</i>    | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                      | 718  |
| <i>SynTaskDialog</i> | Implement TaskDialog window (native on Vista/Seven, emulated on XP)<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1832 |

*mORMotUIOptions class hierarchy*

### Objects implemented in the *mORMotUIOptions* unit

| Objects      | Description            | Page |
|--------------|------------------------|------|
| TOptionsForm | Options setting dialog | 2433 |

**TOptionsForm = class(TRTTIForm)**

*Options setting dialog*

- the settings parameters are taken from the RTTI of supplied objects: all the user interface is created from the code definition of classes; a visual tree node will reflect the properties recursion, and published properties are displayed as editing components
- published textual properties may be defined as generic RawUTF8 or as generic string (with some possible encoding issue prior to Delphi 2009)
- caller must initialize some events, OnComponentCreate at least, in order to supply the objects to be added on the form
- components creation is fully customizable by some events

**SelectedNodeObjectOnShow: TObject;**

*Creator may define this property to force a particular node to be selected at form showing*

**function** AddEditors(Node: TTreeNode; Obj: TObject; **const** aCustomCaption: **string**='';  
**const** aTitle: **string**=''): TTreeNode;

*Create corresponding nodes and components for updating Obj*

- to be used by OnComponentCreate(nil,nil,OptionsForm) in order to populate the object tree of this Form
- properties which name starts by '\_' are not added to the UI window
- published properties of parents of Obj are also added

**procedure** AddToolbars(Scroll: TScrollBox; **const** aToolbarName: **string**; aEnum:  
PTypeInfo; **const** aActionHints: **string**; aActionsBits: pointer; aProp: PPropInfo; Obj:  
TObject);

*Create corresponding checkboxes lists for a given action toolbar*

- aEnum points to the Action RTTI
- aActionHints is a multi line value containing the Hint captions for all available Actions
- if aActionsBits is not nil, its bits indicates the Buttons to appear in the list

## 27.71. mORMotUIQuery.pas unit

*Purpose:* Form handling queries to a User Interface Grid for mORMot

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *mORMotUIQuery* unit

| Unit Name            | Description                                                                                                                                                                                    | Page |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>        | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                               | 1907 |
| <i>mORMoti18n</i>    | Internationalization (i18n) routines and classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18         | 2332 |
| <i>mORMotUI</i>      | Grid to display database content for mORMot<br>- this unit is a part of the freeware mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                 | 2414 |
| <i>mORMotUILogin</i> | Some common User Interface functions and dialogs for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18         | 2428 |
| <i>SynCommons</i>    | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                      | 718  |
| <i>SynTaskDialog</i> | Implement TaskDialog window (native on Vista/Seven, emulated on XP)<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1832 |

*mORMotUIQuery class hierarchy*

### Objects implemented in the *mORMotUIQuery* unit

| Objects    | Description                                       | Page |
|------------|---------------------------------------------------|------|
| TQueryForm | This Form perform simple Visual queries to a Grid | 2435 |

**TQueryForm = class(TVistaForm)**

*This Form perform simple Visual queries to a Grid*

- mark or unmark items, depending of the input of the User on this form
- use TSQLRest.QueryIsTrue() method for standard fields and parameters
- use TSQLQueryCustom records previously registered to the TSQLRest class, by the TSQLRest.QueryAddCustom() method, to add some custom field search (e.g. to search into fields not available on the grid, or some data embedded inside a field - like .INI-like section entries)
- in practice, the query is very fast (immediate for standard fields and parameters), but can demand some bandwidth for custom field search (since data has to be retrieved from the server to search within)

**constructor** Create(aOwner: TComponent; aTableToGrid: TSQLTableToGrid);  
**reintroduce;**

*Create the window instance*

- all parameters (especially TSQLRest instance to use for custom search) are retrieved via the supplied TSQLTableToGrid
- caller must have used TSQLRest.QueryAddCustom() method to register some custom queries, if necessary

## 27.72. mORMotVCL.pas unit

*Purpose:* DB VCL dataset using TSQLTable/TSQLTableJSON data access

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *mORMotVCL* unit

| Unit Name                | Description                                                                                                                                                               | Page |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>            | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18          | 1907 |
| <i>SynCommons</i>        | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 718  |
| <i>SynVirtualDataSet</i> | DB VCL read-only virtual dataset<br>- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                      | 1848 |

*mORMotVCL class hierarchy*

### Objects implemented in the *mORMotVCL* unit

| Objects             | Description                                           | Page |
|---------------------|-------------------------------------------------------|------|
| TDBFieldDef         | Store low-level DB.pas field information              | 2438 |
| TSynSQLTableDataSet | Read-only virtual TDataSet able to access a TSQLTable | 2436 |

**TSynSQLTableDataSet = class(TSynVirtualDataSet)**

*Read-only virtual TDataSet able to access a TSQLTable*

**constructor** Create(Owner: TComponent; Table: TSQLTable ; ForceWideString: boolean=false); **reintroduce;**

*Initialize the virtual TDataSet from a TSQLTable*

- WARNING: the supplied TSQLTable instance shall remain available all the time the returned TSynSQLTableDataSet instance is used, unless the TableShouldBeFreed property is set to true or CreateOwnedTable() constructor is used instead
- with non-Unicode version of Delphi, you can set ForceWideString to force the use of WideString fields instead of AnsiString, if needed
- the TDataSet will be opened once created

**constructor** CreateFromJSON(Owner: TComponent; **const** JSON: RawUTF8; **const** ColumnTypes: **array of** TSQLFieldType ; ForceWideString: boolean=false); **reintroduce**; overload;

*Initialize the virtual TDataSet from a supplied JSON result*

- you can set the expected column types matching the results column layout
- this constructor will parse the supplied JSON content and create an internal TSQLTableJSON instance to process the data
- with non-Unicode version of Delphi, you can set ForceWideString to force the use of WideString fields instead of AnsiString, if needed
- the TDataSet will be opened once created

**constructor** CreateFromJSON(Owner: TComponent; **const** JSON: RawUTF8; **const** Tables: **array of** TSQLRecordClass ; ForceWideString: boolean=false); **reintroduce**; overload;

*Initialize the virtual TDataSet from a supplied JSON ORM result*

- you can set the TSQLRecord classes to retrieve the expected column types
- this constructor will parse the supplied JSON content and create an internal TSQLTableJSON instance to process the data
- with non-Unicode version of Delphi, you can set ForceWideString to force the use of WideString fields instead of AnsiString, if needed
- the TDataSet will be opened once created

**constructor** CreateFromJSON(Owner: TComponent; **const** JSON: RawUTF8 ; ForceWideString: boolean=false); **reintroduce**; overload;

*Initialize the virtual TDataSet from a supplied JSON result*

- this constructor will parse the supplied JSON content and create an internal TSQLTableJSON instance to process the data, guessing the column types from the JSON content
- with non-Unicode version of Delphi, you can set ForceWideString to force the use of WideString fields instead of AnsiString, if needed
- the TDataSet will be opened once created

**constructor** CreateOwnedTable(Owner: TComponent; Table: TSQLTable ; ForceWideString: boolean=false); **reintroduce**;

*Initialize the virtual TDataSet owning a TSQLTable*

- this constructor will set TableShouldBeFreed to TRUE
- with non-Unicode version of Delphi, you can set ForceWideString to force the use of WideString fields instead of AnsiString, if needed
- the TDataSet will be opened once created

**destructor** Destroy; **override**;

*Finalize the class instance*

**property** Table: TSQLTable **read** fTable **write** fTable;

*Access to the internal TSQLTable[JSON] data*

- you can use e.g. the SortFields() methods
- you may change the table content on the fly, if the column remains the same

**property** TableShouldBeFreed: boolean **read** fTableShouldBeFreed **write** fTableShouldBeFreed;

*If the supplied TSQLTable instance should be released with this class*

- Create() will left to FALSE (meaning that the TSQLTable instance shall remain available all the time the TSynSQLTableDataSet instance is used)
- CreateOwnedTable() will set to TRUE if you want the TSQLTable to be freed when this TSynSQLTableDataSet instance will be released
- you can also set it after Create(), on purpose

**TDBFieldDef = record**

*Store low-level DB.pas field information*

- as used by GetDBFieldDef and GetDBFieldValue

### Functions or procedures implemented in the *mORMotVCL* unit

| Functions or procedures | Description                                                                      | Page |
|-------------------------|----------------------------------------------------------------------------------|------|
| GetDBFieldDef           | Get low-level DB.pas field information                                           | 2438 |
| GetDBFieldValue         | Fill a DB.pas field content                                                      | 2438 |
| JSONTableToDataSet      | Convert a JSON ORM result into a VCL DataSet, following TSQLRecord field types   | 2438 |
| JSONToDataSet           | Convert a JSON result into a VCL DataSet, guessing the field types from the JSON | 2439 |
| JSONToDataSet           | Convert a JSON result into a VCL DataSet, with a given set of column types       | 2439 |

**procedure** GetDBFieldDef(aTable: TSQLTable; aField: integer; **out** DBFieldDef: TDBFieldDef; aForceWideString: boolean=false);

*Get low-level DB.pas field information*

- ready to be added to a TDataSet as:  
aDataSet.FieldDefs.Add(FieldName,DBType,DBSize);

**procedure** GetDBFieldValue(aTable: TSQLTable; aRow: integer; aField: TField; aDataSet: TDataSet; **const** DBFieldDef: TDBFieldDef);

*Fill a DB.pas field content*

- used e.g. by mORMotMidasVCL.ToClientDataSet

**function** JSONTableToDataSet(aOwner: TComponent; **const** aJSON: RawUTF8; **const** Tables: **array of** TSQLRecordClass ; aForceWideString: boolean=false): TSynSQLTableDataSet;

*Convert a JSON ORM result into a VCL DataSet, following TSQLRecord field types*

- this function is just a wrapper around TSynSQLTableDataSet.CreateFromJSON()
- with non-Unicode version of Delphi, you can set aForceWideString to force the use of WideString fields instead of AnsiString, if needed
- with Unicode version of Delphi (2009+), string/UnicodeString will be used

```
function JSONToDataSet(aOwner: TComponent; const aJSON: RawUTF8; const ColumnTypes:
array of TSQLFieldType ; aForceWideString: boolean=false): TSynSQLTableDataSet;
overload;
```

*Convert a JSON result into a VCL DataSet, with a given set of column types*

- this function is just a wrapper around TSynSQLTableDataSet.CreateFromJSON()
- with non-Unicode version of Delphi, you can set aForceWideString to force the use of WideString fields instead of AnsiString, if needed
- with Unicode version of Delphi (2009+), string/UnicodeString will be used

```
function JSONToDataSet(aOwner: TComponent; const aJSON: RawUTF8 ; aForceWideString:
boolean=false): TSynSQLTableDataSet; overload;
```

*Convert a JSON result into a VCL DataSet, guessing the field types from the JSON*

- this function is just a wrapper around TSynSQLTableDataSet.CreateFromJSON()
- with non-Unicode version of Delphi, you can set aForceWideString to force the use of WideString fields instead of AnsiString, if needed
- with Unicode version of Delphi (2009+), string/UnicodeString will be used

## 27.73. mORMotWrappers.pas unit

*Purpose:* Generate cross-platform clients code and documentation from a mORMot server

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *mORMotWrappers* unit

| Unit Name          | Description                                                                                                                                                                                             | Page |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>      | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                        | 1907 |
| <i>SynCommons</i>  | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                               | 718  |
| <i>SynLZ</i>       | SynLZ Compression routines<br>- licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                 | 1399 |
| <i>SynMustache</i> | Logic-less mustache template rendering<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                       | 1456 |
| <i>SynTable</i>    | Filter/database/cache/buffer/security/search/multithread/OS features<br>- as a complement to SynCommons, which tended to increase too much<br>- licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1728 |

### Types implemented in the *mORMotWrappers* unit

```
TOnCommandLineCall = procedure(aOptions: TServiceClientCommandLineOptions; const
aService: TInterfaceFactory; aMethod: PServiceMethod; var aParams: TSQLRestURIParams)
of object;
```

*Event handler to let ExecuteFromCommandLine call a remote server*

- before call, aParams.InBody will be set with the expected JSON content

```
TServiceClientCommandLineOptions = set of (cloPrompt, cloNoColor, cloPipe, cloHeaders,
cloVerbose, cloNoExpand, cloNoBody);
```

*The options retrieved during a ExecuteFromCommandLine() call*

### Constants implemented in the *mORMotWrappers* unit

```
EXECUTEFROMCOMMANDLINEHELP = ' % help -> show all services (interfaces)'#13#10 + ' %
[service] [help] -> show all methods of a given service'#13#10 + ' % [service] [method]
help -> show parameters of a given method'#13#10 + ' % [options] [service] [method]
[parameters] -> call a given method ' + 'with [parameters] being name=value or
name=""value with spaces"" or ' + 'name:={"some":"","json"}' + ' and [options] as
/nocolor /pipe /headers /verbose /noexpand /nobody';
```

*Help information displayed by ExecuteFromCommandLine() with no command*

```
WRAPPER_RESOURCENAME = 'WrappersDescription';
```

*Internal Resource name used for bounded description*

- as generated by FillDescriptionFromSource/ResourceDescriptionFromSource

- would be used e.g. by TWrapperContext.Create to inject the available text description from any

matching resource

## Functions or procedures implemented in the *mORMotWrappers* unit

| Functions or procedures       | Description                                                                                                                                   | Page |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|------|
| AddToServerWrapperMethod      | You can call this procedure to add a 'Wrapper' method-based service to a given server, to allow code-generation of an ORM and SOA client      | 2442 |
| ComputeFPCInterfacesUnit      | You can call this procedure to generate the mORMotInterfaces.pas unit needed to register all needed interface RTTI for FPC                    | 2442 |
| ComputeFPCServerUnit          | You can call this procedure to generate the mORMotServer.pas unit needed to compile a given server source code using FPC                      | 2442 |
| ContextFromMethod             | Compute the information of an interface method, ready to be exported as JSON                                                                  | 2442 |
| ContextFromMethods            | Compute the information of an interface, ready to be exported as JSON                                                                         | 2442 |
| ContextFromModel              | Compute the Model information, ready to be exported as JSON                                                                                   | 2443 |
| ExecuteFromCommandLine        | Command-line SOA remote access to mORMot interface-based services                                                                             | 2443 |
| FillDescriptionFromSource     | Rough parsing of the supplied .pas unit, adding the /// commentaries into a TDocVariant content                                               | 2443 |
| GenerateAsynchServices        | This function would generate a pascal unit defining asynchronous (non-blocking) types from a DDD's blocking dual-phase Select/Command service | 2443 |
| ResourceDescriptionFromSource | Rough parsing of the supplied .pas unit, adding the /// commentaries into a compressed binary resource                                        | 2444 |
| WrapperFakeServer             | Instantiate a TSQLRest server instance, including supplied ORM and SOA definitions                                                            | 2444 |
| WrapperForPublicAPI           | Generate a code/doc wrapper for a given set of types and Mustache template content                                                            | 2444 |
| WrapperFromModel              | Generate a code/doc wrapper for a given Model and Mustache template content                                                                   | 2445 |
| WrapperMethod                 | You can call this procedure within a method-based service allow code-generation of an ORM and SOA client from a web browser                   | 2445 |

```
procedure AddToServerWrapperMethod(Server: TSQLRestServer; const Path: array of TFileName; const SourcePath: TFileName='');
```

*You can call this procedure to add a 'Wrapper' method-based service to a given server, to allow code-generation of an ORM and SOA client*

- you have to specify one or several client \*.mustache file paths
- the first path containing any \*.mustache file will be used as templates
- if no path is specified (i.e. as []), it will search in the .exe folder
- the root/wrapper URI will be accessible without authentication (i.e. from any plain browser)
- for instance:

```
aServer := TSQLRestServerFullMemory.Create(aModel, 'test.json', false, true);
AddToServerWrapperMethod(aServer, ['..']);
```

- optional SourcePath parameter may be used to retrieve additional description from the comments of the source code of the unit

```
procedure ComputeFPCInterfacesUnit(const Path: array of TFileName; DestFileName: TFileName='');
```

*You can call this procedure to generate the mORMotInterfaces.pas unit needed to register all needed interface RTTI for FPC*

- to circumvent <http://bugs.freepascal.org/view.php?id=26774> unresolved issue
- will locate FPC-mORMotInterfaces.pas.mustache in the given Path[] array
- will write the unit using specified file name or to mORMotInterfaces.pas in the current directory if DestFileName is "", or to a sub-folder of the matching Path[] if DestFileName starts with '\' (to allow relative folder use)
- all used interfaces will be exported, including SOA and mocking/stubing types: so you may have to run this function AFTER all process is done

```
procedure ComputeFPCServerUnit(Server: TSQLRestServer; const Path: array of TFileName; DestFileName: TFileName='');
```

*You can call this procedure to generate the mORMotServer.pas unit needed to compile a given server source code using FPC*

- will locate FPCServer-mORMotServer.pas.mustache in the given Path[] array
- will write the unit using specified file name or to mORMotServer.pas in the current directory if DestFileName is "", or to a sub-folder of the matching Path[] if DestFileName starts with '\' (to allow relative folder use)
- the missing RTTI for records and interfaces would be defined, together with some patch comments for published record support (if any) for the ORM

```
function ContextFromMethod(const method: TServiceMethod): variant;
```

*Compute the information of an interface method, ready to be exported as JSON*

- to be used e.g. for the implementation of the MVC controller via interfaces
- no description text will be included - use ContextFromModel() if needed

```
function ContextFromMethods(int: TInterfaceFactory): variant;
```

*Compute the information of an interface, ready to be exported as JSON*

- to be used e.g. for the implementation of the MVC controller via interfaces
- no description text will be included - use ContextFromModel() if needed

```
function ContextFromModel(aServer: TSQLRestServer; const aSourcePath: TFileName='';

const aDescriptions: TFileName=''): variant;
```

*Compute the Model information, ready to be exported as JSON*

- will publish the ORM and SOA properties
- to be used e.g. for client code generation via Mustache templates
- optional aSourcePath parameter may be used to retrieve additional description from the comments of the source code of the unit - this text content may also be injected by WRAPPER\_RESOURCE\_NAME
- you may specify a description file (as generated by FillDescriptionFromSource)

```
procedure ExecuteFromCommandLine(const aServices: array of TGUID; const aOnCall:

TOnCommandLineCall; const aDescriptions: TFileName = '');;
```

*Command-line SOA remote access to mORMot interface-based services*

- supports the following EXECUTEFROMCOMMANDLINEHELP commands
- you shall have registered the aServices interface(s) by a previous call to the overloaded Get(TypeInfo(IMyInterface)) method or RegisterInterfaces()
- you may specify an optional description file, as previously generated by mORMotWrappers' FillDescriptionFromSource function - a local 'WrappersDescription' resource will also be checked
- to actually call the remote server, aOnGetClient should be supplied

```
procedure FillDescriptionFromSource(var Descriptions: TDocVariantData; const

SourceFileName: TFileName);
```

*Rough parsing of the supplied .pas unit, adding the /// commentaries into a TDocVariant content*

```
function GenerateAsynchServices(const services: array of TGUID; const queries: array of TClass;

const units: array of const; const additionalcontext: array of const;

Template, FileName, ProjectName, CallType, CallFunction, Key, KeyType, ExceptionType:

RawUTF8; DefaultDelay: integer; const CustomDelays: array of const): RawUTF8;
```

*This function would generate a pascal unit defining asynchronous (non-blocking) types from a DDD's blocking dual-phase Select/Command service*

- you should specify the services to be converted, as an array - note that due to how RTTI is stored by the compiler, all "pure input" parameters should be defined explicitly as "const", otherwise the generated class won't match
- optionally, the TCQRSServiceClass implementing the first Select() phase of the blocking service may be specified in queries array; a set of unit names in which those TCQRSServiceClass are defined may be specified
- a Mustache template content should be provided - e.g. asynch.pas.mustache as published in SQLite3\DDD\dom folder of the source code repository
- FileName would contain the resulting unit filename (without the .pas)
- ProjectName would be written in the main unit comment
- CallType should be the type used at Domain level to identify each asynchronous call - this type should be an integer, or a function may be supplied as CallFunction (matching VariantToInteger signature)
- the first phase of the service should have set Key: KeyType, which would be used to create a single shared asynchronous service instance for all keys
- ExceptionType may be customize, mainly to use a Domain-specific class
- blocking execution may reach some timeout waiting for the asynchronous acknowledgement: a default delay (in ms) is to be supplied, and some custom delays may be specified as trios, e.g. ['IMyInterface', 'Method', 10000, ...]

**function** ResourceDescriptionFromSource(**const** ResourceDestFileName: TFileName; **const** SourceFileNames: **array of** TFileName; **const** JsonDestFileName: TFileName = ''): **variant**;

*Rough parsing of the supplied .pas unit, adding the /// commentaries into a compressed binary resource*

- could be then compiled into a WRAPPER\_RESOURCENAME resource, e.g. via the following .rc source file, assuming ResourceDestFileName='wrapper.desc':

```
WrappersDescription 10 "wrapper.desc"
```

- you may specify a .json file name, for debugging/validation purposes
- calls internally FillDescriptionFromSource
- returns the TDocVariant JSON object corresponding to all descriptions

**function** WrapperFakeServer(**const** aTables: **array of** TSQLRecordClass; **const** aRoot: RawUTF8; **const** aSharedServices: **array of** TGUID; **const** aSharedServicesContract: **array of** RawUTF8; aResultAsJSONObjectWithoutResult: boolean): TSQLRestServerFullMemory;

*Instantiate a TSQLRest server instance, including supplied ORM and SOA definitions*

- will use aTables[] to define the ORM information, and supplied aSharedServices[] aSharedServicesContract[] for SOA definition of a shared API, implemented as abstract classes using TInterfaceStub
- as used e.g. by WrapperForPublicAPI() to generate some code/doc wrappers

**function** WrapperForPublicAPI(**const** aTables: **array of** TSQLRecordClass; **const** aRoot, aMustacheTemplate, aFileName: RawUTF8; **const** aSharedServices: **array of** TGUID; **const** aSharedServicesContract: **array of** RawUTF8; aResultAsJSONObjectWithoutResult: boolean; aPort: integer; aHelpers: TSynMustacheHelpers=nil; aContext: PVariant=nil; **const** aDescriptions: TFileName=''): RawUTF8;

*Generate a code/doc wrapper for a given set of types and Mustache template content*

- will use aTables[] to define the ORM information, and supplied aSharedServices[] aSharedServicesContract[] for SOA definition of a shared API (expected to be called from TSQLRestClientURI.ServiceDefineSharedAPI)
- aFileName will be transmitted as {{filename}}, e.g. 'mORMotClient'
- you should also specify a "fake" HTTP port e.g. 888
- the template content could be retrieved from a file via StringFromFile()
- you may optionally retrieve a copy of the data context as TDocVariant
- this function may be used to generate the client at build time, directly from a just built server, in an automated manner
- you may specify custom helpers (e.g. via TSynMustache.HelpersGetStandardList) and retrieve the generated data context after generation (if aContext is a TDocVariant object, its fields would be added to the rendering context), or a custom description file (as generated by FillDescriptionFromSource)

```
function WrapperFromModel(aServer: TSQLRestServer; const aMustacheTemplate,
aFileName: RawUTF8; aPort: integer; aHelpers: TSynMustacheHelpers=nil; aContext:
PVariant=nil; const aDescriptions: TFileName=''): RawUTF8;
```

*Generate a code/doc wrapper for a given Model and Mustache template content*

- will use all ORM and SOA properties of the supplied server
- aFileName will be transmitted as {{filename}}, e.g. 'mORMotClient'
- you should also specify a "fake" HTTP port e.g. 888
- the template content could be retrieved from a file via StringFromFile()
- you may optionally retrieve a copy of the data context as TDocVariant
- this function may be used to generate the client at build time, directly from a just built server, in an automated manner
- you may specify custom helpers (e.g. via TSynMustache.HelpersGetStandardList) and retrieve the generated data context after generation (if aContext is a TDocVariant object, its fields would be added to the rendering context), or a custom description file (as generated by FillDescriptionFromSource)

```
procedure WrapperMethod(Ctxt: TSQLRestServerURIContext; const Path: array of
TFileName; const SourcePath: TFileName=''; const Descriptions: TFileName='');
```

*You can call this procedure within a method-based service allow code-generation of an ORM and SOA client from a web browser*

- you have to specify one or several client \*.mustache file paths
- the first path containing any \*.mustache file will be used as templates
- for instance:

```
procedure TCustomServer.Wrapper(Ctxt: TSQLRestServerURIContext);
begin // search in the current path
 WrapperMethod(Ctxt,['.']);
end;
```

- optional SourcePath parameter may be used to retrieve additional description from the comments of the source code of the unit
- you may specify a description file (as generated by FillDescriptionFromSource)

### Variables implemented in the *mORMotWrappers* unit

```
DESCRIPTION_ITEM_PREFIX: RawUTF8 = ' [*]';
```

*How FillDescriptionFromSource() handles trailing '-' in parsed comments*

- default is [\*], as expected by buggy AsciiDoc format

## 27.74. TestSQL3FPCInterfaces.pas unit

*Purpose:* SOA interface methods definition to circumvent FPC missing RTTI

- generated at 2016-06-14 13:49:41

### Units used in the *TestSQL3FPCInterfaces* unit

| Unit Name                   | Description                                                                                                                                                                                             | Page |

| <i>SynTable</i>             | Filter/database/cache/buffer/security/search/multithread/OS features<br>- as a complement to SynCommons, which tended to increase too much<br>- licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1728 |

## 27.75. dddDomAuthInterfaces.pas unit

*Purpose:* Shared DDD Domains: Authentication objects and interfaces

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *dddDomAuthInterfaces* unit

| Unit Name         | Description                                                                                                                                                               | Page |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>     | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18          | 1907 |
| <i>mORMotDDD</i>  | Domain-Driven-Design toolbox for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18        | 2295 |
| <i>SynCommons</i> | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 718  |

*dddDomAuthInterfaces class hierarchy*

### Objects implemented in the *dddDomAuthInterfaces* unit

| Objects         | Description                                                              | Page |
|-----------------|--------------------------------------------------------------------------|------|
| IDomAuthCommand | Repository service to update or register new authentication credentials  | 2448 |
| IDomAuthQuery   | Repository service to authenticate credentials via a dual pass challenge | 2447 |
| TAuthInfo       | DDD entity used to store authentication information                      | 2447 |

```
TAuthInfo = class(TSynPersistent)
```

*DDD entity used to store authentication information*

```
property LogonName: TAuthInfoName read fLogonName write fLogonName;
```

*The textual identifier by which the user would recognize himself*

```
IDomAuthQuery = interface(ICQRSService)
```

*Repository service to authenticate credentials via a dual pass challenge*

```
function ChallengeSelectFinal(const aChallengedPassword: TAuthQueryNonce):
TCQRSResult;
```

*Validate the first phase of a dual pass challenge authentication*

**function** ChallengeSelectFirst(**const** aLogonName: RawUTF8): TAuthQueryNonce;

*Initiate the first phase of a dual pass challenge authentication*

**function** Get(**out** aAggregate: TAuthInfo): TCQRSResult;

*Retrieve some information about the current selected credential*

**function** Logged: boolean;

*Returns TRUE if the dual pass challenge did succeed*

**function** LogonName: RawUTF8;

*Returns the logon name of the authenticated user*

**function** SelectByName(**const** aLogonName: RawUTF8): TCQRSResult;

*Set the credential for Get() or further IAuthCommand.Update/Delete*  
- this method execution will be disabled for most clients

IDomAuthCommand = **interface**(IDomAuthQuery)

*Repository service to update or register new authentication credentials*

**function** Add(**const** aLogonName: RawUTF8; aHashedPassword: TAuthQueryNonce): TCQRSResult;

*Register a new credential, from its LogonName/HashedPassword values*  
- aHashedPassword should match the algorithm expected by the actual implementation class, over UTF-8 encoded LogonName+'.'+Password  
- on success, the newly created credential will be the currently selected

**function** Commit: TCQRSResult;

*Write all pending changes prepared by Add/UpdatePassword/Delete methods*

**function** Delete: TCQRSResult;

*Delete the current selected credential*  
- this method execution will be disabled for most clients

**function** UpdatePassword(**const** aHashedPassword: TAuthQueryNonce): TCQRSResult;

*Update the current selected credential password*  
- aHashedPassword should match the algorithm expected by the actual implementation class, over UTF-8 encoded LogonName+'.'+Password  
- will be allowed only for the current challenged user

### Types implemented in the *dddDomAuthInterfaces* unit

TAuthQueryNonce = RawUTF8;

*The data type which will be returned during a password challenge*  
- in practice, will be e.g. Base-64 encoded SHA-256 binary hash

## 27.76. dddDomCountry.pas unit

*Purpose:* Shared DDD Domains: TCountry object definition

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *dddDomCountry* unit

| Unit Name         | Description                                                                                                                                                               | Page |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>     | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18          | 1907 |
| <i>mORMotDDD</i>  | Domain-Driven-Design toolbox for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18        | 2295 |
| <i>SynCommons</i> | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 718  |
| <i>SynTests</i>   | Unit test functions used by Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18   | 1840 |

*dddDomCountry class hierarchy*

### Objects implemented in the *dddDomCountry* unit

| Objects  | Description                         | Page |
|----------|-------------------------------------|------|
| TCountry | Defines a Country identifier object | 2449 |

**TCountry = class(TSynPersistent)**

*Defines a Country identifier object*

- will store internally the country as 16-bit ISO 3166-1 numeric value
- includes conversion methods for ISO 3166-1 alpha-2/alpha-3/numeric codes as explained in [http://en.wikipedia.org/wiki/ISO\\_3166-1](http://en.wikipedia.org/wiki/ISO_3166-1)
- see also some low-level class methods for direct values conversions with no persistence

**function** Equals(another: TCountry): boolean; **reintroduce;**

*Returns TRUE if both Country instances have the same content*

- slightly faster than global function ObjectEquals(self,another)

**class function** FromAlpha2(const alpha: TCountryIsoAlpha2): TCountryIdentifier;

*Low-level Country conversion from its alpha-2 code*

- returns ccUndefined if the supplied text has no case-insensitive match

**class function** FromAlpha3(const alpha: TCountryIsoAlpha3): TCountryIdentifier;

*Low-level Country conversion from its alpha-3 code*

- returns ccUndefined if the supplied Text has no case-insensitive match

**class function** FromEnglish(const text: RawUTF8): TCountryIdentifier;

*Low-level case-insensitive Country conversion from its plain English text*

- returns ccUndefined if the supplied Text has no case-insensitive match

**class function** FromIso(iso: TCountryIsoNumeric): TCountryIdentifier;

*Low-level Country conversion from its alpha-2 code*

- returns ccUndefined if the supplied 16-bit number as no match

**class function** ToAlpha2(id: TCountryIdentifier): TCountryIsoAlpha2;

*Low-level Country conversion into its alpha-2 code*

**class function** ToAlpha3(id: TCountryIdentifier): TCountryIsoAlpha3;

*Low-level Country conversion into its alpha-3 code*

**class function** ToEnglish(id: TCountryIdentifier): RawUTF8;

*Low-level Country conversion into its plain English text*

**class function** ToIso(id: TCountryIdentifier): TCountryIsoNumeric;

*Low-level Country conversion to its ISO 3166-1 numeric 3-digit code*

**class procedure** RegressionTests(test: TSynTestCase);

*Built-in simple unit tests*

**property** Alpha2: TCountryIsoAlpha2 read GetIsoAlpha2 write SetIsoAlpha2;

*The ISO 3166-1 alpha-2 code of this country*

**property** Alpha3: TCountryIsoAlpha3 read GetIsoAlpha3 write SetIsoAlpha3;

*The ISO 3166-1 alpha-3 code of this countr*

**property** English: RawUTF8 read GetEnglish;

*Plain English text of this country, e.g. 'France' or 'United States'*

**property** Identifier: TCountryIdentifier read GetIdentifier write SetIdentifier;

*Internal enumerate corresponding to this country*

**property** Iso: TCountryIsoNumeric read fIso write fIso;

*The stored and transmitted value is this ISO 3166-1 numeric 3-digit code*

## Types implemented in the dddDomCountry unit

TCountryIdentifier = ( ccUndefined, ccAF, ccAX, ccAL, ccDZ, ccAS, ccAD, ccAO, ccAI, ccAQ, ccAG, ccAR, ccAM, ccAW, ccAU, ccAT, ccAZ, ccBS, ccBH, ccBD, ccBB, ccBY, ccBE, ccBZ, ccBJ, ccBM, ccBT, ccBO, ccBQ, ccBA, ccBW, ccBV, ccBR, ccIO, ccBN, ccBG, ccBF, ccBI, ccKH, ccCM, ccCA, ccCV, ccKY, ccCF, ccTD, ccCL, ccCN, ccCX, ccCC, ccCO, ccKM, ccCG, ccCD, ccCK, ccCR, ccCI, ccHR, ccCU, ccCW, ccCY, ccCZ, ccDK, ccDJ, ccDM, ccDO, ccEC, ccEG, ccSV, ccGQ, ccER, ccEE, ccET, ccFK, ccFO, ccFJ, ccFI, ccFR, ccGF, ccPF, ccTF, ccGA, ccGM, ccGE, ccDE, ccGH, ccGI, ccGR, ccGL, ccGD, ccGP, ccGU, ccGT, ccGG, ccGN, ccGW, ccGY, ccHT, ccHM, ccVA, ccHN, ccHK, ccHU, ccIS, ccIN, ccID, ccIR, ccIQ, ccIE, ccIM, ccIL, ccIT, ccJM, ccJP, ccJE, ccJO, ccKZ, ccKE, ccKI, ccKP, ccKR, ccKW, ccKG, ccLA, ccLV, ccLB, ccLS, ccLR, ccLY, ccLI, ccLT, ccLU, ccMO, ccMK, ccMG, ccMW, ccMY, ccMV, ccML, ccMT, ccMH, ccMQ, ccMR, ccMU, ccYT, ccMX, ccFM, ccMD, ccMC, ccMN, ccME, ccMS, ccMA, ccMZ, ccMM, ccNA, ccNR, ccNP, ccNL, ccNC, ccNZ, ccNI, ccNE, ccNG, ccNU, ccNF, ccMP, ccNO, ccOM, ccPK, ccPW, ccPS, ccPA, ccPG, ccPY, ccPE,

```
ccPH, ccPN, ccPL, ccPT, ccPR, ccQA, ccRE, ccRO, ccRU, ccRW, ccBL, ccSH, ccKN, ccLC, ccMF,
ccPM, ccVC, ccWS, ccSM, ccST, ccSA, ccSN, ccRS, ccSC, ccSL, ccSG, ccSX, ccSK, ccSI, ccSB,
ccSO, ccZA, ccGS, ccSS, ccES, ccLK, ccSD, ccSR, ccSJ, ccSZ, ccSE, ccCH, ccSY, ccTW, ccTJ,
ccTZ, ccTH, ccTL, ccTG, ccTK, ccTO, ccTT, ccTN, ccTR, ccTM, ccTC, ccTV, ccUG, ccUA, ccAE,
ccGB, ccUS, ccUM, ccUY, ccUZ, ccVU, ccVE, ccVN, ccVG, ccVI, ccWF, ccEH, ccYE, ccZM, ccZW
);
```

*Country identifiers, following ISO 3166-1 standard*

```
TCountryIsoAlpha2 = type RawUTF8;
```

*Store ISO 3166-1 alpha-2 code*

```
TCountryIsoAlpha3 = type RawUTF8;
```

*Store ISO 3166-1 alpha-3 code*

```
TCountryIsoNumeric = type word;
```

*Store a ISO 3166-1 numeric value as 16-bit unsigned integer*

## 27.77. dddDomUserCQRS.pas unit

*Purpose:* Shared DDD Domains: User CQRS Repository interfaces

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *dddDomUserCQRS* unit

| Unit Name              | Description                                                                                                                                                               | Page |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>dddDomUserTypes</i> | Shared DDD Domains: User objects definition<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18    | 2457 |
| <i>mORMot</i>          | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18          | 1907 |
| <i>mORMotDDD</i>       | Domain-Driven-Design toolbox for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18        | 2295 |
| <i>SynCommons</i>      | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 718  |

*dddDomUserCQRS class hierarchy*

### Objects implemented in the *dddDomUserCQRS* unit

| Objects         | Description                                                           | Page |
|-----------------|-----------------------------------------------------------------------|------|
| IDomUserCommand | Defines an abstract CQRS Repository for Writing TUser Aggregate Roots | 2453 |
| IDomUserQuery   | Defines an abstract CQRS Repository for Reading TUser Aggregate Roots | 2452 |

**IDomUserQuery = interface(ICQRSservice)**

*Defines an abstract CQRS Repository for Reading TUser Aggregate Roots*

- this interface allows only read access to the Aggregate: see IDomUserCommand to modify the content

- you could use SelectByLogonName, SelectByLastName or SelectByEmailValidation methods to initialize a request, then call Get, GetAll or GetNext to retrieve the actual matching Aggregate Roots

**function** Get(out aAggregate: TUser): TCQRSResult;

*Retrieve a single TUser*

**function** GetAll(**out** aAggregates: TUserObjArray): TCQRSResult;

*Retrieve all matching TUser instances*

- the caller should release all returned TUser by calling  
ObjArrayClear(aAggregates);

**function** GetCount: integer;

*Retrieve how many TUser instances do match the selection*

**function** GetNext(**out** aAggregate: TUser): TCQRSResult;

*Retrieve the next matching TUser instances*

- returns cQRSNoMoreData if there is no more pending data

**function** HowManyValidatedEmail: integer;

*Retrieve how many TUser have their email validated*

**function** SelectAll: TCQRSResult;

*Would select all TUser instances*

- you should not use this search criteria, since it may return a huge number of values
- then use GetCount, GetAll() or GetNext() methods to retrieve the items

**function** SelectByEmailValidation(aValidationState: TDomUserEmailValidation): TCQRSResult;

*Would select one or several TUser from their email validation state*

- then use GetCount, GetAll() or GetNext() methods to retrieve the items

**function** SelectByLastName(**const** aName: TLastName; aStartWith: boolean): TCQRSResult;

*Would select one or several TUser from their last name*

- will search for a full matching name, unless aStartWith is TRUE so that it would search for the beginning characters
- then use GetCount, GetAll() or GetNext() methods to retrieve the items

**function** SelectByLogonName(**const** aLogonName: RawUTF8): TCQRSResult;

*Would select a single TUser from its logon name*

- then use Get() method to retrieve its content

IDomUserCommand = **interface**(IDomUserQuery)

*Defines an abstract CQRS Repository for Writing TUser Aggregate Roots*

- would implement a dual-phase commit to change TUser content
- first phase consists in calling Add, Update, Delete or DeleteAll methods which would call the registered validators on the supplied content
- you can call Add, Update, Delete or DeleteAll methods several times, so that several write operations will be recorded for the TUser
- during the first phase, nothing is actually written to the persistence storage itself (which may be a RDBMS or a NoSQL engine)
- then the second phase would take place when the Commit method would be executed, which would save all prepared content to the actual storage engine (e.g. using a transaction via a BATCH process if implemented by mORMot's ORM, via TInfraRepoUser as defined in dddInfraRepoUser)

```
function Add(const aAggregate: TUser): TCQRSResult;
```

*Persist a new TUser aggregate*

```
function Commit: TCQRSResult;
```

*Write all pending changes prepared by Add/Update/Delete methods*

- following the dual-phase pattern, nothing would be written to the actual persistence store unless this method is actually called

```
function Delete: TCQRSResult;
```

*Erase an existing TUser aggregate*

- the existing content should have been retrieved by a previous Select\* method, e.g. IDomUserQuery.SelectByLogonName

```
function DeleteAll: TCQRSResult;
```

*Erase existing TUser aggregate, matching a*

- the existing content should have been retrieved by a previous Select\* method, e.g. IDomUserQuery.SelectByLogonName: a plain DeleteAll call with no prious Select\* would return an error

```
function Rollback: TCQRSResult;
```

*Flush any pending changes prepared by Add/Update/Delete methods*

- is the same as releasing the actual IDomUserCommand instance and creating a new one

```
function Update(const aUpdatedAggregate: TUser): TCQRSResult;
```

*Update an existing TUser aggregate*

- the existing content should have been retrieved by a previous Select\* method, e.g. IDomUserQuery.SelectByLogonName

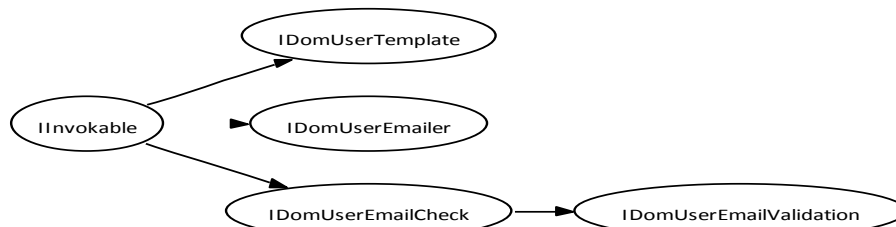

## 27.78. dddDomUserInterfaces.pas unit

*Purpose:* Shared DDD Domains: User interfaces definition

- this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *dddDomUserInterfaces* unit

| Unit Name              | Description                                                                                                                                                               | Page |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>dddDomUserTypes</i> | Shared DDD Domains: User objects definition<br>- this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18    | 2457 |
| <i>mORMot</i>          | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18          | 1907 |
| <i>mORMotDDD</i>       | Domain-Driven-Design toolbox for mORMot<br>- this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18        | 2295 |
| <i>SynCommons</i>      | Common functions used by most Synapse projects<br>- this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 718  |

*dddDomUserInterfaces class hierarchy*

### Objects implemented in the *dddDomUserInterfaces* unit

| Objects                 | Description                                                                 | Page |
|-------------------------|-----------------------------------------------------------------------------|------|
| IDomUserEmailCheck      | Defines a service able to check the correctness of email addresses          | 2455 |
| IDomUserEmailer         | Defines a generic service able to send emails                               | 2456 |
| IDomUserEmailValidation | Defines a service sending a confirmation email to validate an email address | 2456 |
| IDomUserTemplate        | Defines a service for generic rendering of a template                       | 2456 |

**IDomUserEmailCheck = interface(IInvokable)**

*Defines a service able to check the correctness of email addresses*

- will be implemented e.g. by TDDDEmailServiceAbstract and TDDDEmailValidationService as defined in the dddInfraEmail unit

```
function CheckRecipient(const aEmail: RawUTF8): TCQRSResult;
```

*Check if the supplied email address seems correct*

```
function CheckRecipients(const aEmails: TRawUTF8DynArray): TCQRSResult;
```

*Check if the supplied email addresses seem correct*

```
IDomUserEmailValidation = interface(IDomUserEmailCheck)
```

*Defines a service sending a confirmation email to validate an email address*

- will be implemented e.g. by TDDDEmailValidationService as defined in the dddInfraEmail unit

```
function ComputeURIForReply(const aLogonName, aEmail: RawUTF8): RawUTF8;
```

*Internal method used to compute the validation URI*

- will be included as data context to the email template, to create the validation link

```
function StartEmailValidation(const aTemplate: TDomUserEmailTemplate; const
aLogonName, aEmail: RawUTF8): TCQRSResult;
```

*Initiate an email validation process, using the given template*

```
IDomUserEmailer = interface(IInvokable)
```

*Defines a generic service able to send emails*

- will be implemented e.g. by TDDDEmailerDaemon as defined in the dddInfraEmailer unit

```
IDomUserTemplate = interface(IInvokable)
```

*Defines a service for generic rendering of a template*

- will be implemented e.g. via our SynMustache engine by TDDDDTemplateAbstract and  
TDDDDTemplateFromFolder as defined in the dddInfraEmailer unit

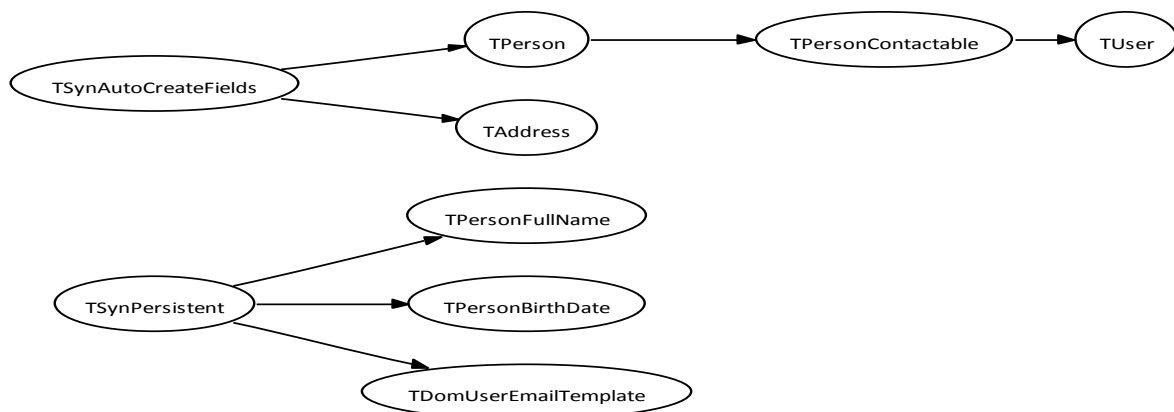

## 27.79. dddDomUserTypes.pas unit

*Purpose:* Shared DDD Domains: User objects definition

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *dddDomUserTypes* unit

| Unit Name            | Description                                                                                                                                                               | Page |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>dddDomCountry</i> | Shared DDD Domains: TCountry object definition<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 2449 |
| <i>mORMot</i>        | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18          | 1907 |
| <i>mORMotDDD</i>     | Domain-Driven-Design toolbox for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18        | 2295 |
| <i>SynCommons</i>    | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 718  |
| <i>SynTests</i>      | Unit test functions used by Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18   | 1840 |

*dddDomUserTypes class hierarchy*

### Objects implemented in the *dddDomUserTypes* unit

| Objects               | Description                                                              | Page |
|-----------------------|--------------------------------------------------------------------------|------|
| TAddress              | Address object                                                           | 2458 |
| TDomUserEmailTemplate | How a confirmation email is to be rendered, for email address validation | 2458 |

| Objects            | Description                                                               | Page |
|--------------------|---------------------------------------------------------------------------|------|
| TPerson            | Person object                                                             | 2458 |
| TPersonBirthDate   | Person birth date                                                         | 2458 |
| TPersonContactable | A Person object, with some contact information                            | 2458 |
| TPersonFullName    | Person full name                                                          | 2458 |
| TUser              | An application level-user, whose account would be authenticated per Email | 2459 |

**TAddress = class(TSynAutoCreateFields)**

*Address object*

- we tried to follow a simple but worldwide layout - see

[http://en.wikipedia.org/wiki/Address\\_%28geography%29#Address\\_format](http://en.wikipedia.org/wiki/Address_%28geography%29#Address_format)

**TPersonFullName = class(TSynPersistent)**

*Person full name*

**TPersonBirthDate = class(TSynPersistent)**

*Person birth date*

**TPerson = class(TSynAutoCreateFields)**

*Person object*

**TPersonContactable = class(TPerson)**

*A Person object, with some contact information*

- an User is a person, in the context of an application

**class procedure** RegressionTests(test: TSynTestCase);

*Built-in simple unit tests*

**TDomUserEmailTemplate = class(TSynPersistent)**

*How a confirmation email is to be rendered, for email address validation*

- this information will be available as data context, e.g. to the Mustache template used for rendering of the email body

**property** Application: RawUTF8 read fApplication write fApplication;

*The name of the application, currently sending the confirmation*

**property** FileName: RawUTF8 read fFileName write fFileName;

*The local file name of the Mustache template*

**property** Info: variant read fInfo write fInfo;

*Any unstructured additional information, also supplied as data context*

**property** SenderEmail: RawUTF8 read fSenderEmail write fSenderEmail;

*The "sender" field of the validation email*

```
property Subject: RawUTF8 read fSubject write fSubject;
```

*The "subject" field of the validation email*

```
TUser = class(TPersonContactable)
```

*An application level-user, whose account would be authenticated per Email*

```
property EmailValidated: TDomUserEmailValidation read fEmailValidated write
fEmailValidated;
```

*Will reflect the current state of email validation process for this user*

- the validation is not handled by this class: this is just a property which reflects the state of  
TDDDEmailValidationService/IDomUserEmailValidation

```
property LogonName: TLogonName read fLogonName write fLogonName;
```

*The logon name would be the main entry point to the application*

#### **Types implemented in the *dddDomUserTypes* unit**

```
TDomUserEmailValidation = (evUnknown, evValidated, evFailed);
```

*The status of an email validation process*

## 27.80. dddInfraApps.pas unit

*Purpose:* Shared DDD Infrastructure: Application/Daemon implementation classes

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *dddInfraApps* unit

| Unit Name               | Description                                                                                                                                                                                                                                                                                                                                   | Page |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>dddInfraSettings</i> | Shared DDD Infrastructure: Application/Daemon settings classes<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                     | 2487 |
| <i>mORMot</i>           | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                              | 1907 |
| <i>mORMotDDD</i>        | Domain-Driven-Design toolbox for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                            | 2295 |
| <i>mORMotHttpClient</i> | HTTP/1.1 RESTful JSON Client classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                    | 2316 |
| <i>mORMotHttpServer</i> | HTTP/1.1 RESTFUL JSON Server classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                    | 2323 |
| <i>mORMotService</i>    | Daemon management classes for mORMot, including low-level Win NT Service<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                           | 2380 |
| <i>SynBidirSock</i>     | Implements bidirectional client and server protocol, e.g. WebSockets<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                               | 681  |
| <i>SynCommons</i>       | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                     | 718  |
| <i>SynCrtSock</i>       | Classes implementing TCP/UDP/HTTP client and server protocol<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                       | 1086 |
| <i>SynCrypto</i>        | Fast cryptographic routines (hashing and cypher)<br>- implements<br>AES,XOR,ADLER32,MD5,RC4,SHA1,SHA256,SHA384,SHA512,SHA3 and JWT<br>- optimized for speed (tuned assembler and SSE3/SSE4/AES-NI/PADLOCK support)<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1143 |

| Unit Name       | Description                                                                                                                                                                                             | Page |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>SynEcc</i>   | Certificate-based public-key cryptography using ECC-secp256r1<br>- this unit is a part of the freeware Synopse mORMot framework,<br>licensed under a MPL/GPL/LGPL tri-license; version 1.18             | 1318 |
| <i>SynLog</i>   | Logging functions used by Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework,<br>licensed under a MPL/GPL/LGPL tri-license; version 1.18                                | 1368 |
| <i>SynTable</i> | Filter/database/cache/buffer/security/search/multithread/OS features<br>- as a complement to SynCommons, which tended to increase too much<br>- licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1728 |

*dddInfraApps class hierarchy*

### Objects implemented in the *dddInfraApps* unit

| Objects | Description | Page |
|---------|-------------|------|
|---------|-------------|------|

| Objects                    | Description                                                                                                      | Page |
|----------------------------|------------------------------------------------------------------------------------------------------------------|------|
| EDDDMockedSocket           | The default exception class raised by TDDDMockedException                                                        | 2467 |
| EDDDRestClient             | Exception raised by TDDDDRestClientSettings classes                                                              | 2463 |
| IDDDSocket                 | Interface allowing to customize/mock a socket connection                                                         | 2465 |
| TDDDMockedException        | Implements IDDDSocket using a fake/mockedException in-memory input/output storage                                | 2467 |
| TDDDDRestClientDefinition  | Advanced parameters for TDDDDRestClientSettings definition                                                       | 2463 |
| TDDDDRestClientHttp        | Abstract client to connect to any daemon service via HTTP or HTTPS                                               | 2465 |
| TDDDDRestClientSettings    | Storage class for initializing an ORM/SOA REST Client class                                                      | 2464 |
| TDDDDRestClientWebSockets  | Abstract client to connect to any daemon service via WebSockets                                                  | 2465 |
| TDDDDRestDaemon            | Abstract class to implement a IAdministratedDaemon service via a TSQLRestServer                                  | 2463 |
| TDDDDRestHttpDaemon        | Abstract class to implement a IAdministratedDaemon service via a TSQLRestServer, publishing its services as HTTP | 2463 |
| TDDDSocketThread           | A generic TThread able to connect and reconnect to a TCP server                                                  | 2469 |
| TDDDSocketThreadMonitoring | The monitoring information of a TDDDSocketThread thread                                                          | 2465 |
| TDDDSynCrtSocket           | Implements IDDDSocket using a SynCrtSocket.TCrtSocket instance                                                   | 2466 |
| TDDDDThreadDaemon          | Abstract class to implement a IAdministratedDaemon service via a TThread                                         | 2462 |

**TDDDDThreadDaemon = class(TDDDDAdministratedThreadDaemon)**

*Abstract class to implement a IAdministratedDaemon service via a TThread*  
- as hosted by TDDDDDaemon service/daemon application

**procedure** SubscribeLog(**const** Levels: TSynLogInfos; **const** Callback: ISynLogCallback; ReceiveExistingKB: cardinal); **override**;

*IAdministratedDaemon command to subscribe to a set of events for real-time remote monitoring of the specified log events*

- this overridden method would disallow remote logs if low-level frames logging is set (i.e. HttpClientFullWebSocketsLog / HttpServerFullWebSocketsLog) to avoid an unexpected race condition

**property** AdministrationHTTPServer: TSQLHttpServer **read** GetAdministrationHTTPServer;

*Reference to the HTTP server publishing IAdministratedDaemon service*  
- may equal nil if TDDDDAdministratedDaemonSettingsFile.AuthHttp.BindPort=""

**TDDRestDaemon = class(TDDAdministratedRestDaemon)**

*Abstract class to implement a IAdministratedDaemon service via a TSQLRestServer*

- as hosted by TDDDaemon service/daemon application

**procedure** SubscribeLog(**const** Levels: TSynLogInfos; **const** Callback: ISynLogCallback;  
 ReceiveExistingKB: cardinal); **override**;

*AdministratedDaemon command to subscribe to a set of events for real-time remote monitoring of the specified log events*

- this overridden method would disallow remote logs if low-level frames logging is set (i.e. HttpClientFullWebSocketsLog / HttpServerFullWebSocketsLog) to avoid an unexpected race condition

**property** AdministrationHTTPServer: TSQLHttpServer **read**  
 GetAdministrationHTTPServer;

*Reference to the HTTP server publishing IAdministratedDaemon service*

- may equal nil if TDDAdministratedDaemonSettingsFile.AuthHttp.BindPort=""

**TDDRestHttpDaemon = class(TDDRestDaemon)**

*Abstract class to implement a IAdministratedDaemon service via a TSQLRestServer, publishing its services as HTTP*

- as hosted by TDDDaemon service/daemon application

**procedure** WrapperGenerate(**const** DestFile: TFileName; **const** Template: TFileName =  
 'API.adoc.mustache');

*Generate API documentation corresponding to REST SOA interfaces*

**property** HttpServer: TSQLHttpServer **read** fHttpServer;

*Reference to the main HTTP server publishing this daemon Services*

- may be nil outside a Start..Stop range

**property** ServicesLogRest: TSQLRest **read** fServicesLogRest;

*Reference to the associated REST server storing the SOA log database*

- may be nil if the daemon did not implement this feature

**EDDRestClient = class(EDDException)**

*Exception raised by TDDRestClientSettings classes*

**TDDRestClientDefinition = class(TSynPersistentWithPassword)**

*Advanced parameters for TDDRestClientSettings definition*

**property** ConnectRetrySeconds: integer **read** fConnectRetrySeconds **write**  
 fConnectRetrySeconds;

*How many seconds the client may try to connect after open socket failure*

**property** Root: RawUTF8 **read** fRoot **write** fRoot;

*The URI Root to be used for the REST Model*

**property** WebSocketsPassword: RawUTF8 **read** fPassWord **write** fPassWord;

*The encrypted password to be used to connect with WebSockets*

**TDDRestClientSettings = class(TSynAutoCreateFields)**

*Storage class for initializing an ORM/SOA REST Client class*

- this class will contain some generic properties to initialize a TSQLRestClientURI pointing to a remote server, using WebSockets by default
- WebSockets support is the reason why this class is defined in dddInfraApps, and not dddInfraSettings

**function** NewRestClientInstance(aRootSettings: TDDAppSettingsAbstract; aModel: TSQLModel = nil; aOptions: TDDNewRestInstanceOptions = [riOwnModel, riCreateVoidModelIfNone, riHandleAuthentication, riRaiseExceptionIfNoRest]): TSQLRestClientURI; **virtual**;

*Is able to instantiate a Client REST instance for the stored definition*

- Definition.Kind is expected to specify a TSQLRestClient class to be instantiated, not a TSQLRestServer instance
- will return nil if the supplied Definition is not correct
- note that the supplied Model.Root is expected to be the default root URI, which will be overridden with this TDDRestSettings.Root property
- will also set the TSQLRest.LogFamily.Level from LogLevels value,

**function** OnAuthenticationFailed(Retry: integer; var aUserName, aPassword: string; out aPasswordHashed: boolean): boolean;

*You may assign this method to a TSQLRestClientURI.OnAuthenticationFailed property, so that the client would automatically try to re-connect*

**procedure** SetDefaults(const Root, Port, WebSocketPassword, UserPassword: RawUTF8; const User: RawUTF8 = 'User'; const Server: RawUTF8 = 'localhost'; ForceSetCredentials: boolean = false; ConnectRetrySeconds: integer = 0; WebSocketsLoopDelayMS: integer = 0);

*Set the default values for Client.Root, ORM.ServerName, Client.WebSocketsPassword and ORM.Password*

**property** Client: TDDRestClientDefinition **read** fClient;

*Advanced connection options*

- ORM.Password defines the authentication main password, and Client.WebSocketsPassword is used for WebSockets binary encryption

**property** ORM: TSynConnectionDefinition **read** fORM;

*Defines a mean of access to a TSQLRest instance*

- using Kind/ServerName/DatabaseName/User/Password properties: Kind would define the TSQLRest class to be instantiated by NewRestClientInstance()

**property** Timeout: integer **read** fTimeout **write** fTimeout;

*You can overload here the TCP timeout delay, in seconds*

**property** WebSocketsLoopDelay: integer **read** fWebSocketsLoopDelay **write** fWebSocketsLoopDelay;

*You can overload here the WebSockets internal loop delay, in milliseconds*

**TDDRestClientWebSockets = class(TSQLHttpClientWebsockets)**

*Abstract client to connect to any daemon service via WebSockets*

- will monitor the connection, to allow automatic reconnection, with proper services resubscription

**constructor** Create(aSettings: TDDRestClientSettings; aOnConnect: TOnRestClientNotify = nil; aOnDisconnect: TOnRestClientNotify = nil); **reintroduce;**  
**overload; virtual;**

*Initialize the client instance with the supplied settings*

**destructor** Destroy; **override;**

*Finalize the client instance*

**property** ApplicationName: RawUTF8 **read** fApplicationName;

*Human-friendly application name, as set by overridden DefineApplication*

**property** ApplicationVersion: RawUTF8 **read** GetSessionVersion;

*Returns the server version, using timestamp/info method-based service*

**property** Connected: boolean **read** fConnected;

*Reflects the current WebSockets connection state*

**TDDRestClientHttp = class(TSQLHttpClient)**

*Abstract client to connect to any daemon service via HTTP or HTTPS*

- defines a simple REST client, without connection tracking

**property** ApplicationName: RawUTF8 **read** fApplicationName;

*Human-friendly application name, as set by overridden DefineApplication*

**property** ApplicationVersion: RawUTF8 **read** GetSessionVersion;

*Returns the server version, using timestamp/info method-based service*

**TDDSocketThreadMonitoring = class(TDDAdministratedDaemonMonitor)**

*The monitoring information of a TDDSocketThread thread*

**property** Owner: TObject **read** fOwner **write** fOwner;

*May be a TDDSocketThread instance, or not (to maintain a global state over several threads)*

**property** Socket: variant **read** GetSocket;

*Information about the associated socket*

**property** State: TDDSocketThreadState **read** fState **write** fState;

*How this thread is currently connected to its associated TCP server*

**IDDDSocket = interface(IIInterface)**

*Interface allowing to customize/mock a socket connection*

**function** DataIn(Content: PAnsiChar; ContentLength: integer): integer;

*Get Length bytes from the (mocked) socket*

- returns the number of bytes read into the Content buffer
- call e.g. TCrtSocket.SockInRead() method

**function** DataInPending(aTimeOut: integer): integer;

*Returns the number of bytes pending in the (mocked) socket*

- call e.g. TCrtSocket.SockInPending() with aSocketForceCheck=true, to return bytes both in the instance memory buffer and the socket API

**function** DataOut(Content: PAnsiChar; ContentLength: integer): boolean;

*Send Length bytes to the (mocked) socket*

- returns false on any error, true on success
- call e.g. TCrtSocket.TrySndLow() method

**function** Handle: integer;

*Returns the low-level handle of this connection*

- is e.g. the socket file description

**function** Identifier: RawUTF8;

*Returns instance identifier*

- e.g. the TCrtSocket.Sock number as text

**function** LastError: RawUTF8;

*Get some low-level information about the last occurred error*

- e.g. TCrtSocket.LastLowSocketError value

**procedure** Connect;

*Connect to the host via the (mocked) socket*

- should raise an exception on error

**TDDDSynCrtSocket = class(TInterfacedObjectLocked)**

*Implements IDDDSocket using a SynCrtSock.TCrtSocket instance*

- used e.g. by TDDDSocketThread for its default network communication
- this class will also create two mutexes, one for DataIn/DataInPending, another for DataOut thread-safe process

**constructor** Create(aOwner: TThread; const aHost, aPort: SockString; aSocketTimeout, aInternalBufferSize: integer); reintroduce; virtual;

*Input lock is TInterfacedObjectLocked.Safe initialize the internal TCrtSocket instance*

**destructor** Destroy; override;

*Finalize the internal TCrtSocket instance*

**function** DataIn(Content: PAnsiChar; ContentLength: integer): integer;

*Call TCrtSocket.SockInRead() method*

**function** DataInPending(aTimeOut: integer): integer;

*Call TCrtSocket.SockInPending() method*

- with aSocketForceCheck=true, to return bytes both in the instance memory buffer and the socket API

**function** DataOut(Content: PAnsiChar; ContentLength: integer): boolean;

*Call TCrtSocket.TrySndLow() method*

**function** Handle: integer;

*Returns TCrtsocket.Sock*

**function** Identifier: RawUTF8;

*Returns TCrtSocket.Sock number as text*

**function** LastError: RawUTF8;

*Get information from TCrtSocket.LastLowSocketError*

**procedure** Connect;

*Call TCrtSocket.OpenBind*

**property** Owner: TThread **read** fOwner;

*Read-only access to the associated processing thread*

- not published, to avoid stack overflow since TDDDSocketThreadMonitoring would point to this instance

**property** Socket: TCrtSocket **read** fSocket;

*Read-only access to the associated processing socket*

**EDDDMockedSocket = class**(EDDDInfraException)

*The default exception class raised by TDDDMockedSocket*

**TDDDMockedSocket = class**(TInterfacedObjectLocked)

*Implements IDDDSocket using a fake/mocked in-memory input/output storage*

- may be supplied to TDDDSocketThread to bypass its default network communication
- you could fake input/output of TCP/IP packets by calling MockDataIn() and MockDataOut() methods - incoming and outgoing packets would be merged in the internal in-memory buffers, as with a regular Socket
- you could fake exception, for any upcoming method call, via MockException()
- you could emulate network latency, for any upcoming method call, via MockLatency() - to emulate remote/wireless access, or thread pool contention
- this implementation is thread-safe, so multiple threads could access the same IDDDSocket instance, and settings be changed in real time

**constructor** Create(aOwner: TThread); **reintroduce**; **virtual**;

*Initialize the mocked socket instance*

**function** DataIn(Content: PAnsiChar; ContentLength: integer): integer;

*IDDDSocket method to get Length bytes from the mocked socket*

- returns the number of bytes read into the Content buffer
- note that all pending data is returned as once, i.e. all previous calls to MockDataIn() would be gathered in a single buffer

**function** DataInPending(aTimeOut: integer): integer;

*IDDDSocket method to return the number of bytes pending*

- note that the total length of all pending data is returned as once, i.e. all previous calls to MockDataIn() would be sum as a single count
- this method will emulate blocking process, just like a regular socket: if there is no pending data, it will wait up to aTimeOut milliseconds

**function** DataOut(Content: PAnsiChar; ContentLength: integer): boolean;

*IDDDSocket method to send Length bytes to the mocked socket*

- returns false on any error, true on success
- then MockDataOut could be used to retrieve the sent data

**function** Handle: integer;

*Returns 0 (no associated file descriptor)*

**function** Identifier: RawUTF8;

*IDDDSocket method to return a fake instance identifier*

- in fact, the hexa pointer of the TDDDMockedSocket instance

**function** LastError: RawUTF8;

*IDDDSocket method to get some low-level information about the last error*

- i.e. the latest ExceptionMessage value as set by MockException()

**function** MockDataOut: RawByteString;

*Return the bytes from the internal fake output storage*

- as has be previously set by the DataOut() method
- will gather all data from several DataOut() calls in a single buffer

**procedure** Connect;

*IDDDSocket method to connect to the host via the mocked socket*

- won't raise any exception unless ConnectShouldCheckRaiseException is set

**procedure** MockDataIn(const Content: RawByteString);

*Add some bytes to the internal fake input storage*

- would be made accessible to the DataInPending/DataIn methods
- the supplied buffer would be gathered to any previous MockDataIn() call, which has not been read yet by the DataIn() method

**procedure** MockException(NextActions: TDDDMockedSocketExceptions; **const** ExceptionMessage: **string** = ''; ExceptionClass: ExceptClass = **nil**);

*The specified methods would raise an exception*

- only a single registration is memorized: once raised, any further method execution would continue as usual
- optional Exception.Message which should be raised with the exception
- also optional exception class instead of default EDDDMockedSocket
- msaDataOutReturnsFalse won't raise any exception, but let DataOut method return false (which is the normal way of indicating a socket error) - in this case, ExceptionMessage would be available from LastError
- msaDataInPendingTimeout won't raise any exception, but let DataInPending sleep for the timeout period, and return 0
- msaDataInPendingFails won't raise any exception, but let DataInPending fails immediately, and return -1 (emulating a broken socket)
- you may use ALL\_DDDMOCKED\_EXCEPTIONS to set all possible actions
- you could reset any previous registered exception by calling MockException([]);

**procedure** MockLatency(NextActions: TDDDMockedSocketLatencies; MilliSeconds: **integer**);

*Will let the specified methods to wait for a given number of milliseconds*

- allow to emulate network latency, on purpose
- you may use ALL\_DDDMOCKED\_LATENCIES to slow down all possible actions

**property** Owner: TThread **read** fOwner;

*Read-only access to the associated processing thread*

- not published, to avoid stack overflow since TDDDSocketThreadMonitoring would point to this instance

**property** PendingInBytes: **integer** **read** GetPendingInBytes;

*How many bytes are actually in the internal input buffer*

**property** PendingOutBytes: **integer** **read** GetPendingOutBytes;

*How many bytes are actually in the internal output buffer*

TDDDSocketThread = **class**(TSQLRestThread)

*A generic TThread able to connect and reconnect to a TCP server*

- initialize and own a TCrtSocket instance for TCP transmission
- allow automatic reconnection
- inherit from TSQLRestThread, so should be associated with a REST instance

**constructor** Create(aSettings: TDDDSocketThreadSettings; aRest: TSQLRest; aMonitoring: TDDDSocketThreadMonitoring);

*Initialize the thread for a given REST instance*

**destructor** Destroy; **override**;

*Finalize the thread process, and its associated REST instance*

**function** StatsAsJson: RawUTF8;

*Returns the Monitoring and Rest statistics as a JSON object*  
 - resulting format is  
 {...MonitoringProperties..., "Rest": {...RestStats...}}

**procedure** Shutdown(andTerminate: boolean); **virtual**;

*Will pause any communication with the associated socket*  
 - could be used before stopping the service for cleaner shutdown

**property** Host: SockString **read** fHost;

*The IP Host name used to connect with TCP*

**property** Port: SockString **read** fPort;

*The IP Port value used to connect with TCP*

**property** Settings: TDDDSocketThreadSettings **read** fSettings;

*The parameters used to setup this thread process*

### Types implemented in the *dddInfraApps* unit

TDDDMockedSocketException = ( msaConnectRaiseException, msaDataInPendingTimeout, msaDataInPendingFails, msaDataInRaiseException, msaDataOutRaiseException, msaDataOutReturnsFalse );

*Defines the potential mocked actions for TDDDMockedSocket.MockException()*

TDDDMockedSocketExceptions = **set of** TDDDMockedSocketException;

*Defines a set of mocked actions for TDDDMockedSocket.MockException()*

TDDDMockedSocketLatencies = **set of** TDDDMockedSocketLatency;

*Defines a set of mocked actions for TDDDMockedSocket.MockLatency()*

TDDDMockedSocketLatency = ( mslConnect, mslDataIn, mslDataOut );

*Defines the potential mocked actions for TDDDMockedSocket.MockLatency()*

TDDDSocketThreadState = ( tpsDisconnected, tpsConnecting, tpsConnected );

*The current connection state of the TCP client associated to a TDDDSocketThread thread*

TECCAAuthorize = ( eaSuccess, eaInvalidSecret, eaMissingUnlockFile, eaInvalidUnlockFile, eaInvalidJson );

*Result codes of the ECCAAuthorize() function*

### Constants implemented in the *dddInfraApps* unit

ALL\_DDDMOCKED\_EXCEPTIONS = [msaConnectRaiseException, msaDataInPendingFails, msaDataInRaiseException, msaDataOutReturnsFalse];

*Map realistic exceptions steps for a mocked socket*  
 - could be used to simulate a global socket connection drop

ALL\_DDDMOCKED\_LATENCIES =  
 [Low(TDDDMockedSocketLatency)..high(TDDDMockedSocketLatency)];

*Map realistic latencies steps for a mocked socket*  
 - could be used to simulate a slow network

EXEVERSION\_RCTEMPLATE: RawUTF8 = '1 VERSIONINFO'#13#10 + 'FILEVERSION

```

*A Mustache template of a .rc version information*

- could be used to compile a custom .res version file in an automated way
- if you use this generated .res, ensure your "Version Info" is disabled (unchecked) in the Delphi IDE project options

#### Functions or procedures implemented in the **dddInfraApps** unit

| Functions or procedures   | Description                                                                                                                                                                      | Page |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| AdministratedDaemonClient | Create a client safe asynchronous connection to a IAdministratedDaemon service                                                                                                   | 2471 |
| AdministratedDaemonServer | Create a WebSockets server instance, publishing a IAdministratedDaemon service                                                                                                   | 2471 |
| ECCAuthorize              | Any sensitive, or licensed program, could call this method to check for authorized execution for a given user on a given computer, using very secure asymmetric ECC cryptography | 2472 |

**function** AdministratedDaemonClient(Definition: TDDRestClientSettings; Model: TSQLModel = nil): TSQLHttpClientWebsockets;

*Create a client safe asynchronous connection to a IAdministratedDaemon service*

**function** AdministratedDaemonServer(Settings: TDDAdministratedDaemonSettings; DaemonClass: TDDAdministratedDaemonClass): TDDAdministratedDaemon;

*Create a WebSockets server instance, publishing a IAdministratedDaemon service*

```
function ECCAuthorize(aContent: TObject; aSecretDays: integer; const aSecretPass,
aDPAPI, aDecryptSalt, aAppLockPublic64: RawUTF8; const aSearchFolder: TFileName = '';
aSecretInfo: PECCCertificateSigned = nil; aLocalFile: PFileName = nil):
TECCAuthorize;
```

*Any sensitive, or licensed program, could call this method to check for authorized execution for a given user on a given computer, using very secure asymmetric ECC cryptography*

- applock.public/.private keys pair should have been generated, applock.public stored as aAppLockPublic64 in the executables, and applock.private kept secret
- will search for encrypted authorization in a local user@host.unlock file
- if no user@host.unlock file is found, will create local user@host.public and user@host.secret files and return eaMissingUnlockFile: user should then send user@host.public to the product support to receive its user@host.unlock file (a dedicated UI may be developed, or an unencrypted email can be used for transfer with the support team, thanks to asymmetric cryptography)
- local user@host.secret file is encrypted via DPAPI/CryptDataForCurrentUser for the specific computer and user (to avoid .unlock reuse on another PC)
- support team should create a user@host.json file matching aContent: TObject published properties, containing all application-specific settings and authorization scope; then it could create the unlock file using e.g. an unlock.bat file running the ECC tool over secret applock.private keys:

```
@echo off
echo Usage: unlock user@host
echo.
ecc sign -file %1.json -auth applock -pass applockprivatepassword -rounds 60000
ecc crypt -file %1.json -out %1.unlock -auth %1 -saltpass decryptsalt -saltrounds 10000
del %1.json.sign
```

- returns eaInvalidUnlockFile if the local user@host.unlock file is not correctly signed and encrypted for this user (e.g. corrupted or deprecated)
- eaInvalidJson will indicate some error in the .json created by support team, i.e. if it does not match aContent: TObject published properties
- eaSuccess should let the application execute, on the returned scope
- returns eaSuccess if a local user@host.unlock file has been successfully decrypted and validated (using ECDSA over aAppLockPublic64) and successfully unserialized from JSON into aContent object instance
- user@host.\* files are searched in the executable folder if aSearchFolder="", but you may specify a custom location, e.g. use ECCKeyFileFolder
- aSecretPass could be entered by the end-user, to authenticate its identity; you may specify a string constant if local applock.public/.private key files is enough secure for your application
- will use the supplied aDPAPI/aDecryptSalt parameters to restrict this authorization to a specific product (i.e. isolate the execution context to reduce forensic scope), for dedicated applock.public/.private keys pair - just pass some application-specific string constant to those parameters
- aSecretInfo^ could be set to retrieve the user@host.secret information (e.g. validity dates), and aLocalFile^ the '<fullpath>user@host' file prefix

### Variables implemented in the *dddInfraApps* unit

```
GlobalCopyright: string = '';
```

*You could set a text to this global variable at runtime, so that it would be displayed as copyright older name for the console*

## 27.81. dddInfraAuthRest.pas unit

**Purpose:** Shared DDD Infrastructure: Authentication implementation

- this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *dddInfraAuthRest* unit

| Unit Name                   | Description                                                                                                                                                                                                                                                                                                                                         | Page |

*dddInfraAuthRest class hierarchy*

### Objects implemented in the *dddInfraAuthRest* unit

| Objects | Description | Page |
|---------|-------------|------|
|---------|-------------|------|

| Objects                               | Description                                                                                              | Page |
|---------------------------------------|----------------------------------------------------------------------------------------------------------|------|
| TDDDAuthenticationAbstract            | Generic class for implementing authentication                                                            | 2474 |
| TDDDAuthenticationMD5                 | Implements authentication using MD5 hashing                                                              | 2475 |
| TDDDAuthenticationRestFactoryAbstract | Abstract factory of IDomAuthCommand repository instances using REST                                      | 2475 |
| TDDDAuthenticationRestFactoryMD5      | Factory of IDomAuthCommand repository instances using a RESTful ORM access and SHA-256 hashing algorithm | 2476 |
| TDDDAuthenticationRestFactorySHA256   | Factory of IDomAuthCommand repository instances using a RESTful ORM access and SHA-256 hashing algorithm | 2475 |
| TDDDAuthenticationSHA256              | Implements authentication using SHA-256 hashing                                                          | 2475 |
| TSQLRecordUserAuth                    | ORM object to persist authentication information, i.e. TAuthInfo                                         | 2474 |

**TSQLRecordUserAuth = class(TSQLRecord)**

*ORM object to persist authentication information, i.e. TAuthInfo*

**property** HashedPassword: RawUTF8 **read** fHashedPassword **write** fHashedPassword;

*The password, stored in a hashed form*

- this property does not exist at TAuthInfo level, so will be private to the storage layer - which is the safest option possible

**property** Logon: RawUTF8 **read** fLogon **write** fLogon **stored** AS\_UNIQUE;

*Will map TAuthInfo.LogonName*

- is defined as "stored AS\_UNIQUE" so that it may be used as primary key

**TDDDAuthenticationAbstract = class(TDDDDepositoryRestCommand)**

*Generic class for implementing authentication*

- do not instantiate this abstract class, but e.g. TDDDAuthenticationSHA256 or TDDDAuthenticationMD5

**function** Add(**const** aLogonName: RawUTF8; aHashedPassword: TAuthQueryNonce): TCQRSResult;

*Register a new credential, from its LogonName/HashedPassword values*

- on success, the newly created credential will be the currently selected

**function** ChallengeSelectFinal(**const** aChallengedPassword: TAuthQueryNonce): TCQRSResult;

*Validate the first phase of a dual pass challenge authentication*

**function** ChallengeSelectFirst(**const** aLogonName: RawUTF8): TAuthQueryNonce;

*Initiate the first phase of a dual pass challenge authentication*

```
class function ClientComputeChallengedPassword(const aLogonName,aPlainPassword:
RawUTF8; const aChallengeFromServer: TAuthQueryNonce): TAuthQueryNonce; virtual;
```

*Class method to be used on the client side to resolve the challenge*

- is basically

```
result := DoHash(aLogonName+'':'+aChallengeFromServer+'':'+
ComputeHashPassword(aLogonName,aPlainPassword));
```

```
class function ComputeHashPassword(const aLogonName,aPassword: RawUTF8):
TAuthQueryNonce;
```

*Class method to be used to compute a password hash from its plain value*

```
function Get(out aAggregate: TAuthInfo): TCQRSResult;
```

*Retrieve some information about the current selected credential*

```
function Logged: boolean;
```

*Returns TRUE if the dual pass challenge did succeed*

```
function LogonName: RawUTF8;
```

*Returns the logon name of the authenticated user*

```
function SelectByName(const aLogonName: RawUTF8): TCQRSResult;
```

*Set the credential for Get() or further IDomAuthCommand.Update/Delete*

- this method execution will be disabled for most clients

```
function UpdatePassword(const aHashedPassword: TAuthQueryNonce): TCQRSResult;
```

*Update the current selected credential password*

```
class procedure RegressionTests(test: TSynTestCase);
```

*Built-in simple unit tests*

```
TDDDAuthenticationSHA256 = class(TDDDAuthenticationAbstract)
```

*Implements authentication using SHA-256 hashing*

- more secure than TDDDAuthenticationMD5

```
TDDDAuthenticationMD5 = class(TDDDAuthenticationAbstract)
```

*Implements authentication using MD5 hashing*

- less secure than TDDDAuthenticationSHA256

```
TDDDAuthenticationRestFactoryAbstract = class(TDDDDepositoryRestFactory)
```

*Abstract factory of IDomAuthCommand repository instances using REST*

```
constructor Create(aRest: TSQLRest; aImplementationClass: TDDDAuthenticationClass;
aOwner: TDDDDepositoryRestManager); reintroduce;
```

*Initialize a factory with the supplied implementation algorithm*

```
TDDDAuthenticationRestFactorySHA256 =
class(TDDDAuthenticationRestFactoryAbstract)
```

*Factory of IDomAuthCommand repository instances using a RESTful ORM access and SHA-256 hashing algorithm*

```
constructor Create(aRest: TSQLRest; aOwner: TDDRepositoryRestManager=nil);
reintroduce;
```

*Initialize a factory with the SHA-256 implementation algorithm*

```
TDDDAuthenticationRestFactoryMD5 =
class(TDDDAuthenticationRestFactoryAbstract)
```

*Factory of IDomAuthCommand repository instances using a RESTful ORM access and SHA-256 hashing algorithm*

```
constructor Create(aRest: TSQLRest; aOwner: TDDRepositoryRestManager=nil);
reintroduce;
```

*Initialize a factory with the SHA-256 implementation algorithm*

### Types implemented in the *dddInfraAuthRest* unit

```
TDDDAuthenticationClass = class of TDDDAuthenticationAbstract;
```

*Allows to specify which actual hashing algorithm would be used*

- i.e. either TDDDAuthenticationSHA256 or TDDDAuthenticationMD5

## 27.82. dddInfraEmail.pas unit

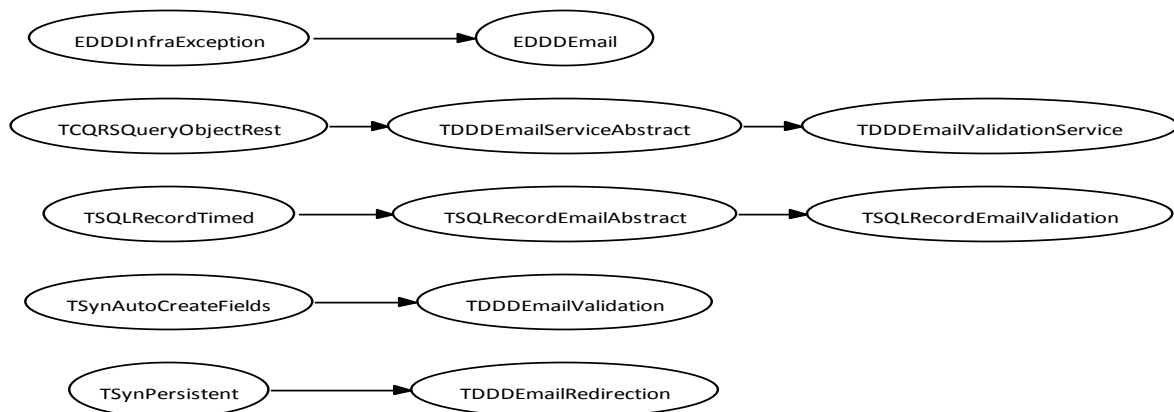

*Purpose:* Shared DDD Infrastructure: implement an email validation service

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *dddInfraEmail* unit

| Unit Name                   | Description                                                                                                                                                                                                                                                                                                                                         | Page |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>dddDomUserInterfaces</i> | Shared DDD Domains: User interfaces definition<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                           | 2455 |
| <i>dddDomUserTypes</i>      | Shared DDD Domains: User objects definition<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                              | 2457 |
| <i>mORMot</i>               | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                                    | 1907 |
| <i>mORMotDDD</i>            | Domain-Driven-Design toolbox for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                                  | 2295 |
| <i>SynCommons</i>           | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                           | 718  |

| <i>SynTable</i>             | Filter/database/cache/buffer/security/search/multithread/OS features<br>- as a complement to SynCommons, which tended to increase too much<br>- licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                             | 1728 |
| <i>SynTests</i>             | Unit test functions used by Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                             | 1840 |

*dddInfraEmail class hierarchy*

### Objects implemented in the *dddInfraEmail* unit

| Objects                    | Description                                                                           | Page |
|----------------------------|---------------------------------------------------------------------------------------|------|
| EDDDEmail                  | Exception raised during any email process of this DDD's infrastructure implementation | 2478 |
| TDDDEmailRedirection       | Parameters used for the validation link of an email address                           | 2478 |
| TDDDEmailServiceAbstract   | Abstract parent of any email-related service                                          | 2479 |
| TDDDEmailValidation        | Parameters used for the validation/verification process of an email address           | 2479 |
| TDDDEmailValidationService | Service used to validate an email address via an URL link to be clicked               | 2479 |
| TSQLRecordEmailAbstract    | ORM class storing an email in addition to creation/modification timestamps            | 2480 |
| TSQLRecordEmailValidation  | ORM class for email validation process                                                | 2480 |

**EDDDEmail = class(EDDDInfraException)**

*Exception raised during any email process of this DDD's infrastructure implementation*

**TDDDEmailRedirection = class(TSynPersistent)**

*Parameters used for the validation link of an email address*

- may be stored as daemon/service level settings, using e.g. dddInfraSettings

**property** RestServerPublicRootURI: RawUTF8 **read** fRestServerPublicRootURI **write** fRestServerPublicRootURI;

*The public URI which would be accessible from the Internet*

- may be e.g 'http://publicserver/restroot'

**property** SuccessRedirectURI: RawUTF8 read fSuccessRedirectURI write fSuccessRedirectURI;

*The URI on which the browser will be redirected on validation success*

- you can specify some '%' parameter markers, ordered as logon, email, and validation IP
- may be e.g. 'http://publicwebsite/success&logon=%'

**property** ValidationMethodName: RawUTF8 read fValidationMethodName write fValidationMethodName;

*The validation method name for the URI*

- if not set, TDDDEmailValidationService will use 'EmailValidate'
- clickable URI would be RestServerPublicRootURI+'/' + ValidationMethodName

**TDDDEmailValidation = class**(TSynAutoCreateFields)

*Parameters used for the validation/verification process of an email address*

- may be stored as daemon/service level settings, using e.g. dddInfraSettings

**procedure** SetDefaultValuesIfVoid(const aSenderEmail, aApplication, aRedirectionURIPublicRoot, aRedirectionURISuccess: RawUTF8);

*Will fill some default values in the properties, if none is set*

**property** Redirection: TDDDEmailRedirection read fRedirection;

*Parameters defining the validation link of an email address*

**property** Template: TDomUserEmailTemplate read fTemplate;

*How the email should be created from a given template*

**property** TemplateFolder: TFileName read fTemplateFolder write fTemplateFolder;

*Where the template files are to be found*

**TDDDEmailServiceAbstract = class**(TCQRSQueryObjectRest)

*Abstract parent of any email-related service*

- will define some common methods to validate an email address

**property** EmailValidate: TSynValidate read fEmailValidate write SetEmailValidate;

*Direct access to the email validation instance*

- you can customize the default TSynValidateEmail to meet your own expectations - once set, it will be owned by this class instance

**TDDDEmailValidationService = class**(TDDDEmailServiceAbstract)

*Service used to validate an email address via an URL link to be clicked*

**constructor** Create(aRest: TSQLRest); **override**;

*Initialize the validation service for a given ORM persistence*

- would recognize the TSQLRecordEmailValidation class from aRest.Model
- will use aRest.Services for IoC, e.g. EMailer/Template properties

**function** ComputeURIForReply(const aLogonName, aEmail: RawUTF8): RawUTF8;

*Compute the target URI corresponding to SetURIForServer() parameters*

**function** IsEmailValidated(const aLogonName,aEmail: RawUTF8): boolean; **virtual**;

*Check if an email has been validated for a given logon*

**function** StartEmailValidation(const aTemplate: TDomUserEmailTemplate; const aLogonName,aEmail: RawUTF8): TCQRSResult; **virtual**;

*Check the supplied parameters, and send an email for validation*

**procedure** SetURIForServer(aRestServerPublic: TSQLRestServer; aParams: TDDDEmailRedirection); **overload**;

*Register the callback URI service*

**procedure** SetURIForServer(aRestServerPublic: TSQLRestServer; const aRestServerPublicRootURI,aSuccessRedirectURI,aValidationMethodName: RawUTF8); **overload**;

*Register the callback URI service*

- same as the overloaded function, but taking parameters one by one

**property** EMailer: IDomUserMailer **read** fMailer;

*Will be injected (and freed) with the emailer service*

**property** RestClass: TSQLRecordEmailValidationClass **read** fRestClass;

*The associated ORM class used to store the email validation process*

- any class inheriting from TSQLRecordEmailValidation in the aRest.Model will be recognized by Create(aRest) to store its information

- this temporary storage should not be the main user persistence domain

**property** Template: IDomUserTemplate **read** fTemplate;

*Will be injected (and freed) with the email template service*

**property** ValidationServerRoot: RawUTF8 **read** fValidationServerRoot;

*The public URI which would be accessible from the Internet*

- may be e.g 'http://publicserver/restroot'

**property** ValidationURI: RawUTF8 **read** fValidationMethodName;

*The validation method name for the URI*

- if not set, TDDDEmailValidationService will use 'EmailValidate'

- clickable URI would be ValidationServerRoot+'/' + ValidationMethodName

**TSQLRecordEmailAbstract = class**(TSQLRecordTimed)

*ORM class storing an email in addition to creation/modification timestamps*

- declared as its own class, since may be reused

**property** Email: RawUTF8 **read** fEmail **write** fEmail;

*The stored email address*

**TSQLRecordEmailValidation = class**(TSQLRecordEmailAbstract)

*ORM class for email validation process*

- we do not create a whole domain here, just an ORM persistence layer

- any class inheriting from TSQLRecordEmailValidation in the Rest.Model will be recognized by TDDDEmailValidationService to store its information

## 27.83. dddInfraEmailer.pas unit

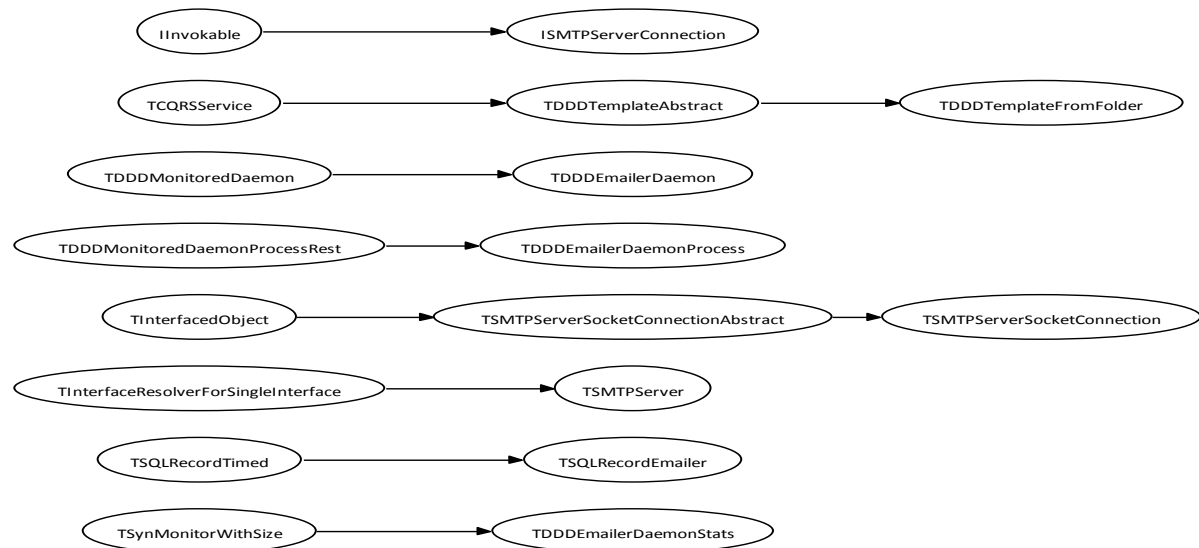

*Purpose:* Shared DDD Infrastructure: generic emailing service

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

*dddInfraEmailer class hierarchy*

### Objects implemented in the *dddInfraEmailer* unit

| Objects                             | Description                                                               | Page |
|-------------------------------------|---------------------------------------------------------------------------|------|
| ISMTPServerConnection               | Used to inject the exact SMTP process to TDDDEmailerDaemon                | 2482 |
| TDDDEmailerDaemon                   | Daemon used to send emails via SMTP                                       | 2483 |
| TDDDEmailerDaemonProcess            | Thread processing a SMTP connection                                       | 2483 |
| TDDDEmailerDaemonStats              | Statistics about a TDDDEmailerDaemon instance                             | 2483 |
| TDDDTemplateAbstract                | Abstract Mustache-Based templating                                        | 2484 |
| TDDDTemplateFromFolder              | Mustache-Based templating from a local folder                             | 2484 |
| TSMTPServer                         | Abstract class used to resolve ISMTPServerConnection                      | 2483 |
| TSMTPServerSocketConnection         | Implements ISMTPServerConnection using SynCrtSock's low-level SMTP access | 2483 |
| TSMTPServerSocketConnectionAbstract | Implements an abstract ISMTPServerConnection class                        | 2483 |
| TSQLRecordEmailer                   | ORM class for email validation process                                    | 2484 |

**ISMTPServerConnection = interface(IInvokable)**

*Used to inject the exact SMTP process to TDDDEmailerDaemon*

**function** SendEmail(**const** aRecipient: TRawUTF8DynArray; **const** aSender, aSubject, aHeader, aBody: RawUTF8): RawUTF8;

*This method should send the email, returning an error message on issue  
- if no header is supplied, it will expect one UTF-8 encoded text message*

**TSMTPServer = class(TInterfaceResolverForSingleInterface)**

*Abstract class used to resolve ISMTPServerConnection*

- see TSMTPServerSocket for actual implementation

**constructor** Create(aImplementation: TInterfacedObjectClass; aParameters: TSMTPServer); overload;

*Initialize the class with the parameters of another TSMTPServer instance*

- in fact, TSMTPServer could be used as parameter storage of its needed published properties, e.g. in a TApplicationSettingsAbstract sub-class

**constructor** Create(aImplementation: TInterfacedObjectClass; **const** aAddress: RawUTF8; aPort: cardinal; **const** aLogin,aPassword: RawUTF8); overload;

*Initialize the class with the supplied parameters*

**procedure** SetDefaultValuesIfVoid;

*Will fill some default values in the properties, if none is set*

- i.e. 'dummy:dummy@localhost:25'

**TSMTPServerSocketConnectionAbstract = class(TInterfacedObject)**

*Implements an abstract ISMTPServerConnection class*

**TSMTPServerSocketConnection = class(TSMTPServerSocketConnectionAbstract)**

*Implements ISMTPServerConnection using SynCrtSock's low-level SMTP access*

**TDDDEmailerDaemonStats = class(TSynMonitorWithSize)**

*Statistics about a TDDDEmailerDaemon instance*

- in addition to a standard TSynMonitor, will maintain the connection count

**procedure** NewConnection;

*Will increase the connection count*

**property** Connection: cardinal **read** fConnection;

*The connection count*

**TDDDEmailerDaemonProcess = class(TDDDMonitoredDaemonProcessRest)**

*Thread processing a SMTP connection*

**TDDDEmailerDaemon = class(TDDDMonitoredDaemon)**

*Daemon used to send emails via SMTP*

- it will maintain a list of action in a TSQLRecordEmailer ORM storage

**function** SendEmail(**const** aRecipients: TRawUTF8DynArray; **const** aSender,aSubject,aHeaders,aBody: RawUTF8): TCQRSResult;

*This is the main entry point of this service*

- here the supplied message body is already fully encoded, as expected by SMTP (i.e. as one text message, or multi-part encoded)

- if no header is supplied, it will expect one UTF-8 encoded text message

**property** RestClass: TSQLRecordEmailerClass read fRestClass;

*The associated class TSQLRecordEmailer used for status persistence*  
- any class inheriting from TSQLRecordEmailer in the Rest.Model will be recognized by TDDDEmailerDaemon to store its information

**property** SMTPServer: TSMTPServer read fSMTPServer write fSMTPServer;

*The associated class used as actual SMTP client*

**TSQLRecordEmailer = class**(TSQLRecordTimed)

*ORM class for email validation process*  
- we do not create a whole domain here, just an ORM persistence layer

**class procedure** InitializeTable(Server: TSQLRestServer; const FieldName: RawUTF8; Options: TSQLInitializeTableOptions); **override**;

*Will create an index on State+ID*

**TDDDDemplateAbstract = class**(TCQRSService)

*Abstract Mustache-Based templating*

**TDDDDemplateFromFolder = class**(TDDDDemplateAbstract)

*Mustache-Based templating from a local folder*

#### Types implemented in the *dddInfraEmailer* unit

**TSQLRecordEmailerState = ( esPending, esSending, esSent, esFailed );**

*State machine used during email validation process*

#### Functions or procedures implemented in the *dddInfraEmailer* unit

| Functions or procedures | Description                                                                                                       | Page |
|-------------------------|-------------------------------------------------------------------------------------------------------------------|------|
| TestDddInfraEmailer     | You can call this function within a TSynTestCase class to validate the email validation via a full regression set | 2484 |

**procedure** TestDddInfraEmailer(serverClass: TSQLRestServerClass; test: TSynTestCase);

*You can call this function within a TSynTestCase class to validate the email validation via a full regression set*

- could be used as such:

```
procedure TTestCrossCuttingFeatures.Emailer;
begin // TSQLRestServerDB is injected to avoid any dependency to mORMotSQLite3
 TestDddInfraEmailer(TSQLRestServerDB, self);
end;
```

## 27.84. dddInfraRepoUser.pas unit

*Purpose:* Shared DDD Infrastructure: User CQRS Repository via ORM

- this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *dddInfraRepoUser* unit

| Unit Name              | Description                                                                                                                                                                                                                                                                                                                                         | Page |

| <i>dddDomUserCQRS</i>  | Shared DDD Domains: User CQRS Repository interfaces<br>- this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                      | 2452 |
| <i>dddDomUserTypes</i> | Shared DDD Domains: User objects definition<br>- this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                              | 2457 |
| <i>mORMot</i>          | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                                    | 1907 |
| <i>mORMotDDD</i>       | Domain-Driven-Design toolbox for mORMot<br>- this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                                  | 2295 |
| <i>SynCommons</i>      | Common functions used by most Synapse projects<br>- this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                           | 718  |
| <i>SynCrypto</i>       | Fast cryptographic routines (hashing and cypher)<br>- implements<br>AES,XOR,ADLER32,MD5,RC4,SHA1,SHA256,SHA384,SHA512,SHA3 and<br>JWT<br>- optimized for speed (tuned assembler and<br>SSE3/SSE4/AES-NI/PADLOCK support)<br>- this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1143 |
| <i>SynTable</i>        | Filter/database/cache/buffer/security/search/multithread/OS features<br>- as a complement to SynCommons, which tended to increase too much<br>- licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                             | 1728 |
| <i>SynTests</i>        | Unit test functions used by Synapse projects<br>- this unit is a part of the freeware Synapse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                             | 1840 |

*dddInfraRepoUser class hierarchy*

## Objects implemented in the *dddInfraRepoUser* unit

| Objects                     | Description                                                             | Page |
|-----------------------------|-------------------------------------------------------------------------|------|
| TInfraRepoUser              | Implements a User CQRS Repository via mORMot's RESTful ORM              | 2486 |
| TInfraRepoUserFactory       | Implements a Factory of User CQRS Repositories via mORMot's RESTful ORM | 2486 |
| TSQLRecordPerson            | ORM class able to store a TPerson object                                | 2486 |
| TSQLRecordPersonContactable | ORM class able to store a TPersonContactable object                     | 2486 |
| TSQLRecordUser              | ORM class used to persist a TUser domain aggregate                      | 2486 |

**TInfraRepoUser = class(TDDDRepositoryRestCommand)**

*Implements a User CQRS Repository via mORMot's RESTful ORM*

- this class will use a supplied TSQLRest instance to persist TUser Aggregate Roots, following the IDomUserCommand CQRS methods
- each TUser aggregate will be mapped into a TSQLRecordUser ORM table

**TInfraRepoUserFactory = class(TDDDRepositoryRestFactory)**

*Implements a Factory of User CQRS Repositories via mORMot's RESTful ORM*

- this class will associate the TUser Aggregate Root with a TSQLRecordUser ORM table, as managed in a given TSQLRest instance

**constructor** Create(aRest: TSQLRest; aOwner: TDDDRepositoryRestManager=nil);  
**reintroduce;**

*Initialize the association with the ORM*

**class procedure** RegressionTests(test: TSynTestCase);

*Perform some tests on this Factory/Repository implementation*

**TSQLRecordPerson = class(TSQLRecord)**

*ORM class able to store a TPerson object*

- the TPerson.Name property has been flattened to Name\_\* columns as expected by TDDDRepositoryRestFactory.ComputeMapping

**TSQLRecordPersonContactable = class(TSQLRecordPerson)**

*ORM class able to store a TPersonContactable object*

- the TPersonContactable.Address property has been flattened to Address\_\* columns as expected by TDDDRepositoryRestFactory.ComputeMapping

**TSQLRecordUser = class(TSQLRecordPersonContactable)**

*ORM class used to persist a TUser domain aggregate*

## 27.85. dddInfraSettings.pas unit

*Purpose:* Shared DDD Infrastructure: Application/Daemon settings classes

- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *dddInfraSettings* unit

| Unit Name             | Description                                                                                                                                                                                                                                                                                                                                   | Page |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>         | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                              | 1907 |
| <i>mORMotDB</i>       | Virtual Tables for external DB access for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                   | 2286 |
| <i>mORMotDDD</i>      | Domain-Driven-Design toolbox for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                            | 2295 |
| <i>mORMotMongoDB</i>  | Direct optimized MongoDB access for mORMot's ORM<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                   | 2344 |
| <i>mORMotSQLite3</i>  | SQLite3 embedded Database engine used as the mORMot SQL kernel<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                     | 2392 |
| <i>mORMotWrappers</i> | Generate cross-platform clients code and documentation from a mORMot server<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                        | 2440 |
| <i>SynCommons</i>     | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                     | 718  |
| <i>SynCrtSock</i>     | Classes implementing TCP/UDP/HTTP client and server protocol<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                       | 1086 |
| <i>SynCrypto</i>      | Fast cryptographic routines (hashing and cypher)<br>- implements<br>AES,XOR,ADLER32,MD5,RC4,SHA1,SHA256,SHA384,SHA512,SHA3 and JWT<br>- optimized for speed (tuned assembler and SSE3/SSE4/AES-NI/PADLOCK support)<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1143 |
| <i>SynDB</i>          | Abstract database direct access classes<br>- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                                   | 1208 |

### Objects implemented in the *dddInfraSettings* unit

Page 2489 of 2562

| Objects                    | Description                                                          | Page |
|----------------------------|----------------------------------------------------------------------|------|
| TDDDMongoDBRestSettings    | Storage class for a remote MongoDB server direct access settings     | 2498 |
| TDDRestHttpLogSettings     | Stand-alone property to publish a secondary logged service over HTTP | 2498 |
| TDDRestHttpSettings        | Stand-alone property to publish a secondary TSQLRestServer over HTTP | 2498 |
| TDDRestSettings            | Storage class for initializing an ORM REST class                     | 2492 |
| TDDServicesLogRestSettings | Storage class for a ServicesLog settings                             | 2497 |
| TDDSocketThreadSettings    | The settings of a TDDThreadSocketProcess thread                      | 2496 |

**TDDLogSettings = class(TSynPersistent)**

*Settings used to define how logging take place*

- will map the most used TSynLogFamily parameters

**constructor** Create; **override**;

*Initialize the settings to their (TSynLogFamily) default values*

**property** AutoFlushTimeOut: integer **read** fAutoFlush **write** fAutoFlush;

*The time (in seconds) after which the log content must be written on disk, whatever the current content size is*

- by default, the log file will be written for every 4 KB of log (see TSynLogFamily.BufferSize property) - this will ensure that the main application won't be slow down by logging  
- in order not to loose any log, a background thread can be created and will be responsible of flushing all pending log content every period of time (e.g. every 10 seconds)

**property** ConsoleLevels: TSynLogInfos **read** fConsoleLevels **write** fConsoleLevels;

*The optional log levels to be used for the console*

- by default, only errors would be logged to the console  
- you can specify here another set of levels, e.g. '\*' for a verbose console output - note that console is very slow to write, so usually you should better not set a verbose definition here, unless you are in debugging mode

**property** CustomFileName: TFileName **read** fCustomFileName **write** fCustomFileName;

*Allows to customize the log file name*

**property** DestinationPath: TFileName **read** FDestinationPath **write** FDestinationPath;

*Allows to customize where the log files will be stored*

**property** Levels: TSynLogInfos **read** fLevels **write** fLevels;

*The log levels to be used for the log file*

- i.e. a combination of none or several logging event  
- if "\*" is serialized, unneeded sllNone won't be part of the set

**property** LowLevelWebSocketsFrames: boolean **read** fLowLevelWebSocketsFrames **write** fLowLevelWebSocketsFrames;

*If low-level WebSockets frames should be logged*

- disabled by default, to minimize logged content
- may be enabled to monitor most (asynchronous) activity, especially in background threads

**property** RotateFileCount: cardinal **read** fRotateFileCount **write** fRotateFileCount;

*Auto-rotation of logging files*

- set to 0 by default, meaning no rotation

**property** RotateFileDailyAtHour: integer **read** fRotateFileAtHour **write** fRotateFileAtHour;

*Fixed hour of the day where logging files rotation should be performed*

**property** RotateFileSizeKB: cardinal **read** fRotateFileSize **write** fRotateFileSize;

*Maximum size of auto-rotated logging files, in kilo-bytes (per 1024 bytes)*

**property** StackTraceViaAPI: boolean **read** FStackTraceViaAPI **write** FStackTraceViaAPI;

*By default (false), logging will use manual stack trace browsing*

- if you experiment unexpected EAccessViolation, try to set this setting to TRUE so that the RtlCaptureStackBackTrace() API would be used instead

**property** SyslogFacility: TSyslogFacility **read** fSyslogFacility **write** fSyslogFacility;

*The optional log levels to be used for remote UDP syslog server sending*

- works in conjunction with SyslogServer/SyslogLevels properties
- default is sfLocal0

**property** SyslogLevels: TSynLogInfos **read** fSyslogLevels **write** fSyslogLevels;

*The optional log levels to be used for remote UDP syslog server sending*

- works in conjunction with SyslogServer property
- default will transmit all warnings, errors and exceptions

**property** SyslogServer: RawUTF8 **read** fSyslogServer **write** fSyslogServer;

*The optional remote UDP syslog server*

- expecting <https://tools.ietf.org/html/rfc5424> messages over UDP
- e.g. '1.2.3.4' to connect to UDP server 1.2.3.4 using default port 514 - but you can specify an alternative port as '1.2.3.4:2514'
- works in conjunction with SyslogLevels/SyslogFacility properties
- default is "" to disable syslog remote logging

**TDDAppSettingsStorageAbstract = class(TSynAutoCreateFields)**

*Abstract parent class for storing application settings*

**constructor** Create(const aInitialJSON: RawUTF8); **reintroduce**; **virtual**;

*Initialize the storage instance*

**procedure** Store(const aJSON: RawUTF8); **virtual**;

*TDDAppSettingsAbstract would use this to actually persist the data*

**property** InitialJsonContent: RawUTF8 read fInitialJsonContent;

*The JSON content, as specified when creating the instance*

- will allow SettingsDidChange to check if has changed
- here the JSON content is stored with default ObjectToJSON() options, so will be the normalized representation of the content, which may not match the JSON supplied to SetInitialJsonContent() protected method

**property** Owner: TDDAppSettingsAbstract read fOwner;

*The associated settings values*

**TDDAppSettingsAbstract = class**(TInterfacedObjectAutoCreateFields)

*Abstract class for storing application settings*

- this class implements IAutoCreateFieldsResolve so is able to inject its own values to any TInjectableAutoCreateFields instance
- you have to manage instance lifetime of these inherited classes with a local IAutoCreateFieldsResolve variable, just like any TInterfaceObject

**constructor** Create(aStorage: TDDAppSettingsStorageAbstract); reintroduce;

*Initialize the settings, with a corresponding storage process*

**destructor** Destroy; override;

*Persist if needed, and finalize the settings*

**function** AsJson: RawUTF8; virtual;

*Serialize the settings as JSON*

- any enumerated or set published property will be commented with their textual values, and 'stored false' properties would be included
- returns the new JSON content corresponding to the updated settings

**class function** PasswordFields: RawUTF8;

*Low-level method returning all TSynPersistentPassword full paths of all previously created TDDAppSettingsStorageFile .settings*

- as settingsfile=class1@full.path.to.pass1,class2@full.path.to.pass2,...
- you may use this method to create a 'passwords' resource for /HardenPasswords command line switch as implemented in dddInfraSettings.pas:

```
passwords := SynLZCompress(TDDAppSettingsAbstract.PasswordFields);
FileFromString(passwords, 'passwords.data');
```

then create e.g. a passwords.rc file as such:

```
passwords 10 "passwords.data"
```

compile this resource:

```
brcc32 passwords.rc
```

and link the resulting .res file to your daemon executable:

```
{$R passwords.res}
```

then /HardenPasswords and /PlainPasswords command line switches will cypher/uncypher all TSynPersistentPassword protected fields using safe per-user CryptDataForCurrentUser() encryption

**procedure** Initialize(const aDescription: string); virtual;

*To be called when the application starts, to initialize settings*

- you can specify a default Description value
- it will set the global SQLite3Log.Family according to Log values

**procedure** StoreIfUpdated; **virtual**;

*Persist the settings if needed*

- just a wrapper around Storage.Store(AsJson)
- implements IDDDSettingsStorable for "#settings save" admin command

**property** Description: **string** **read** FDescription **write** FDescription;

*Some text which will be used to describe this application*

**property** Log: TDDLogSettings **read** fLog;

*Defines how logging will be done for this application*

**property** Storage: TDDAppSettingsStorageAbstract **read** fStorage;

*Access to the associated settings storage*

**property** SyslogProcID: RawUTF8 **read** fSyslogProcID **write** fSyslogProcID;

*Transmitted as PROCID as part of any Log.SyslogServer message*

TDDAppSettingsStorageFile = **class**(TDDAppSettingsStorageAbstract)

*Class used for storing application settings as a JSON file*

**constructor** Create(**const** aSettingsJsonFileName: TFileName=''); **reintroduce**;  
**virtual**;

*Initialize and read the settings from the supplied JSON file name*

- if no file name is specified, will use the executable name with '.settings' as extension

**function** FileNameRelativeToSettingsFile(**const** aFileName: TFileName): TFileName;

*Compute a file name relative to the .settings file path*

**property** SettingsJsonFileName: TFileName **read** fSettingsJsonFileName **write**  
 fSettingsJsonFileName;

*The .settings file name, including full path*

TDDRestSettings = **class**(TSynAutoCreateFields)

*Storage class for initializing an ORM REST class*

- this class will contain some generic properties to initialize a TSQLRest pointing to a local or remote SQL/NoSQL database, with optional wrappers

**function** NewRestInstance(aRootSettings: TDDAppSettingsAbstract; **const** aTables:  
**array of** TSQLRecordClass; aOptions: TDDNewRestInstanceOptions ;  
 aExternalDBOptions:  
 TVirtualTableExternalRegisterOptions=[regDoNotRegisterUserGroupTables] ;  
 aMongoDBIdentifier: word=0; aMongoDBOptions:  
 TStaticMongoDBRegisterOptions=[mrDoNotRegisterUserGroupTables]): TSQLRest;  
**overload**; **virtual**;

*Is able to instantiate a REST instance according to the stored definition*

- just an overloaded version which will create an owned TSQLModel with the supplied TSQLRecord classes

```
function NewRestInstance(aRootSettings: TDDDAppSettingsAbstract; aModel:
TSQLModel; aOptions: TDDNewRestInstanceOptions ; aExternalDBOptions:
TVirtualTableExternalRegisterOptions=[regDoNotRegisterUserGroupTables] ;
aMongoDBIdentifier: word=0; aMongoDBOptions:
TStaticMongoDBRegisterOptions=[mrDoNotRegisterUserGroupTables]): TSQLRest;
overload; virtual;
```

*Is able to instantiate a REST instance according to the stored definition*

- Definition.Kind will identify the TSQLRestServer or TSQLRestClient class to be instantiated, or if equals 'MongoDB'/'MongoDBS' use a full MongoDB engine, or an external SQL database if it matches a TSQLDBConnectionProperties classname
- if aDefaultLocalSQLite3 is TRUE, then if Definition.Kind is "", a local SQLite3 file database will be initiated
- if aMongoDBIdentifier is not 0, then it will be supplied to every TSQLRestStorageMongoDB.SetEngineAddComputeIdentifier() created
- will return nil if the supplied Definition is not correct
- note that the supplied Model.Root is expected to be the default root URI, which will be overridden with this TDDRestSettings.Root property
- will also publish /wrapper HTML page if WrapperTemplateFolder is set

```
function NewRestServerDB(const aDBFileName: TFileName; const aModelRoot: RawUTF8;
const aModelTables: array of TSQLRecordClass; aOptions: TDDRestSettingsOptions=[];
aCacheSize: cardinal=10000): TSQLRestServerDB;
```

*Initialize a stand-alone TSQLRestServerDB instance*

- with its own database file located in DefaultDataFileName + aDBFileName
- will own its own TSQLModel with aModelRoot/aModelTables
- you can tune aCacheSize if the default 40MB value is not right
- will eventually call CreateMissingTables
- define custom TDDRestSettingsOptions if needed

```
function WrapperSourceFolderFixed: TFileName;
```

*Returns the WrapperSourceFolder property, all / chars replaced by \*

- so that you would be able to store the paths with /, avoiding JSON escape

```
function WrapperTemplateFolderFixed(ReturnLocalIfNoneSet: boolean=false):
TFileName;
```

*Returns the WrapperTemplateFolder property, all / chars replaced by \*

- so that you would be able to store the paths with /, avoiding JSON escape

```
class procedure RestServerDBSetOptions(DB: TSQLRestServer; Options:
TDDRestSettingsOptions);
```

*If DB is a TSQLRestServerDB, will define the expection options*

- DB.FileName will be erased from disk if optEraseDBFileAtStartup is defined
- force LockingMode=exclusive and Synchronounous=off unless optSQLite3FileSafeNonExclusive/optSQLite3FileSafeSlowMode options are set

```
procedure WrapperGenerate(Rest: TSQLRestServer; Port: integer; const DestFile:
TFileName; const Template: TFileName = 'API.adoc.mustache');
```

*Generate API documentation corresponding to REST SOA interfaces*

```
property DefaultDataFileName: RawUTF8 read fDefaultDataFileName write
fDefaultDataFileName;
```

*The default database file name*

**property** DefaultDataFolder: TFileName **read** fDefaultDataFolder **write** fDefaultDataFolder;

*The default folder where database files are to be stored*  
- will be used by NewRestInstance instead of the .exe folder, if set

**property** Options: TDDRestSettingsOptions **read** fOptions **write** fOptions;

*How the REST instance is to be initialized*

**property** ORM: TSynConnectionDefinition **read** fORM;

*Defines a mean of access to a TSQLRest instance*  
- using Kind/ServerName/DatabaseName/User properties: Kind would define the TSQLRest class to be instantiated by function NewRestInstance()

**property** Root: RawUTF8 **read** fRoot **write** fRoot;

*The URI Root to be used for the REST Model*

**property** WrapperSourceFolders: TFileName **read** fWrapperSourceFolders **write** fWrapperSourceFolders;

*Where the source code may be searched, for comment extraction of types*  
- several folders may be defined, separated by ; (just like in Delphi IDE)  
- only used if WrapperTemplateFolder is defined

**property** WrapperTemplateFolder: TFileName **read** fWrapperTemplateFolder **write** fWrapperTemplateFolder;

*If set to a valid folder, the generated TSQLRest will publish a '/Root/wrapper' HTML page so that client code could be generated*

**TDDAppSettingsRest = class(TDDAppSettingsAbstract)**

*Parent class for storing REST-based application settings*  
- this class could be used for an application with a single REST server running on a given HTTP port

**procedure** Initialize(**const** aDescription: **string**); **override**;

*To be called when the application starts, to initialize settings*  
- will call inherited TDDAppSettingsFile.Initialize, and set ServerPort to a default 888/8888 value under Windows/Linux

**property** Rest: TDDRestSettings **read** fRest;

*Allow to instantiate a REST instance from its JSON definition*

**property** ServerPort: RawUTF8 **read** fServerPort **write** fServerPort;

*The IP port to be used for the HTTP server associated with the application*

**TDDAdministratedDaemonRemoteAdminSettings = class(TSynAutoCreateFields)**

*Define how an administrated service/daemon is remotely accessed via REST*  
- the IAdministratedDaemon service will be published to administrate this service/daemon instance  
- those values should match the ones used on administrative tool side

**property** AuthHashedPassword: RawUTF8 **read** FAuthHashedPassword **write** FAuthHashedPassword **stored** false;

*The SHA-256 hashed password to authenticate AuthUserName*  
- follows the TSQLAuthUser.ComputeHashedPassword() encryption  
- marked as 'stored false' so that it won't appear e.g. in the logs

**property** AuthHttp: TSQLHttpServerDefinition **read** FAuthHttp;

*If defined, these parameters would be used for REST publishing over HTTP*

**property** AuthNamedPipeName: TFileName **read** FAuthNamedPipeName **write** FAuthNamedPipeName;

*If defined, the following pipe name would be used for REST publishing*  
- by definition, will work only on Windows

**property** AuthRootURI: RawUTF8 **read** FAuthRootURI **write** FAuthRootURI;

*The root URI used for the REST data model*  
- default URI is 'admin'

**property** AuthUserName: RawUTF8 **read** FAuthUserName **write** FAuthUserName;

*If set, expect authentication with this single user name*  
- that is, the TSQLRestServer will register a single TSQLAuthUser instance with the supplied AuthUserName/AuthHashedPassword credentials

**TDDDAministratedDaemonSettings = class(TDDDApplSettingsAbstract)**

*Parent class for storing a service/daemon settings*  
- under Windows, some Service\* properties will handle installation as a regular Windows Service, thanks to TDDDDaemon

**function** SettingsFolder: TFileName; **virtual**;

*Returns the folder containing .settings files - .exe folder by default*

**procedure** Initialize(**const** aDescription, aServiceName, aServiceDisplayName, aAppUserModelID: **string**; **const** aServiceDependencies: TStringDynArray = **nil**); **reintroduce**; **virtual**;

*To be called when the application starts, to initialize settings*  
- you can specify default Description and Service identifiers  
- the service-related parameters are Windows specific, and will be ignored on other platforms

**property** AppUserModelID: **string** **read** FAppUserModelID **write** FAppUserModelID;

*Under Windows 7 and later, will set an unique application-defined Application User Model ID (AppUserModelID) that identifies the current process to the taskbar*  
- this identifier allows an application to group its associated processes and windows under a single taskbar button  
- should follow SetAppUserModelID() expectations, i.e. 'Company.Product'

**property** RemoteAdmin: TDDDAministratedDaemonRemoteAdminSettings **read** FRemoteAdmin;

*Define how this administrated service/daemon is accessed via REST*

**property** ServiceAutoStart: **boolean** **read** FServiceAutoStart **write** FServiceAutoStart;

*Under Windows, will define if the Service should auto-start at boot*  
- FALSE means that it should be started on demand

**property** ServiceDependencies: TStringDynArray **read** FServiceDependencies **write** FServiceDependencies;

*Under Windows, will define optional Service internal Dependencies*  
- not published by default: could be defined if needed, or e.g. set in overridden constructor

**property** ServiceDisplayName: string **read** FServiceDisplayName **write** FServiceDisplayName;

*Under Windows, will define the Service displayed name*

**property** ServiceName: string **read** FServiceName **write** FServiceName;

*Under Windows, will define the Service internal name*

**TDDDSocketThreadSettings = class**(TSynAutoCreateFields)

*The settings of a TDDDDThreadSocketProcess thread*  
- defines how to connect (and reconnect) to the associated TCP server

**constructor** Create; **override**;

*Used to set the default values*

**function** GetHostPort: RawUTF8;

*Retrieve Host and Port values as a single 'ip:port' text*

**function** SetHostPort(const IpPort: RawByteString; defaultPort: integer): boolean;

*Set Host and Port values from a 'ip:port' or 'ip' text*

**property** AutoReconnectAfterSocketError: boolean **read** FAutoReconnectAfterSocketError **write** FAutoReconnectAfterSocketError;

*If TRUE, any communication error would try to reconnect the socket*

**property** ConnectionAttemptsInterval: Integer **read** fConnectionAttemptsInterval **write** fConnectionAttemptsInterval;

*The time, in seconds, between any reconnection attempt*  
- default value is 5 - i.e. five seconds  
- if you set -1 as value, thread would end without any retrial

**property** Host: RawUTF8 **read** FHost **write** FHost;

*The associated TCP server host*

**property** MonitoringLogInterval: integer **read** FMonitoringInterval **write** FMonitoringInterval;

*The period, in milliseconds, on which Monitoring information is logged*  
- default value is 120000, i.e. 2 minutes

**property** OnIDDDSocketThreadCreate: TOnIDDDSocketThreadCreate **read** fOnIDDDSocketThreadCreate **write** fOnIDDDSocketThreadCreate;

*You could set here a factory method to mock the socket connection*  
- this property is public, but not published, since it should not be serialized on the settings file, but overloaded at runtime

**property** Port: integer **read** FPort **write** FPort;

*The associated TCP server port*

**property** SocketBufferBytes: integer **read** FSocketBufferBytes **write** FSocketBufferBytes;

*The internal size of the input socket buffer*  
- default is 32768, i.e. 32 KB

**property** SocketLoopPeriod: integer **read** fSocketLoopPeriod **write** fSocketLoopPeriod;

*How many millisecond the main socket reading loop should wait for pending data, before calling TDDDSocketThread.InternalExecutIdle*  
- default is 100 ms

**property** SocketMaxBufferBytes: integer **read** FSocketMaxBufferBytes **write** FSocketMaxBufferBytes;

*The maximum size of the thread input buffer*  
- i.e. how many bytes are stored in fSocketInputBuffer memory, before nothing is retrieved from the socket buffer  
- set to avoid any "out of memory" of the current process, if the incoming data is not processed fast enough  
- default is 16777216, i.e. 16 MB

**property** SocketTimeout: integer **read** FSocketTimeout **write** FSocketTimeout;

*The time out period, in milliseconds, for socket access*  
- default is 2000 ms, i.e. 2 seconds

TDDDServicesLogRestSettings = **class**(TDDDRestSettings)

*Storage class for a ServicesLog settings*

**function** NewRestInstance(aRootSettings: TDDAppSettingsAbstract;  
aMainRestWithServices: TSQLRestServer; **const** aLogClass: **array of**  
TSQLRecordServiceLogClass; **const** aExcludedMethodNamesCSV: RawUTF8; aShardRange:  
TID=50000): TSQLRest; **reintroduce**;

*Compute a stand-alone REST instance for interface-based services logging*  
- all services of aMainRestWithServices would log their calling information into a dedicated table, but the methods defined in aExcludedMethodNamesCSV (which should be specified, even as "", to avoid FPC compilation error)  
- by default, will create a local SQLite3 file for storage, optionally via TSQLRestStorageShardDB if ShardDBCount is set  
- the first supplied item of aLogClass array would be used for the service logging; any additional item would be part of the model of the returned REST instance, but may be used later on (e.g. to handle DB-based asynchronous remote notifications as processed by TServiceFactoryClient.SendNotificationsVia method)  
- if aLogClass=[], plain TSQLRecordServiceLog would be used as default  
- aShardRange is used for TSQLRestStorageShardDB if ShardDBCount>0

**property** ShardDBCount: Integer **read** fShardDBCount **write** fShardDBCount;

*If set, will define MaxShardCount for TSQLRestStorageShardDB persistence*

TDDAdministratedDaemonHttpSettings =  
**class**(TDDAdministratedDaemonSettings)

*Parent class for storing a HTTP published service/daemon settings*

**property** Http: TSQLHttpServerDefinition **read** fHttp;

*How the HTTP server should be defined*

**property** Rest: TDDRestSettings **read** fRest;

*How the main REST server is implemented*

- most probably using a TSQLRestServerDB, i.e. local SQLite3 storage

**property** ServicesLog: TDDServicesLogRestSettings **read** fServicesLog;

*How the SOA calls would be logged into their own SQLite3 database*

**TDDRestHttpSettings = class**(TSynAutoCreateFields)

*Stand-alone property to publish a secondary TSQLRestServer over HTTP*

**property** Http: TSQLHttpServerDefinition **read** fHttp;

*How the HTTP server should be defined*

**property** Rest: TDDRestSettings **read** fRest;

*How the REST server is implemented*

- most probably using a TSQLRestServerDB, i.e. local SQLite3 storage

**TDDRestHttpLogSettings = class**(TDDRestHttpSettings)

*Stand-alone property to publish a secondary logged service over HTTP*

**property** ServicesLog: TDDServicesLogRestSettings **read** fServicesLog;

*How the SOA calls would be logged into their own SQLite3 database*

**TDDMongoDBRestSettings = class**(TDDRestSettings)

*Storage class for a remote MongoDB server direct access settings*

**procedure** SetDefaults(**const** Root, MongoServerAddress, MongoDBase, MongoUser, MongoPassword: RawUTF8; TLS: boolean=false);

*Set the default values for direct MongoDB server connection*

- if MongoServerAddress is e.g. '?:27017', entry with default value would be saved in the settings, but NewRestInstance() would ignore it: once the remote MongoDB server IP is known, you may just replace '?' to use it

- if MongoUser and MongoPassword are set, would call TMongoClient.OpenAuth()

## Types implemented in the *dddInfraSettings* unit

**TDDAppSettingsAbstractClass = class of** TDDAppSettingsAbstract;

*Class type used for storing application settings*

**TDDNewRestInstanceOptions = set of** ( riOwnModel, riCreateVoidModelIfNone, riHandleAuthentication, riDefaultLocalSQLite3IfNone, riDefaultInMemorySQLite3IfNone, riDefaultFullMemoryIfNone, riDefaultLocalBinaryFullMemoryIfNone, riCreateMissingTables, riRaiseExceptionIfNoRest, riWithInternalState);

*How TDDRestSettings.NewRestInstance would create its instances*

- riOwnModel will set ModelInstance.Owner := RestInstance

- riHandleAuthentication will set the corresponding parameter to true

- riDefaultLocalSQLite3IfNone/riDefaultInMemorySQLite3IfNone will create a SQLite3 engine with a

local file/memory storage, if TDDRestSettings\ORM.Kind is not set

- riDefaultFullMemoryIfNone will create a TSQLRestServerFullMemory non persistent storage, or riDefaultLocalBinaryFullMemoryIfNone with a binary local file, if TDDRestSettings\ORM.Kind is not set
- riCreateMissingTables will call RestInstance.CreateMissingTables
- riRaiseExceptionIfNoRest will raise an EDDInfraException if TDDRestSettings.NewRestInstance would return nil
- riWithInternalState will enable 'Server-InternalState:' header transmission i.e. disable rsoNoInternalState for TSQLRestServer.Options

```
TDDRestSettingsOption = (optEraseDBFileAtStartup, optSQLite3FileSafeSlowMode,
optSQLite3FileSafeNonExclusive, optNoSystemUse, optSQLite3File4MBCacheSize,
optForceAjaxJson, optSQLite3LogQueryPlan);
```

*Some options to be used for TDDRestSettings*

- as part of the .settings, they may be tuned for specific installations, whereas TDDNewRestInstanceOptions are defined in code

```
TDDRestSettingsOptions = set of TDDRestSettingsOption;
```

*Define options to be used for TDDRestSettings*

```
TOnIDDDSocketThreadCreate = procedure(aOwner: TObject; out Obj) of object;
```

*A Factory event allowing to customize/mock a socket connection*

- the supplied aOwner should be a TDDSocketThread instance
- returns a IDDDSocket interface instance (e.g. a TDDSynCrtSocket)

## 27.86. SynDBBDE.pas unit

*Purpose:* BDE access classes for SynDB units

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the SynDBBDE unit

| Unit Name           | Description                                                                                                                                                                            | Page |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>SynCommons</i>   | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18              | 718  |
| <i>SynDB</i>        | Abstract database direct access classes<br>- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                            | 1208 |
| <i>SynDBDataset</i> | DB.pas TDataSet-based direct access classes (abstract TQuery-like)<br>- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1271 |
| <i>SynLog</i>       | Logging functions used by Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                  | 1368 |

*SynDBBDE class hierarchy*

### Objects implemented in the SynDBBDE unit

| Objects                       | Description                                             | Page |
|-------------------------------|---------------------------------------------------------|------|
| ESQDBBDE                      | Exception type associated to the direct BDE connection  | 2501 |
| TSQLDBBDEConnection           | Implements a direct connection via the BDE access layer | 2501 |
| TSQLDBBDEConnectionProperties | Implement properties shared by BDE connections          | 2501 |
| TSQLDBBDEStatement            | Implements a statement via a BDE connection             | 2502 |

```
ESQLDBBDE = class(ESQLDBDataset)
```

*Exception type associated to the direct BDE connection*

```
TSQLDBBDEConnectionProperties = class(TSQLDBDatasetConnectionProperties)
```

*Implement properties shared by BDE connections*

```
constructor Create(const aServerName, aDatabaseName, aUserID, aPassWord: RawUTF8);
override;
```

*Initialize the properties to connect to the BDE engine*

- aServerName shall contain the BDE Alias name
- aDatabaseName is ignored

```
function NewConnection: TSQLDBConnection; override;
```

*Create a new connection*

- caller is responsible of freeing this instance
- this overridden method will create an TSQLDBBDEConnection instance

```
TSQLDBBDEConnection = class(TSQLDBConnectionThreadSafe)
```

*Implements a direct connection via the BDE access layer*

```
constructor Create(aProperties: TSQLDBConnectionProperties); override;
```

*Prepare a connection to a specified BDE database server*

```
destructor Destroy; override;
```

*Release memory and connection*

```
function IsConnected: boolean; override;
```

*Return TRUE if Connect has been already successfully called*

```
function NewStatement: TSQLDBStatement; override;
```

*Create a new statement instance*

```
procedure Commit; override;
```

*Commit changes of a Transaction for this connection*

- StartTransaction method must have been called before

```
procedure Connect; override;
```

*Connect to the specified BDE server*

- should raise an ESQLDBBDE on error

```
procedure Disconnect; override;
```

*Stop connection to the specified BDE database server*

- should raise an ESQLDBBDE on error

```
procedure Rollback; override;
```

*Discard changes of a Transaction for this connection*

- StartTransaction method must have been called before

```
procedure StartTransaction; override;
```

*Begin a Transaction for this connection*

**property** Database: TDatabase **read** fDatabase;

*Access to the associated BDE connection instance*

**property** DBMS: TSQLDBDefinition **read** fDBMS;

*The remote DBMS type, as retrieved at BDE connection creation*

**property** DBMSName: RawUTF8 **read** fDBMSName;

*The remote DBMS name, as retrieved at BDE connection creation*

TSQLDBBDEStatement = **class**(TSQLDBDatasetStatement)

*Implements a statement via a BDE connection*

## 27.87. SynDBFireDAC.pas unit

*Purpose:* FireDAC/AnyDAC-based classes for SynDB units

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the SynDBFireDAC unit

| Unit Name           | Description                                                                                                                                                                                             | Page |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|

*SynDBFireDAC class hierarchy*

### Objects implemented in the SynDBFireDAC unit

| Objects                           | Description                                                           | Page |
|-----------------------------------|-----------------------------------------------------------------------|------|
| ESQldbFireDAC                     | Exception type associated to FireDAC/AnyDAC database access           | 2504 |
| TSQLDBFireDACConnection           | implements a direct connection via FireDAC/AnyDAC database access     | 2505 |
| TSQLDBFireDACConnectionProperties | connection properties definition using FireDAC/AnyDAC database access | 2504 |

| Objects                | Description                                     | Page |
|------------------------|-------------------------------------------------|------|
| TSQldbFireDACStatement | implements a statement via a FireDAC connection | 2506 |

**ESQldbFireDAC = class(ESQldbDataset)**

*Exception type associated to FireDAC/AnyDAC database access*

**TSQldbFireDACConnectionProperties =**

**class(TSQldbDatasetConnectionProperties)**

*connection properties definition using FireDAC/AnyDAC database access*

**constructor** Create(**const** aServerName, aDatabaseName, aUserID, aPassword: RawUTF8);  
**override;**

*Initialize the properties to connect via FireDAC/AnyDAC database access*

- aServerName shall contain the FireDAC provider DriverID, e.g. 'Ora', and some optional parameters (e.g. remote server name if needed), after a '?' and separated by ';' - for instance:

```
Create('Ora', 'TNSNAME', 'User', 'Password');
Create('Ora?CharacterSet=cl8mswin1251', 'TNSNAME', 'User', 'Password');
Create('MSSQL?Server=127.0.0.1\SQLEXPRESS', 'Northwind', 'User', 'Password');
Create('MSSQL?Server=. \SQLEXPRESS;OSAuthent=Yes', '', '', '');
Create('MSAcc', 'c:\data\access.mdb', '', '');
Create('MySQL?Server=127.0.0.1;Port=3306', 'MyDB', 'User', 'Password');
Create('SQLite', 'c:\data\myapp.db3', '', '');
Create('SQLite', SQLITE_MEMORY_DATABASE_NAME, '', '');
Create('IB', '127.0.0.1:C:\ib\ADDEMO_IB2007.IB', 'User', 'Password');
Create('IB?Server=my_host/3055', 'C:\ib\ADDEMO_IB2007.IB', 'User', 'Password');
Create('IB?CreateDatabase=Yes', '127.0.0.1:C:\ib\ADDEMO_IB2007.IB', 'User', 'Password');
Create('DB2?Server=localhost;Port=50000', 'SAMPLE', 'db2admin', 'db2Password');
Create('PG?Server=localhost;Port=5432', 'postgres', 'postgres', 'postgresPassword');
Create('MySQL?Server=localhost;Port=3306', 'test', 'root', '');
```

- aDatabaseName shall contain the database server name

- note that you need to link the FireDAC driver by including the expected uADPhys\*.pas / FireDAC.Phy\*.pas units into a uses clause of your application, e.g. uADPhysOracle, uADPhysMSSQL, uADPhysMSAcc, uADPhysMySQL, uADPhysSQLite, uADPhysIB or uADPhysDB2 (depending on the expected provider) - or FireDAC.Phy.Oracle, FireDAC.Phy.MSAcc, FireDAC.Phy.MSSQL, FireDAC.Phy.SQLite, FireDAC.Phy.IB, FireDAC.Phy.PG or FireDAC.Phy.DB2 since Delphi XE5 namespace modifications

**destructor** Destroy; **override;**

*Release internal structures*

**function** NewConnection: TSQldbConnection; **override;**

*Create a new connection*

- caller is responsible of freeing this instance

- this overridden method will create an TSQldbFireDACConnection instance

**procedure** GetFields(**const** aTableName: RawUTF8; **out** Fields: TSQldbColumnDefineDynArray); **override;**

*Retrieve the column/field layout of a specified table*

- this overridden method will use FireDAC metadata to retrieve the information

```
procedure GetIndexes(const aTableName: RawUTF8; out Indexes:
TSQLDBIndexDefineDynArray); override;
```

*Retrieve the advanced indexed information of a specified Table*  
- this overridden method will use FireDAC metadata to retrieve the information

```
procedure GetTableNames(out Tables: TRawUTF8DynArray); override;
```

*Get all table names*  
- this overridden method will use FireDAC metadata to retrieve the information

```
property Parameters: TStringList read fFireDACOptions;
```

*Allow to set the options specific to a FireDAC driver*  
- by default, ServerName, DatabaseName, UserID and Password are set by the Create()  
constructor according to the underlying FireDAC driver  
- you can add some additional options here

```
TSQLDBFireDACConnection = class(TSQLDBConnectionThreadSafe)
```

*implements a direct connection via FireDAC/AnyDAC database access*

```
constructor Create(aProperties: TSQLDBConnectionProperties); override;
```

*Prepare a connection for a specified FireDAC/AnyDAC database access*

```
destructor Destroy; override;
```

*Release memory and connection*

```
function IsConnected: boolean; override;
```

*Return TRUE if Connect has been already successfully called*

```
function NewStatement: TSQLDBStatement; override;
```

*Create a new statement instance*

```
procedure Commit; override;
```

*Commit changes of a Transaction for this connection*  
- StartTransaction method must have been called before

```
procedure Connect; override;
```

*Connect to the specified database server using FireDAC*  
- should raise an ESQLDBFireDAC on error

```
procedure Disconnect; override;
```

*Stop connection to the specified database server using FireDAC*  
- should raise an ESQLDBFireDAC on error

```
procedure Rollback; override;
```

*Discard changes of a Transaction for this connection*  
- StartTransaction method must have been called before

```
procedure StartTransaction; override;
```

*Begin a Transaction for this connection*

```
property Database: TADConnection read fDatabase;
```

*Access to the associated FireDAC connection instance*

```
TSQLDBFireDACStatement = class(TSQLDBDatasetStatementAbstract)
```

*implements a statement via a FireDAC connection*

- this specific version will handle the FireDAC specific parameter classes
- it will also handle Array DML commands, if possible

```
procedure Prepare(const aSQL: RawUTF8; ExpectResults: boolean = false); overload;
override;
```

*Prepare an UTF-8 encoded SQL statement*

- parameters marked as ? will be bound later, before ExecutePrepared call
- if ExpectResults is TRUE, then Step() and Column\*() methods are available to retrieve the data rows
- raise an ESQLDBFireDAC on any error

### Constants implemented in the *SynDBFireDAC* unit

```
FIREDAC_PROVIDER: array[dOracle..high(TSQLDBDefinition)] of RawUTF8 = (
'Ora', 'MSSQL', 'MSAcc', 'MySQL', 'SQLite', 'IB', '', 'PG', 'DB2', 'Infx');
```

*FireDAC DriverID values corresponding to SynDB recognized SQL engines*

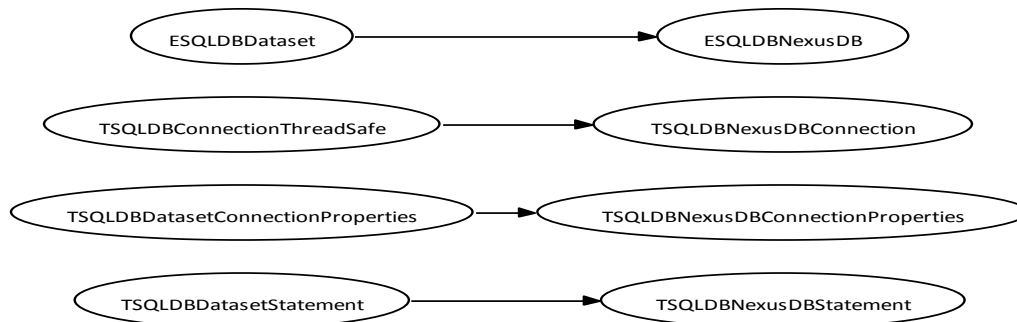

## 27.88. SynDBNexusDB.pas unit

*Purpose:* NexusDB 3.x direct access classes (embedded engine only)

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *SynDBNexusDB* unit

| Unit Name           | Description                                                                                                                                                                                             | Page |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>SynCommons</i>   | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                               | 718  |
| <i>SynDB</i>        | Abstract database direct access classes<br>- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                             | 1208 |
| <i>SynDBDataset</i> | DB.pas TDataset-based direct access classes (abstract TQuery-like)<br>- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                  | 1271 |
| <i>SynLog</i>       | Logging functions used by Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                   | 1368 |
| <i>SynTable</i>     | Filter/database/cache/buffer/security/search/multithread/OS features<br>- as a complement to SynCommons, which tended to increase too much<br>- licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1728 |

*SynDBNexusDB class hierarchy*

### Objects implemented in the *SynDBNexusDB* unit

| Objects                           | Description                                                   | Page |
|-----------------------------------|---------------------------------------------------------------|------|
| ESQldbNexusDB                     | Exception type associated to the direct NexusDB connection    | 2508 |
| TSQLDBNexusDBConnection           | Implements a direct connection to the native NexusDB database | 2509 |
| TSQLDBNexusDBConnectionProperties | Implement properties shared by native NexusDB connections     | 2508 |

| Objects                | Description                                              | Page |
|------------------------|----------------------------------------------------------|------|
| TSQLDBNexusDBStatement | Implements a statement via the native NexusDB connection | 2509 |

**ESQLDBNexusDB** = **class**(ESQLDBDataset)

*Exception type associated to the direct NexusDB connection*

**TSQLDBNexusDBConnectionProperties** =  
**class**(TSQLDBDatasetConnectionProperties)

*Implement properties shared by native NexusDB connections*

- note that only the embedded engine is implemented by now - feedback needed!

**constructor** Create(**const** aServerName, aDatabaseName, aUserID, aPassword: RawUTF8);  
**override**;

*Initialize the properties to connect to the NexusDB engine*

- this overridden method will initialize the protocol to be used as stated by aServerName i.e.

npxTCIP://11.23.34.43

- Default protocol is nxpFolder

- if protocol is nxpFolder then aDatabaseName will contain the path to the folder to be used

- if protocol is other than nxpFolder than aServerName will contain the server to connect to and

aDatabaseName will contains the alias of the database

- Possible aServerName formats:

<protocol>://<servername>/<alias> (aDatabaseName will be overwritten by this alias)

<protocol>://servername (aDatabaseName will contain alias)

'' (aDatabaseName contains path to nxpFOLDER database)

**function** ColumnTypeNativeToDB(**const** aNativeType: RawUTF8; aScale: integer):  
TSQLDBFieldType; **override**;

*Convert a textual column data type, as retrieved e.g. from SQLGetField, into our internal primitive types*

**function** CreateDatabase: boolean; **virtual**;

*Create the database folder (if not existing)*

**function** DatabaseExists: boolean; **virtual**;

*Determine if database exists*

- just test if the corresponding folder exists

**function** DeleteDatabase: boolean; **virtual**;

*Delete the database folder*

- including all its files - so to be used carefully!

**function** NewConnection: TSQLDBConnection; **override**;

*Create a new connection*

- caller is responsible of freeing this instance

- this overridden method will create an TSQLDBNexusDBConnection instance

**property** Protocol: TNXProtocol **read** fProtocol;

*The transport protocol used to connect to the NexusDB engine*

**TSQLDBNexusDBConnection = class(TSQLDBConnectionThreadSafe)**

*Implements a direct connection to the native NexusDB database*

**constructor** Create(aProperties: TSQLDBConnectionProperties); **override;**

*Prepare a connection to a specified NexusDB database server*

**destructor** Destroy; **override;**

*Release memory and connection*

**function** IsConnected: boolean; **override;**

*Return TRUE if Connect has been already successfully called*

**function** NewStatement: TSQLDBStatement; **override;**

*Create a new statement instance*

**procedure** Commit; **override;**

*Commit changes of a Transaction for this connection*

- StartTransaction method must have been called before

**procedure** Connect; **override;**

*Connect to the specified NexusDB server*

- should raise an ESQLDBNexusDB on error

**procedure** Disconnect; **override;**

*Stop connection to the specified NexusDB database server*

- should raise an ESQLDBNexusDB on error

**procedure** Rollback; **override;**

*Discard changes of a Transaction for this connection*

- StartTransaction method must have been called before

**procedure** StartTransaction; **override;**

*Begin a Transaction for this connection*

**property** Database: TnxDatabase **read** fDatabase;

*Access to the associated NexusDB connection instance*

**property** ServerEngine: TnxBaseServerEngine **read** fServerEngine **write** SetServerEngine;

*Associated NexusDB server engine*

**TSQLDBNexusDBStatement = class(TSQLDBDatasetStatement)**

*Implements a statement via the native NexusDB connection*

### Types implemented in the SynDBNexusDB unit

**TNXProtocol = ( nxpUnknown, nxpFOLDER, nxpTCPIP, nxpPIPE, nxpCOM, nxpMEM, nxpBFISH );**

*Available communication protocols used by NexusDB between client and server*

- nxpFOLDER: default protocol, accessing NexusDB database in a Windows Folder
- nxpTCPIP: TCP/IP transport, indicated by ntcp://
- nxpPIPE: Windows Named Pipe transport, indicated by nxpipe://
- nxpMEM: direct memory transport, indicated by nxmem://
- nxpBFISH: BlowFish transport, indicated by nxbfish://

## Constants implemented in the *SynDBNexusDB* unit

**NEXUSDB\_INMEMORY** = '#INMEM';

*Set aServerName to this value to create an in-memory table*

- do not use this constant, since it was not working as expected yet

## Functions or procedures implemented in the *SynDBNexusDB* unit

| Functions or procedures | Description                                                                                                     | Page |
|-------------------------|-----------------------------------------------------------------------------------------------------------------|------|
| DropNexusEmbeddedEngine | Release any internal NexusDB embedded engine                                                                    | 2510 |
| GetNXProtocol           | Determine NexusDB transport protocol (TNXProtocol) to be used, based on protocol indicator in connection string | 2510 |
| NexusEmbeddedEngine     | Return the internal NexusDB embedded engine                                                                     | 2510 |

**function** DropNexusEmbeddedEngine: TnxServerEngine;

*Release any internal NexusDB embedded engine*

- returns nil on success, or PtrInt(-1) if was not initialized

**function** GetNXProtocol(const aConnectionString: RawUTF8; out aServerName: RawUTF8; out aAlias: RawUTF8): TNXProtocol;

*Determine NexusDB transport protocol (TNXProtocol) to be used, based on protocol indicator in connection string*

- if no protocol specifier is included in the connectionstring then nxpFOLDER is assumed.

- aServerName will contain the URL to the Server if the protocol is not nxpFOLDER

**function** NexusEmbeddedEngine: TnxServerEngine;

*Return the internal NexusDB embedded engine*

- initialize it, if was not already the case

## 27.89. SynDBUniDAC.pas unit

*Purpose:* UniDAC-based classes for SynDB units

- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18

### Units used in the *SynDBUniDAC* unit

| Unit Name           | Description                                                                                                                                                                                             | Page |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>SynCommons</i>   | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                               | 718  |
| <i>SynDB</i>        | Abstract database direct access classes<br>- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                             | 1208 |
| <i>SynDBDataset</i> | DB.pas TDataset-based direct access classes (abstract TQuery-like)<br>- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                  | 1271 |
| <i>SynLog</i>       | Logging functions used by Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                   | 1368 |
| <i>SynOleDB</i>     | Fast OleDB direct access classes<br>- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                    | 1464 |
| <i>SynTable</i>     | Filter/database/cache/buffer/security/search/multithread/OS features<br>- as a complement to SynCommons, which tended to increase too much<br>- licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1728 |

*SynDBUniDAC class hierarchy*

### Objects implemented in the *SynDBUniDAC* unit

| Objects                | Description                                               | Page |
|------------------------|-----------------------------------------------------------|------|
| ESQldbUniDAC           | Exception type associated to UniDAC database access       | 2512 |
| TSQLDBUniDACConnection | implements a direct connection via UniDAC database access | 2513 |

| Objects                          | Description                                                   | Page |
|----------------------------------|---------------------------------------------------------------|------|
| TSQldbUniDACConnectionProperties | connection properties definition using UniDAC database access | 2512 |
| TSQldbUniDACStatement            | implements a statement via a UniDAC connection                | 2514 |

**ESQldbUniDAC = class(ESQldbDataset)**

*Exception type associated to UniDAC database access*

**TSQldbUniDACConnectionProperties = class(TSQldbDatasetConnectionProperties)**  
*connection properties definition using UniDAC database access*

**constructor** Create(**const** aServerName, aDatabaseName, aUserID, aPassword: RawUTF8);  
**override;**

*Initialize the properties to connect via UniDAC database access*

- aServerName shall contain the UniDAC provider name, e.g. 'Oracle' - you can use the TSQldbUniDACConnectionProperties.URI() to retrieve the provider name from its SynDB.TSQldbDefinition enumeration, and optionally set some options, which will be added to the internal SpecificOptions[]:

```
'Oracle?ClientLibrary=oci64\oci.dll'
'MySQL?Server=192.168.2.60;Port=3306', 'world', 'root', 'dev'
```

- aDatabaseName shall contain the database server name

**destructor** Destroy; **override;**

*Release internal structures*

**function** NewConnection: TSQldbConnection; **override;**

*Create a new connection*

- caller is responsible of freeing this instance
- this overridden method will create an TSQldbUniDACConnection instance

**class function** URI(aServer: TSQldbDefinition; **const** aServerName: RawUTF8; **const** aLibraryLocation: TFileName=''; aLibraryLocationAppendExePath: boolean=true): RawUTF8;

*Compute the UniDAC URI from a given database engine and server name*

- the optional server name can contain a port number, specified after ':'
- you can set an optional full path to the client library name, to be completed on the left side with the executable path

- possible use may be:

```
PropsOracle := TSQldbUniDACConnectionProperties.Create(
 TSQldbUniDACConnectionProperties.URI(dOracle, '', 'oci64\oci.dll'),
 'tnsname', 'user', pass);
PropsFirebird := TSQldbUniDACConnectionProperties.Create(
 TSQldbUniDACConnectionProperties.URI(dFirebird, '',
 'Firebird\fbembed.dll'), 'databasefilename', '', '');
PropsMySQL := TSQldbUniDACConnectionProperties.Create(
 TSQldbUniDACConnectionProperties.URI(dMySQL, '192.168.2.60:3306'),
 'world', 'root', 'dev');
```

```
procedure GetFields(const aTableName: RawUTF8; out Fields:
 TSQldbColumnDefineDynArray); override;
```

*Retrieve the column/field layout of a specified table*

- this overridden method will use UniDAC metadata to retrieve the information

```
procedure GetIndexes(const aTableName: RawUTF8; out Indexes:
 TSQldbIndexDefineDynArray); override;
```

*Retrieve the advanced indexed information of a specified Table*

- this overridden method will use UniDAC metadata to retrieve the information

```
procedure GetTableNames(out Tables: TRawUTF8DynArray); override;
```

*Get all table names*

- this overridden method will use UniDAC metadata to retrieve the information

```
property SpecificOptions: TStringList read fSpecificOptions;
```

*Allow to set the options specific to a UniDAC driver*

- for instance, you can set for both SQLite3 and Firebird/Interbase:

```
Props.SpecificOptions.Values['ClientLibrary'] := ClientDllName;
```

```
TSQldbUniDACConnection = class(TSQldbConnectionThreadSafe)
```

*implements a direct connection via UniDAC database access*

```
constructor Create(aProperties: TSQldbConnectionProperties); override;
```

*Prepare a connection for a specified UniDAC database access*

```
destructor Destroy; override;
```

*Release memory and connection*

```
function IsConnected: boolean; override;
```

*Return TRUE if Connect has been already successfully called*

```
function NewStatement: TSQldbStatement; override;
```

*Create a new statement instance*

```
procedure Commit; override;
```

*Commit changes of a Transaction for this connection*

- StartTransaction method must have been called before

```
procedure Connect; override;
```

*Connect to the specified database server using UniDAC*

- should raise an ESQldbUniDAC on error

```
procedure Disconnect; override;
```

*Stop connection to the specified database server using UniDAC*

- should raise an ESQldbUniDAC on error

```
procedure Rollback; override;
```

*Discard changes of a Transaction for this connection*

- StartTransaction method must have been called before

```
procedure StartTransaction; override;
```

*Begin a Transaction for this connection*

```
property Database: TUniConnection read fDatabase;
```

*Access to the associated UniDAC connection instance*

```
TSQLDBUniDACStatement = class(TSQLDBDatasetStatement)
```

*implements a statement via a UniDAC connection*

#### **Constants implemented in the *SynDBUniDAC* unit**

```
UNIDAC_PROVIDER: array[dOracle..high(TSQLDBDefinition)] of RawUTF8 = ('Oracle','SQL
Server','Access','MySQL','SQLite','InterBase', 'NexusDB','PostgreSQL','DB2','');
```

*UniDAC provider names corresponding to SynDB recognized SQL engines*

## 28. SynFile application

---

*Adopt a mORMot*

This sample application is a simple database tool which stores text content and files into the database, in both clear and "safe" manner. Safe records are stored using *AES/SHA* 256-bit encryption. There is an *Audit Trail* table for tracking the changes made to the database.

This document will follow the application architecture and implementation, in order to introduce the reader to some main aspects of the Framework:

- General architecture - see *Multi-tier architecture* (page 88);
- Database design - see *Object-Relational Mapping (ORM)* (page 92);
- User Interface generation.

We hope this part of the *Software Architecture Design* (SAD) document will be able to be a reliable guideline for using our framework for your own projects.

## 28.1. General architecture

According to the Multi-tier architecture, some units will define the three layers of the *SynFile* application:

### Database Model

First, the database tables are defined as regular *Delphi* classes, like a true ORM framework. Classes are translated to database tables. Published properties of these classes are translated to table fields. No external configuration files to write - only *Delphi* code. Nice and easy. See `FileTables.pas` unit.

This unit is shared by both client and server sides, with a shared data model, i.e. a `TSQLModel` class instance, describing all ORM tables/classes.

It contains also internal event descriptions, and actions, which will be used to describe the software UI.

### Business Logic

The *server side* is defined in a dedicated class, which implements an automated Audit Trail, and a service named "Event" to easily populate the Audit Trail from the Client side. See `FileServer.pas` unit.

The *client side* is defined in another class, which is able to communicate with the server, and fill/update/delete/add the database content playing with classes instances. It's also used to call the Audit Trail related service, and create the reports. See `FileClient.pas` unit.

Client-Server logic will be detailed in the next paragraph.

### Presentation Layer

The main form of the Client is void, if you open its `FileMain.dfm` file. All the User Interface is created by the framework, dynamically from the database model and some constant values and enumeration types (thanks to *Delphi* RTTI) as defined in `FileTables.pas` unit (the first one, which defines also the classes/tables).

It's main method is `TMainForm.ActionClick`, which will handle the actions, triggered when a button is pressed.

The reports use *GDI+* for anti-aliased drawing, can be zoomed and saved as pdf or text files.

The last `FileEdit.pas` unit is just the form used for editing the data. It also performs the encryption of "safe memo" and "safe data" records, using our `SynCrypto.pas` unit. It will use AES-NI hardware instructions, if available, so will be very fast, even for big content.

You'll discover how the ORM plays its role here: you change the data, just like changing any class instance properties.

It also uses our `SynGdiPlus.pas` unit to create thumbnails of any picture (emf+jpg+tif+gif+bmp) of data inserted in the database, and add a BLOB data field containing these thumbnails.

## 28.2. Database design

The FileTables.pas unit is implementing all TSQLRecord child classes, able to create the database tables, using the ORM aspect of the framework - see *Object-Relational Mapping (ORM)* (page 92). The following class hierarchy was designed:

*SynFile TSQLRecord classes hierarchy*

Most common published properties (i.e. Name, Created, Modified, Picture, KeyWords) are taken from the TSQLFile abstract parent class. It's called "*abstract*", not in the current *Delphi* OOP terms, but as a class with no "real" database table associated. It was used to defined the properties only once, without the need of writing the private variables nor the getter/setter for children classes. Only TSQLAuditTrail won't inherit from this parent class, because it's purpose is not to contain data, but just some information.

The database itself will define TSQLAuditTrail, TSQLMemo, TSQLData, TSQLSafeMemo, and TSQLSafeData classes. They will be stored as *AuditTrail*, *Memo*, *Data*, *SafeMemo* and *SafeData* tables in the *SQLite3* database (the table names are extract from the class name, trimming the left 'TSQL' characters).

Here is this common ancestor type declaration:

```

TSQLFile = class(TSQLRecordSigned)
public
 fName: RawUTF8;
 fModified: TTimeLog;
 fCreated: TTimeLog;
 fPicture: TSQLRawBlob;
 fKeyWords: RawUTF8;
published
 property Name: RawUTF8 read fName write fName;
 property Created: TTimeLog read fCreated write fCreated;
 property Modified: TTimeLog read fModified write fModified;
 property Picture: TSQLRawBlob read fPicture write fPicture;
 property KeyWords: RawUTF8 read fKeyWords write fKeyWords;
end;

```

Sounds like a regular *Delphi* class, doesn't it? The only fact to be noticed is that it does not inherit from a TPersistent class, but from a TSQLRecord class, which is the parent object type to be used for our

ORM. The TSQLRecordSigned class type just defines some Signature and SignatureTime additional properties, which will be used here for handling digital signing of records.

Here follows the *Delphi* code written, and each corresponding database field layout of each registered class:

```
TSQLMemo = class(TSQLFile)
public
 fContent: RawUTF8;
published
 property Content: RawUTF8 read fContent write fContent;
end;
```

|                         |
|-------------------------|
| ID : TID                |
| Content : RawUTF8       |
| Created : TTimeLog      |
| KeyWords : RawUTF8      |
| Modified : TTimeLog     |
| Name : RawUTF8          |
| Picture : TSQLRawBlob   |
| Signature : RawUTF8     |
| SignatureTime: TTimeLog |

*Memo Record Layout*

```
TSQLData = class(TSQLFile)
public
 fData: TSQLRawBlob;
published
 property Data: TSQLRawBlob read fData write fData;
end;
```

|                         |
|-------------------------|
| ID : TID                |
| Data : TSQLRawBlob      |
| Created : TTimeLog      |
| KeyWords : RawUTF8      |
| Modified : TTimeLog     |
| Name : RawUTF8          |
| Picture : TSQLRawBlob   |
| Signature : RawUTF8     |
| SignatureTime: TTimeLog |

*Data Record Layout*

```
TSQLSafeMemo = class(TSQLData);
```

|                         |
|-------------------------|
| ID : TID                |
| Data : TSQLRawBlob      |
| Created : TTimeLog      |
| KeyWords : RawUTF8      |
| Modified : TTimeLog     |
| Name : RawUTF8          |
| Picture : TSQLRawBlob   |
| Signature : RawUTF8     |
| SignatureTime: TTimeLog |

*SafeMemo Record Layout*

```
TSQLSafeData = class(TSQLData);
```

|                         |
|-------------------------|
| ID : TID                |
| Data : TSQLRawBlob      |
| Created : TTimeLog      |
| KeyWords : RawUTF8      |
| Modified : TTimeLog     |
| Name : RawUTF8          |
| Picture : TSQLRawBlob   |
| Signature : RawUTF8     |
| SignatureTime: TTimeLog |

*SafeData Record Layout*

You can see that TSQLSafeMemo and TSQLSafeData are just a direct sub-class of TSQLData to create "SafeMemo" and "SafeData" tables with the exact same fields as the "Data" table. Since they were declared as class(TSQLData), they are some new class type,

Then the latest class is not inheriting from TSQLFile, because it does not contain any user data, and is used only as a log of all actions performed using *SynFile*:

```

TSQLAuditTrail = class(TSQLRecord)
protected
 fStatusMessage: RawUTF8;
 fStatus: TFileEvent;
 fAssociatedRecord: TRecordReference;
 fTime: TTimeLog;
published
 property Time: TTimeLog read fTime write fTime;
 property Status: TFileEvent read fStatus write fStatus;
 property StatusMessage: RawUTF8 read fStatusMessage write fStatusMessage;
 property AssociatedRecord: TRecordReference read fAssociatedRecord write fAssociatedRecord;
end;

```

|                                     |
|-------------------------------------|
| ID : TID                            |
| AssociatedRecord : TRecordReference |
| Status : TFileEvent                 |
| StatusMessage : RawUTF8             |
| Time : TTimeLog                     |

*AuditTrail Record Layout*

The AssociatedRecord property was defined as TRecordReference. This special type (mapped as an INTEGER field in the database) is able to define a "one to many" relationship with ANY other record of the database model.

- If you want to create a "one to many" relationship with a particular table, you should define a property with the corresponding TSQLRecord sub-type (for instance, if you want to link to a particular *SafeData* row, define the property as AssociatedData: TSQLSafeData;) - in this case, this will create an INTEGER field in the database, holding the *RowID* value of the associated record (and this field content will be filled with pointer(RowID) and not with a real TSQLSafeData instance).
- Using a TRecordReference type won't link to a particular table, but any table of the database model: it will store in its associated INTEGER database field not only the *RowID* of the record, but also the table index as registered at TSQLModel creation. In order to access this AssociatedRecord property content, you could use either TSQLRest. Retrieve(AssociatedRecord) to get the corresponding record instance, or typecast it to RecordRef wrapper structure to easily retrieve or set the associated table and *RowID*. You could also use the TSQLRecord. RecordReference(Model) method in order to get the value corresponding to an existing TSQLRecord instance.

According to the MVC model - see *Model-View-Controller* (page 86) - the framework expects a common database model to be shared between client and server. A common function has been defined in the `FileTables.pas` unit, as such:

```
function CreateFileModel(Owner: TSQLRest): TSQLModel;
```

We'll see later its implementation. Just note for the moment that it will register the `TSQLAuditTrail`, `TSQLMemo`, `TSQLData`, `TSQLSafeMemo`, and `TSQLSafeData` classes as part of the database model. The order of the registration of those classes will be used for the `AssociatedRecord: TRecordReference` field of `TSQLAuditTrail` - e.g. a `TSQLMemo` record will be identified with a table index of 1 in the `RecordReference` encoded value. So it's mandatory to NOT change this order in any future modification of the database schema, without providing any explicit database content conversion mechanism.

Note that all above graphs were created directly from our *SynProject* tool, which is able to create custom graphs from the application source code it parsed.

## 28.3. Client Server implementation

Server-side is implemented in unit FileServer, with the following class:

```
TFileServer = class(TSQLRestserverDB)
(...)
Server: TSQLHttpServer;
procedure AddAuditTrail(aEvent: TFileEvent; const aMessage: RawUTF8='';
aAssociatedRecord: TRecordReference=0);
function OnDatabaseUpdateEvent(Sender: TSQLRestServer;
Event: TSQLEvent; aTable: TSQLRecordClass; aID: TID): boolean;
published
procedure Event(Ctxt: TSQLRestServerURIContext);
end;
```

As stated above, it inherits from TSQLRestserverDB to define a RESTful ORM based on the *SQLite3* database engine, and define a custom method-based service named Event.

The class constructor creates the whole server-side logic, following the shared data *Model* as defined in the FileTables unit:

```
constructor TFileServer.Create;
begin
inherited Create(CreateFileModel(self),ChangeFileExt(paramstr(0),'.db3'));
CreateMissingTables(ExeVersion.Version32);
Server := TSQLHttpServer.Create(SERVER_HTTP_PORT,self,'+',useHttpApiRegisteringURI);
AddAuditTrail(feServerStarted);
OnUpdateEvent := OnDatabaseUpdateEvent;
end;
```

A dedicated TSQLHttpServer instance is initialized to publish the TFileServer content over HTTP.

Automatic logging in the *Audit Trail* table of most database changes is performed via the OnDatabaseUpdateEvent callback.

Client-side is implemented in unit FileClient, with the following class:

```
TFileClient = class(TSQLHttpClient)
public
(...)
procedure AddAuditTrail(aEvent: TFileEvent; aAssociatedRecord: TSQLRecord);
end;
```

You'll see that BLOB fields are handled just like other fields, even if they use their own RESTful GET/PUT dedicated URI (they are not JSON encoded, but transmitted as raw data, to save bandwidth and maintain the RESTful model). The framework handles it for you, thanks to its ORM orientation, in the TFileClient constructor:

```
constructor TFileClient.Create(const aServer: AnsiString);
begin
inherited Create(aServer,SERVER_HTTP_PORT,CreateFileModel(self));
ForceBlobTransfert := true;
end;
```

Here, we set ForceBlobTransfert := true, since by default all BLOB fields won't be transmitted by TSQLRestClientURI, whereas our simple application expect them to be always available.

The same data *Model*, as defined in the FileTables unit, is used also on the client side.

On both sides, a AddAuditTrail() is defined, to allow direct logging to the internal TSQLAuditTrail table. From the client, it uses the Event method-based service to perform the remote action:

```
procedure TFileClient.AddAuditTrail(aEvent: TFileEvent;
aAssociatedRecord: TSQLRecord);
```

```
begin
 if aAssociatedRecord=nil then
 CallbackGetResult('Event',['event',ord(aEvent)]) else
 with aAssociatedRecord do
 CallbackGetResult('Event',['event',ord(aEvent)],RecordClass,ID);
end;
```

## 28.4. User Interface generation

You could of course design your own User Interface without our framework. That is, this is perfectly feasible to use only the ORM part of it. For instance, it should be needed to develop AJAX applications using its RESTful model - see *REST* (page 312) - since such a feature is not yet integrated to our provided source code.

But for producing easily applications, the framework provides a mechanism based on both ORM description and RTTI compiler-generated information in order to create most User Interface by code.

It is able to generated a Ribbon-based application, in which each table is available via a Ribbon tab, and some actions performed to it.

So the framework will need to know:

- Which tables must be displayed;
- Which actions should be associated with each table;
- How the User Interface should be customized (e.g. hint texts, grid layout on screen, reporting etc...);
- How generic automated edition, using the `mORMotUIEdit.pas` unit, is to be generated.

To this list could be added an integrated event feature, which can be linked to actions and custom status, to provide a centralized handling of user-level logging (as used e.g. in the *SynFile* `TSQLAuditTrail` table) - please do not make confusion between this user-level logging and technical-level logging using `TSynLog` and `TSQLLog` classes and "families" - see *Enhanced logging* (page 632).

### 28.4.1. Rendering

The current implementation of the framework User Interface generation handles two kind of rendering:

- Native VCL components;
- Proprietary TMS components.

You can select which set of components are used, by defining - globally to your project (i.e. in the *Project/Options/Conditionals* menu) - the `USETMSPACK` conditional. If it is not set (which is by default), it will use VCL components.

The native VCL components will use native Windows API components. So the look and feel of the application will vary depending on the Windows version it is running on. For instance, the resulting screen will be diverse if the application is run under Windows 2000, XP, Vista and Seven. The "ribbon" as generated with VCL components has most functionalities than the Office 2007/2010 ribbon, but will have a very diverse layout.

The TMS components will have the same rendering whatever the Windows it's running on, and will display a "ribbon" very close to the official Office 2007/2010 version.

Here are some PROs and CONs about both solutions:

| Criteria   | VCL     | TMS           |
|------------|---------|---------------|
| Rendering  | Basic   | Sophisticated |
| OS version | Variant | Constant      |

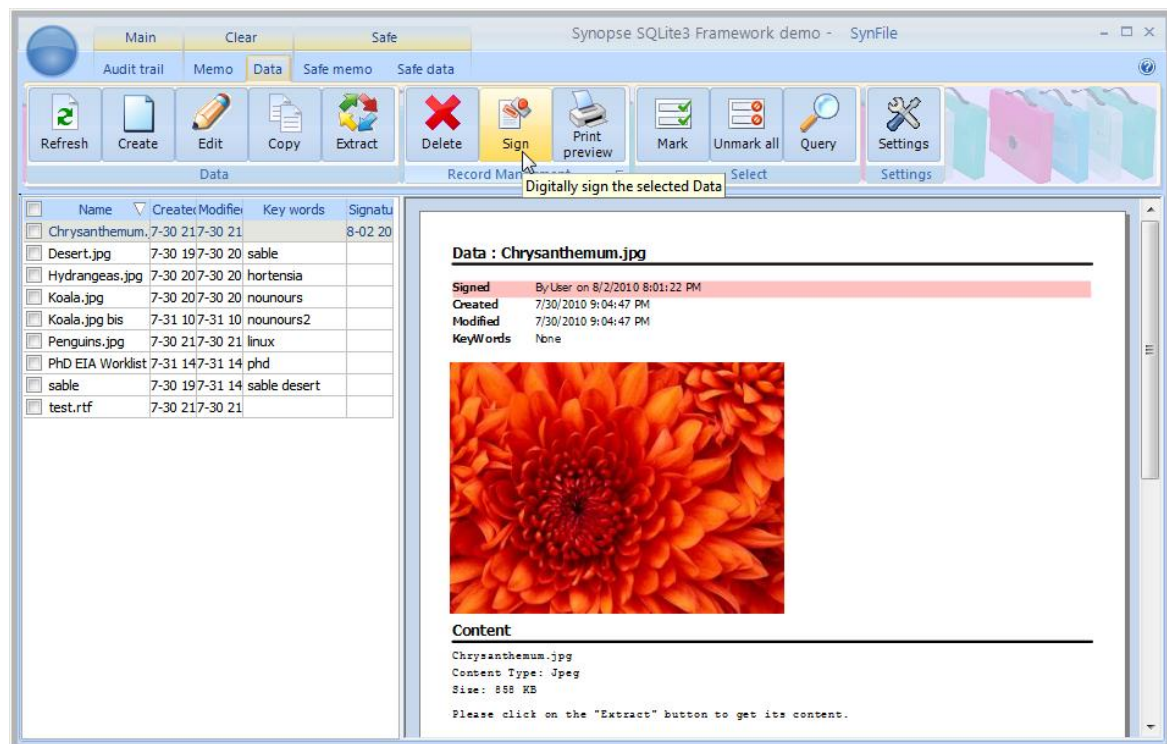

|                            |                 |             |
|----------------------------|-----------------|-------------|
| Ribbon look                | Unusual         | Office-like |
| Preview button & Shortcuts | None by default | Available   |
| Extra Price                | None            | High        |
| GPL ready                  | Yes             | No          |
| Office UI Licensing        | N/A             | Required    |
| EXE size                   | Smaller         | Bigger      |

It's worth saying that the choice of one or other component set could be changed on request. If you use the generic components as defined in mORMotToolBar (i.e. the TSynForm, TSynToolBar, TSynToolButton, TSynPopupMenu, TSynPage, TSynPager, TSynBodyPager and TSynBodyPage classes) and SynTaskDialog (for TSynButton) in your own code, the USETMSPACK conditional will do all the magic for you.

The *Office UI licensing program* was designed by *Microsoft* for software developers who wish to implement the Office UI as a software component and/or incorporate the Office UI into their own applications. If you use TMS ribbon, it does not require any more acceptance of the Office UI License terms - see at <http://msdn.microsoft.com/en-us/office/aa973809.aspx..>

If you want to design your user interface using a Office 2007/2010 ribbon look, please take a look at those official guidelines: <http://msdn.microsoft.com/en-us/library/cc872782.aspx..>

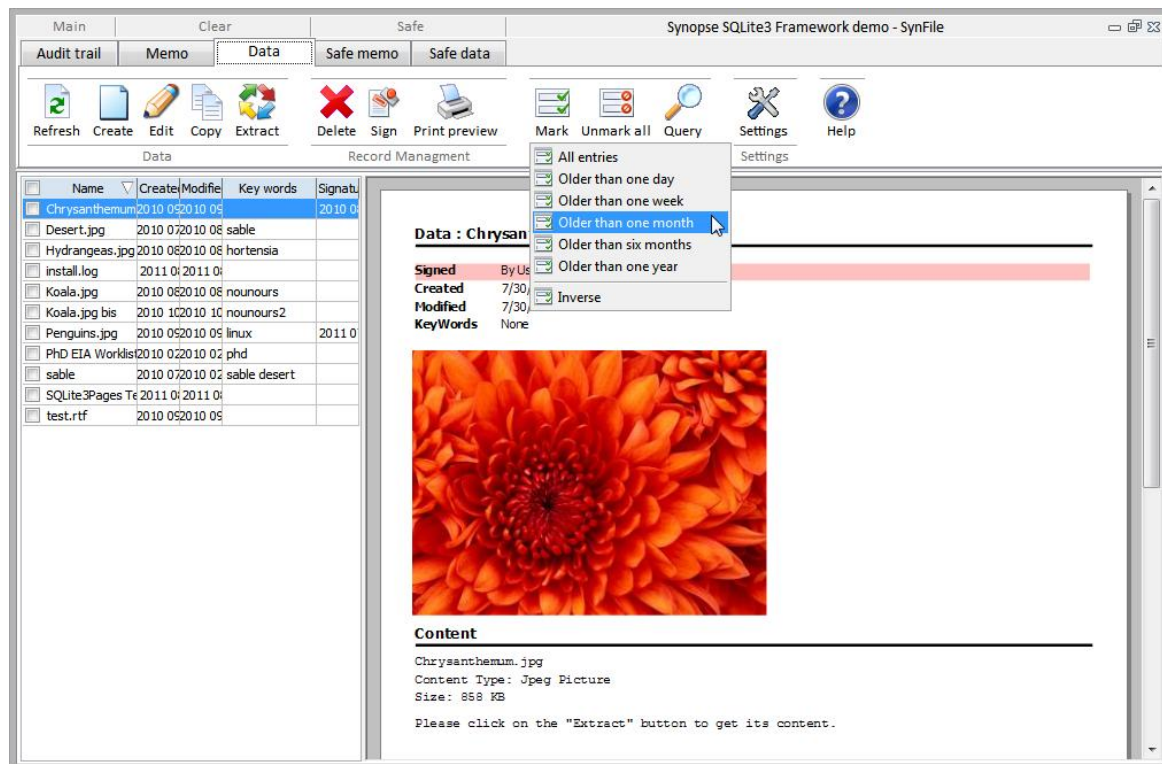

Here is the screen content, using the TMS components:

*User Interface generated using TMS components*

And here is the same application compiled using only VCL components, available from *Delphi* 6 up to the latest *Delphi* version:

*User Interface generated using VCL components*

We did not use yet the Ribbon component as was introduced in *Delphi 2009*. Its action-driven design won't make it easy to interface with the event-driven design of our User Interface handling, and we have to confess that this component has rather bad reputation (at least in the *Delphi 2009* version). Feel free to adapt our Open Source code to use it - we'll be very pleased to release a new version supporting it, but we don't have time nor necessity to do it by ourself.

## 28.4.2. Enumeration types

A list of available actions should be defined, as an enumeration type:

```
TFileAction = (
 faNoAction, faMark, faUnmarkAll, faQuery, faRefresh, faCreate,
 faEdit, faCopy, faExport, faImport, faDelete, faSign, faPrintPreview,
 faExtract, faSettings);
```

Thanks to the *Delphi* RTTI, and "*Un Camel Casing*", the following list will generate a set of available buttons on the User Interface, named "Mark", "Unmark all", "Query", "Refresh", "Create", "Edit", "Copy", "Export", "Import", "Delete", "Sign", "Print preview", "Extract" and "Settings". Thanks to the *mORMoti18n.pas* unit (responsible of application i18n) and the *TLanguageFile*. *Translate* method, it could be translated on-the-fly from English into the current desired language, before display on screen or report creation.

See both above screen-shots to guess how the button captions match the enumeration names - i.e. *User Interface generated using VCL components* (page 2525) and *User Interface generated using VCL components* (page 2525).

A list of events, as used for the *TSQLAuditTrail* table, was also defined. Some events reflect the change made to the database rows (like *feRecordModified*), or generic application status (like *feServerStarted*):

```
TFileEvent = (
 feUnknownState, feServerStarted, feServerShutdown,
 feRecordCreated, feRecordModified, feRecordDeleted,
 feRecordDigitallySigned, feRecordImported, feRecordExported);
```

In the grid and the reports, RTTI and *"uncamelcasing"* will be used to display this list as regular text, like *"Record digitally signed"*, and translated to the current language, if necessary.

### 28.4.3. ORM Registration

The User Interface generation will be made by creating an array of objects inheriting from the `TSQLRibbonTabParameters` type.

Firstly, a custom object type is defined, associating

```
TFileRibbonTabParameters = object(TSQLRibbonTabParameters)
 /// the SynFile actions
 Actions: TFileActions;
end;
```

Then a constant array of such objects is defined:

```
const
FileTabs: array[0..4] of TFileRibbonTabParameters = (
 (Table: TSQLAuditTrail;
 Select: 'Time,Status,StatusMessage'; Group: GROUP_MAIN;
 FieldWidth: 'gIZ'; ShowID: true; ReverseOrder: true; Layout: llClient;
 Actions: [faDelete,faMark,faUnmarkAll,faQuery,faRefresh,faPrintPreview,faSettings]),
 (Table: TSQLMemo;
 Select: DEF_SELECT; Group: GROUP_CLEAR; FieldWidth: 'IddId'; Actions: DEF_ACTIONS),
 (Table: TSQLData;
 Select: DEF_SELECT; Group: GROUP_CLEAR; FieldWidth: 'IddId'; Actions: DEF_ACTIONS_DATA),
 (Table: TSQLSafeMemo;
 Select: DEF_SELECT; Group: GROUP_SAFE; FieldWidth: 'IddId'; Actions: DEF_ACTIONS),
 (Table: TSQLSafeData;
 Select: DEF_SELECT; Group: GROUP_SAFE; FieldWidth: 'IddId'; Actions: DEF_ACTIONS_DATA));
```

The `Table` property will map the ORM class to the User Interface ribbon tab. A custom CSV list of fields should be set to detail which database columns must be displayed on the grids and the reports, in the `Select` property. Each ribbon tab could contain one or more `TSQLRecord` table: the `Group` property is set to identify on which ribbon group it should be shown. The grid column widths are defined as a `FieldWidth` string in which each displayed field length mean is set with one char per field (A=first Select column,Z=26th column) - lowercase character will center the field data. For each table, the available actions are also set, and will be used to create the possible buttons to be shown on the ribbon toolbars (enabling or disabling a button is to be done at runtime).

Note that this array definition uses some previously defined individual constants (like `DEF_SELECT`, `DEF_ACTIONS_DATA` or `GROUP_SAFE`). This is a good practice, and could make code maintenance easier later on.

### 28.4.4. Main window

Once all this ORM and action information is available, the `FileMain` unit defines the following class to generate the expected ribbon-based User Interface:

```
TMainForm = class(TSynForm)
 ImageList32: TImageList;
 ImageList16: TImageList;
 procedure FormCreate(Sender: TObject);
 procedure FormShow(Sender: TObject);
private
{$ifdef DEBUGINTERNALSERVER}
```

```

 Server: TFileServer;
{$endif}
protected
 procedure ActionClick(Sender: TObject; const RecordClass: TSQLRecordClass;
 ActionValue: integer);
 procedure HelpClick(Sender: TObject);
 procedure ListDbClick(Sender: TObject);
 procedure WMRefreshTimer(var Msg: TWMTimer); message WM_TIMER;
 function Edit(aRec: TSQLFile; const aTitle: string; aReadOnly: boolean): boolean;
public
 Client: TFileClient;
 Ribbon: TFileRibbon;
 destructor Destroy; override;
end;

```

The following method will do all the initialization, from the given Data and Presentation Models:

```

procedure TMainForm.FormCreate(Sender: TObject);
var P: integer;
begin
 {$ifdef DEBUGINTERNALSERVER}
 try
 Server := TFileServer.Create;
 except
 on E: Exception do begin
 ShowException(E);
 exit;
 end;
 end;
 {$endif}
 LoadImageListFromEmbeddedZip(ImageList32, 'buttons.bmp');
 ImageListStretch(ImageList32, ImageList16);
 Client := TFileClient.Create('localhost');
 Client.OnIdle := TLoginForm.OnIdleProcessForm;
 Ribbon := TFileRibbon.Create(self, nil, nil, ImageList32, ImageList16,
 Client, ALL_ACCESS_RIGHTS, nil, Client.OnSetAction, sFileActionsToolbar,
 sFileActionsHints, nil, ActionClick, integer(faRefresh), 1, false,
 length(FileTabs), @FileTabs[0], sizeof(FileTabs[0]),
 sFileTabsGroup, ',BannerData,BannerSafe',true);
 Ribbon.ToolBar.Caption.Caption := Caption;
 Ribbon.ToolBar.HelpButton.OnClick := HelpClick;
 for P := 0 to high(Ribbon.Page) do
 with Ribbon.Page[P] do
 if Lister<>nil then
 Lister.Grid.OnDbClick := ListDbClick;
 end;
 end;
end;

```

Even if a real application may be truly Client-Server, we define a stand-alone mode. That is, a TFileServer instance is instantiated within the main application execution. Just un-define the DEBUGINTERNALSERVER conditional if you want a "pure client" version of the application - in this case, a stand-alone server shall be running.

All the ORM and actions defined in the FileTables unit are used to initialize the TFileRibbon content in the Ribbon field which will be the main entry point of all User Interface process.

The ActionClick() method is the main entry point of the application, and is called when the User clicks on any ribbon button. It is just a case Action of ... switch instruction, handling each TFileAction event as expected.

The Edit() method will allow edition of a given record fields, via the separated TEditForm window, as defined in FileEdit unit. We won't use the auto-generated window from RTTI in this case, since we expect a dedicated process to attach a picture to the corresponding TSQLFile item.

The ListDbClick() method will process any double click on the list to edit the corresponding item (faEdit action), or go to the record an audit trail row refers to, using a convenient local RecordRef

wrapper variable:

```
procedure TMainForm.ListDbClick(Sender: TObject);
var P: TSQLRibbonTab;
 ref: RecordRef;
begin
 P := Ribbon.GetActivePage;
 if P<>nil then
 if P.Table=TSQLAuditTrail then begin
 if P.Retrieve(Client,P.List.Row) then begin
 ref.Value := TSQLAuditTrail(P.CurrentRecord).AssociatedRecord;
 Ribbon.GotoRecord(ref.Table(Client.Model),ref.ID);
 end;
 end else
 ActionClick(Sender,P.Table,ord(faEdit));
end;
```

The `WMRefreshTimer()` method will just transmit any `WM_TIMER` event to the ribbon process, in order to handle automatic refresh of the content, following the *stateless* approach of our RESTful framework:

```
procedure TMainForm.WMRefreshTimer(var Msg: TWMTimer);
begin
 Ribbon.WMRefreshTimer(Msg);
end;
```

You probably noticed that `Client.OnIdle` is set in the `FormCreate` method to map the `TLoginForm.OnIdleProcessForm` callback. This will let the HTTP client class to use a background thread for all communication, instead of blocking the main application thread. The main User Interface will still be responsive (since `OnIdleProcessForm` will call `Application.ProcessMessages`), and change the cursor to `crHourGlass` in case of a slow request, or even display a temporary pop-up with *"Please wait..."* if the network is really slow, and the request takes more than 2 seconds (all those notification parameters can be changed in `mORMotUILogin.pas`).

## 28.5. Report generation

The following CreateReport method is overridden in FileClient.pas:

```
/// class used to create the User interface
TFileRibbon = class(TSQLRibbon)
public
 /// overridden method used customize the report content
 procedure CreateReport(aTable: TSQLRecordClass; aID: TID; aReport: TGDIPages;
 AlreadyBegan: boolean=false); override;
end;
```

The reporting engine in the framework is implemented via the TGDIPages class, defined in the mORMotReport.pas:

- Data is drawn in memory, they displayed or printed as desired;
- High-level reporting methods are available (implementing tables, columns, titles and such), but you can have access to a TCanvas property which allows any possible content generation via standard VCL methods;
- Allow preview (with anti-aliased drawing via GDI+) and printing;
- Direct export as .txt or .pdf file;
- Handle bookmark, outlines and links inside the document.

By default, the CreateReport method of TSQLRibbon will write all editable fields value to the content.

The method is overridden by the following code:

```
procedure TFileRibbon.CreateReport(aTable: TSQLRecordClass; aID: TID; aReport: TGDIPages;
 AlreadyBegan: boolean=false);
var Rec: TSQLFile;
 Pic: TBitmap;
 s: string;
 PC: PChar;
 P: TSQLRibbonTab;
begin
 with aReport do
 begin
 // initialize report
 Clear;
 BeginDoc;
 Font.Size := 10;
 if not aTable.InheritsFrom(TSQLFile) then
 P := nil else
 P := GetActivePage;
 if (P=nil) or (P.CurrentRecord.ID<>aID) or (P.Table<>aTable) then
 begin
 inherited; // default handler
 exit;
 end;
 Rec := TSQLFile(P.CurrentRecord);
 Caption := U2S(Rec.fName);
```

The report is cleared, and BeginDoc method is called to start creating the internal canvas and band positioning. The font size is set, and parameters are checked against expected values. Then the current viewed record is retrieved from GetActivePage. CurrentRecord, and the report caption is set via the record Name field.

```
// prepare page footer
SaveLayout;
Font.Size := 9;
AddPagesToFooterAt(sPageN, LeftMargin);
TextAlign := taRight;
AddTextToFooterAt('SynFile https://synopse.info - '+Caption, RightMarginPos);
```

```
RestoreSavedLayout;
```

Page footer are set by using two methods:

- AddPagesToFooterAt to add the current page number at a given position (here the left margin);
- AddTextToFooterAt to add some custom text at a given position (here the right margin, after having changed the text alignment into right-aligned).

Note that SaveLayout/RestoreSavedLayout methods are used to modify temporary the current font and paragraph settings for printing the footer, then restore the default settings.

```
// write global header at the beginning of the report
DrawTitle(P.Table.CaptionName+' : '+Caption,true);
NewHalfLine;
AddColumns([6,40]);
SetColumnBold(0);
if Rec.SignatureTime<>0 then
begin
 PC := Pointer(Format(sSignedN,[Rec.SignedBy,Iso2S(Rec.SignatureTime)]));
 DrawTextAcrossColsFromCSV(PC,$C0C0FF);
end;
if Rec.fCreated<>0 then
 DrawTextAcrossCols([sCreated,Iso2S(Rec.fCreated)]);
if Rec.fModified<>0 then
 DrawTextAcrossCols([sModified,Iso2S(Rec.fModified)]);
if Rec.fKeywords='' then
 s := sNone else
begin
 s := U2S(Rec.fKeywords);
 ExportPDFKeywords := s;
end;
DrawTextAcrossCols([sKeywords,s]);
NewLine;
Pic := LoadFromRawByteString(Rec.fPicture);
if Pic<>nil then
try
 DrawBMP(Pic,0,Pic.Width div 3);
finally
 Pic.Free;
end;
```

Report header is written using the following methods:

- DrawTitle to add a title to the report, with a black line below it (second parameter to true) - this title will be added to the report global outline, and will be exported as such in .pdf on request;
- NewHalfLine and NewLine will leave some vertical gap between two paragraphs;
- AddColumns, with parameters set as percentages, will initialize a table with the first column content defined as bold (SetColumnBold(0));
- DrawTextAcrossCols and DrawTextAcrossColsFromCSV will fill a table row according to the text specified, one string per column;
- DrawBMP will draw a bitmap to the report, which content is loaded using the generic LoadFromRawByteString function implemented in SynGdiPlus.pas;
- U2S and Iso2S function, as defined in mORMoti18n.pas, are used for conversion of some text or TTimeLog/TUnixTime into a text formatted with the current language settings (i18n).

```
// write report content
DrawTitle(sContent,true);
SaveLayout;
Font.Name := 'Courier New';
if Rec.InheritsFrom(TSQLSafeMemo) then
 DrawText(sSafeMemoContent) else
if Rec.InheritsFrom(TSQLMemo) then
 DrawTextU(TSQLMemo(Rec).Content) else
if Rec.InheritsFrom(TSQLData) then
with TSQLData(Rec) do
```

```
begin
 DrawTextU(Rec.fName);
 s := PictureName(TSynPicture.IsPicture(TFileName(Rec.fName)));
 if s<>' ' then
 s := format(sPictureN,[s]) else
 if not Rec.InheritsFrom(TSQLSafeData) then
 s := U2S(GetMimeContentType(Pointer(Data),Length(Data),TFileName(Rec.fName)));
 if s<>' ' then
 DrawTextFmt(sContentTypeN,[s]);
 DrawTextFmt(sSizeN,[U2S(KB(Length(Data)))]);
 NewHalfLine;
 DrawText(sDataContent);
end;
RestoreSavedLayout;
```

Then the report content is appended, according to the record class type:

- DrawText, DrawTextU and DrawTextFmt are able to add a paragraph of text to the report, with the current alignment - in this case, the font is set to 'Courier New' so that it will be displayed with fixed width;
- GetMimeContentType is used to retrieve the exact type of the data stored in this record.

```
// set custom report parameters
ExportPDFApplication := 'SynFile https://synopse.info';
ExportPDFForceJPEGCompression := 80;
end;
end;
```

Those ExportPDFApplication and ExportPDFForceJPEGCompression properties (together with the ExportPDFKeywords) are able to customize how the report will be exported into a .pdf file. In our case, we want to notify that *SynFile* generated those files, and that the header bitmap should be compressed as JPEG before writing to the file (in order to produce a small sized .pdf).

You perhaps did notice that textual constant were defined as resourcestring, as such:

```
resourcestring
 sCreated = 'Created';
 sModified = 'Modified';
 sKeyWords = 'KeyWords';
 sContent = 'Content';
 sNone = 'None';
 sPageN = 'Page %d / %d';
 sSizeN = 'Size: %s';
 sContentTypeN = 'Content Type: %s';
 sSafeMemoContent = 'This memo is password protected.'#13+
 'Please click on the "Edit" button to show its content.';
 sDataContent = 'Please click on the "Extract" button to get its content.';
 sSignedN = 'Signed,By %s on %s';
 sPictureN = '%s Picture';
```

The mORMoti18n.pas unit is able to parse all those resourcestring from a running executable, via its ExtractAllResources function, and create a reference text file to be translated into any handled language.

Creating a report from code does make sense in an ORM. Since we have most useful data at hand as *Delphi* classes, code can be shared among all kind of reports, and a few lines of code is able to produce complex reports, with enhanced rendering, unified layout, direct internationalization and export capabilities.

Note that the mORMotReport.pas unit uses UTF-16 encoded string, i.e. our SynUnicode type, which is either UnicodeString since Delphi 2009, or WideString for older versions. WideString is known to have performance issues, due to use of slow BSTR API calls - so if you want to create huge reports with pre-Unicode versions of Delphi and our report engine, consider adding a reference to our

SynFastWideString.pas unit at first place of your .dpr uses clause, for potential huge speed enhancement. See *Unicode and UTF-8* (page 105) for more details, especially the restriction of use, since it will break any attempt to use BSTR parameters with any OLE/COM object.

## 28.6. Application i18n and L10n

In computing, internationalization and localization (also spelled internationalisation and localisation) are means of adapting computer software to different languages, regional differences and technical requirements of a target market:

- *Internationalization* (i18n) is the process of designing a software application so that it can be adapted to various languages;
- *Localization* (L10n) is the process of adapting internationalized software for a specific region or language by adding locale-specific components and translating text, e.g. for dates display.

Our framework handles both features, via the `mORMoti18n.pas` unit. We just saw above how `resourcestring` defined in the source code are retrieved from the executable and can be translated on the fly. The unit extends this to visual forms, and even captions generated from RTTI - see *RTTI* (page 504).

The unit expects all textual content (both `resourcestring` and RTTI derived captions) to be correct English text. A list of all used textual elements will be retrieved then hashed into a unique numerical value. When a specific locale is set for the application, the unit will search for a `.msg` text file in the executable folder matching the expected locale definition. For instance, it will search for `FR.msg` for translation into French.

In order to translate all the user interface, a corresponding `.msg` file is to be supplied in the executable folder. Neither the source code, nor the executable is to be rebuild to add a new language. And since this file is indeed a plain textual file, even a non developer (e.g. an end-user) is able to add a new language, starting from another `.msg`.

### 28.6.1. Creating the reference file

In order to begin a translation task, the `mORMoti18n.pas` unit is able to extract all textual resource from the executable, and create a reference text file, containing all English sentences and words to be translated, associated with their numerical hash value.

It will in fact:

- Extract all `resourcestring` text;
- Extract all captions generated from RTTI (e.g. from enumerations or class properties names);
- Extract all embedded `dfm` resources, and create per-form sections, allowing a custom translation of displayed captions or hints.

This creation step needs a compilation of the executable with the `EXTRACTALLRESOURCES` conditional defined, *globally* to the whole application (a full *rebuild* is necessary after having added or suppressed this conditional from the *Project / Options / Folders-Conditionals* IDE field).

Then the `ExtractAllResources` global procedure is to be called somewhere in the code.

For instance, here is how this is implemented in `FileMain.pas`, for the framework main demo:

```
procedure TMainForm.FormShow(Sender: TObject);
begin
 {$ifdef EXTRACTALLRESOURCES}
 ExtractAllResources(
 // first, all enumerations to be translated
 [TypeInfo(TFileEvent), TypeInfo(TFileAction), TypeInfo(TPreviewAction)],
 // then some class instances (including the TSQLModel will handle all TSQLRecord)
 [Client.Model],
 // some custom classes or captions
);
 {$endif}
end;
```

```
 [],[]);
 Close;
{$else}
 //i18nLanguageToRegistry(LngFrench);
{$endif}
 Ribbon.ToolBar.ActivePageIndex := 1;
end;
```

A global EXTRACTALLRESOURCES conditional can be defined temporarily for the project: from the *Delphi* IDE, *Project/Options* then enabling the conditional, *Project/Run* to create the .messages file as expected, and finally *Project/Options* to undefine the EXTRACTALLRESOURCES conditional and rebuild a regular executable.

The TFileEvent and TFileAction enumerations RTTI information is supplied, together with the current TSQLModel instance. All TSQLRecord classes (and therefore properties) will be scanned, and all needed English caption text will be extracted.

The Close method is then called, since we don't want to use the application itself, but only extract all resources from the executable.

Running once the executable will create a SynFile.messages text file in the SynFile.exe folder, containing all English text:

```
[TEditForm]
Name.EditLabel.Caption=_2817614158 Name
KeyWords.EditLabel.Caption=_3731019706 KeyWords

[TLoginForm]
Label1.Caption=_1741937413 &User name:
Label2.Caption=_4235002365 &Password:

[TMainForm]
Caption=_16479868 Synopse mORMot demo - SynFile

[Messages]
2784453965=Memo
2751226180=Data
744738530=Safe memo
895337940=Safe data
2817614158=Name
1741937413=&User name:
4235002365=&Password:
16479868= Synopse mORMot demo - SynFile
940170664=Content
3153227598=None
3708724895=Page %d / %d
2767358349=Size: %s
4281038646=Content Type: %s
2584741026=This memo is password protected.|Please click on the "Edit" button to show its content.
3011148197=Please click on the "Extract" button to get its content.
388288630=Signed,By %s on %s
(...)
```

The main section of this text file is named [Messages]. In fact, it contains all English extracted texts, as NumericalKey=EnglishText pairs. Note this will reflect the exact content of resourcestring or RTTI captions, including formatting characters (like %d), and replacing line feeds (#13) by the special | character (a line feed is not expected on a one-line-per-pair file layout). Some other text lines are separated by a comma. This is usual for instance for hint values, as expected by the code.

As requested, each application form has its own section (e.g. [TEditForm], [TMainForm]), proposing some default translation, specified by a numerical key (for instance Label1.Caption will use the text identified by 1741937413 in the [Messages] section). The underline character before the numerical

key is used to refers to this value. Note that if no `_NumericalKey` is specified, a plain text can be specified, in order to reflect a specific use of the generic text on the screen.

### 28.6.2. Adding a new language

In order to translate the whole application into French, the following `FR.msg` file could be made available in the `SynFile.exe` folder:

```
[Messages]
2784453965=Texte
2751226180=Données
744738530=Texte sécurisé
895337940=Données sécurisées
2817614158=Nom
1741937413=&Nom utilisateur:
4235002365=&Mot de passe:
16479868= Synopse mORMot Framework demo - SynFile
940170664=Contenu
3153227598=Vide
3708724895=Page %d / %d
2767358349=Taille: %s
4281038646=Type de contenu: %s
84741026=Le contenu de ce memo est protégé par un mot de passe. Choisissez "Editer" pour le visualiser.
3011148197=Choisissez "Extraire" pour enregistrer le contenu.
388288630=Signé,Par %s le %s
(....)
```

Since no form-level custom captions (e.g. `TLoginForm`]) have been defined in this `FR.msg` file, the default numerical values will be used. In our case, `Name.EditLabel.Caption` will be displayed using the text specified by 2817614158, i.e. 'Nom'. You can specify a custom translation for a given field on any form: sometimes, the text should be adapted with a given context.

Note that the special characters `%s %d , |` markup was preserved: only the plain English text has been translated to the corresponding French.

### 28.6.3. Language selection

User Interface language can be specified at execution.

There are two ways to change the application language:

- Manual translation of every form;
- Hook of the common `TForm` / `TFrame` classes, for automatic translation.

In manual translation mode:

- You can change languages on the fly, i.e. no need to restart the application;
- But you must modify your code to explicitly translate the forms after their creation;
- And you won't be able to translate dialogs without sources (e.g. third-party dialogs).

`TForm`/`TFrame` hook, on its side, has the following behavior:

- You do not need to modify your code, since it will be global to the application;
- It will work also for any third-party dialog, even if you do not have the source of it;
- But you can't change the language on the fly: you need to restart the application.

### 28.6.4. Manual translation

Once for the application, you should call `SetCurrentLanguage()` to set the global `Language` object and all related *Delphi* locale settings.

The, in each OnShow event of any form, you should call `FormTranslateOne()` e.g.

```
procedure TMyForm.FormShow(Sender: TObject);
begin
 Language.FormTranslateOne(self);
end;
```

Another possibility may be to translate all already allocated forms at once, e.g. in the OnShow event of the application's main form:

```
Language.FormTranslate([MainForm, FormTwo, FormAbout]);
```

Note that a list of already translated forms is maintained by the unit, when you call `FormTranslate()`. Therefore:

- All specified forms will be translated again by any further `SetCurrentLanguage()` call;
- But none of these forms must be freed after a `FormTranslate([])` call - use `FormTranslateOne()` instead to translate a given form once, e.g. for all temporary created forms.

### 28.6.5. TForm / TFrame hook

If the `USEFORMCREATEHOOK` conditional is defined, the `mORMoti18n.pas` unit will hook `TCustomForm.OnCreate` method to translate all its nested components. It will also intercept `TCustomFrame.Create()` to allow automatic translation of its content.

Since the language must be known at program startup, before any `TForm` is actually created, the language will be set in the Operating System registry.

The `HKEY_CURRENT_USER\Software\[CompanyName]i18n\` key should contain one value per application (i.e. the lowercase .exe file name without its path), which will identify the abbreviation of the expected language. If there is no entry in this registration key for the given application, the current Windows local will be used.

For instance, if you define `USEFORMCREATEHOOK` conditional for your project, and run at least e.g. once in `FileMain.pas`, for the framework main demo:

```
i18nLanguageToRegistry(lngFrench);
```

.. then it will set the main application language as French. At next startup, the unit will search for a `FR.msg` file, which will be used to translate all screen layout, including all RTTI-generated captions.

Of course, for a final application, you'll need to change the language by a common setting. See `i18nAddLanguageItems`, `i18nAddLanguageMenu` and `i18nAddLanguageCombo` functions and procedures to create your own language selection dialog, using a menu or a combo box, for instance.

### 28.6.6. Localization

Take a look at the `TLanguageFile` class. After the main language has been set, you can use the global `Language` instance in order to localize your application layout.

The `mORMoti18n` unit will register itself to some methods of `mORMot.pas`, in order to translate the RTTI-level text into the current selected language. See for instance `i18nDateText`.

## 29. Main SynFile Demo source

### 29.1. Main SynFile Demo used Units

The Main SynFile Demo makes use of the following units.

**Units located in the "Lib\" directory:**

| Source File Name     | Description                                                              | Page |
|----------------------|--------------------------------------------------------------------------|------|
| <i>SynCommons</i>    | Common functions used by most Synopse projects                           | 718  |
| <i>SynCrypto</i>     | Fast cryptographic routines (hashing and cypher)                         | 1143 |
| <i>SynGdiPlus</i>    | GDI+ library API access                                                  | 1355 |
| <i>SynTable</i>      | Filter/database/cache/buffer/security/search/multithread/<br>OS features | 1728 |
| <i>SynTaskDialog</i> | Implement TaskDialog window (native on Vista/Seven,<br>emulated on XP)   | 1832 |
| <i>SynZip</i>        | Low-level access to ZLib compression (1.2.5 engine<br>version)           | 1853 |

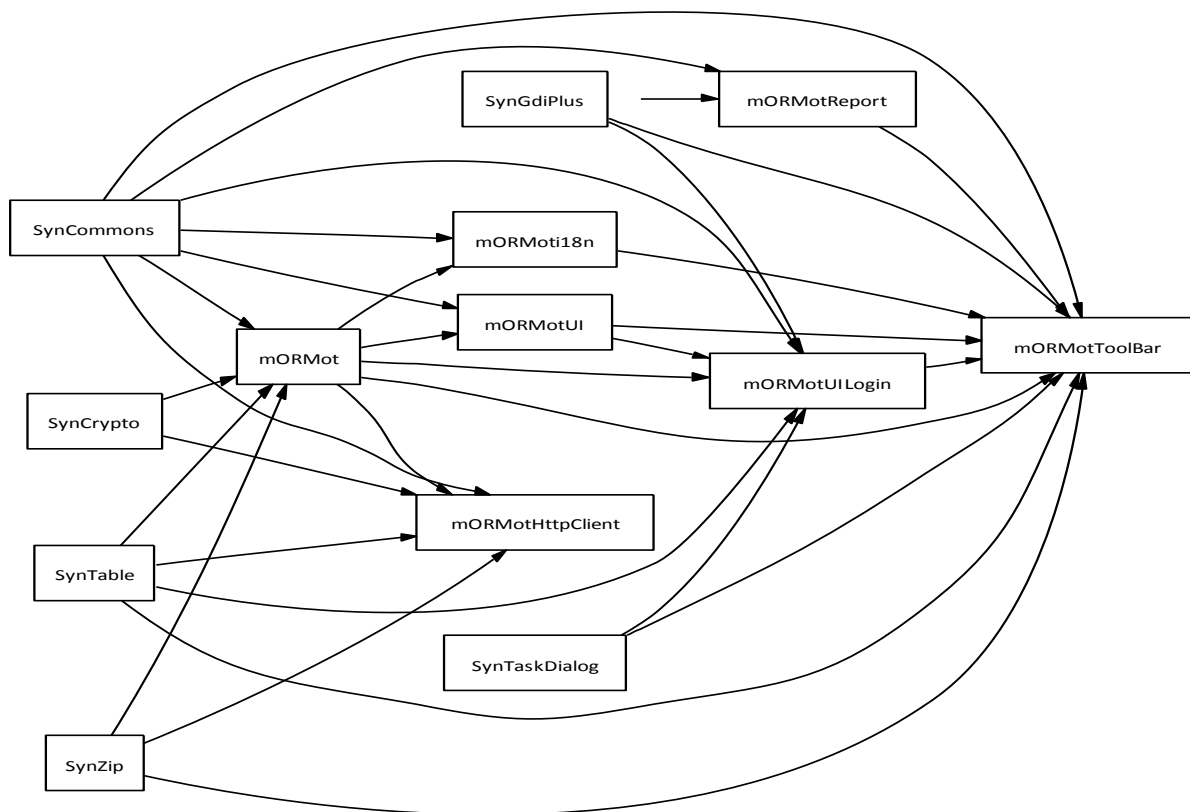

*Unit dependencies in the "Lib" directory*

**Units located in the "Lib\SQLite3\" directory:**

| Source File Name        | Description                                                    | Page |
|-------------------------|----------------------------------------------------------------|------|
| <i>mORMot</i>           | Common ORM and SOA classes for mORMot                          | 1907 |
| <i>mORMotHttpClient</i> | HTTP/1.1 RESTful JSON Client classes for mORMot                | 2316 |
| <i>mORMoti18n</i>       | Internationalization (i18n) routines and classes for<br>mORMot | 2332 |

| Source File Name     | Description                                                 | Page |
|----------------------|-------------------------------------------------------------|------|
| <i>mORMotReport</i>  | Reporting unit                                              | 2362 |
| <i>mORMotToolBar</i> | ORM-driven Office 2007 Toolbar for mORMot                   | 2400 |
| <i>mORMotUI</i>      | Grid to display database content for mORMot                 | 2414 |
| <i>mORMotUILogin</i> | Some common User Interface functions and dialogs for mORMot | 2428 |

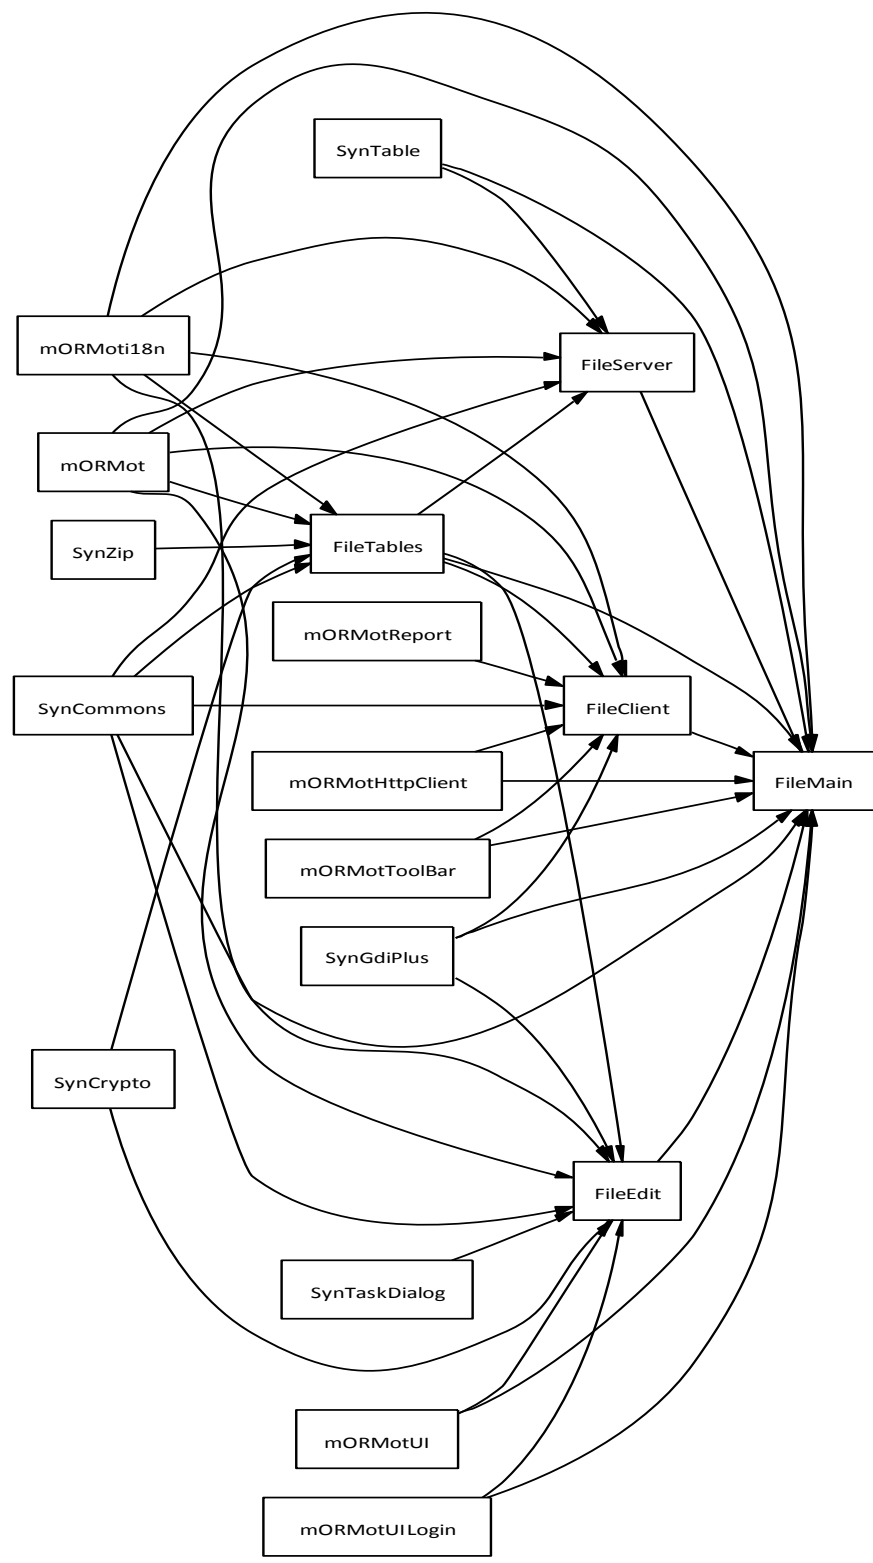

Unit dependencies in the "Lib\SQLite3" directory

**Units located in the "Lib\SQLite3\Samples\MainDemo\" directory:**

| Source File Name  | Description                                              | Page |
|-------------------|----------------------------------------------------------|------|
| <i>FileClient</i> | SynFile client handling                                  | 2540 |
| <i>FileEdit</i>   | SynFile Edit window                                      | 2542 |
| <i>FileMain</i>   | SynFile main Window                                      | 2544 |
| <i>FileServer</i> | SynFile server handling                                  | 2546 |
| <i>FileTables</i> | SynFile ORM definitions shared by both client and server | 2548 |

Unit dependencies in the "Lib\SQLite3\Samples\MainDemo" directory

## 29.2. FileClient.pas unit

*Purpose:* SynFile client handling

### Units used in the *FileClient* unit

| Unit Name               | Description                                                                                                                                                                                                                                                                                                                                    | Page |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>FileTables</i>       | SynFile ORM definitions shared by both client and server                                                                                                                                                                                                                                                                                       | 2548 |
| <i>mORMot</i>           | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                               | 1907 |
| <i>mORMotHttpClient</i> | HTTP/1.1 RESTful JSON Client classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                     | 2316 |
| <i>mORMoti18n</i>       | Internationalization (i18n) routines and classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                         | 2332 |

*FileClient class hierarchy*

### Objects implemented in the *FileClient* unit

| Objects     | Description                         | Page |
|-------------|-------------------------------------|------|
| TFileClient | A HTTP/1.1 client to access SynFile | 2541 |

| Objects     | Description                             | Page |
|-------------|-----------------------------------------|------|
| TFileRibbon | Class used to create the User interface | 2541 |

**TFileClient = class(TSQLHttpClient)**

*A HTTP/1.1 client to access SynFile*

**constructor** Create(**const** aServer: AnsiString); **reintroduce**;

*Initialize the Client for a specified network Server name*

**function** OnSetAction(TableIndex, ToolbarIndex: integer; TestEnabled: boolean; **var** Action): **string**;

*Used internally to retrieve a given action*

**procedure** AddAuditTrail(aEvent: TFileEvent; aAssociatedRecord: TSQLRecord);

*Client-side access to the remote RESTful service*

**TFileRibbon = class(TSQLRibbon)**

*Class used to create the User interface*

**procedure** CreateReport(aTable: TSQLRecordClass; aID: TID; aReport: TGDIPages; AlreadyBegan: boolean=false); **override**;

*Overridden method used customize the report content*

## 29.3. FileEdit.pas unit

*Purpose:* SynFile Edit window

### Units used in the *FileEdit* unit

| Unit Name            | Description                                                                                                                                                                                                                                                                                                                                    | Page |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>FileTables</i>    | SynFile ORM definitions shared by both client and server                                                                                                                                                                                                                                                                                       | 2548 |

| <i>mORMoti18n</i>    | Internationalization (i18n) routines and classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                         | 2332 |
| <i>mORMotUI</i>      | Grid to display database content for mORMot<br>- this unit is a part of the freeware mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                                 | 2414 |
| <i>mORMotUILogin</i> | Some common User Interface functions and dialogs for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                         | 2428 |
| <i>SynCommons</i>    | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                      | 718  |
| <i>SynCrypto</i>     | Fast cryptographic routines (hashing and cypher)<br>- implements<br>AES,XOR,ADLER32,MD5,RC4,SHA1,SHA256,SHA384,SHA512,SHA3 and JWT<br>- optimized for speed (tuned assembler and SSE3/SSE4/AES-NI/PADLOCK support)<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18  | 1143 |
| <i>SynGdiPlus</i>    | GDI+ library API access<br>- adds GIF, TIF, PNG and JPG pictures read/write support as standard TGraphic<br>- make available most useful GDI+ drawing methods<br>- allows Antialiased rendering of any EMF file using GDI+<br>- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1355 |
| <i>SynTaskDialog</i> | Implement TaskDialog window (native on Vista/Seven, emulated on XP)<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                 | 1832 |

*FileEdit class hierarchy*

## Objects implemented in the *FileEdit* unit

| Objects   | Description         | Page |
|-----------|---------------------|------|
| TEditForm | SynFile Edit window | 2543 |

```
TEditForm = class(TVistaForm)
```

*SynFile Edit window*

- we don't use the standard Window generation (from mORMotUIEdit), but a custom window, created as RAD

```
function LoadPicture(const FileName: TFileName; var Picture: RawByteString): boolean;
```

*Used to load a picture file into a BLOB content after 80% JPEG compression*

```
function SetRec(const Value: TSQLFile): boolean;
```

*Set the associated record to be edited*

```
property ReadOnly: boolean read fReadOnly write fReadOnly;
```

*Should be set to TRUE to disable any content editing*

```
property Rec: TSQLFile read fRec;
```

*Read-only access to the edited record*

## Functions or procedures implemented in the *FileEdit* unit

| Functions or procedures | Description                                                                                | Page |
|-------------------------|--------------------------------------------------------------------------------------------|------|
| Cypher                  | Will display a modal form asking for a password, then encrypt or uncrypt some BLOB content | 2543 |

```
function Cypher(const Title: string; var Content: TSQLRawBlob; Encrypt: boolean): boolean;
```

*Will display a modal form asking for a password, then encrypt or uncrypt some BLOB content*

- returns TRUE if the password was correct and the data processed

- returns FALSE on error (canceled or wrong password)

## Variables implemented in the *FileEdit* unit

```
EditForm: TEditForm;
```

*SynFile Edit window instance*

## 29.4. FileMain.pas unit

*Purpose:* SynFile main Window

### Units used in the *FileMain* unit

| Unit Name               | Description                                                                                                                                                                                                                                                                                                                                    | Page |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>FileClient</i>       | SynFile client handling                                                                                                                                                                                                                                                                                                                        | 2540 |
| <i>FileEdit</i>         | SynFile Edit window                                                                                                                                                                                                                                                                                                                            | 2542 |

*FileMain class hierarchy*

### Objects implemented in the *FileMain* unit

| Objects   | Description         | Page |
|-----------|---------------------|------|
| TMainForm | SynFile main Window | 2545 |

```
TMainForm = class(TSynForm)
```

*SynFile main Window*

```
Client: TFileClient;
```

*The associated database client*

```
Ribbon: TFileRibbon;
```

*The associated Ribbon which will handle all User Interface*

```
destructor Destroy; override;
```

*Release all used memory*

## 29.5. FileServer.pas unit

*Purpose:* SynFile server handling

### Units used in the *FileServer* unit

| Unit Name         | Description                                                                                                                                                                                             | Page |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>FileTables</i> | SynFile ORM definitions shared by both client and server                                                                                                                                                | 2548 |
| <i>mORMot</i>     | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                        | 1907 |
| <i>mORMoti18n</i> | Internationalization (i18n) routines and classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                  | 2332 |
| <i>SynCommons</i> | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                               | 718  |
| <i>SynTable</i>   | Filter/database/cache/buffer/security/search/multithread/OS features<br>- as a complement to SynCommons, which tended to increase too much<br>- licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1728 |

*FileServer class hierarchy*

### Objects implemented in the *FileServer* unit

| Objects     | Description                             | Page |
|-------------|-----------------------------------------|------|
| TFileServer | A server to access SynFile data content | 2546 |

**TFileServer = class(TSQLRestserverDB)**

*A server to access SynFile data content*

**Server:** TSQLHttpServer;

*The runing HTTP/1.1 server*

**constructor** Create;

*Create the database and HTTP/1.1 server*

**destructor** Destroy; **override;**

*Release used memory and data*

**function** OnDatabaseUpdateEvent(Sender: TSQLRestServer; Event: TSQLEvent; aTable: TSQLRecordClass; **const** aID: TID; **const** aSentData: RawUTF8): boolean;

*Database server-side trigger which will add an event to the TSQLAuditTrail table*

**procedure** Event(Ctxt: TSQLRestServerURIContext);

*A RESTful service used from the client side to add an event to the TSQLAuditTrail table*  
- an optional database record can be specified in order to be associated with the event

**procedure** AddAuditTrail(aEvent: TFileEvent; **const** aMessage: RawUTF8='';  
aAssociatedRecord: TRecordReference=0);

*Add a row to the TSQLAuditTrail table*

## 29.6. FileTables.pas unit

*Purpose:* SynFile ORM definitions shared by both client and server

### Units used in the *FileTables* unit

| Unit Name         | Description                                                                                                                                                                                                                                                                                                                                | Page |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i>     | Common ORM and SOA classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                           | 1907 |
| <i>mORMoti18n</i> | Internationalization (i18n) routines and classes for mORMot<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                     | 2332 |
| <i>SynCommons</i> | Common functions used by most Synopse projects<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                                  | 718  |
| <i>SynCrypto</i>  | Fast cryptographic routines (hashing and cypher)<br>- implements AES,XOR,ADLER32,MD5,RC4,SHA1,SHA256,SHA384,SHA512,SHA3 and JWT<br>- optimized for speed (tuned assembler and SSE3/SSE4/AES-NI/PADLOCK support)<br>- this unit is a part of the freeware Synopse mORMot framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18 | 1143 |
| <i>SynZip</i>     | Low-level access to ZLib compression (1.2.5 engine version)<br>- this unit is a part of the freeware Synopse framework, licensed under a MPL/GPL/LGPL tri-license; version 1.18                                                                                                                                                            | 1853 |

*FileTables class hierarchy*

### Objects implemented in the *FileTables* unit

| Objects                  | Description                                                   | Page |
|--------------------------|---------------------------------------------------------------|------|
| TFileRibbonTabParameters | The type of custom main User Interface description of SynFile | 2549 |
| TSQLAuditTrail           | An AuditTrail table, used to track events and status          | 2549 |
| TSQLData                 | An unencrypted Data table                                     | 2549 |
| TSQLFile                 | An abstract class, with common fields                         | 2549 |

| Objects      | Description              | Page |
|--------------|--------------------------|------|
| TSQLMemo     | An uncripted Memo table  | 2549 |
| TSQLSafeData | A crypted SafeData table | 2549 |
| TSQLSafeMemo | A crypted SafeMemo table | 2549 |

**TSQLFile = class(TSQLRecordSigned)**

*An abstract class, with common fields*

**TSQLMemo = class(TSQLFile)**

*An uncripted Memo table*

- will contain some text

**TSQLData = class(TSQLFile)**

*An uncripted Data table*

- can contain any binary file content

- is also used a parent for all cyphered tables (since the content is crypted, it should be binary, i.e. a BLOB field)

**TSQLSafeMemo = class(TSQLData)**

*A crypted SafeMemo table*

- will contain some text after AES-256 cypher

- just a direct sub class of TSQLData to create the "SafeMemo" table with the exact same fields as the "Data" table

**TSQLSafeData = class(TSQLData)**

*A crypted SafeData table*

- will contain some binary file content after AES-256 cypher

- just a direct sub class of TSQLData to create the "SafeData" table with the exact same fields as the "Data" table

**TSQLAuditTrail = class(TSQLRecord)**

*An AuditTrail table, used to track events and status*

**TFileRibbonTabParameters = object(TSQLRibbonTabParameters)**

*The type of custom main User Interface description of SynFile*

**Actions: TFileActions;**

*The SynFile actions*

### Types implemented in the *FileTables* unit

**TFileAction = ( faNoAction, faMark, faUnmarkAll, faQuery, faRefresh, faCreate, faEdit, faCopy, faExport, faImport, faDelete, faSign, faPrintPreview, faExtract, faSettings );**

*The internal available actions, as used by the User Interface*

**TFileActions = set of TFileAction;**

*Set of available actions*

**TFileEvent = ( feUnknownState, feServerStarted, feServerShutdown, feRecordCreated,**

```
feRecordModified, feRecordDeleted, feRecordDigitallySigned, feRecordImported,
feRecordExported);
```

*The internal events/states, as used by the TSQLAuditTrail table*

```
TPreviewAction = (paPrint, paAsPdf, paAsText, paWithPicture, paDetails);
```

*Some actions to be used by the User Interface of a Preview window*

### Constants implemented in the *FileTables* unit

```
DEF_ACTIONS = [faMark..faPrintPreview,faSettings];
```

*Some default actions, available for all tables*

```
DEF_ACTIONS_DATA = DEF_ACTIONS+[faExtract]-[faImport,faExport];
```

*Actions available for data tables (not for TSQLAuditTrail)*

```
DEF_SELECT = 'Name,Created,Modified,Keywords,SignatureTime';
```

*Default fields available for User Interface Grid*

```
FileActionsToolbar: array[0..3] of TFileActions = (
[faRefresh,faCreate,faEdit,faCopy,faExtract], [faExport..faPrintPreview],
[faMark..faQuery], [faSettings]);
```

*Used to map which actions/buttons must be grouped in the toolbar*

```
FileActionsToolbar_MARKINDEX = 2;
```

*FileActionsToolbar[FileActionsToolbar\_MARKINDEX] will be the marked actions i.e. [faMark..faQuery]*

```
FileTabs: array[0..4] of TFileRibbonTabParameters = ((Table: TSQLAuditTrail; Select:
'Time,Status,StatusMessage'; Group: GROUP_MAIN; FieldWidth: 'gIZ'; ShowID: true;
ReverseOrder: true; Layout: llClient; Actions:
[faDelete,faMark,faUnmarkAll,faQuery,faRefresh,faPrintPreview,faSettings]), (Table:
TSQLMemo; Select: DEF_SELECT; Group: GROUP_CLEAR; FieldWidth: 'IddId'; Actions:
DEF_ACTIONS), (Table: TSQLData; Select: DEF_SELECT; Group: GROUP_CLEAR; FieldWidth:
'IddId'; Actions: DEF_ACTIONS_DATA), (Table: TSQLSafeMemo; Select: DEF_SELECT; Group:
GROUP_SAFE; FieldWidth: 'IddId'; Actions: DEF_ACTIONS), (Table: TSQLSafeData; Select:
DEF_SELECT; Group: GROUP_SAFE; FieldWidth: 'IddId'; Actions: DEF_ACTIONS_DATA));
```

*This constant will define most of the User Interface property*

- the framework will create most User Interface content from the values stored within

```
GROUP_CLEAR = 1;
```

*Will define the 2nd User Interface ribbon group, i.e. uncripted tables*

```
GROUP_MAIN = 0;
```

*Will define the first User Interface ribbon group, i.e. main tables*

```
GROUP_SAFE = 2;
```

*Will define the 3d User Interface ribbon group, i.e. crypted tables*

```
SERVER_HTTP_PORT = '888';
```

*The TCP/IP port used for the HTTP server*

- this is shared as constant by both client and server side

- in a production application, should be made customizable

### Functions or procedures implemented in the *FileTables* unit

| Functions or procedures | Description                          | Page |
|-------------------------|--------------------------------------|------|
| CreateFileModel         | Create the database model to be used | 2551 |

```
function CreateFileModel(Owner: TSQLRest): TSQLModel;
 Create the database model to be used
 - shared by both client and server sides
```

## 30. SWRS implications

### Software Architecture Design Reference Table

The following table is a quick-reference guide to all the *Software Requirements Specifications* (SWRS) document items.

| SWRS #       | Description                                                                                                                                                                                                           | Page |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| DI-2.1.1     | The framework shall be Client-Server oriented                                                                                                                                                                         | 2553 |
| DI-2.1.1.1   | A RESTful mechanism shall be implemented                                                                                                                                                                              | 2553 |
| DI-2.1.1.2.1 | Client-Server Direct communication shall be available inside the same process                                                                                                                                         | 2554 |
| DI-2.1.1.2.2 | Client-Server Named Pipe communication shall be made available by some dedicated classes                                                                                                                              | 2554 |
| DI-2.1.1.2.3 | Client-Server Windows Messages communication shall be made available by some dedicated classes                                                                                                                        | 2554 |
| DI-2.1.1.2.4 | Client-Server HTTP/1.1 over TCP/IP protocol communication shall be made available by some dedicated classes, and ready to be accessed from outside any <i>Delphi</i> Client (e.g. the implement should be AJAX ready) | 2555 |
| DI-2.1.2     | UTF-8 JSON format shall be used to communicate                                                                                                                                                                        | 2555 |
| DI-2.1.3     | The framework shall use an innovative ORM (Object-relational mapping) approach, based on classes RTTI (Runtime Type Information)                                                                                      | 2556 |
| DI-2.1.4     | The framework shall provide some Cross-Cutting components                                                                                                                                                             | 2557 |
| DI-2.1.5     | The framework shall offer a complete SOA process                                                                                                                                                                      | 2557 |
| DI-2.2.1     | The <i>SQLite3</i> engine shall be embedded to the framework                                                                                                                                                          | 2558 |
| DI-2.2.2     | The framework libraries, including all its <i>SQLite3</i> related features, shall be tested using Unitary testing                                                                                                     | 2559 |
| DI-2.3.1.1   | A Database Grid shall be made available to provide data browsing in the Client Application - it shall handle easy browsing, by column resizing and sorting, on the fly customization of the cell content              | 2559 |

| SWRS #     | Description                                                                                                                                                                                                                                                                                                                               | Page |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| DI-2.3.1.2 | Toolbars shall be able to be created from code, using RTTI and enumerations types for defining the action                                                                                                                                                                                                                                 | 2559 |
| DI-2.3.1.3 | Internationalization (i18n) of the whole User Interface shall be made available by defined some external text files: <i>Delphi</i> resourcestring shall be translatable on the fly, custom window dialogs automatically translated before their display, and User Interface generated from RTTI should be included in this i18n mechanism | 2560 |
| DI-2.3.2   | A reporting feature, with full preview and export as PDF or TXT files, shall be integrated                                                                                                                                                                                                                                                | 2560 |

## 30.1. Client Server ORM/SOA framework

### 30.1.1. SWRS # DI-2.1.1

#### The framework shall be Client-Server oriented

*Design Input 2.1.1 (Initial release): The framework shall be Client-Server oriented.*

Client-Server model of computing is a distributed application structure that partitions tasks or workloads between service providers, called servers, and service requesters, called clients.

Often clients and servers communicate over a computer network on separate hardware, but both client and server may reside in the same system. A server machine is a host that is running one or more server programs which share its resources with clients. A client does not share any of its resources, but requests a server's content or service function. Clients therefore initiate communication sessions with servers which await (listen for) incoming requests.

The *Synopse mORMot Framework* shall implement such a Client-Server model by a set of dedicated classes, over various communication protocols, but in a unified way. Application shall easily change the protocol used, just by adjusting the class type used in the client code. By design, the only requirement is that protocols and associated parameters are expected to match between the Client and the Server.

**This specification is implemented by the following units:**

| Unit Name     | Description                                                                                                                                  | Page |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i> | Common ORM and SOA classes for mORMot<br><i>See in particular</i> TSQLRecord, TSQLRest, TSQLRestServer, TSQLRestClientURI and TSQLTableJSON. | 1907 |

### 30.1.2. SWRS # DI-2.1.1.1

#### A RESTful mechanism shall be implemented

*Design Input 2.1.1.1 (Initial release): A RESTful mechanism shall be implemented.*

REST-style architectures consist of clients and servers, as was stated in *SWRS # DI-2.1.1*. Clients initiate requests to servers; servers process requests and return appropriate responses. Requests and responses are built around the transfer of "representations" of "resources". A resource can be

essentially any coherent and meaningful concept that may be addressed. A representation of a resource is typically a document that captures the current or intended state of a resource.

In the *Synapse mORMot Framework*, so called "resources" are individual records of the underlying database, or list of individual fields values extracted from these databases, by a SQL-like query statement.

**This specification is implemented by the following units:**

| Unit Name     | Description                                                                                                       | Page |
|---------------|-------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i> | Common ORM and SOA classes for mORMot<br><i>See in particular</i> TSQLRest, TSQLRestServer and TSQLRestClientURI. | 1907 |

### 30.1.3. SWRS # DI-2.1.1.2.1

#### **Client-Server Direct communication shall be available inside the same process**

*Design Input 2.1.1.2 (Initial release): Communication should be available directly in the same process memory, or remotely using Named Pipes, Windows messages or HTTP/1.1 protocols.*

Client-Server Direct communication shall be available inside the same process.

**This specification is implemented by the following units:**

| Unit Name     | Description                                                                                                                                    | Page |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i> | Common ORM and SOA classes for mORMot<br><i>See in particular</i> TSQLRestServer, URIRequest, USEFASTMM4ALLOC and TSQLRestClientURIDll.Create. | 1907 |

### 30.1.4. SWRS # DI-2.1.1.2.2

#### **Client-Server Named Pipe communication shall be made available by some dedicated classes**

Client-Server Named Pipe communication shall be made available by some dedicated classes.

**This specification is implemented by the following units:**

| Unit Name     | Description                                                                                                                                                      | Page |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i> | Common ORM and SOA classes for mORMot<br><i>See in particular</i> TSQLRestServer.ExportServerNamedPipe, TSQLRestClientURINamedPipe.Create and TSQLRestClientURI. | 1907 |

### 30.1.5. SWRS # DI-2.1.1.2.3

#### **Client-Server Windows Messages communication shall be made available by some dedicated classes**

Client-Server Windows Messages communication shall be made available by some dedicated classes.

**This specification is implemented by the following units:**

| Unit Name     | Description                                                                                                                                                                                                     | Page |

### 30.1.7. SWRS # DI-2.1.2

**UTF-8 JSON format shall be used to communicate**

*Design Input 2.1.2 (Initial release): UTF-8 JSON format shall be used to communicate.*

JSON, as defined in the *Software Architecture Design (SAD)* document, is used in the *Synopse mORMot Framework* for all Client-Server communication. JSON (an acronym for *JavaScript* Object Notation) is a lightweight text-based open standard designed for human-readable data interchange. Despite its relationship to *JavaScript*, it is language-independent, with parsers available for virtually every programming language.

JSON shall be used in the framework for returning individual database record content, in a disposition which could make it compatible with direct *JavaScript* interpretation (i.e. easily creating *JavaScript* object from JSON content, in order to facilitate AJAX application development). From the Client to the Server, record content is also JSON-encoded, in order to be easily interpreted by the Server, which will convert the supplied field values into proper SQL content, ready to be inserted to the underlying database.

JSON should be used also within the transmission of request rows of data. It therefore provide an easy way of data formating between the Client and the Server.

The *Synapse mORMot Framework* shall use UTF-8 encoding for the character transmission inside its JSON content. UTF-8 (8-bit Unicode Transformation Format) is a variable-length character encoding for Unicode. UTF-8 encodes each character (code point) in 1 to 4 octets (8-bit bytes). The first 128 characters of the Unicode character set (which correspond directly to the ASCII) use a single octet with the same binary value as in ASCII. Therefore, UTF-8 can encode any Unicode character, avoiding the need to figure out and set a "code page" or otherwise indicate what character set is in use, and allowing output in multiple languages at the same time. For many languages there has been more than one single-byte encoding in usage, so even knowing the language was insufficient information to display it correctly.

**This specification is implemented by the following units:**

| Unit Name         | Description                                                                                                                                                                                                                                                                                                                                                                                   | Page |

| <i>mORMot</i>     | Common ORM and SOA classes for mORMot<br><br><i>See in particular</i> <code>TSQLTable.GetJSONValues</code> ,<br><code>TSQLTableJSON.Create</code> , <code>TSQLTableJSON.UpdateFrom</code> ,<br><code>TJSONWriter.Create</code> , <code>TSQLRecord.CreateJSONWriter</code> ,<br><code>TSQLRecord.GetJSONValues</code> , <code>GetJSONObjectAsSQL</code> and<br><code>UnJSONFirstField</code> . | 1907 |

### 30.1.8. SWRS # DI-2.1.3

**The framework shall use an innovative ORM (Object-relational mapping) approach, based on classes RTTI (Runtime Type Information)**

*Design Input 2.1.3 (Initial release): The framework shall use an innovative ORM (Object-relational mapping) approach, based on classes RTTI (Runtime Type Information).*

ORM, as defined in the *Software Architecture Design* (SAD) document, is used in the *Synapse mORMot Framework* for accessing data record fields directly from *Delphi* Code.

Object-relational mapping (ORM, O/RM, and O/R mapping) is a programming technique for converting data between incompatible type systems in relational databases and object-oriented programming languages. This creates, in effect, a "virtual object database" that can be used from within the *Delphi* programming language.

The published properties of classes inheriting from a new generic type named `TSQLRecord` are used to define the field properties of the data. Accessing database records (for reading or update) shall be made by using these classes properties, and some dedicated Client-side methods.

**This specification is implemented by the following units:**

| Unit Name     | Description                                                                                                                                                                                                                                                                                                                                                       | Page |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMot</i> | Common ORM and SOA classes for mORMot<br><br><i>See in particular</i> <code>TClassProp</code> , <code>TClassType</code> , <code>TEnumType</code> , <code>TTypeInfo</code> , <code>TSQLRecord.ClassProp</code> , <code>TSQLRecord.GetJSONValues</code> , <code>TPropInfo.GetValue</code> , <code>TPropInfo.SetValue</code> and <code>TSQLRecordProperties</code> . | 1907 |

### 30.1.9. SWRS # DI-2.1.4

**The framework shall provide some Cross-Cutting components**

*Design Input 2.1.4 (Initial release): The framework shall provide some Cross-Cutting components.*

*Cross-Cutting infrastructure layers* shall be made available for handling data filtering and validation, security, session, cache, logging and testing (framework uses test-driven approach and features stubbing and mocking).

All crosscutting scenarios are coupled, so you benefit of consisting APIs and documentation, a lot of code-reuse, JSON/RESTful orientation from the ground up.

**This specification is implemented by the following units:**

| Unit Name         | Description                                                                                                                             | Page |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>SynCommons</i> | Common functions used by most Synapse projects<br><br><i>See in particular</i> <code>TSynLog</code> and <code>PatchCodePtrUInt</code> . | 718  |

### 30.1.10. SWRS # DI-2.1.5

**The framework shall offer a complete SOA process**

*Design Input 2.1.5 (Initial release): The framework shall offer a complete SOA process.*

In order to follow a *Service Oriented Architecture* design, your application's business logic can be implemented in several ways using *mORMot*:

- Via some `TSQLRecord` inherited classes, inserted into the database *model*, and accessible via some RESTful URI - this is implemented by our ORM architecture - see *SWRS # DI-2.1.3*;
- By some RESTful services, implemented in the Server as *published methods*, and consumed in the Client via native *Delphi* methods;
- Defining some RESTful *service contracts* as standard *Delphi* interface, and then run it seamlessly on both client and client sides.

**This specification is implemented by the following units:**

| Unit Name | Description | Page |
|-----------|-------------|------|
|-----------|-------------|------|

| Unit Name     | Description                                                                                                                                                            | Page |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
|               | Common ORM and SOA classes for mORMot                                                                                                                                  |      |
| <i>mORMot</i> | <i>See in particular</i> TServiceFactory, TServiceFactoryServer, TServiceFactoryClient, TServiceContainerClient, TServiceContainerServer <i>and</i> TServiceContainer. | 1907 |

## 30.2. SQLite3 engine

### 30.2.1. SWRS # DI-2.2.1

#### The SQLite3 engine shall be embedded to the framework

*Design Input 2.2.1 (Initial release): The SQLite3 engine shall be embedded to the framework.*

The *SQLite3* database engine is used in the *Synapse mORMot Framework* as its kernel database engine. *SQLite3* is an ACID-compliant embedded relational database management system contained in a C programming library.

This library shall be linked statically to the *Synapse mORMot Framework*, or using official external *sqlite3.dll* distribution, and interact directly from the *Delphi* application process.

The *Synapse mORMot Framework* shall enhance the standard *SQLite3* database engine by introducing some new features stated in the *Software Architecture Design (SAD)* document, related to the Client-Server purpose or the framework - see *SWRS # DI-2.1.1*.

**This specification is implemented by the following units:**

| Unit Name               | Description                                                                                                                                                                                                                                                                                               | Page |

### 30.2.2. SWRS # DI-2.2.2

**The framework libraries, including all its *SQLite3* related features, shall be tested using Unitary testing**

*Design Input 2.2.2 (Initial release): The framework libraries, including all its SQLite3 related features, shall be tested using Unitary testing.*

The *Synapse mORMot Framework* shall use all integrated Unitary testing features provided by a common testing framework integrated to all Synapse products. This testing shall be defined by classes, in which individual published methods define the actual testing of most framework features.

All testing shall be run at once, for example before any software release, or after any modification to the framework code, in order to avoid most regression bug.

**This specification is implemented by the following units:**

| Unit Name           | Description                                                                                                                                                                               | Page |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
|                     | Automated tests for common units of the Synapse mORMot Framework                                                                                                                          |      |
| <i>SynSelfTests</i> | <i>See in particular</i> TTestLowLevelCommon, TTestLowLevelTypes, TTestBasicClasses, TTestSQLite3Engine, TTestFileBased, TTestMemoryBased, TTestFileBasedWAL and TTestClientServerAccess. | 1535 |

## 30.3. User interface

### 30.3.1. SWRS # DI-2.3.1.1

**A Database Grid shall be made available to provide data browsing in the Client Application - it shall handle easy browsing, by column resizing and sorting, on the fly customization of the cell content**

*Design Input 2.3.1 (Initial release): An User Interface, with buttons and toolbars shall be easily being created from the code, with no RAD needed, using RTTI and data auto-description.*

A Database Grid shall be made available to provide data browsing in the Client Application - it shall handle easy browsing, by column resizing and sorting, on the fly customization of the cell content.

**This specification is implemented by the following units:**

| Unit Name            | Description                                                                                     | Page |
|----------------------|-------------------------------------------------------------------------------------------------|------|
| <i>mORMotUI</i>      | Grid to display database content for mORMot<br><i>See in particular</i> TSQLTableToGrid.Create. | 2414 |
| <i>mORMotToolBar</i> | ORM-driven Office 2007 Toolbar for mORMot<br><i>See in particular</i> TSQLLister.Create.        | 2400 |

### 30.3.2. SWRS # DI-2.3.1.2

**Toolbars shall be able to be created from code, using RTTI and enumerations types**

### for defining the action

Toolbars shall be able to be created from code, using RTTI and enumerations types for defining the action.

**This specification is implemented by the following units:**

| Unit Name            | Description                                                                                                                                    | Page |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMotToolBar</i> | ORM-driven Office 2007 Toolbar for mORMot<br><i>See in particular</i> TSQLRibbon.Create, TSQLRibbonTab, TSQLLister and TSQLCustomToolBar.Init. | 2400 |

### 30.3.3. SWRS # DI-2.3.1.3

**Internationalization (i18n) of the whole User Interface shall be made available by defined some external text files: *Delphi* resourcestring shall be translatable on the fly, custom window dialogs automatically translated before their display, and User Interface generated from RTTI should be included in this i18n mechanism**

Internationalization (i18n) of the whole User Interface shall be made available by defined some external text files: *Delphi* resourcestring shall be translatable on the fly, custom window dialogs automatically translated before their display, and User Interface generated from RTTI should be included in this i18n mechanism.

**This specification is implemented by the following units:**

| Unit Name         | Description                                                                                                                                                                                                                                                                                                 | Page |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|
| <i>mORMoti18n</i> | Internationalization (i18n) routines and classes for mORMot<br><i>See in particular</i> TLanguage, TLanguageFile.Create, S2U, U2S, TLanguageFile.StringToUTF8, TLanguageFile.TimeToText, TLanguageFile.DateToText, TLanguageFile.DateTimeToText, TLanguageFile.UTF8ToString, TLanguageFile.Translate and -. | 2332 |

### 30.3.4. SWRS # DI-2.3.2

**A reporting feature, with full preview and export as PDF or TXT files, shall be integrated**

*Design Input 2.3.2 (Initial release): A reporting feature, with full preview and export as PDF or TXT files, shall be integrated.*

The *Synapse mORMot Framework* shall provide a reporting feature, which could be used stand-alone, or linked to its database mechanism. Reports shall not be created using a RAD approach (e.g. defining bands and fields with the mouse on the IDE), but shall be defined from code, by using some dedicated methods, adding text, tables or pictures to the report. Therefore, any kind of report shall be generated.

This reports shall be previewed on screen, and exported as PDF or TXT on request.

**This specification is implemented by the following units:**

| Unit Name           | Description                                                                                                            | Page |
